$$R = \frac{\text{average crash frequency in a period}}{\text{exposure in same period}} \quad [\text{HSM Eq. 3-2}] \quad 75.33$$

Statistical methods can also be used to estimate future crashes at a site from the current crash rate and other frequency data. The potential for future crashes at a site can also be determined indirectly and qualitatively by observing the conflicts and other factors that exist at the site.

These three techniques (historical crash rate analysis, statistical extrapolation, and qualitative observations) are commonly affected by limited data, dissimilar sites and elements, and the nonlinear effect of traffic volume on frequency. To address these limitations, standardized, quantitative, and predictive methods should be used. These predictive methods use statistical base models with data from similar sites and adjustments for local site conditions to predict an estimate of the average expected crash frequencies.<sup>6</sup>

In the HSM, the statistical models are referred to as *safety performance functions* (SPFs). SPFs are correlations used to arrive at frequencies,  $N_{\text{SPF}}$ . The HSM has developed SPFs for three types of facilities (rural two-lane roads, rural multiline highways, and urban/suburban

<sup>5</sup>Although the terms are often used interchangeably, a crash *frequency* should be used to describe the number of crashes per unit time (e.g., crashes/yr). A crash *rate* is used to describe the number of crashes per unit time per unit distance (e.g., crashes/mi-yr).

<sup>6</sup>Statisticians will recognize the redundancy and overlap of the terms “predict,” “estimate,” “average,” and “expected.” These terms are loosely used interchangeably, singularly and together in the literature.

arterials) and four main site types (undivided roadway segments, divided roadway segments, signalized intersections, and unsignalized intersections.) Jurisdictional (locally developed) SPFs may also be used. Equation 75.34 is an example of an SPF for a rural two-lane highway segment.<sup>7</sup>

$$N_{\text{SPF},\text{rural},\text{crashes/yr}} = \text{AADT}_{\text{veh/day}} \times L_{\text{mi}} \times 365 \times 10^{-6} \times e^{-4.865} \quad [HSM \text{ Eq. 3-4}] \quad 75.34$$

The adjustments are referred to as *crash modification factors* (CMFs). A CMF is a ratio of the effectiveness at one condition to the effectiveness at another condition, with all other factors being held equal. A multiplicative *calibration factor* ( $C$ ) is included to account for specific site conditions. The HSM provides Eq. 75.35 for calculation of the calibration factor. (See the HSM Part C Appendix.) The summations are taken over all sites.

$$C = \frac{\sum N_{\text{observed}}}{\sum N_{\text{predicted}}} \quad 75.35$$

The HSM predictive method formula takes on the form of Eq. 75.36.

$$N_{\text{predicted}} = N_{\text{SPF}} \times C \times (\text{CMF}_1 \times \text{CMF}_2 \times \dots \times \text{CMF}_n) \quad [HSM \text{ Eq. 3-3}] \quad 75.36$$

### 24. HSM CRASH MODIFICATION FACTORS

Site modifications that are intended to reduce crash frequency are known as *countermeasures*. Countermeasures that would require CMF adjustments include adding more street lights, increasing roadway width, signalizing an intersection, and modifying signal cycle lengths.

*Crash modification factors* (CMFs) adjust crash frequency for changes in one condition at a site, holding all other conditions the same. Therefore, a CMF is the ratio of crash frequencies at a site for two different conditions. A CMF with a value less than 1.00 represents an effective safety treatment, since crash frequency is reduced. From Eq. 75.37, a CMF is calculated as

$$\text{CMF} = \frac{\text{expected average crash frequency with modified site}}{\text{expected average crash frequency with base site}} \quad [HSM \text{ Eq. 3-5}] \quad 75.37$$

<sup>7</sup>Equation 75.34 illustrates an SPF. Insufficient background is presented in this chapter for its use.

CMFs are multiplicative. For example, if the CMF for adding street lights along a unit increment of highway is known, the CMF for  $n$  increments is given by Eq. 75.38 as

$$\text{CMF}_n = (\text{CMF}_1)^n \quad [\text{HSM Eq. 3-7}] \quad 75.38$$

The percentage reduction in crash frequency due to a particular countermeasure is given by Eq. 75.39. For example, changing the traffic control of an urban intersection from a two-way, stop-controlled intersection to a roundabout has a CMF of 0.61 for all collision types and crash severities. This value indicates that the expected average crash frequency will decrease by 39% after converting the intersection control.

$$\begin{aligned} & \text{percent reduction in crash frequency} \\ &= (1.00 - \text{CMF}) \times 100\% \quad [\text{HSM Eq. 3-6}] \end{aligned} \quad 75.39$$

## 25. HSM NETWORK SCREENING

In the HSM quantitative predictive method, *network screening* is the process of reviewing a transportation network in order to identify the sites most likely to benefit from countermeasures. Network screening consists of five steps.

- step 1: Establish focus* by defining the purpose of the analysis project. Typically, the purpose is either to identify and rank sites where improvements have potential to reduce crashes, or to identify sites with a particular crash type.
- step 2: Identify the network* by specifying the elements (e.g., intersections) to be screened. Then categorize, separate, and group them by type (e.g., unsignalized and signalized intersections).
- step 3: Select network screening performance measures* by identifying one or more performance measures that will be used to quantify safety. Common measures include crash frequency, crash rate, crash severity, property damage, and fatality rate, among others. When estimating past performance, the choice of measures is driven primarily by the data available.
- step 4: Select screening methods* by identifying which segments, nodes, or elements can most benefit from countermeasures. There are three standardized methods. All three methods can be used with segments and facilities; however, simple ranking must be used with nodes.

- The *sliding window method* uses a “window” of specified length, which is moved along the roadway segment.
- The *peak searching method* divides a roadway segment into separate, nonoverlapping windows.

- The *simple ranking method* calculates and orders the performance measures for all sites.

*step 5: Screen and evaluate results* by ordering the sites from most- to least- likely to benefit from countermeasures.

One screening method used to evaluate a network of facilities for sites likely to respond to safety improvements is the *excess expected average crash frequency with empirical Bayes (EB) adjustment*. This performance measure combines predictive model crash estimates with historical crash data to obtain a more reliable estimate of crash frequency. An advantage of this method is that it can be used to create a single ranking for a mix of facility types and traffic volumes.

With this method, each site is evaluated to determine how much the predicted average crash frequency for the site differs from the long-term EB adjusted expected average crash frequency for the same site. This difference is referred to as the *excess value*. Sites with a high excess value are the most likely to respond to safety improvements because they theoretically experience more crashes than other similar sites. The basic procedure contains three steps. (See the HSM Part C Appendix for details on these steps.)

- step 1:* For each site, calculate the *predicted average crash frequency* from the appropriate SPF. Take into consideration property damage only (PDO) crashes and fatal injury (FI) crashes.
- step 2:* For each site, calculate the *expected average crash frequency* using the EB method.
- step 3:* Calculate the excess value from Eq. 75.40.

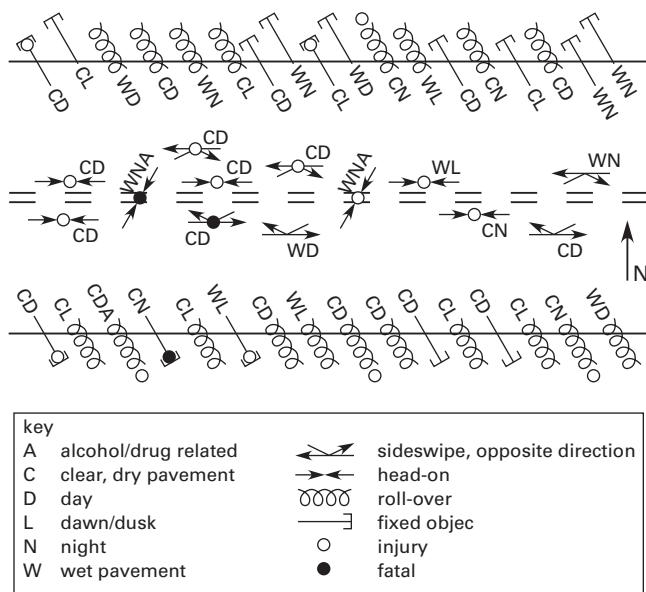

$$\begin{aligned} \text{excess} = & (N_{\text{expected } n(\text{PDO})} - N_{\text{predicted } n(\text{PDO})}) \\ & + (N_{\text{expected } n(\text{FI})} - N_{\text{predicted } n(\text{FI})}) \end{aligned} \quad 75.40$$

[HSM Eq. 4-45]

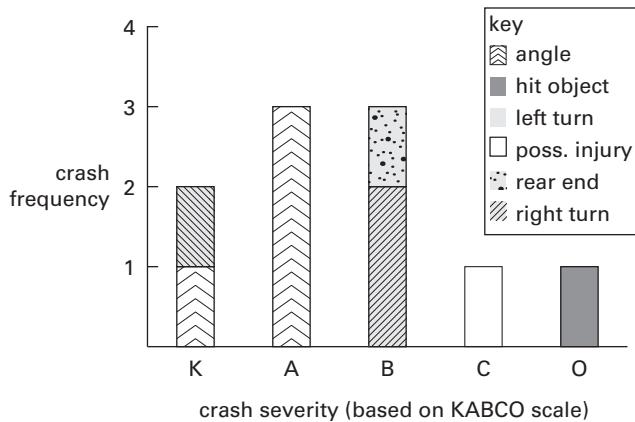

## 26. HSM NETWORK DIAGNOSIS

In the HSM *diagnosis procedure*, causes of the crashes are identified by analyzing crash patterns, past studies, and physical site characteristics. The diagnosis procedure involves the following three steps.

- step 1: Perform safety data review* by collecting data (often from police reports) and looking for patterns in the crash data (e.g., time of day, direction of travel), crash severity, crash type (e.g., rear-end, sideswipe), type of vehicle, driver information, and roadway conditions (e.g., pavement, traffic control, lighting). *Collision diagrams*, as shown in Fig. 75.5, may be used. (Collision diagrams are described in Sec. 75.9.) The crash frequency data may be summarized in a graph, as in Fig. 75.6.

**Figure 75.5** Collision Diagram

From *Highway Safety Manual*, 2010, by the American Association of State Highway and Transportation Officials, Washington, D.C. Used by permission.

**Figure 75.6** Graphical Summary of Crash Frequency Data

From *Highway Safety Manual*, 2010, by the American Association of State Highway and Transportation Officials, Washington, D.C. Used by permission.

*step 2: Assess supporting documentation* by reviewing current traffic counts, as-built construction plans, inventories of field conditions, historic weather patterns, land use maps, and other records that may provide additional insight. For instance, documentation may show that the frequency of rear-end collisions increased after a stop sign was added to an intersection.

*step 3: Assess field conditions* by conducting a firsthand field investigation of site conditions. Direct observations may reveal important aspects of pedestrian and vehicle travel at the site. For instance, a field observation may reveal a blind spot for drivers. Checklists are used to ensure a

consistent and comprehensive field assessment of the various *site conditions*, which are observable characteristics. Some of these site conditions include the following.

- *roadway and roadside characteristics*: signing and striping, posted speed limits, overhead lighting, pavement conditions, sight distances, lane and shoulder widths, roadside furniture
- *traffic conditions*: types of users (e.g., cars, trucks, bicyclists, pedestrians, student drivers), travel conditions (e.g., free-flow, congested), queue storage, speed, traffic control, signal clearance
- *travel behavior*: aggressive driving, speeding, ignoring traffic control devices, bicyclists using the sidewalk instead of the bike lane, pedestrians jaywalking
- *roadway consistency*: roadway cross-section is consistent with intended use
- *land uses*: adjacent land use is consistent with road travel conditions, driveway placement, types of users associated with land use (e.g., schools, parks, residential areas, senior facilities)
- *weather conditions*: seasonal and historical weather patterns that may affect roadway conditions
- *evidence of problems*: broken glass, skid marks, damaged signs, damaged guardrails, damaged road furniture

## 27. HSM ECONOMIC APPRAISAL

In the HSM *analysis process*, a traditional *cost-benefit analysis* may be used to select the preferred treatment from all of the countermeasures with CMFs greater than 1.0. The present worth of all costs and benefits is determined first. Costs are associated with right-of-way acquisition, construction materials, labor, grading, utility relocation, environmental impacts, engineering and design, and maintenance. Benefits depend on reductions in crash frequencies and values of the various crash severities.<sup>8</sup> Table 75.6 presents representative values from the HSM that are categorized by the KABCO scale. (See Sec. 75.22.)

The cost-benefit (or benefit-cost ratio) analysis is calculated for each countermeasure evaluated.<sup>9</sup> The

<sup>8</sup>Property damage is easier to value than loss of life. Table 75.6 is an example of possible sets of crash values that might be used. Statutory and legislated values are rare. Values are greatly affected by locale. In reality, the value of an individual life is often a matter of litigation.

<sup>9</sup>A list of benefit-cost ratios cannot and should not be used to rank countermeasures simplistically. Incremental benefit-cost analyses must be used to compare competing alternatives.

**Table 75.6** Societal Crash Cost Estimates Versus KABCO Crash Severity

collision type	comprehensive societal crash costs
fatal (K)	\$4,008,900
disabling injury (A)	\$216,000
evident injury (B)	\$79,000
fatal/injury (K/A/B)	\$158,200
possible injury (C)	\$44,900
PDO (O)	\$7400

From *Highway Safety Manual*, 2010, by the American Association of State Highway and Transportation Officials, Washington, D.C. Used by permission.

traditional benefit-cost ratio, as calculated from Eq. 75.41 using present worth (present values),  $P$ , should have a value greater than 1.0.

$$\frac{B}{C} = \frac{P_{\text{benefits}} - P_{\text{disbenefits}}}{P_{\text{cost}}} \quad [\text{HSM Eq. 7-4}] \quad 75.41$$

Another approach, known as the *cost-effectiveness method*, avoids the difficulties of establishing values for crashes of different severities and for values of human life. This method combines the crash frequency reduction directly with project costs.<sup>10</sup> The *cost-effectiveness index* (CEI) is used in comparing various alternatives. According to this method, the most cost-effective countermeasure will have the smallest CEI. Equation 75.42 is used to calculate CEI.

$$\text{CEI} = \frac{P_{\text{cost}}}{N_{\text{predicted}} - N_{\text{observed}}} \quad [\text{HSM Eq. 7-5}] \quad 75.42$$

<sup>10</sup>The cost-effectiveness method effectively assumes that all crashes included have the same crash cost.

**1. ASPHALT CONCRETE PAVEMENT**

*Hot mix asphalt* (HMA)—commonly referred to as *asphalt concrete* (AC), *bituminous mix* (BM), and sometimes *hot mix asphaltic concrete* (HMAC)—is a mixture of *asphalt cement (asphalt binder)* and well-graded, high-quality aggregate. The mixture is heated and compacted by a paving machine into a uniform dense mass.

AC pavement is used in the construction of traffic lanes, auxiliary lanes, ramps, parking areas, frontage roads, and shoulders. AC pavement adjusts to limited amounts of differential settlement. It is easily repaired, and additional thicknesses can be placed at any time to withstand increased usage and loading. Over time, its nonskid properties do not significantly deteriorate. However, as the asphalt oxidizes, it loses some of its flexibility and cohesion, often requiring resurfacing sooner than would be needed with portland cement concrete. Asphalt concrete is not normally chosen where water is expected to permeate the surface layer.

Most AC pavement is applied over several other structural layers, not all of which are necessarily AC layers. A *full-depth asphalt pavement* consists of asphalt mixtures in all courses above the subgrade. Since asphalt and asphalt-treated bases are stronger than untreated granular bases, the surface pavement can be thinner. Other advantages of full-depth pavements include a potential decrease in trapped water within the pavement, a decrease in the moisture content of the subgrade, and little or no reduction in subgrade strength.

If the asphalt layer is thicker than approximately 4 in (102 mm) and is placed all in one lift, or if lift layers are thicker than 4 in (102 mm), the construction is said to be *deep strength asphalt pavement*. Using deep lifts to place layers of hot mix asphalt concrete is advantageous

for several reasons: (a) Thicker layers hold heat longer, making it easier to roll the layer to the required density. (b) Lifts can be placed in cooler weather. (c) One lift of a given thickness is more economical to place than multiple lifts equaling the same thickness. (d) Placing one lift is faster than placing several lifts. (e) Less distortion of the asphalt course will result than if thin lifts are rolled.

Modern advances in asphalt concrete paving include *Superpave™* and *stone matrix asphalt*. (See Sec. 76.17 and Sec. 76.29.) Both of these are outgrowths of the U.S. Strategic Highway Research Program (SHRP), although stone matrix asphalt has its roots in the German Autobahn.

**2. OTHER ASPHALT APPLICATIONS**

Other types of asphalt products used in paving include *emulsified asphalts*, both anionic and cationic (depending on the charge of the emulsifying agent), and *cutback asphalts*, which are graded based on the speed at which the volatile substance used to liquefy the asphalt cement evaporates. Cutback asphalts may be referred to as RC, MC, and SC, referring to *rapid cure*, *medium cure*, and *slow cure* agents, respectively. Other applications of asphalt cement in construction include cold-mix asphalt mixtures, recycled road mixtures (both hot and cold), and surface treatments, which include seal coats, chip seals, slurry seals, and fog seals.

**3. ASPHALT GRADES**

Asphalt varies significantly in its properties. In general, softer grades are used in colder climates to resist the expansion and contraction of the asphalt concrete caused by thermal changes. Harder grades of asphalt are specified in warmer climates to protect against rutting.

In the past, asphalt cement has been graded by *viscosity grading* and *penetration grading* methods. *Penetration grading* is based upon the penetration of a standard-sized needle loaded with a mass of 100 g in 5 sec at 77°F (25°C). A penetration of 40–50 (in units of mm) is graded as hard, and a penetration of 200–300 is soft. Intermediate ranges of 60–70, 85–100, and 120–150 have also been established. A penetration-graded asphalt is identified by its range and the word “pen” (e.g., “120–150 pen”).

*Viscosity grading* is based on a measure of the absolute viscosity (tendency to flow) at 140°F (60°C). A viscosity measurement of AC-40 is graded as hard, and a measurement of AC-2.5 is soft. Intermediate ranges of AC-5, AC-10, and AC-20 have been established.

To meet the minimum specified viscosity requirements, oil suppliers have typically added more “light ends” (liquid petroleum distillates) to soften asphalt, regardless of the effects that such additions might have on structural characteristics. Concerns about the effects of

such additions include oily buildup in mixing plant bag-houses, light-end evaporation during pavement life, and possible reduced roadway performance.

Most state transportation and highway departments have stopped using penetration grading and have switched to performance grading. The *performance grading* (PG) system, which is used in Superpave and other designs, eliminates the structural concerns by specifying other characteristics. PG grading is specified by two numbers, such as PG 64-22. These two numbers represent the high and low (seven-day average) pavement temperatures in degrees Celsius that the project location will likely experience in its lifetime. Both high and low temperature ratings have been established in 6° increments. (See Table 76.1.)

**Table 76.1** Superpave Binder Grades (°C)\*

high-temperature grades	low-temperature grades
PG 46	-34, -40, -46
PG 52	-10, -16, -22, -28, -34, -40, -46
PG 58	-16, -22, -28, -34, -40
PG 64	-10, -16, -22, -28, -34, -40
PG 70	-10, -16, -22, -28, -34, -40
PG 76	-10, -16, -22, -28, -34
PG 82	-10, -16, -22, -28, -34

\*For example, PG 52-16 would be applicable in the range of 52°C down to -16°C.

PG ratings can be achieved with or without polymers, at the supplier's preference. However, the "rule of 90" says that if the sum of the absolute values of the two PG numbers is 90 or greater, then a polymer-modified asphalt is needed. Asphalts without polymers can be manufactured "straight-run."

The use of *recycled asphalt pavement* (RAP) in the mixture has an effect on the asphalt grade specified. However, specifying less than 15–25% RAP generally does not require a different asphalt cement grade to be used.

#### 4. AGGREGATE

The *mineral aggregate* component of the asphalt mixture comprises 90–95% of the weight and 75–85% of the mix volume. Mineral aggregate consists of sand, gravel, or crushed stone. The size and grading of the aggregate is important, as the minimum lift thickness depends on the maximum aggregate size. Generally, the minimum lift thickness should be at least three times the nominal maximum aggregate size. However, compaction is not an issue with open-graded mixes, since it is intended that the final result be very open. Therefore, the maximum-size aggregate can be as much as 80% of the lift thickness.

Generally, *coarse aggregate* is material retained on a no. 8 sieve (2.36 mm openings), *fine aggregate* is material passing through a no. 8 sieve (2.36 mm openings), and *mineral filler* is fine aggregate for which at least 70% passes through a no. 200 sieve (0.075 mm openings). The fine aggregate should not contain organic materials.

Aggregate size grading is done by sieving. Results may be expressed as either the percent passing through the sieve or the percent retained on the sieve, where the percent passing and the percent retained add up to 100%.

The maximum size of the aggregate is determined from the smallest sieve through which 100% of the aggregate passes. The *nominal maximum size* is designated as the largest sieve that retains some (but not more than 10%) of the aggregate.

An *asphalt mix* is specified by its nominal size and a range of acceptable passing percentages for each relevant sieve size, such as is presented in Table 76.2. The properties of the final mixture are greatly affected by the grading of aggregate. Aggregate grading can be affected by stockpile handling, cold-feed proportioning, degradation at impact points (more of an issue with batch plants), dust collection, and the addition of baghouse fines to the mix. Aggregates not only can become segregated; they also can be contaminated with other materials in adjacent stockpiles.

*Dense-graded* mixtures contain enough fine, small, and medium particles to fill the majority of void space between the largest particles without preventing direct contact between all of the largest particles. Aggregate for most HMA pavement is *open graded*, which means that insufficient fines and sand are available to fill all of the volume between the aggregate. Asphalt cement is expected to fill such voids. *Gap-graded mixtures* (as used in stone matrix asphalt and Superpave) are mixtures where two sizes (very large and very small) predominate.

*Open-graded friction courses* (OGFCs) have experienced problems with asphalt stripping, drain down, and raveling. Properly formulated, mixes perform reasonably well, though they are susceptible to problems when the voids become plugged, retain moisture, or become oxidized.

#### 5. PAVEMENT PROPERTIES

Several properties are desirable in an asphalt mixture, including stability, durability, flexibility, fatigue resistance, skid resistance, impermeability, and workability. *Stability* refers to the ability to resist permanent deformation, usually at high temperatures over a long time period. It depends on the amount of internal friction present in the mixture, which is in turn dependent on aggregate shape and surface texture, mix density, and asphalt viscosity. Lack of stability results in rutting in wheel paths, shoving at intersections, bleeding or flushing, and difficulty in compaction.

**Table 76.2** Typical Composition of Asphalt Concrete

		mix designation and nominal maximum size of aggregate				
		1½ in (37.5 mm)	1 in (25.0 mm)	¾ in (19.0 mm)	½ in (12.5 mm)	⅜ in (9.5 mm)
sieve size		total percent passing (by weight)				
2 in	(50 mm)	100	—	—	—	—
1½ in	(37.5 mm)	90 to 100	100	—	—	—
1 in	(25.0 mm)	—	90 to 100	100	—	—
¾ in	(19.0 mm)	56 to 80	—	90 to 100	100	—
½ in	(12.5 mm)	—	56 to 80	—	90 to 100	100
⅜ in	(9.5 mm)	—	—	56 to 80	—	90 to 100
no. 4	(4.75 mm)	23 to 53	29 to 59	35 to 65	44 to 74	55 to 85
no. 8 <sup>a</sup>	(2.36 mm)	15 to 41	19 to 45	23 to 49	28 to 58	32 to 67
no. 16	(1.18 mm)	—	—	—	—	—
no. 30	(0.60 mm)	—	—	—	—	—
no. 50	(0.30 mm)	4 to 16	5 to 17	5 to 19	5 to 21	7 to 23
no. 100	(0.15 mm)	—	—	—	—	—
no. 200 <sup>b</sup>	(0.075 mm)	0 to 6	1 to 7	2 to 8	2 to 10	2 to 10
bitumen weight, percent of total mixture <sup>c</sup>		3 to 8	3 to 9	4 to 10	4 to 11	5 to 12
suggested coarse aggregate size numbers						
		4 and 67 or 4 and 68	5 and 7 or 57	67 or 68 or 6 and 8	7 or 78	8

(Multiply in by 25.4 to obtain mm.)

<sup>a</sup>In considering the total grading characteristics of an asphalt paving mixture, the amount passing the no. 8 (2.36 mm) sieve is a significant and convenient field control point between fine and coarse aggregate. Gradings approaching the maximum amount permitted to pass the no. 8 (2.36 mm) sieve will result in pavement surfaces having a comparatively fine texture, while gradings approaching the minimum amount passing the no. 8 (2.36 mm) sieve will result in surfaces with a comparatively coarse texture.

<sup>b</sup>The material passing the no. 200 (0.075 mm) sieve may consist of fine particles of the aggregates or mineral filler, or both, but must be free of organic matter and clay particles. The blend of aggregates and filler, when tested in accordance with ASTM Standard Test Method D4318, must have a plasticity index not greater than 4, except that this plasticity requirement must not apply when the filler material is hydrated lime or hydraulic cement.

<sup>c</sup>The quantity of bitumen is given in terms of weight percent of the total mixture. The wide difference in the specific gravity of various aggregates, as well as a considerable difference in absorption, results in a comparatively wide range in the limiting amount of bitumen specified. The amount of bitumen required for a given mixture should be determined by appropriate laboratory testing or on the basis of past experience with similar mixtures, or by a combination of both.

**Durability** refers to the ability of a mixture to resist disintegration by weathering. A mixture's durability is enhanced by a high asphalt content, dense aggregate gradation, and high density. Lack of durability results in raveling, early aging of the asphalt cement, and stripping.

A mixture's **flexibility** refers to its ability to conform to the gradual movement due to temperature changes or settlement of the underlying pavement layers. Flexibility is enhanced by a high asphalt content, open gradation, and low asphalt viscosity. A lack of flexibility can result in transverse or block cracking and shear failure cracking.

**Fatigue resistance** refers to the ability to withstand repeated wheel loads. A mixture's fatigue resistance

can be enhanced with the presence of dense aggregate gradation and high asphalt content. Lack of fatigue resistance will result in fatigue or alligator cracking.

**Skid resistance** refers to the ability to resist tire slipping or skidding. An asphalt mixture with the optimum asphalt content, angular surface aggregates, and hard, durable aggregates will provide adequate skid resistance. The *polishing characteristics* of the aggregate need to be determined before use, either by lab polishing, insoluble residue tests, or previous service records. ASTM C131, "Standard Test Method for Resistance to Degradation of Small-Size Coarse Aggregate by Abrasion and Impact in the Los Angeles Machine," known as the *Los Angeles Abrasion Test* and the *Los Angeles Rattle Test*, is used to determine the durability of the aggregate and quality of long-term skid resistance.

Prepared aggregate is placed in a drum with steel balls. The drum is rotated a specific number of times (e.g., 500), and the mass loss is measured.

A mixture's *impermeability* refers to its resistance to the passage of water and air. Impermeability is enhanced with a dense aggregate gradation, high asphalt content, and increased compaction. Permeable mixtures may result in stripping, raveling, and early hardening.

*Workability* refers to the ease of placement and compaction. A mixture's workability is enhanced by a proper asphalt content, smaller-size coarse aggregates, and proper mixing and compacting temperatures.

## 6. PROBLEMS AND DEFECTS

Various terms are used to describe the problems and defects associated with the mixing, placing, and functionality of HMA pavements.

- *alligator cracks*: interconnected cracks forming a series of small blocks resembling the marking on alligator skin or chicken wire
- *bleeding*: forming a thin layer of asphalt that has migrated upward to the surface (same as "flushing")
- *blowing*: see "pumping"
- *blowup*: a disintegration of the pavement in a limited area
- *channeling*: see "rutting"
- *cold cracking*: separation of pavement caused by temperature extremes, usually observed as cracks running perpendicular to the road's centerline
- *corrugations*: plastic deformation characterized by ripples across the pavement
- *cracking*: separation of pavement caused by loading, temperature extremes, and fatigue
- *disintegration*: breakup of pavement into small, loose pieces
- *drain down*: liquid asphalt draining through the aggregate in a molten stage
- *faulting*: a difference in the elevations of the edges of two adjacent slabs
- *flushing*: see "bleeding"
- *lateral spreading cracking*: longitudinal cracking that occurs when the two edges of a road embankment supporting a pavement move away from the center
- *placement problems*: tender mixes
- *plastic instability*: excessive displacement under traffic
- *polishing*: aggregate surfaces becoming smooth and rounded (and subsequently, slippery) under the action of traffic

- *pothole*: a bowl-shaped hole in the pavement
- *pumping*: a bellows-like movement of the pavement, causing trapped water to be forced or ejected through cracks and joints
- *raveling*: a gradual, progressive loss of surface material caused by the loss of fine and increasingly larger aggregate from the surface, leaving a pock-marked surface
- *reflective cracking (crack reflection)*: cracking in asphalt overlays that follow the crack or joint pattern of layers underneath
- *rutting*: channelized depressions that occur in the normal paths of wheel travel
- *scaling*: the peeling away of an upper layer
- *shoving*: pushing the pavement around during heavy loading, resulting in bulging where the pavement abuts an immobile edge
- *slippage cracking*: cracks in the pavement surface, sometimes crescent-shaped, that point in the direction of the wheel forces
- *spalling*: breaking or chipping of the pavement at joints, cracks, and edges
- *streaking*: alternating areas (longitudinal or transverse) of asphalt caused by uneven spraying
- *stripping*: asphalt not sticking to aggregate, water susceptibility
- *tender mix*: a slow-setting pavement that is difficult to roll or compact, and that shoves (slips or scuffs) under normal loading
- *upheaving*: a local upward displacement of the pavement due to swelling of layers below
- *washboarding*: see "corrugations"

## 7. ASPHALT MODIFIERS

By itself, asphalt performance cannot be predicted with a good degree of confidence, particularly in the modern mixtures (e.g., Superpave) that place greater demands on asphalt. *Asphalt modifiers* are added to improve the characteristics and reliability of the asphalt binder, improve the performance of the HMA, and reduce cost. Table 76.3 lists some of the types of modifiers.

One major type of modifier is *polymers*, which come in two varieties: rubber types and plastic types. Rubber-type "elastomers" (e.g., latexes, block copolymers, and reclaimed rubber) toughen asphalt, whereas plastic-type "plastomers" (polybutadiene and polyisoprene) stiffen it. *Polymer-modified asphalt* (PMA) is more resistant to rutting, cold cracking, and other durability problems.

In hot mix, dense-graded mixtures, *synthetic latex* is the most common additive, providing improved resistance to rutting, shoving, and thermal cracking; improved

**Table 76.3** Types of Asphalt Modifiers

category	examples
mineral fillers	dust, lime, portland cement, and carbon black
extenders	sulfur and lignin
rubbers	natural latex, synthetic latex (styrene-butadiene), block copolymer (styrene-butadiene-styrene), and reclaimed rubber
plastics	polyethylene, polypropylene, ethylene-vinyl-acetate, and polyvinyl chloride
fibers	asbestos*, rock wool, polypropylene, and polyester
oxidants	manganese and other mineral salts
antioxidants	lead compounds, carbon, and calcium salts
hydrocarbons	recycling oils and rejuvenating oils
antistrip materials	amines and lime

\*Asbestos may be prohibited in current formulations.

load-carrying ability; improved fracture resistance; improved durability; and water resistance. Synthetic latex is also the most common additive in chip seals, used to improve chip retention and resistance to bleeding and chip embedment.

Lime and other anti-strip commercial additives in HMA reduce pavement raveling and strength degradation in the presence of water. Antioxidant additives increase asphalt's tensile strength and stiffness.

## 8. ASPHALT MIXERS AND PLANTS

The earliest asphalt mixers were of the *batch mixer* variety. Aggregate was heated and dried in a rotating drum exposed to a burner flame. Mixing with asphalt cement took place in a separate pugmill.

The highest-quality asphalt concrete mixtures are produced in stationary mixing plants, and these are referred to as *plant mixes*.

In modern *drum mixers*, graded aggregate is dried and heated by a large burner flame at 2500–2800°F (1370–1540°C) at one end of a rotating drum. Aggregate and asphalt cement are added, and at some point, *recycled asphalt pavement* (RAP) can be added. In *parallel-flow mixers* (also known as *center-entry mixers*), virgin aggregate moves in the same direction as the burner flame. RAP is added farther into the drum, away from the main flame, so as not to burn off the RAP's asphalt cement. RAP must be heated essentially entirely by conduction. RAP cannot be added until the mixture temperature is down to about 800°F (430°C), otherwise the RAP asphalt cement will be burned off as "blue smoke."

Parallel flow mixers can make up to 50% of their mix from RAP, but not much more, since smaller quantities of virgin aggregate cannot transfer enough heat by conduction to the RAP to soften it. Also, if the virgin

aggregate has a high moisture content, the RAP fraction must be decreased. Inasmuch as most paving specifications limit RAP to maximums between 25% and 40%, parallel-flow mixers can still be used effectively with recycled materials.

In modern *counterflow mixers*, graded virgin aggregate enters from the end and moves by rotation and gravity toward the burner flame. Counterflow uses fuel more efficiently, and it is easier to use with RAP. Emissions and air pollution rules are easier to satisfy.

Tough air pollution standards apply to asphalt plants. Applicable standards affect the release of carbon monoxide, total hydrocarbons, NOx gases, and particulates. Current technology, however, makes "zero opacity" operations possible, without any visible emissions.

## 9. WEIGHT-VOLUME RELATIONSHIPS

The objectives of an asphalt mixture design are to provide enough asphalt cement to adequately coat, waterproof, and bind the aggregate; provide adequate stability for traffic demands; provide enough air voids to avoid bleeding and loss of stability; and produce a mixture with adequate workability to permit efficient placement and compaction.

Figure 76.1 illustrates the weight-volume relationships for asphalt concrete. The total weight of an asphalt mixture is the sum of the weight of the asphalt and the aggregate. The total volume is the sum of the volume of aggregate and the asphalt not absorbed by the aggregate, plus the air voids.

Although the specific gravity of the asphalt cement can vary widely, the percentage of the total mixture weight contributed by asphalt cement varies from 3–8% (by weight) for large nominal maximum sizes (e.g., 1½ in or 37.5 mm) and from 5–12% for small nominal maximum sizes (e.g., ¾ in or 9.5 mm).

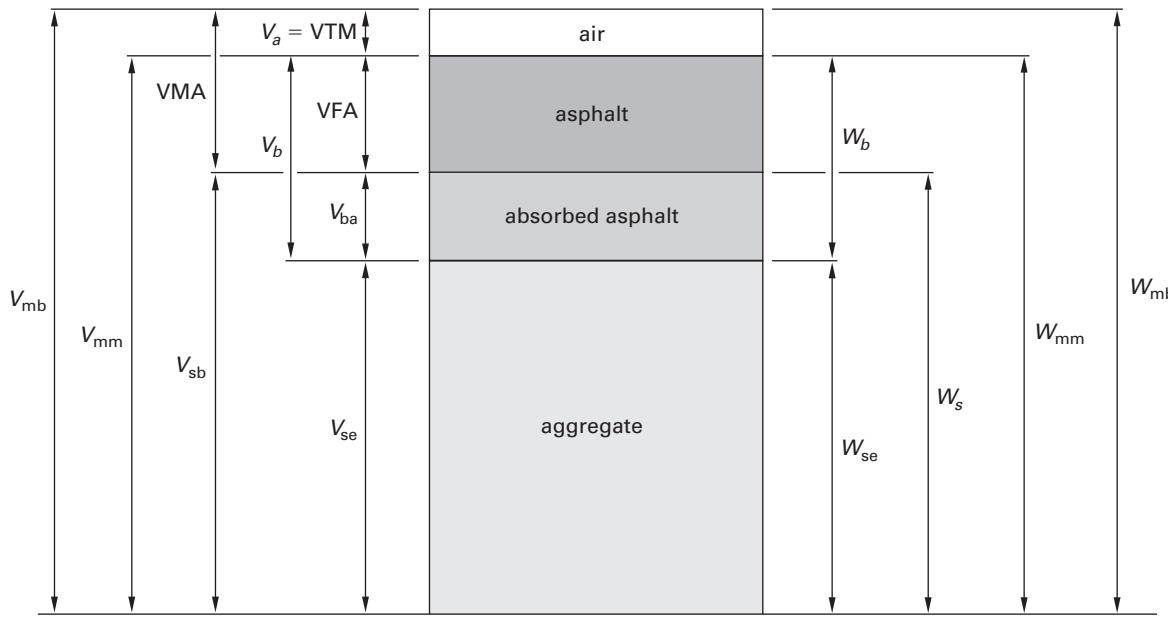

The *surface area method* can be used as a starting point in mix design for determining the percent of asphalt needed. The percentage of asphalt binder,  $P_b$ , is

$$P_b = \frac{(\text{aggregate surface area})}{(\text{asphalt thickness})} \times (\text{specific weight asphalt}) \times 100\% \quad 76.1$$

(The aggregate surface area is measured in units of ft<sup>2</sup>/lbf or m<sup>2</sup>/kg, the asphalt thickness is in in or mm, and the specific weight of asphalt is in lbf/ft<sup>3</sup> or kg/m<sup>3</sup>.)

The aggregate surface area is obtained by multiplying the weight (mass) of the aggregate by a *surface area factor* (ft<sup>2</sup>/lb or m<sup>2</sup>/kg). The factor must be known, as it is different for each type of aggregate and for each sieve size. In practice, each surface area factor is multiplied by the percent (converted to a decimal) passing each associated sieve, not by the actual aggregate weight, and the products are summed. The total is the surface area in ft<sup>2</sup>/lb (m<sup>2</sup>/kg) for the aggregate mixture.

**Figure 76.1** Weight-Volume Relationships for Asphalt Mixtures

VMA = volume of voids in mineral aggregate

$V_{mb}$  = bulk volume of compacted mix

$V_{mm}$  = voidless volume of paving mix

$V_a$  = volume of air voids

$V_b$  = volume of asphalt

$V_{ba}$  = volume of absorbed asphalt

$V_{sb}$  = volume of mineral aggregate (by bulk specific gravity)

$V_{se}$  = volume of mineral aggregate (by effective specific gravity)

## 10. PLACEMENT AND PAVING EQUIPMENT

Paving machines consist of a loading hopper, distribution equipment, and an adjustable *scree*d. Hot paving mix is brought from the plant in trucks and loaded directly from the trucks into the paving machine. *Low-lift loaders* are able to pick up asphalt paving mix that has been dumped in windrows in front of the paver by trucks. Normally, a mixture *paving temperature* that is in the range of 250–285°F (120–140°C) is satisfactory. Compaction must be completed before the mix cools below 185°F (85°C).

Hydrostatic drive systems are the norm, eliminating mechanical shifting and keeping the operation smooth. One-pass paving is not generally possible, and roller compaction is required. However, *high-density screeds* are used to achieve densities as high as 92% of specification, about 10% more than with conventional screeds. A tamper bar before the screed also improves final density. High-density screeds are larger (i.e., more expensive) and require more power, or they must run at a slower speed. High-density screeds are preferred with cold-recycling since the rejuvenated mixtures tend to be stiffer than virgin materials.

Self-widening machines (*extending screeds*) enable a paving contractor to change paving widths “on the

fly,” without having to stop and add or remove parts. Extending screeds provide the same compaction as the main screen.

Paving machines can run on rubber tires or crawlers. Crawlers provide better traction on soft subgrades, but they must be loaded on lowboys to be moved any great distance. Rubber-tired pavers have greater mobility but less traction.

Large asphalt *paving machines* can place a layer, or *lift*, of asphalt concrete with a thickness of 1–10 in (25–250 mm) over a width of 6–32 ft (1.8–9.8 m) at a forward speed of 10–70 ft/min (3–21 m/min).

The asphalt pavement *linear yield*, also known as the *length of spread*,  $L$ , is calculated from the volumetric relationship of the layer being placed.

$$L_{\text{m/tonne}} = \frac{1000}{w_m t_m \rho_{\text{compacted,kg/m}^3}} \frac{\text{kg}}{\text{tonne}} \quad [\text{SI}] \quad 76.2(a)$$

$$L_{\text{ft/ton}} = \frac{2000}{w_{\text{ft}} t_{\text{ft}} \gamma_{\text{compacted,lbf/ft}^3}} \frac{\text{lbf}}{\text{ton}} \quad [\text{U.S.}] \quad 76.2(b)$$

Some paving is placed on the basis of weight per unit area and depends on the *spreading rate*,  $r$ .

$$L_{\text{m/tonne}} = \frac{1000 \frac{\text{kg}}{\text{tonne}}}{r_{\text{kg/m}^2} w_m} \quad [\text{SI}] \quad 76.3(a)$$

$$L_{\text{ft/ton}} = \frac{18,000 \frac{\text{lbf-ft}^2}{\text{ton-yd}^2}}{r_{\text{lbf/yd}^2} w_{\text{ft}}} \quad [\text{U.S.}] \quad 76.3(b)$$

The actual speed,  $v$ , will depend on many factors and should not exceed the value for which a quality pavement is produced. The forward speed should also coincide with the plant production rate,  $R_p$ , of asphalt concrete.

$$\begin{aligned} v_{\text{m/min}} &= \frac{R_{p,\text{tonne/h}} L_{\text{m/tonne}}}{60 \frac{\text{min}}{\text{h}}} \\ &= \frac{R_{p,\text{tonne/h}} \left(1000 \frac{\text{kg}}{\text{tonne}}\right) \left(1000 \frac{\text{mm}}{\text{m}}\right)}{w_m t_{\text{mm}} \rho_{\text{kg/m}^3} \left(60 \frac{\text{min}}{\text{h}}\right)} \end{aligned} \quad [\text{SI}] \quad 76.4(a)$$

$$\begin{aligned} v_{\text{ft/min}} &= \frac{R_{p,\text{ton/hr}} L_{\text{ft/ton}}}{60 \frac{\text{min}}{\text{hr}}} \\ &= \frac{R_{p,\text{ton/hr}} \left(2000 \frac{\text{lbf}}{\text{ton}}\right) \left(12 \frac{\text{in}}{\text{ft}}\right)}{w_{\text{ft}} t_{\text{in}} \gamma_{\text{lbf/ft}^3} \left(60 \frac{\text{min}}{\text{hr}}\right)} \end{aligned} \quad [\text{U.S.}] \quad 76.4(b)$$

## 11. ROLLING EQUIPMENT

Most specifications now require 92–97% density, which means rolling is necessary even with high-density screeds. Roller forward speeds are usually between 1 mph and 2½ mph. Compaction must be completed before the mix cools below 185°F (85°C).

Production efficiency is higher with *vibratory rollers* than with *static rollers*, but consistency, noise, and control are sometimes issues. Because of this, many specifications still require a compaction train that includes static rollers. Modern technology is moving toward *density-on-the-run meters* attached to vibratory rollers. These gauges can determine density on the spot, allowing the operator to adjust vibration frequency and amplitude to maintain a consistent density.

Rubber-tired *pneumatic rollers* provide a kneading action in the finish roll. This is particularly important with chip-seal and other thin-surface treatments.

Lift thickness is dependent on the type of compaction equipment used. When static steel-wheeled rollers are used, the maximum lift thickness that can be compacted is about 3 in (75 mm). When pneumatic or vibratory rollers are used, the maximum thickness that can be

compacted is almost unlimited. Generally, lift thickness is limited to 6–8 in (150–200 mm). Proper placement is problematic with greater thicknesses.

## 12. CHARACTERISTICS OF ASPHALT CONCRETE

(The following material is consistent with the methods presented in the Asphalt Institute's *Asphalt Handbook* (MS-4).)

There are three specific gravity terms used to describe aggregate. The *apparent specific gravity*,  $G_{\text{sa}}$ , of an aggregate (coarse or fine) is

$$G_{\text{sa}} = \frac{m}{V_{\text{aggregate}} \rho_{\text{water}}} \quad [\text{SI}] \quad 76.5(a)$$

$$G_{\text{sa}} = \frac{W}{V_{\text{aggregate}} \gamma_{\text{water}}} \quad [\text{U.S.}] \quad 76.5(b)$$

Each of the components, including the coarse aggregate, fine aggregate, and mineral filler, has its own specific gravity,  $G$ , and proportion,  $P$ , by weight in the total mixture. The *bulk specific gravity*,  $G_{\text{sb}}$ , of the combined aggregate is

$$G_{\text{sb}} = \frac{P_1 + P_2 + \dots + P_n}{\frac{P_1}{G_1} + \frac{P_2}{G_2} + \dots + \frac{P_n}{G_n}} \quad 76.6$$

ASTM C127 "Standard Test Method for Relative Density (Specific Gravity) and Absorption of Coarse Aggregate" is used to measure the specific gravity of coarse aggregate without having to measure its volume. In Eq. 76.7 through Eq. 76.9,  $A$  represents the oven-dried weight,  $B$  is the weight at saturated-surface dry conditions, and  $C$  is the submerged weight of the aggregate in water.

$$G_{\text{sa}} = \frac{A}{A - C} \quad 76.7$$

$$G_{\text{sb}} = \frac{A}{B - C} \quad 76.8$$

$$\text{absorption} = \frac{B - A}{A} \times 100\% \quad 76.9$$

ASTM C128 "Standard Test Method for Relative Density (Specific Gravity) and Absorption of Fine Aggregate" is used for the fine aggregate. In Eq. 76.10 through Eq. 76.12,  $A$  is the oven-dried weight,  $B$  represents the weight of a *pycnometer* filled with water,  $S$  is the weight of the soil sample (standardized as 500 g), and  $C$  is the weight of a pycnometer filled with the soil sample and water added to the calibration mark.

$$G_{\text{sa}} = \frac{A}{B + A - C} \quad 76.10$$

$$G_{\text{sb}} = \frac{A}{B + S - C} \quad 76.11$$

$$\text{absorption} = \frac{S - A}{A} \times 100\% \quad 76.12$$

The *bulk specific gravity*,  $G_{sb}$ , of the aggregate mixture is found from Eq. 76.6. The *apparent specific gravity* of the aggregate mixture,  $G_{sa}$ , is also calculated from Eq. 76.6, except that the apparent specific gravities are used in place of the bulk specific gravities.

The *effective specific gravity* of the aggregate,  $G_{se}$ , is calculated from the maximum specific gravity, the specific gravity of the asphalt,  $G_b$ , and the proportion of the asphalt in the total mixture,  $P_b$ , expressed as a percentage. The effective specific gravity is always between the bulk and apparent specific gravities.

$$G_{se} = \frac{100\% - P_b}{\frac{100\%}{G_{mm}} - \frac{P_b}{G_b}} \quad 76.13$$

ASTM D2041 "Standard Test Method for Theoretical Maximum Specific Gravity and Density of Bituminous Paving Mixtures," also known as the Rice method, is used to measure the *maximum specific gravity*,  $G_{mm}$ , of the paving mixture, which is the specific gravity if the mix had no air voids. However, in practice, some air voids always remain and this maximum specific gravity cannot be achieved.

The maximum specific gravity is calculated from the proportions of aggregate and asphalt,  $P_s$  and  $P_b$ , respectively, in percent, and the specific gravity of the asphalt,  $G_b$ .

$$G_{mm} = \frac{100\%}{\frac{P_s}{G_{se}} + \frac{P_b}{G_b}} \quad 76.14$$

If ASTM D2041 is used to determine the maximum specific gravity,  $G_{mm}$ , Eq. 76.15 is used.  $A$  is the mass of an oven-dried sample,  $D$  is the mass of a container filled with water at 77°F (25°C), and  $E$  is the mass of the container filled with the sample and water at 77°F (25°C).

$$G_{mm} = \frac{A}{A + D - E} \quad 76.15$$

By convention, the *absorbed asphalt*,  $P_{ba}$ , is expressed as a percentage by weight of the aggregate, not as a percentage of the total mixture.

$$P_{ba} = \frac{G_b(G_{se} - G_{sb})}{G_{sb}G_{se}} \times 100\% \quad 76.16$$

The *effective asphalt content* of the paving mixture,  $P_{be}$ , is the total percentage of asphalt in the mixture less the percentage of asphalt lost by absorption into the aggregate.

$$P_{be} = P_b - \frac{P_{ba}P_s}{100\%} \quad 76.17$$

The *bulk specific gravity of the compacted mixture*,  $G_{mb}$ , is determined through testing according to ASTM D2726 "Standard Test Method for Specific Bulk Gravity

and Density of Non-Absorptive Compacted Bituminous Mixtures."

The *percent VMA (voids in mineral aggregate)* in the compacted paving mixture is the total of the air voids volume and the volume of aggregate available for binding.

$$VMA = 100\% - \frac{G_{mb}P_s}{G_{sb}} \quad 76.18$$

The percent *total air voids*,  $P_a$ , in the compacted mixture represents the air spaces between coated aggregate particles. The *voids in the total mix* (total air voids in the compacted mixture), VTM, should be 3–5%. With higher void percentages, voids can interconnect and allow air and moisture to permeate the pavement. If air voids are less than 3%, there will be inadequate room for expansion of the asphalt binder in hot weather. Below 2%, the asphalt becomes plastic and unstable.

$$P_a = VTM = \frac{G_{mm} - G_{mb}}{G_{mm}} \times 100\% \quad 76.19$$

The *voids filled with asphalt*, VFA, indicates how much of the VMA contains asphalt and is found using Eq. 76.20.

$$VFA = \frac{VMA - VTM}{VMA} \times 100\% \quad 76.20$$

Nondestructive *nuclear gauge testing* (with the gauge in the surface or backscatter position) can be used to determine actual relative density or percent air voids of new pavement. *Extraction methods* (which use dangerous and expensive chemicals) of determining density and air voids are essentially outdated.

### Example 76.1

A compacted HMA specimen had a volume of 499 cm<sup>3</sup> and a dry mass in air of 1155 g. The specimen was taken from a mixture with the following components.

component	mass, m (g)	specific gravity, $G$
aggregate 1	800	2.62
aggregate 2	1100	2.51
aggregate 3	350	2.47
aggregate 4	150	2.42
asphalt	100	1.06

Assume that the absorption of asphalt into the aggregate is insignificant. Determine the (a) bulk specific gravity of the combined (coarse and sand) aggregate, (b) maximum theoretical specific gravity of the mixture, (c) bulk specific gravity of the compacted mixture, (d) total air voids as a percentage of bulk volume, (e) voids in the mineral aggregate, VMA, and (f) percentage of voids filled with asphalt, VFA.

**Solution**

(a) The bulk specific gravity of the combined aggregate is given by Eq. 76.6.

$$\begin{aligned} G_{\text{sb}} &= \frac{\sum P_i}{\sum \frac{P_i}{G_i}} = \frac{\sum \frac{m_i}{m_t}}{\sum \frac{m_i}{G_i}} = \frac{\sum m_i}{\sum \frac{m_t}{G_i}} \\ &= \frac{800 \text{ g} + 1100 \text{ g} + 350 \text{ g} + 150 \text{ g}}{\frac{800 \text{ g}}{2.62} + \frac{1100 \text{ g}}{2.51} + \frac{350 \text{ g}}{2.47} + \frac{150 \text{ g}}{2.42}} \\ &= 2.534 \end{aligned}$$

(b) The maximum specific gravity would be the solid (zero air voids) specific gravity of the mixture. Using Eq. 76.6 and including the asphalt component,  $G_b = 1.06$ , is equivalent to using Eq. 76.14.

$$\begin{aligned} G_{\text{mm}} &= \frac{\sum P_i}{\sum \frac{P_i}{G_i}} = \frac{\sum \frac{m_i}{m_t}}{\sum \frac{m_i}{G_i}} = \frac{\sum m_i}{\sum \frac{m_t}{G_i}} \\ &= \frac{800 \text{ g} + 1100 \text{ g} + 350 \text{ g} + 150 \text{ g} + 100 \text{ g}}{\frac{800 \text{ g}}{2.62} + \frac{1100 \text{ g}}{2.51} + \frac{350 \text{ g}}{2.47} + \frac{150 \text{ g}}{2.42} + \frac{100 \text{ g}}{1.06}} \\ &= 2.400 \end{aligned}$$

(c) The bulk specific gravity of the compacted mixture is

$$G_{\text{mb}} = \frac{m}{V\rho_w} = \frac{1155 \text{ g}}{(499 \text{ cm}^3) \left(1 \frac{\text{g}}{\text{cm}^3}\right)} = 2.315$$

(d) Use Eq. 76.19. The total air voids expressed as a percentage of bulk volume is

$$\begin{aligned} P_a &= \frac{G_{\text{mm}} - G_{\text{mb}}}{G_{\text{mm}}} \times 100\% = \frac{2.400 - 2.315}{2.400} \times 100\% \\ &= 3.542\% \end{aligned}$$

(e) The percent aggregate by weight is

$$P_s = \frac{2500 \text{ g} - 100 \text{ g}}{2500 \text{ g}} \times 100\% = 96\%$$

Use Eq. 76.18 to determine the percent voids in the mineral aggregate.

$$\begin{aligned} \text{VMA} &= 100\% - \frac{G_{\text{mb}} P_s}{G_{\text{sb}}} = 100\% - \frac{(2.315)(96\%)}{2.534} \\ &= 12.297\% \end{aligned}$$

(f) The voids filled with asphalt, VFA, is found from Eq. 76.20.

$$\begin{aligned} \text{VFA} &= \frac{\text{VMA} - P_a}{\text{VMA}} \times 100\% \\ &= \frac{12.297\% - 3.542\%}{12.297\%} \times 100\% \\ &= 71.196\% \end{aligned}$$

## 13. HOT MIX ASPHALT CONCRETE MIX DESIGN METHODS

*Hot mix asphalt (HMA) concrete*, also known as bituminous concrete, hot plant mix, asphalt concrete, flexible pavement, blacktop, macadam, and even just “asphalt,” is a mixture of asphalt binder and mixed aggregate. The quantities of ingredients are known as “the mix.” There are several methods of designing the mix, including the traditional Marshall and Hveem mix design methods and the newer Superpave mix design “gyratory” method, as well as several commercial and state DOT procedures. All of these methods share the common goal of designing a mix that is workable, stable, and durable. The methodology used at the DOT level varies from state to state.

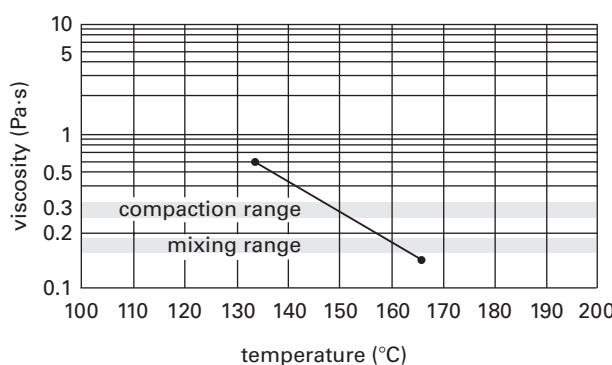

## 14. MARSHALL MIX DESIGN

The Marshall mix design method was developed in the late 1930s and was subsequently modified by the U.S. Army Corps of Engineers for higher airfield tire pressures and loads. It was subsequently adopted by the entire U.S. military. Although the method disregards shear strength, it considers strength, durability, and voids. It also has the advantages of being a fairly simple procedure, not requiring complex equipment, and being portable.

The primary goal of the Marshall mix design method is to determine the optimum asphalt content. The method starts by determining routine properties of the chosen asphalt and aggregate. The specific gravities of the components are determined by standard methods, as are the mixing and blending temperatures from the asphalt viscosities. (See Fig. 76.2.) Trial blends with varying asphalt contents are formulated, and samples are heated and compacted. Density and voids are determined.

The stability portion of the Marshall mix design method measures the maximum load supported by the test specimen at a loading rate of 2 in/min (50.8 mm/min). The load is increased until it reaches a maximum, then when the load just begins to decrease, the loading is stopped and the maximum load is recorded. During the loading, an attached dial gauge measures the specimen's plastic flow. The flow value is recorded in 0.01 in (0.25 mm) increments at the same time the maximum load is recorded.

**Figure 76.2** Determining Asphalt Mixing and Compaction Temperatures\*

\*Compaction and mixing temperature are found by connecting two known temperature-viscosity points with a straight line.

Various parameters are used to determine the best mix. Three asphalt contents are averaged to determine the *target optimum asphalt content*: the 4% air voids content, the maximum stability content, and the maximum density (unit weight) content. The target optimum asphalt content is subsequently validated by checking against flow and VMA minimums.

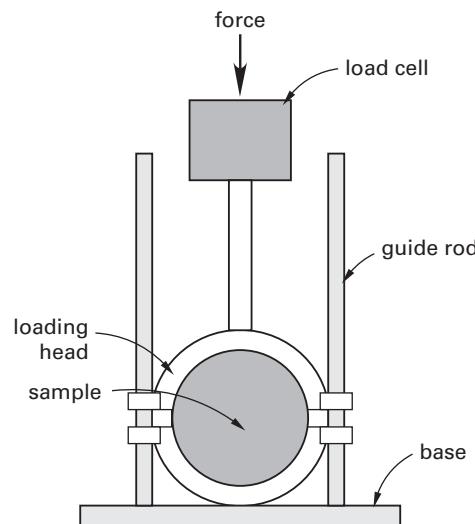

## 15. MARSHALL MIX TEST PROCEDURE

The *Marshall test method* (ASTM D6927) is a density voids analysis and a stability-flow test of the compacted test specimen. (See Fig. 76.3.) The size of a test specimen for a Marshall test is 2.5 in  $\times$  4 in (64 mm  $\times$  102 mm) in diameter. Specimens are prepared using a specified procedure for heating, mixing, and compacting the asphalt aggregate mixtures. When preparing data for a Marshall mix design, the stability of the samples that are not 2.5 in (63.5 mm) high must be multiplied by the correlation ratios in Table 76.4.

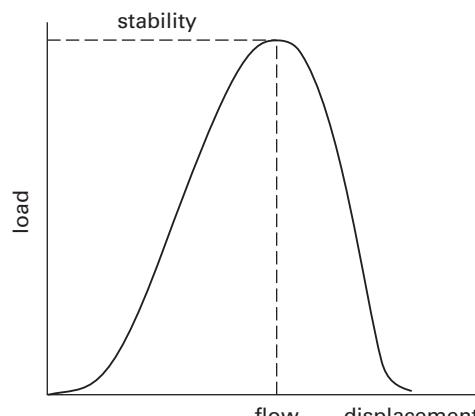

The objective of a Marshall test is to find the optimum asphalt content for the blend or gradation of aggregates. To accomplish this, a series of test specimens is prepared for a range of different asphalt contents so that when plotted, the test data will show a well-defined optimum value. Tests are performed in 0.5% increments of asphalt content, with at least two asphalt content samples above the optimum and at least two below.

After each sample is prepared, it is placed in a mold and compacted with 35, 50, or 75 hammer blows, as specified by the design traffic category. The compaction hammer is dropped from a height of 18 in (457 mm), and after compaction the sample is removed and subjected to the bulk specific gravity test, stability and flow test, and density and voids analysis. Results of these tests are plotted, a smooth curve giving the best fit is drawn for each set of data, and an optimum asphalt content

**Figure 76.3** Marshall Testing

(a) Marshall test device

(b) results

determined that meets the criteria of (a) maximum stability and unit weight and (b) median of limits for percent air voids from Table 76.5. (See Fig. 76.4 and Fig. 76.5.)

The *stability* of the test specimen is the maximum load resistance in pounds that the test specimen will develop at 140°F (60°C). The *flow value* is the total movement (strain) in units of  $1/100$  in occurring in the specimen between the points of no load and maximum load during the stability test.

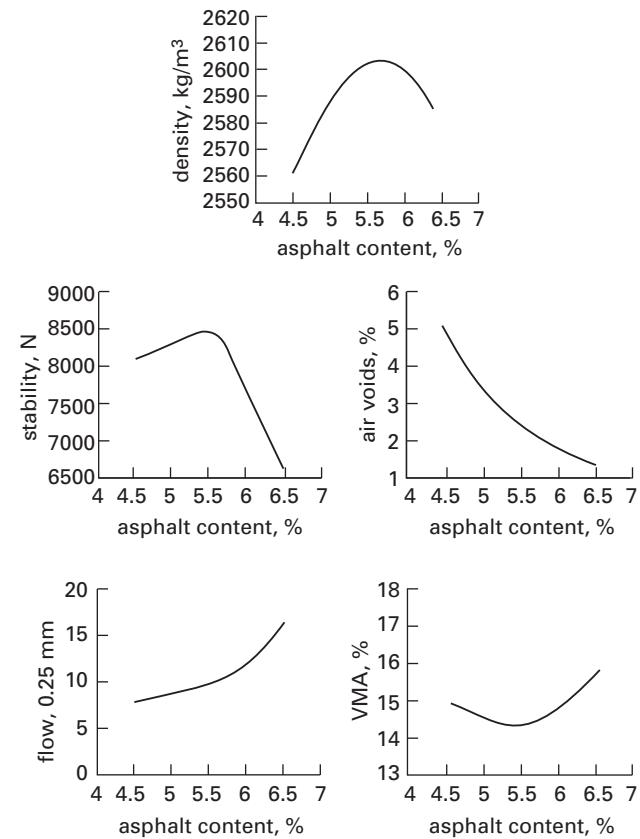

The *optimum asphalt content* for the mix is the numerical average of the values for the asphalt content. This value represents the most economical asphalt content that will satisfactorily meet all of the established criteria.

**Table 76.4** Stability Correlation Factors

specimen volume (cm <sup>3</sup> (in <sup>3</sup> ))	approximate specimen thickness (mm (in))	correlation ratio
406–420 (25.0–25.6)	50.8 (2.0)	1.47
421–431 (25.7–26.3)	52.4 (2.06)	1.39
432–443 (26.4–27.0)	54.0 (2.13)	1.32
444–456 (27.1–27.8)	55.6 (2.25)	1.25
457–470 (27.9–28.6)	57.2 (2.25)	1.19
471–482 (28.7–29.4)	58.7 (2.31)	1.14
483–495 (29.5–30.2)	60.3 (2.37)	1.09
496–508 (30.2–31.0)	61.9 (2.44)	1.04

**Figure 76.5** VMA Criterion for Mix Design**Example 76.2**

An asphalt mix uses an aggregate blend of 56% coarse aggregate (specific gravity of 2.72) and 44% fine aggregate (specific gravity of 2.60). The maximum aggregate size for the mixture is  $\frac{3}{4}$  in (19 mm). The resulting asphalt mixture is to have a specific gravity of 2.30. The asphalt content is to be selected on the basis of medium traffic and the following Marshall test data.

maximum content, % by weight of mix	Marshall stability (N)	flow (0.25 mm)	theoretical density ( $\text{kg}/\text{m}^3$ )	mixture specific gravity
4	4260	10.0	2300	2.42
5	4840	12.3	2330	2.44
6	5380	14.4	2340	2.44
7	5060	16.0	2314	2.40
8	3590	19.0	2250	2.30

*Solution*

*step 1:* Calculate air voids for each asphalt content and graph these values versus asphalt content. For example, for the 4% asphalt mixture, using Eq. 76.19,

$$\text{VTM}_{4\%} = \frac{G_{\text{mm}} - G_{\text{mb}}}{G_{\text{mm}}} \times 100\% = \frac{2.42 - 2.30}{2.42} \times 100\% = 4.96\%$$

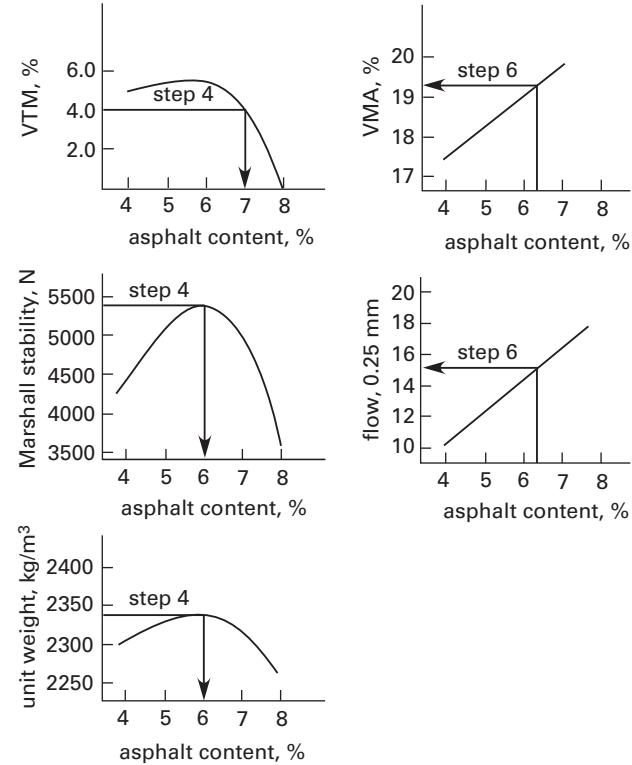

*step 2:* Calculate the voids in mineral aggregate for each asphalt content. Use Eq. 76.14.

$$G_{\text{sb}} = \frac{100\%}{\frac{P_{\text{ca}}}{G_{\text{ca}}} + \frac{P_{\text{fa}}}{G_{\text{fa}}}} = \frac{100\%}{\frac{56\%}{2.72} + \frac{44\%}{2.60}} = 2.67$$

Use Eq. 76.18.

$$\begin{aligned} \text{VMA}_{4\%} &= 100\% - \frac{G_{\text{mb}} P_s}{G_{\text{sb}}} = 100\% - \frac{(2.30)(96\%)}{2.67} \\ &= 17.3\% \end{aligned}$$

*step 3:* Graph the results.

*step 4:* Obtain asphalt contents for maximum stability, maximum unit weight, and VTM corresponding to median air voids (4% from Table 76.5) from the graphs.

*step 5:* Determine the optimum AC content.

$$\begin{aligned} \text{optimum AC} &= \frac{\text{AC}_{\text{stability}} + \text{AC}_{\text{unit weight}} + \text{AC}_{4\% \text{ air voids}}}{3} \\ &= \frac{6.0\% + 6.0\% + 7.0\%}{3} \\ &= 6.33\% \end{aligned}$$

*step 6:* Check stability against the criteria for light traffic. Stability  $\approx 5280 > 3336$  [OK]. Check VMA = 19.25 against Fig. 76.5 [OK]. Check flow = 14.8 against Table 76.5 [OK].

## 16. HVEEM MIX DESIGN

The Hveem mix design method was developed in the 1920s and has been extensively used in the western states. Like the Marshall mix design method, the goal is to determine the optimum asphalt content. Unlike the Marshall mix design method, it has the additional sophistications of measuring resistance to shear and considering asphalt absorption by aggregates. It has the disadvantage of requiring more specialized and non-portable equipment for mixing, compaction, and testing.

The method makes three assumptions: (1) The optimum asphalt binder content depends on the aggregate surface area and absorption. (2) Stability is a function of aggregate particle friction and mix cohesion. (3) HMA durability increases with asphalt binder content.

After selecting the materials, the *centrifuge kerosene equivalent* (CKE) of the fine aggregate and the retained surface oil content of the coarse aggregate are determined. These measures of surface absorption are used to estimate the optimum asphalt content.<sup>1</sup> Trial blends are formulated over the asphalt range of [CKE-1%, CKE+2%] in 0.5% increments. Then, specimens of the trial blends are prepared by heating and densifying in a California kneading compactor.<sup>2</sup>

A Hveem stabilometer, a closed-system triaxial test device, is used to determine the stability (i.e., the horizontal deformation under axial load). The stabilometer applies an increasing load to the top of the sample at a predetermined rate. As the load increases, the lateral pressure is read at specified intervals. The stability (*stabilometer value*),  $S$ , is calculated as

$$S = \frac{22.2}{\frac{p_h D}{p_v - p_h} - 0.222} \quad 76.21$$

In Eq. 76.21,  $p_v$  is the vertical pressure, which is typically 400 lbf/in<sup>2</sup> (2.8 MPa), and  $p_h$  is the corresponding horizontal pressure.  $D$  is the deflection in units of 0.01 in (0.25 mm). The stabilometer value ranges from 0 to 90. Zero represents a liquid, a condition where lateral pressure is equal to vertical pressure. 90 represents an incompressible solid, a condition where there is no lateral pressure regardless of the vertical pressure. Minimum stabilities of 30, 35, and 37 are typically specified for light (ESALs < 10<sup>4</sup>), medium (10<sup>4</sup> < ESALs < 10<sup>6</sup>), and heavy (ESALs > 10<sup>6</sup>) traffic, respectively.

<sup>1</sup>It is important that the trial blends include asphalt contents greater than and less than the optimum content. The purpose of determining the CKE and surface oil content is to estimate the optimum content prior to formulating trial blends. However, it is also practical to simply formulate trial blends within a range of 4–7% of asphalt, varying each blend by an increment such as 0.5%. Because of this alternative methodology of bracketing the optimum asphalt content, the CKE process has become essentially obsolete.

<sup>2</sup>The kneading compactor produces compactions that are more similar to pavements that have been roller-compacted with steel- and rubber-tired rollers.

HMA mixtures rarely fail from cohesion, but oil mixtures may require subsequent testing in a cohesiometer to determine cohesive strength. Basically, the sample used in the stability test is loaded as a cantilevered beam until it fails. The cohesiometer value,  $C$ , is determined from the mass of the load (shot),  $L$ , in grams, the width (diameter),  $W$ , of the sample in inches, and the height of the specimen,  $H$ , in inches. A minimum cohesiometer value of 100 is typical for HMA, while acceptance values for oil mixtures may be 50.

$$C = \frac{L}{W} (0.20H + 0.044H^2) \quad [\text{U.S. only}] \quad 76.22$$

Visual observation, volumetrics (air voids, voids filled with asphalt, and voids in the mineral aggregate), and stability are used to determine the optimum asphalt content. The design asphalt content is selected as the content that produces the highest durability without dropping below a minimum allowable stability. Essentially, as much asphalt binder as possible is used while still meeting minimum stability requirements. The *pyramid method* can be used to select the optimum asphalt content.

*step 1:* Place all sample asphalt percentages in the base of the pyramid.

*step 2:* Eliminate any samples with moderate to severe surface *flushing*.<sup>3</sup>

*step 3:* Place the three highest asphalt percentages in the next pyramid level.

*step 4:* Eliminate any samples that do not meet the stability requirements.

*step 5:* Place the two highest asphalt percentages in the next pyramid level.

*step 6:* Choose the mixture that has the highest asphalt content while still having 4% air voids. This is the optimum mixture.

### Example 76.3

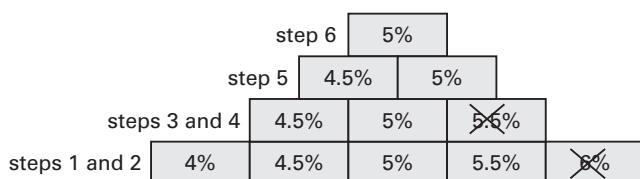

An HMA sample with a minimum Hveem stability of 37 is required. The following specimens were prepared. What is the optimum asphalt content?

sample	asphalt content	stability	air voids content	comments
1	4%	37	3.9%	
2	4.5%	38	4.0%	
3	5%	39	4.1%	
4	5.5%	35	3.9%	
5	6%	38	3.8%	moderate surface flushing noted

<sup>3</sup>Another name for flushing is *bleeding*. This is an indication of excessive asphalt. A specimen with light flushing will have sheen. With moderate flushing, paper will stick to the specimen. With heavy flushing, surface puddling or specimen distortion will be noted.

### Solution

Use the pyramid method. The optimum mixture has 5% asphalt.

## 17. SUPERPAVE

Superpave (Superior Performing Asphalt Pavement) mixture design is one of the products of the FHWA's 1988–1993 SHRP. Superpave has rapidly become the standard design methodology for HMA highway pavements in the United States and Canada. It greatly increases the stone-on-stone contact in the pavement, thus improving its load-bearing capacity. More than 80% of new highway construction in the United States uses Superpave mixture design.

There are three elements that make up the Superpave concept. Level 1 mix design includes specifying asphalts by a set of performance-based *binder specifications*. Specifications include stiffness, dynamic shear (stiffness at high and medium temperatures), bending (stiffness at low temperatures), and in some cases, direct tension. The binder specifications relate laboratory tests to actual field performance.

Level 1 mix design is used by most highway agencies and in most new highway construction and has replaced older methods of asphalt call-outs. Performance-graded (PG) asphalts are selected based on the climate and traffic expected. The physical property requirements are the same for all performance grades. The distinction between the various asphalt grades is the minimum and maximum temperatures at which the requirements must be met. For example, an asphalt classified as a PG 64-22 will meet the high temperature physical property requirements of the pavement up to a temperature of 147°F (64°C) and the low temperature physical property requirements of the pavement down to -8°F (-22°C). Selection of the asphalt grade depends on the expected temperatures, as well as the nature of the loading. (See Table 76.1.) Although the highest pavement temperature in the United States is about 160°F (70°C), a PG 70-22 specification may be insufficient. In general, one grade increase (e.g., to PG 76-22) should be considered for 20 yr ESALs greater than 20 million and slow moving traffic. Two grade increases (e.g., to PG 82-22) should be considered for standing traffic and stationary loads.

Level 2 mix design includes performance-based tests that measure primary mixture performance factors, such as fatigue, cracking, permanent deformation, low-temperature (thermal) cracking, aging, and water sensitivity. Much of Superpave's success is related to its

strict requirements regarding aggregate blending and quality. Mixes are designed at 9.5 mm (0.375 in), 12.5 mm (0.5 in), 19.0 mm (0.75 in), and 25.0 mm (1 in) according to their nominal maximum aggregate size. (In general, surface courses should use 9.5 mm or 12.5 mm mixes.) Evaluations include the aggregate's *dust-to-binder ratio*,<sup>4</sup>  $P_{0.075}/P_{be}$ , coarse and fine aggregate angularities, percentage of flat or elongated particles with length/thickness ratios greater than 5, and sand-equivalent clay content. Dust-to-binder ratios are normally 0.6–1.2, but a ratio of up to 1.6 may be used in some cases. The percentage of flat or elongated particles is limited to approximately 10%. Angularity and clay content specifications depend on traffic level (ESALs) and distance from the wearing surface.

Level 3 mix design is a computer-aided volumetric mix design and analysis that incorporates test results, geographical location, and climatological data, as well as mix-testing technology such as the *Superpave gyratory compactor*, SGC. The level 3 mix design proceeds similarly to the Marshall mix design method, with the exception that the Superpave gyratory compactor is used instead of the Marshall hammer for compacting mixture specimens. The Superpave gyratory compactor is a laboratory compaction device that orients the aggregate particles in a manner similar to standard rollers, resulting in laboratory densities equivalent to field densities. Specimens with a range of asphalt contents less than and greater than the anticipated optimum value are compacted in the gyratory compactor based on a specified number of gyrations determined by design traffic levels and design high air temperatures.

Because Superpave greatly increases stone-on-stone contact in the pavement, it is important to pay close attention to voids in the mineral aggregate (VMA), the percentage of air voids in the total mix (VTM), and voids filled with asphalt (VFA) in Superpave mixtures. Like the Marshall mix design method, the Superpave mix design method uses volumetrics (e.g.,  $G_{mm}$ ,  $G_{mb}$ ,  $V_a$  or VTM, VMA, and VFA) to select the optimum asphalt content corresponding to 4% air voids that satisfies all other DOT requirements (e.g., minimum VMA and a range of VFA) when compacted  $N_{design}$  gyrations. A minimum density of 96% of maximum is required for the specimens compacted to  $N_{design}$ . Unlike the Marshall and Hveem mix design methods, there are no standard performance (e.g., stability, flow, or cohesion) tests. (See Table 76.6.)

## 18. FLEXIBLE PAVEMENT STRUCTURAL DESIGN METHODS

The goal of flexible pavement structural design methods is to specify the thicknesses of all structural layers in a pavement. Different methodologies are used for full-depth asphalt pavements, asphalt courses over an

<sup>4</sup>What Superpave refers to as "dust" is referred to as "silt-clay" by AASHTO. It is the portion of the aggregate that passes through a no. 200 (0.075 mm) sieve.

**Table 76.6** Minimum VMA Requirements and VFA Range Requirements

20 yr traffic loading (in millions of ESALs)	minimum VMA (%)					VFA range (%)
	9.5 mm (0.375 in)	12.5 mm (0.5 in)	19.0 mm (0.75 in)	25.0 mm (1 in)	37.5 mm (1.5 in)	
<0.3	15.0					70–80
0.3 to <3		14.0				65–78
3 to <10			13.0			
10 to <30				12.0		
>30					11.0	65–75

(Multiply in by 25.4 to obtain mm.)

Source: AASHTO MP2, *Standard Specification for Superpave Volumetric Mix Design*, 2001.

aggregate base, asphalt courses over emulsified base, and overlays. Aside from generic catalog methods, design methods can be divided into two types: state-of-the-practice empirical methods and state-of-the-art mechanistic and mechanistic-empirical (ME) methods.<sup>5</sup> Like the choice of HMA mix design methods, the methodology used at the DOT level varies from state to state. All of the methods can be implemented manually or by computer.

Empirical methods, which include the 1993 AASHTO design procedure contained in the AASHTO *Guide for Design of Pavement Structures* (AASHTO *GDPS*), the 1998 *Supplement* containing a modified AASHTO design procedure, Asphalt Institute methods, and the Texas Modified Triaxial Design Method (not covered in this book), are based on the extrapolated performance of experimental test tracks.

ME methods build on multilayer elastic theory, finite element analysis, and simulation. They typically take into consideration reliability, climate, and life-cycle costs. Traffic is characterized by its spectrum, rather than in the form of a single (ESALs) number. Although ME methods have been implemented in Washington and Minnesota by WSDOT and MnDOT, respectively, for all practical purposes, ME design now refers only to the National Cooperative Highway Research Program (NCHRP) 1-37A method, as presented in the 2008 AASHTO *Mechanistic-Empirical Pavement Design Guide* (AASHTO *MEPDG*). ME methods require more training and situational awareness (environmental

knowledge) than empirical methods and, unless implemented on a computer, tend to be dauntingly complex. Even then, computer “runs” can take hours.

Design of overlays of existing pavements can employ both empirical and mechanistic-empirical methods, as well as surface deflection methods using the results of *falling weight deflectometer* tests. These methods tend to use *back-calculation* of parameters obtained from in situ testing.

The design of an HMA pavement requires knowledge of climate, traffic, subgrade soils support, and drainage. Stiffness of the asphalt layer varies with temperature, and unbound layers (aggregate and subgrade) are affected by freeze-thaw cycles. Climate is characterized by the *mean annual air temperature*, MAAT, of the design area. MAATs of 45°F (7°C) or less require attention to frost effect; at 60°F (16°C), frost effects are considered possible; and at 75°F (24°C), frost effects can be neglected. In empirical methods, the traffic is characterized by the numbers and weights of truck and bus axle loads expected during a given period of time, specified in ESALs. ESALs are calculated by multiplying the number of vehicles in each weight class by the appropriate truck factor and summing the products. Consideration must be given to subsurface drainage (e.g., installation of underdrains and/or interceptor drains) where high water tables occur or where water may accumulate in low areas. Good surface drainage, obtained through proper crown design, is also essential.

## 19. TRAFFIC

(The information included in this section is consistent with AASHTO *GDPS*, 1993.)

The AASHTO pavement design method requires that all traffic be converted into *equivalent single-axle loads*

<sup>5</sup>Mechanistic methods are based on familiar mechanics (strengths) of materials concepts that relate wheel loading to pavement stresses, strains, and deflections according to the material properties. The term “mechanistic-empirical” acknowledges that the theory is calibrated and corrected according to observed performance.

(ESALs). This is the number of 18,000 lbf single axles (with dual tires) on pavements of specified strength that would produce the same amount of traffic damage over the design life of the pavement.

AASHTO *GDPS* App. D gives *load equivalency factors* (LEFs) for flexible pavements for various *terminal serviceability indices*,  $p_t$ . A  $p_t$  value of 2.5 is assumed unless other information is available. This book's App. 76.A, App. 76.B, and App. 76.C can be used for  $p_t = 2.5$ .

$$\text{ESALs} = (\text{no. of axles})(\text{LEF}) \quad 76.23$$

Since the structural number, SN, is not known until the design is complete, initial values of 3 and 5 are assumed for the structural number of low-volume roads and high-volume roads, respectively. Once the design is complete, the ESALs can be recomputed and the design verified.

## 20. TRUCK FACTORS

*Truck factors*, TFs, are the average LEF for a given class of vehicle and are computed using *loadometer data*. The truck factor is calculated as the total ESALs for all axles divided by the number of trucks.

$$\text{TF} = \frac{\text{ESALs}}{\text{no. of trucks}} \quad 76.24$$

### Example 76.4

Using the axle loading data given, calculate the truck factor for 165 total trucks with five or more axles, assuming SN = 5 and  $p_t = 2.5$ .

*Solution*

ESALs are obtained by multiplying the number of axles by the LEF for each entry. Obtain LEF values from App. 76.A through App. 76.C.

$$\text{axle load (lbf)} \quad (\text{no. of axles}) \times (\text{LEF}) = \text{ESALs}$$

<i>single axle</i>			
< 3000	0	0.0002	0.000
4000	1	0.002	0.002
8000	6	0.034	0.204
10,000	144	0.088	12.672
16,000	16	0.623	9.968
28,000	1	5.39	5.390

axle load (lbf)	(no. of axles)	×	(LEF)	=	ESALs
<i>tandem axles</i>					
< 6000	0		0.0003		0.000
10,000	14		0.007		0.098
16,000	21		0.047		0.987
22,000	44		0.180		7.920
27,000	42		0.430		18.039
30,000	44		0.658		28.952
32,000	21		0.857		17.997
34,000	101		1.09		110.090
36,000	43		1.38		59.340

total ESALs for all axles: 271.659

The truck factor is

$$\begin{aligned} \text{TF} &= \frac{\text{ESALs}}{\text{no. of trucks}} = \frac{271.659 \text{ ESALs}}{165 \text{ trucks}} \\ &= 1.65 \text{ ESALs/truck} \end{aligned}$$

## 21. DESIGN TRAFFIC

Once the truck factors are computed, the design ESALs can be computed from the distribution of vehicle classes in the AADT and the expected growth rate. If the 20 yr ESAL (i.e., the total number of vehicles over 20 years) is to be predicted from the current (first) year ESAL and if a constant growth rate of  $g\%$  per year is assumed, traffic *growth factors*, GFs (also known as *projection factors*), for growth rates,  $g$ , can be read as the  $(F/A, g\%, 20)$  factors from economic analysis tables.  $\text{ESAL}_{20}$  is the cumulative number of vehicles over 20 years, not the 20th year traffic.

$$\text{ESAL}_{20} = (\text{ESAL}_{\text{first year}})(\text{GF}) \quad 76.25$$

The *design traffic* is calculated as the product of the AADT, the fraction of AADT that represents truck traffic, the days in one year, and the growth factor over the design life. The ESAL is obtained by multiplying by the truck factor.

The *directional distribution factor*,  $D_D$ , is used to account for the differences in loading according to travel direction. It is usually assumed to be 50%. Table 76.7 gives recommended values for *lane distribution factors*,  $D_L$ , on multilane facilities. The ESALs for the design lane are computed from Eq. 76.26.

$$w_{18} = D_D D_L \hat{w}_{18} \quad 76.26$$

### Example 76.5

Given the traffic data in columns 1 through 3 of the following table, as well as the truck factors, compute the design ESALs for a 20 yr period and a growth rate of 2%. Disregard contributions of passenger cars to ESALs.

*Solution*

vehicle type [given]	(AADT) [given]	fraction of AADT) [given]	$\left(\frac{\text{days}}{\text{yr}}\right)$	(GF)	= (design traffic) × [given]	(design TF) [given]	= ESALs

represents the approximate wheelbase distance between the front (cab) axle and the last trailer axle.

Classification into axle types is also common. An axle may be defined as “single” or “tandem,” and each axle may have single or dual tires. *Spread-tandem axles*, where two axles are separated by more than 96 in (2.2 m), generally are classified as two single axles. (All axles in a truck are included in the calculation of ESALs. For example, a typical tractor/trailer would contribute three quantities to the ESALs—one for the tractor front axle, one for the tractor tandem axles, and one for the trailer tandem axles.)

Except in theoretical stress studies, no attempt is made to account for the number of tires per axle. Although stresses at shallow depths are caused principally by individual wheels acting singly, stresses at greater depths are highest approximately midway between adjacent tires. Deep stresses due to dual-wheeled axles are approximately the same as for single-wheeled axles. Therefore, required pavement thickness is determined by the total axle load, not the number of tires.

Table 76.8 and Fig. 76.6 illustrate standard truck loads commonly used for design. Figure 76.7 shows types of axles and axle sets.

Prior to the use of LRFD, a bridge was traditionally designed for either a standard HS20-44 truck or a uniform lane loading of 640 lbf/ft (9.3 kN/m). Alternatively, two 25 kip (111 kN) axles spaced 4 ft (1.2 m) apart could be used to represent a tandem load. Bridge design under LRFD uses a standard HL-93 “truck.” Since LRFD bridge design does not consider point loads, the HL-93 loading actually refers to a simultaneous combination of truck and lane loading. The HS20-44 truck is combined with a 640 lbf/ft lane (9.3 kN/m) loading over the length of the span. (The truck is placed at the point of maximum positive moment influence line,  $M_{\text{pos.}}$ ) While it would not be possible to simultaneously load the lane with both, for the purposes of LRFD design, this is assumed to occur. (See Fig. 76.8.)

### Example 76.6

The traffic described in Ex. 76.5 has a directional traffic split of 60%/40%, and there are two lanes in each direction. What are the ESALs for the design lane?

*Solution*

From Table 76.7,  $D_L \approx 0.9$  (the midpoint of the 0.8–1.0 range). The total design ESALs were computed for Ex. 76.5.

From Eq. 76.26,

$$\begin{aligned} w_{18} &= D_D D_L \hat{w}_{18} \\ &= (0.6)(0.9)(43,009,022 \text{ ESALs}) \\ &= 23,224,872 \text{ ESALs} \end{aligned}$$

## 22. STANDARD VEHICLE CLASSIFICATIONS AND DESIGNATIONS

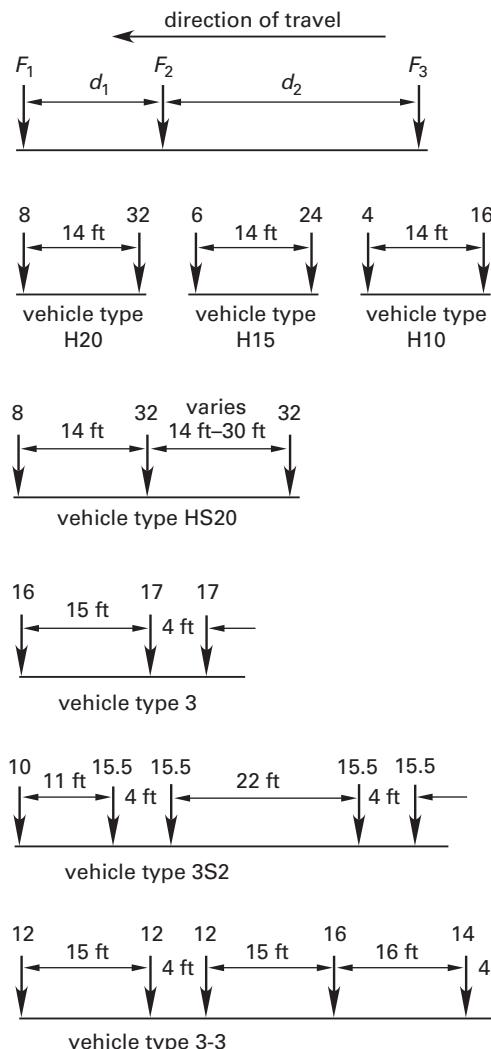

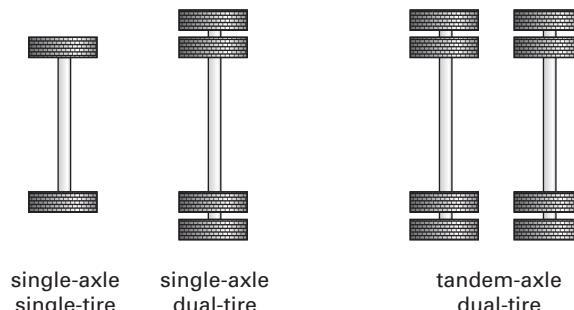

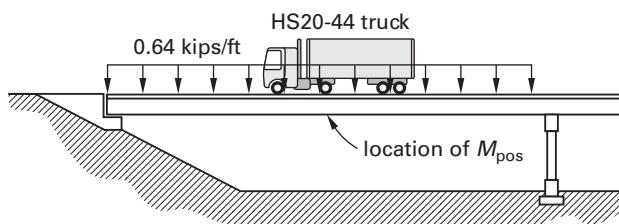

For designing road geometry, AASHTO defines design vehicles according to the following categories: passenger car (P), single-unit truck (SU), single-unit bus (BUS), intermediate-length semitrailer (WB-40), large semitrailer (WB-50), and semitrailer/full trailer combination (WB-60). In the case of WB vehicles, the number

**Table 76.8** Standard Truck Loadings<sup>a,b</sup>

load designation	$F_1$ (lbf (kN))	$F_2$ (lbf (kN))	$F_3$ (lbf (kN))	$d_1$ (ft (m))	$d_2$ (ft (m))
H20-44 (M-18)	8000 (36)	32,000 (142)	0	14 (4)	—
H15-44	6000 (27)	24,000 (107)	0	14 (4)	—
H10-44	4000 (18)	16,000 (71)	0	14 (4)	—
HS20-44 (MS-18)	8000 (36)	32,000 (142)	32,000 (142)	14 (4)	14–30 (4–8.3)
HS15-44	6000 (27)	24,000 (107)	24,000 (107)	14 (4)	14–30 (4–8.3)
P5	26,000 (116)	48,000 (214)	48,000 (214)	18 (5.4)	18 (5.4)
3	16,000 (71)	17,000 (76)	17,000 (76)	15 (4.2)	4 (1.1)
3S2	(See Fig. 76.6.)				
3-3	(See Fig. 76.6.)				

(Multiply lbf by 0.004448 to obtain kN.)

(Multiply ft by 0.3048 to obtain m.)

<sup>a</sup>All loads are axle loads in lbf (kN). The mass, in lbm, supported per axle is numerically the same as the force, in lbf, experienced by the pavement.<sup>b</sup>If the separation between axles is variable, the distance,  $d$ , that produces the maximum stress in the section should be used.**Figure 76.6** Standard Truck Loadings (all loads in kips)\***Figure 76.7** Types of Axles and Axle Sets**Figure 76.8** HL-93 Loading for LRFD Bridge Design\*

\*Per AASHTO, HL-93 stands for "highway load, year 1993."

## 23. AASHTO METHOD OF FLEXIBLE PAVEMENT DESIGN

The AASHTO *GDPS* is the basis of the conventional flexible pavement design method presented in this chapter. It is a conservative methodology, so average values can be used for all design variables. The design is based on four main design variables: time, traffic, reliability, and environment. Performance criteria, material properties, and pavement structural characteristics are also considered.

**Time:** The *analysis period* is the length of time that a given design strategy covers (the *design life* or *design period*). The *performance period* is the time that the

\*Per AASHTO, "H" and "HS" stand for highway and semitrailer. The 10, 15, and 20 refer to the truck's tonnage per side.

initial pavement structure is expected to perform adequately before needing rehabilitation. For example, on a high-volume urban roadway, the analysis period should be 30 to 50 years, which may include the initial performance period and several *rehabilitation periods* following overlays or maintenance operations.

**Traffic:** The traffic counts are converted into standard 18 kip ESALs.

**Reliability:** Reliability considerations ensure that the structure will last for the designated design period. They take into consideration variations in traffic and performance predictions. Facilities that are considered to be more critical are designed using higher reliability factors. Table 76.9 gives suggested levels of reliability for various functional classifications. It is necessary to select an *overall standard deviation*,  $S_o$ , for reliability to account for traffic and pavement performance that is representative of local conditions. Based on historical information obtained during the AASHO Road Test, appropriate standard deviations for flexible pavements are 0.4–0.5.

**Table 76.9** Suggested Levels of Reliability for Various Functional Classifications

functional classification	recommended level of reliability (%)	
	urban	rural
interstates and freeways	85–99.9	80–99.9
principal arterials	80–99	75–95
collectors	80–95	75–95
local	50–80	50–80

From *AASHTO Guide for Design of Pavement Structures*, Sec. II, p. II-9, Table 2.2, copyright © 1993 by the American Association of State Highway and Transportation Officials, Washington, D.C. Used by permission.

## 24. PERFORMANCE CRITERIA

The *terminal pavement serviceability index*,  $p_t$ , represents the lowest pavement serviceability index that can be experienced before rehabilitation, resurfacing, or reconstruction is required. Suggested levels are between 2 and 3, with 2.5 recommended for major highways and 2.0 recommended for less important roads. If costs are to be kept low, the design traffic volume or design period should be reduced. Terminal serviceability should not be reduced, as small changes in it will result in large differences in pavement design.

The *actual initial pavement serviceability*,  $p_o$ , represents the actual ride quality of the new roadway immediately after it is installed. This value is not usually known during the initial design, but it may be assumed to be 4.2 for flexible pavement and 4.5 for rigid pavement.

The *change in pavement serviceability index*,  $\Delta\text{PSI}$ , is calculated as the difference between the initial pavement

serviceability index and the terminal pavement serviceability index.

$$\Delta\text{PSI} = p_o - p_t$$

76.27

## 25. LAYER STRENGTHS

Prior to designing a flexible pavement, the strengths of the pavement layers and the underlying soil must be determined or assumed.

There may be a considerable range in the strength values of the underlying soil. If the range is small for a given area, the lowest value should be selected for design. If there are a few exceptionally low values that come from one area, it may be possible to specify replacing that area's soil with borrow soil to increase the localized weak spots. If there are changing geological formations along the route that modify the value, it may be necessary to design different pavement sections as appropriate.

The *effective roadbed soil resilient modulus*,  $M_R$ , must be determined. The resilient modulus can either be measured in the laboratory using the AASHTO T274 test procedure, or it can be predicted from correlations with nondestructive deflection measurements. For roadbed materials, laboratory resilient modulus tests should be performed on representative soils under different representative seasonal moisture conditions. The effective roadbed modulus represents the combined effect of all the seasonal modulus values. The *relative fatigue damage value*,  $u_f$ , is estimated using the vertical scale on the right side of Fig. 76.9 or by Eq. 76.28. All  $u_f$  values are then summed, and the total is divided by the number of seasons, giving the average  $u_f$  value. The corresponding effective subgrade modulus value is read from the vertical scale.

$$u_f = (1.18 \times 10^8) M_R^{-2.32} \quad [\text{U.S. only}]$$

76.28

The resilient modulus,  $M_R$ , is the same as the modulus of elasticity,  $E$ , of the soil. It is not the same as the *modulus of subgrade reaction*,  $k$ , used in rigid pavement design, although the two are related. For positive values of the resilient modulus,  $M_R \approx 19.4k$ .

Different state departments of transportation use different methods of classifying materials. The *California bearing ratio* (CBR) and *soil resistance value* ( $R$ -value) are widely used. It may be necessary to convert one known strength parameter to another parameter for use with a particular design procedure. Equation 76.29 and Eq. 76.31 are used to make such conversions. However, correlations of the resilient modulus with other measured parameters, such as the  $R$ -value, are usually poor.

$$M_{R,\text{MPa}} = 10.3(\text{CBR})$$

[SI] 76.29(a)

$$M_R = 1500(\text{CBR})$$

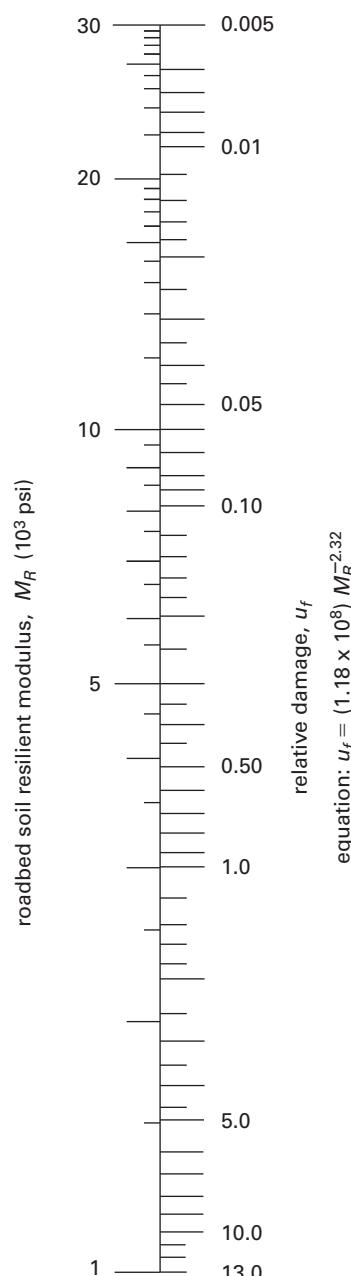

$$\left[ \begin{array}{l} \text{AASHTO GDPS} \\ \text{Eq. 1.5.1} \end{array} \right] \quad [\text{U.S.}] \quad 76.29(b)$$

effective roadbed soil resilient modulus,  $M_R$  (psi) =        (corresponds to  $\bar{u}_f$ )

From *AASHTO Guide for Design of Pavement Structures*, Sec. II, p. II-14, Fig. 2.3, copyright © 1993 by the American Association of State Highway and Transportation Officials, Washington, D.C. Used by permission.

Equation 76.29 was originally formulated in 1962. It is limited to fine-grained soils with soaked CBR values of 10 or less. Like all correlations, it should be used with caution.<sup>6</sup> More recently, the NCHRP, in Project 1-37A, has proposed an alternative correlation.

$$M_R = 2555(\text{CBR})^{0.64} \quad [\text{U.S. only}] \quad 76.30$$

Table 76.10 compares the different subgrade parameters.

**Table 76.10** Comparison of Subgrade Parameters

subgrade quality	$M_R$ (psi (MPa))	CBR	R
poor	4500 (30)	3	6
medium	12,000 (80)	8	20
good	25,000 (170)	17	42

(Multiply psi by 6.895 to obtain MPa.)

In preliminary studies, only an estimate of subgrade support strength may be known. However, in follow-up analyses, multiple tests of subgrade support along the route can result in a range of values. Particularly when 30 or more samples are taken, these values can be assumed to be normally distributed. Mechanistic and other modern methods use the mean and standard deviation of the distribution to determine the design subgrade parameter based on the desired reliability (i.e., confidence level). (See Table 76.11.)

**Table 76.11** Suggested Subgrade Design Confidence Levels (highway pavements)

traffic	ESALs	confidence
light	$< 10^4$	60%
moderate	$10^4\text{--}10^6$	75%
heavy	$> 10^6$	87.5%

To convert from the R-value to the resilient modulus for fine-grained soils, use Eq. 76.31.

$$M_R = 1000 + 555R \quad \begin{bmatrix} \text{U.S. only; AASHTO GDPS} \\ \text{Eq. 1.5.3; } R \leq 20 \end{bmatrix} \quad 76.31$$

$$M_{R,\text{MPa}} = 8.0 + 3.8R \quad [\text{SI}] \quad 76.32(a)$$

$$M_R = 1155 + 555R \quad \begin{bmatrix} \text{Asphalt Institute,} \\ \text{MS-1} \end{bmatrix} \quad [\text{U.S.}] \quad 76.32(b)$$

<sup>6</sup>CBR and R-value correlations are considered applicable to fine-grained soils classified as CL, CH, ML, SC, SM, and SP (Unified Soil Classification) and for materials that have a resilient modulus of 30,000 psi or less. Such correlations are *not* applicable to granular materials (e.g., base aggregate). Direct laboratory testing is required to obtain resilient modulus values in such cases.

Figure 76.10 is a nomograph provided by AASHTO for determining the design structural number for specific design conditions: estimated future traffic,  $w_{18}$ , over the performance period; the reliability,  $R$ , which assumes all input variables are average values; the overall standard deviation,  $S_o$ ; the effective resilient modulus of the roadbed material,  $M_R$ ; and the design serviceability loss,  $\Delta\text{PSI}$ .

## 26. PAVEMENT STRUCTURAL NUMBER

AASHTO combines pavement layer properties and thicknesses into one variable called the design *structural number*, SN. Once the structural number for a pavement is determined, a set of pavement layer thicknesses are chosen. When combined, these layer thicknesses must provide the load-carrying capacity corresponding to the design structural number.

Equation 76.33 is the AASHTO *layer-thickness equation*.  $D_1$ ,  $D_2$ , and  $D_3$  represent actual thicknesses (in inches) of surface, base, and subbase courses, respectively. (If a subbase layer is not used, the third term is omitted.) The  $a_i$  are the *layer coefficients*, also known as *strength coefficients*.  $m_2$  and  $m_3$  represent *drainage coefficients* for base and subbase layers, respectively. Typical values of drainage coefficients vary from 0.4 to 1.40, as recommended in AASHTO *GDPS* Table 2.4. Values greater than 1.0 are assigned to bases and subbases with good/excellent drainage and that are seldom saturated [AASHTO *GDPS* Table 2.4].

Theoretically, any combinations of thicknesses that satisfy Eq. 76.33 will work. However, minimum layer thicknesses result from construction techniques and strength requirements. Therefore, the thickness of the flexible pavement layers should be rounded to the nearest  $1/2$  in (12 mm). When selecting layer thicknesses, cost effectiveness as well as placement and compaction issues must be considered to avoid impractical designs. (See Table 76.12.)

$$\text{SN} = D_1 a_1 + D_2 a_2 m_2 + D_3 a_3 m_3 \quad 76.33$$

The layer coefficients,  $a_i$ , vary from material to material, but the values given in Table 76.13 can be used for general calculations. The AASHTO *GDPS* contains correlations for all three layer coefficients as functions of the materials' elastic (resilient) moduli. Although the  $a_1$  correlation is purely graphical, mathematical correlations are given for  $a_2$  and  $a_3$  for granular materials. (See AASHTO *GDPS* Fig. 2.5.)  $E_{\text{BS}}$  in Eq. 76.34 is the resilient modulus of the granular base material. In Eq. 76.35,  $E_{\text{SB}}$  is the resilient modulus of the subbase material.

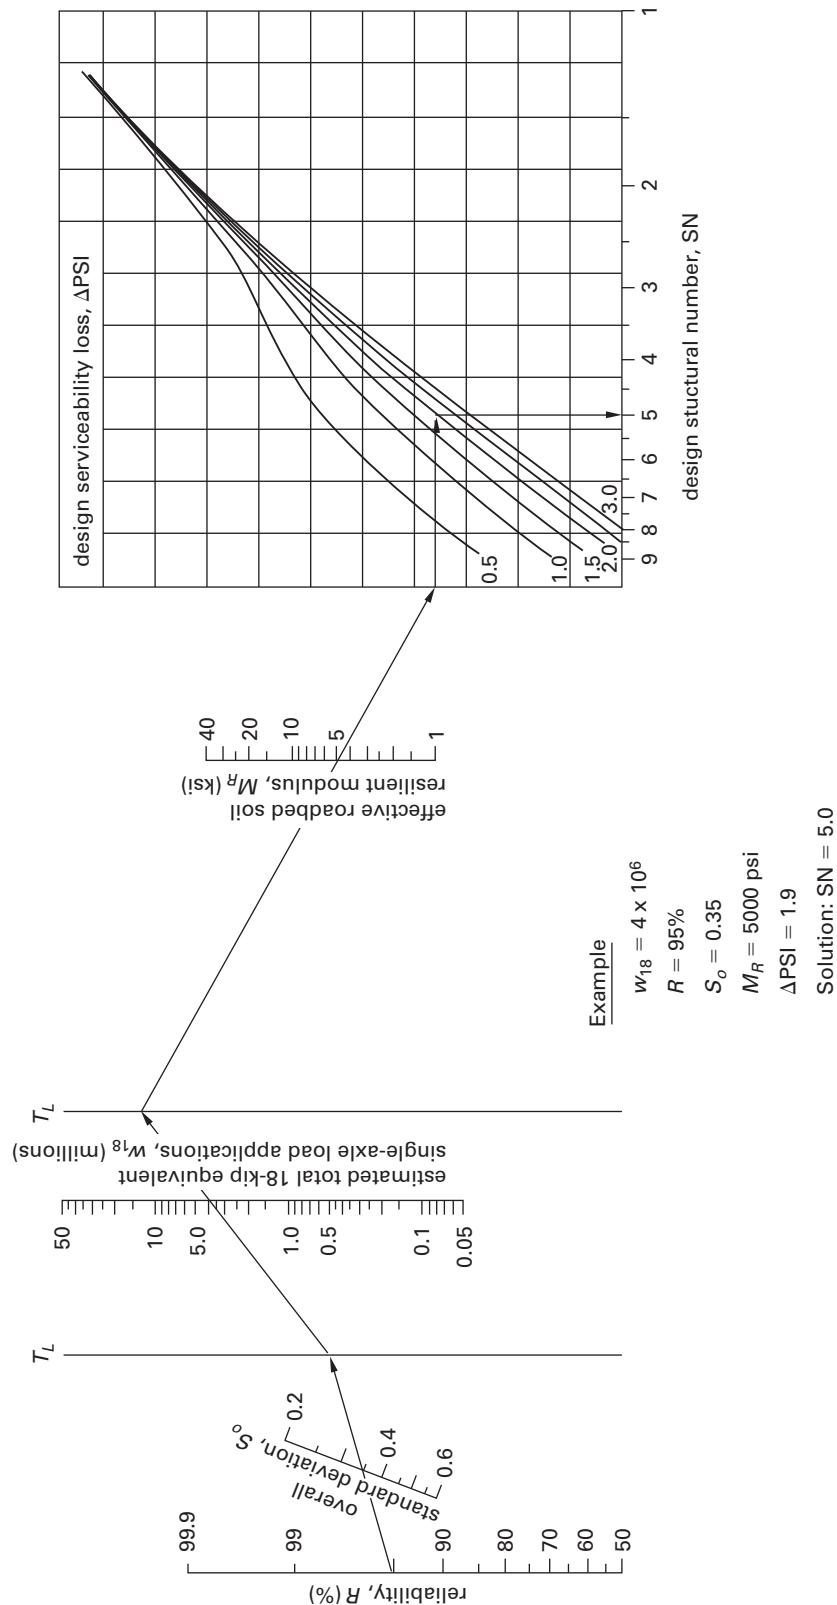

$$a_2 = 0.249(\log_{10} E_{\text{BS}}) - 0.977$$

$$[\text{U.S. only; AASHTO GDPS Sec. 2.3.5}] \quad 76.34$$

$$a_3 = 0.227(\log_{10} E_{\text{SB}}) - 0.839$$

$$[\text{U.S. only; AASHTO GDPS Sec. 2.3.5}] \quad 76.35$$

**Figure 76.10** AASHTO Nomograph for Flexible Pavement Design

asphaltic concrete surface course	0.44
crushed stone base course	0.14
sandy gravel subbase	0.11

Compiled from a variety of sources.

Flexible pavements are layered systems and are designed accordingly. First, the required structural number over the native soil is determined, followed by the structural number over the subbase and base layers, using applicable strength values for each. The maximum allowable thickness of any layer can be computed from the differences between the computed structural numbers. (See Fig. 76.11.)

**Figure 76.11** Procedure for Determining Thicknesses of Layers Using a Layered Analysis Approach\*

$$D_1^* \geq \frac{S_{N_1}}{a_1}$$

$$S_{N_1}^* = a_1 D_1^* \geq S_{N_1}$$

$$D_2^* \geq \frac{S_{N_2} - S_{N_1}^*}{a_2 m_2}$$

$$S_{N_1}^* + S_{N_2}^* \geq S_{N_2}$$

$$D_3^* \geq \frac{S_{N_3} - (S_{N_1}^* + S_{N_2}^*)}{a_3 m_3}$$

\*Asterisks indicate values actually used, which must be equal to or greater than the required values.

This method should not be used to determine the structural number required above subbase or base materials having moduli of resilience greater than 40,000 psi (275 MPa). Layer thicknesses for materials above high-strength subbases and bases should be based on cost effectiveness and minimum practical thickness considerations.

### Example 76.7

Determine the pavement thicknesses for two pavement layers over subgrade that have a required structural number of 5. Layer 1 consists of asphalt concrete with a strength coefficient, *a*<sub>1</sub>, of 0.44 and a minimum thickness of 3.00 in. Layer 2 is a granular base with a strength coefficient, *a*<sub>2</sub>, of 0.13; a drainage coefficient, *m*<sub>2</sub>, of 1.00; a minimum thickness of 6.00 in; and a maximum thickness of 25 in.

#### Solution

**Trial 1:** Try a 3 in thick bituminous pavement. Use Eq. 76.33.

$$S_{N_1} = D_1 a_1 = \left(0.44 \frac{1}{\text{in}}\right)(3.00 \text{ in}) = 1.32$$

Determine the thickness of aggregate base required.

$$D_2 = \frac{SN_2 - SN_1}{a_2 m_2} = \frac{5 - 1.32}{(0.13 \frac{1}{in})(1.00)} \\ = 28.3 \text{ in } [ > 25 \text{ in}]$$

*Trial 2:* Try a 5 in thick bituminous pavement.

$$SN_1 = D_1 a_1 = (0.44 \frac{1}{in})(5.00 \text{ in}) = 2.20 \\ D_2 = \frac{SN_2 - SN_1}{a_2 m_2} = \frac{5 - 2.20}{(0.13 \frac{1}{in})(1.00)} \\ = 21.5 \text{ in } [\text{OK}]$$

## 27. ASPHALT INSTITUTE METHOD OF FULL-DEPTH FLEXIBLE PAVEMENT DESIGN

The Asphalt Institute's *Thickness Design: Asphalt Pavements for Highways and Streets* (MS-1), ninth edition, is the source for the information in this section. The Asphalt Institute pavement design method was developed in 1981. It makes several assumptions regarding material properties, enabling the design to be read from a series of charts. Like the AASHTO method, it uses 18 kip ESALs as a measure of traffic loading.<sup>7</sup>

Two designs are considered in this chapter: full-depth asphalt (asphalt concrete over asphalt subgrade) and asphalt concrete over a 6 in (150 mm) untreated granular base. By using the chart corresponding to the mean average annual temperature (MAAT), environmental conditions are considered for the effects of temperature on asphalt stiffness and the effects of freezing and thawing on subgrade and untreated base materials.

The following steps constitute the design procedure.

- step 1:* Determine the 20 yr, 18 kip equivalent single-axle loading (ESAL) for the pavement.
- step 2:* The resilient modulus of the subgrade is the design parameter, and it is a function of traffic. Select a design subgrade percentile based on Table 76.14 and design ESALs.
- step 3:* For full-depth bituminous asphalt pavement, use Fig. 76.12 or Fig. 76.13 to determine the minimum pavement thickness. For asphalt concrete over a granular base, determine the minimum asphalt concrete surface thickness according to Fig. 76.14 or Fig. 76.15.
- step 4:* Specify the aggregate base thickness as 6 in (150 mm) or 12 in (300 mm). (Figure 76.14 and Fig. 76.15 assume the base will be 6 in (150 mm) thick.)

**Table 76.14** Design Resilient Modulus Percentiles (highways)

traffic (ESALs)	design subgrade percentile
≤ 10,000	60
10,000–1,000,000	75
≥ 1,000,000	87.5

Reprinted with permission of the Asphalt Institute from *Asphalt Pavements for Highways and Streets, Manual Series No. 1 (MS-1)*, 9th ed., Table V-2, copyright © 2008.

### Example 76.8

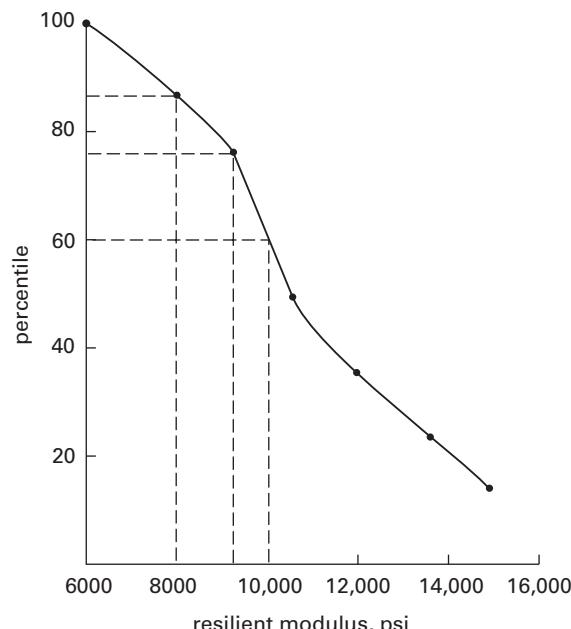

The following California bearing ratio (CBR) values were obtained from multiple tests on the base soil over a proposed roadway: 7, 6, 8, 4, 6, 9, 5, and 10. Determine the design resilient modulus,  $M_R$ , for a traffic level of 100,000.

*Solution*

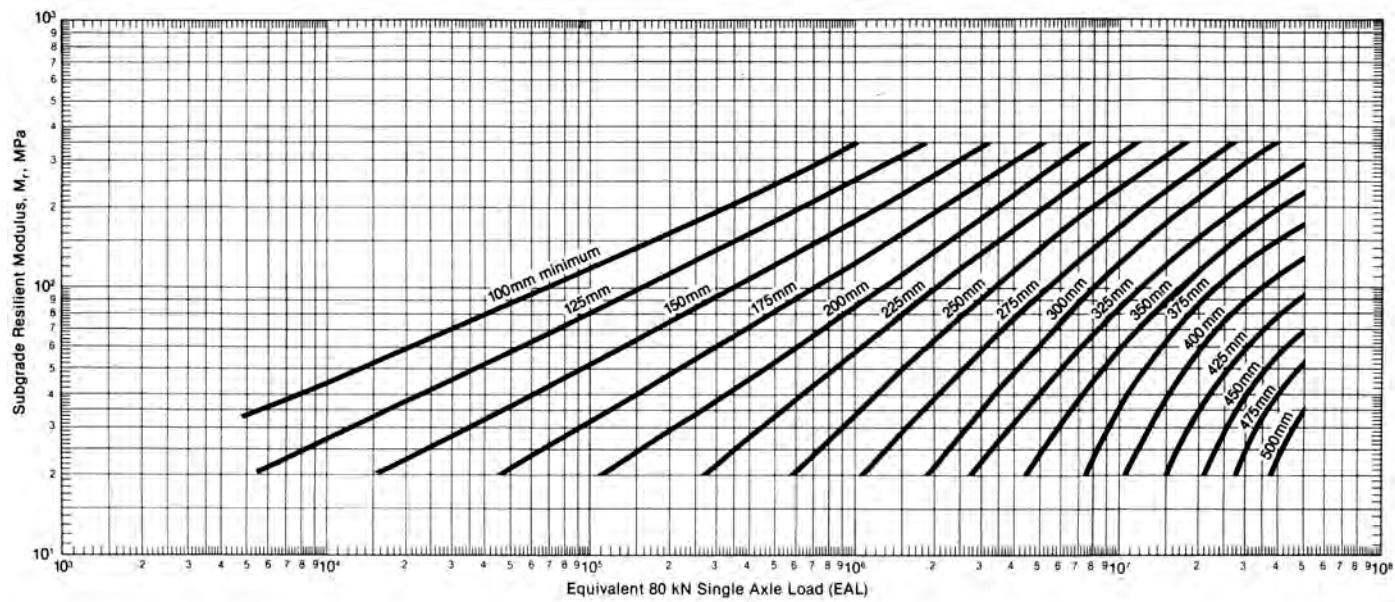

Use Eq. 76.29 for each sample.

CBR	$M_R$ (psi)	number greater	quantity percentage
10	15,000	1	$\frac{1}{8} \times 100\% = 12.5\%$
9	13,500	2	25%
8	12,000	3	37.5%
7	10,500	4	50%
6	9,000	6	75%
6	9,000	6	75%
5	7,500	7	87.5%
4	6,000	8	100%

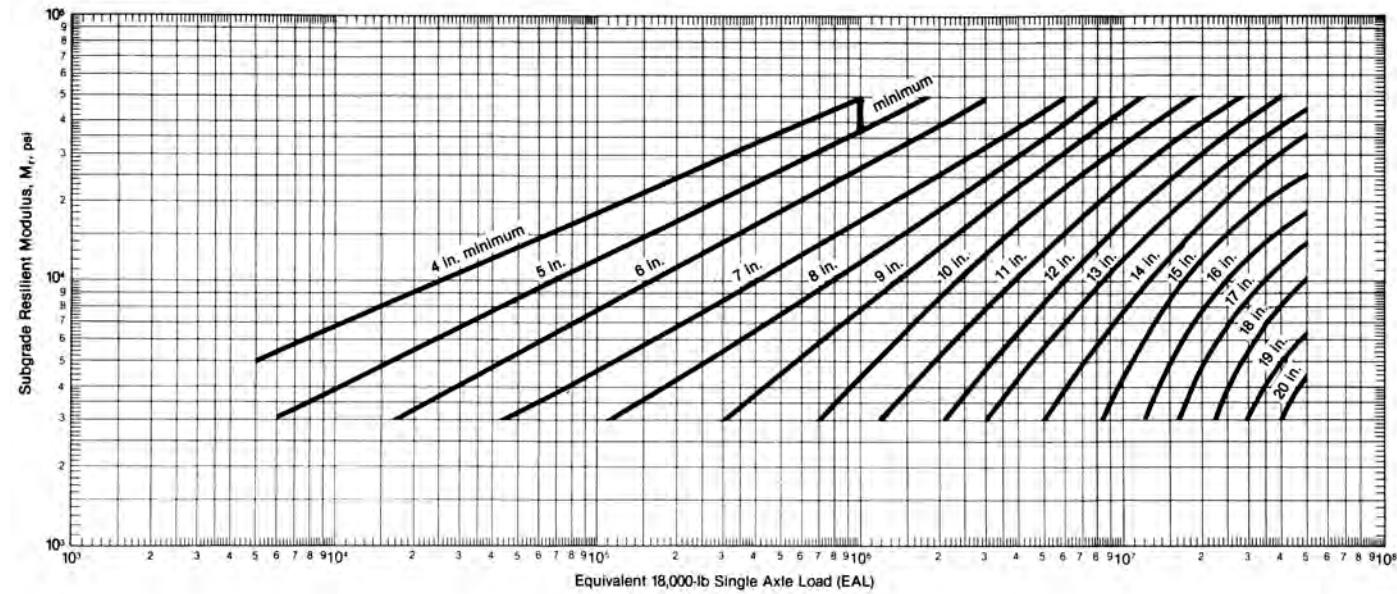

Plot the values. From the plot and Table 76.14, the required resilient modulus at 100,000 ESALs is the 75th percentile, and  $M_R = 9000$  psi.

<sup>7</sup>MS-1 also contains design charts for asphalt courses over 12 in (300 mm) of untreated aggregate base, as well as charts for three types of emulsified asphalt mixes.

**Figure 76.15** Asphalt Concrete on Untreated Aggregate Base, 6 in Thickness (customary U.S. units, MAAT 60°F)

Reprinted with permission of the Asphalt Institute from *Asphalt Pavements for Highways and Streets, Manual Series No. 1 (MS-1)*, 9th ed., Design Chart A-29, copyright © 2008.

**Example 76.9**

A local area has a mean average annual temperature of 60°F (15.5°C). Design a full-depth asphalt pavement for a subgrade modulus of 6000 psi and 1,000,000 ESALs.

*Solution*

Use Fig. 76.13. At 1,000,000 ESALs, the full-depth pavement design is 9.5 in.

**Example 76.10**

A local area has a mean average annual temperature of 60°F (15.5°C). Design an asphalt concrete pavement over a 6 in (150 mm) granular base for a subgrade modulus of 6000 psi and 1,000,000 ESALs.

*Solution*

Use Fig. 76.15. At 1,000,000 ESALs and a 6 in granular base, the required asphalt pavement thickness is 8.5 in.

**28. ASPHALT PAVEMENT RECYCLING**

There are a variety of processes that collectively comprise *recycled asphalt pavement* (RAP) technology. The primary benefit of recycling is cost effectiveness, although strength and reliability do not appear to be affected. *Full-depth reclamation* turns a roadway into the base material for a new surface. The original roadway pavement and some of the underlying material are removed, pulverized, and reused.

*Profiling*, also known as *surface recycling*, is a modification of the visible surface of the pavement. *Cold planing* is the removal of asphalt pavement by special pavement milling and planing machines (i.e., *profiling equipment*). The resulting pavement with long striations provides a good skid-resistant surface. Cold planing is used to restore a road to an even surface. The material removed is 95% aggregate and 5% asphalt cement. Conventional milling machines run at 5–10 ft/min (1.5–3 m/min) with a 1–2 in (25–50 mm) cut. High-capacity machines can run at up to 80 ft/min (24 m/min) with a 4–6 in (100–150 mm) cut (though half this speed is more typical).

*Cold in-place recycling* employs a *cold train* of equipment to mill 1–6 in (25–150 mm) of pavement, crush, size, add asphalt rejuvenating agents and/or light asphalt oil in a pug mill, and finally redeposit and recompact the mixture in a conventional manner. A cold-recycled mix will have at least 6% voids, requiring some type of seal or overlay to keep air and water from entering. The overlay can be a sand, slurry, or chip seal. To achieve the required density, roller compaction is required.

*Hot in-place recycling*, also known as *hot in-place remixing* and *surface recycling*, begins by heating the pavement to above 250°F (120°C) with high-intensity

indirect propane heaters. Then, a scarifier loosens and removes a layer of up to 2 in (50 mm) of softened asphalt concrete. The removed material is mixed with a rejuvenator in a traveling pugmill, augured out laterally, redistributed, and compressed by a screed and rollers. A petroleum-based agent may be subsequently applied to restore the asphalt cement's adhesive qualities, or up to 2 in (50 mm) of additional new hot mix asphalt cement can be applied over the replaced surface. Alternatively, a heavier petroleum product can be applied to help the recycled surface withstand direct traffic. The entire paving train runs at approximately 2 ft/min and the pavement can be used almost immediately.

*Hot mix recycling* is used in the majority of pavement rehabilitation projects. This process removes the existing asphalt pavement, hauls it to an offsite plant, and blends it with asphalt cement and virgin rock aggregate. Batch plants can blend 20–40% RAP with virgin material, though 10–20% is more typical. Drum mixers can blend as much as 50% RAP with virgin material.

*Microwave asphalt recycling* produces hot mix with 100% RAP. Warm air is first used to dry and preheat the reclaimed pavement. Microwave radiation is used to heat the stones in the mixture (since asphalt is not easily heated by microwaves) to approximately 300°F (150°C) without coking any hydrocarbons. Rejuvenating agents restore the pavement's original characteristics, or new aggregate can be used to improve performance.

**29. STONE MATRIX ASPHALT**

*Stone matrix asphalt* (SMA), also known as *split mastic*, *stone-filled asphalt*, and *stone mastic asphalt*, is a design method that has been imported from Europe. SMA has withstood years of punishment under Europe's heavier axle loads and studded tires without undue deterioration or rutting.

SMA requires different aggregates, different mixing technology, and different paving methods. Because of this, it is a specialty tool for highways that carry the heaviest traffic.

SMA uses single-sized cubical stones, typically 100% crushed rock or stone, in close contact. In the United States, typically 100% of an SMA aggregate will pass through a  $\frac{3}{4}$  in (19 mm) sieve and 80–90% will pass through a  $\frac{1}{2}$  in (13 mm) sieve, but only 25–30% will pass through a no. 4 sieve. (By contrast, a conventional mix will pass about 55% through a no. 4 sieve.) A rich mortar of asphalt cement, fibers, and fine aggregate (i.e., sand) is used to fill the voids and prevent asphalt drain down. The sand fraction contains a large amount of manufactured crushed sand that may be washed out if it contains too many fine particles. The mortar provides durability.

SMA contains a higher fraction (6–8%) of hard, low-penetration grade asphalt cement. The mixture often incorporates cellulose fibers, mineral (rock wool) fibers,

or, less frequently, polymers to stiffen the mix and improve toughness.

When placed, SMA compacts less than  $\frac{1}{8}$  in (3 mm) per inch of thickness, and very little at all under 240°F (115°C). Paving rates are lower because the mix is stiffer. Since SMA compacts less and sets up faster, rollers have to follow closely. Most contractors roll SMA with a team of three 10 or 12 ton rollers, one working right behind the other, all closely following the paver.

SMA is currently more expensive than conventional mixes, but the general consensus is that lower life-cycle costs and extended life more than offset the initial cost premium.

Although SMA can be (and has been) designed with the traditional 50- and 75-blow Marshall mix design methods, cutting-edge efforts include using the PG system for specifying asphalt cements. Like Superpave, SMA's strength comes from its stone-on-stone contact. SMA differs from Superpave, however, in the methods used to specify the asphalt and to design and test the mixture. However, the differences are becoming less distinct.

### **30. ADVANCED, ALTERNATIVE, AND EXPERIMENTAL FLEXIBLE PAVEMENTS**

*Asphalt rubber* (AR) is a general term referring to a wide range of paving products that combine virgin or reclaimed rubber with asphalt cement. *Rubber-modified asphalt*, also known as *crumb-rubber modified* (CRM) *asphalt*, is made from scrap rubber from tires.

In the "wet process" (*reacted asphalt process* or *asphalt hot rubber mix* (AHRM)), the rubber is blended into hot asphalt, creating an asphalt-rubber binder with 10–25% rubber by weight. The mixture is held at 375–400°F (190–205°C) and agitated for 20–60 min. In the "dry process" (*rubberized asphalt process*), *crumb rubber*, also known as *crumb rubber modifier* (CRM), in the form of pea-sized beads replaces about 3% of the stone aggregate.

Asphalt rubber has attracted considerable attention in recent years. Federal requirements mandating the use of crumb rubber have been eliminated, mainly out of concerns over the health effects on paving workers. But some states continue to require it. Concerns have been raised about recyclability and combustible roads catching fire. Experience in California seems to indicate that asphalt rubber may result in pavement sections half the thickness of conventional asphalt concrete pavement. Asphalt rubber also holds heat longer than conventional mixes, allowing night placement at temperatures as low as 50°F (10°C). Other preliminary tests are mixed, indicating higher costs without significant structural or durability benefits.

*Fast-track pavement* is a fast-setting (using type III portland cement) concrete. Fast-track pavement is used for asphalt overlays, where quick restoration without significant traffic interruption is needed. 4 in (100 mm)

layers typically set up in 12 hr and are ready for traffic in 18 hr.

*Whitetopping* (also known as *ultra-thin whitetopping*, UTW) is a rehabilitation method used for rutted asphalt. It creates an economic surface for high-use areas. The technique involves placing a thin (e.g., 75–100 mm) layer of fiber-reinforced, high-performance concrete over rutted asphalt. The process forms a highly durable bond (lasting three to four times longer than asphalt), and it does not need the regular milling or maintenance that asphalt does. The whitetopping has the flexibility of asphalt and the load-bearing capacity of concrete. Although asphalt can be placed less expensively per volume than concrete, the life-cycle costs of whitetopping repair appear to be lower.

*Roller-compacted concrete* (RCC) is a zero-slump mixture that is placed and compacted. RCC is good for pothole repair.

*Trashphalt* is asphalt paving using a wide variety of scrap and waste materials including glass, rubber tire scrap, fly ash, steel refining waste, porcelain from crushed plumbing fixtures, roofing shingles, concrete, and brick. Concern has been raised that such paving materials will probably preclude pavement recycling efforts in later years.

Coal-derived *synthetic asphalt* is a technology that has become less important than when it was first developed. As long as oil prices remain low, it is unlikely that synthetic asphalt will be used much.

*Sulfur concrete* (*sulfur-asphalt concrete*, *sulfur-extended concrete*, *sulphex*, etc.) is manufactured by heating sulfur (20–40% by weight) to approximately 280–290°F (138–143°C) until it is molten, combining with asphalt, and then adding mineral filler and aggregate. (Below 300°F (150°C), elemental sulfur is the primary vapor component. Above that, sulfur dioxide and hydrogen sulfide become the dominant pollutants. Therefore, molten sulfur must be kept below 300°F (150°C).) First-generation sulfur concrete using pure sulfur experienced early rutting. Second-generation sulfur concrete used sulfur that had been chemically modified to reduce brittleness, and it performs better. There is currently little incentive to perfect sulfur concrete.

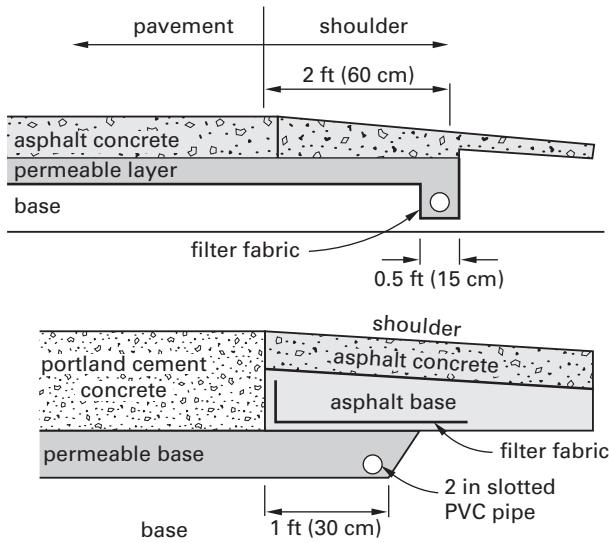

### **31. SUBGRADE DRAINAGE**

*Subgrade drains* are applicable whenever the following conditions exist: (a) high groundwater levels that reduce subgrade stability and provide a source of water for frost action, (b) subgrade soils of silts and very fine sands that become quick or spongy when saturated, (c) water seepage from underlying water-bearing strata, (d) drainage path of higher elevations intercepts sag curves with low-permeability subgrade soils below.

Figure 76.16 illustrates typical subgrade drain placement. In general, drains should not be located too close to the pavement (to prevent damage to one while the

other is being worked on), and some provision should be made to prevent the infiltration of silt and fines into the drain. Roofing felt or geotextile sleeves can be placed around the drains for this purpose.

**Figure 76.16 Typical Subgrade Drain Details**

### 32. DAMAGE FROM FROST AND FREEZING

Frost heaving and reduced subgrade strength, along with the accompanying pumping during spring thaw, can quickly destroy a pavement. The following techniques can be used to reduce damage to a flexible pavement in areas susceptible to frost: (a) constructing stronger and thicker pavement sections, (b) lowering the water table by use of subdrains and drainage ditches, (c) using layers of coarse sands or waterproof sheets beneath the pavement surface to reduce capillary action, (d) removing and replacing frost-susceptible materials to a level beneath the zone of frost penetration, and (e) using rigid foam sheets to insulate and reduce the depth of frost penetration.

## 1. RIGID PAVEMENT

Information for this chapter is primarily derived from the AASHTO *Guide for Design of Pavement Structures* (AASHTO *GDPS*), 1993 edition, the 1998 *Supplement to the AASHTO Guide for Design of Pavement Structures*, and the Portland Cement Association (PCA) *Design and Control of Concrete Mixtures*, fifteenth edition.

The Federal Highway Administration's (FHWA) Long-Term Pavement Performance (LTPP) program is a long-term study designed to provide the data required to better understand pavement performance. Based on data from the LTPP studies, guidelines have been prepared to aid in the design of better-performing asphalt and Portland cement concrete (PCC) pavements, to more accurately predict pavement performance, and to reduce dependence on empirical design procedures in favor of more advanced mechanistic design procedures. Alternative guidelines for PCC have been published as a 1998 supplement to the 1993 AASHTO *GDPS*. The guidelines are meant to help reduce the likelihood of cracking or faulting in new or reconstructed pavements by providing tools to tailor pavement designs to the base course and underlying soil layers at the project site. These design procedures can be used in place of or in conjunction with the 1993 procedures for rigid pavement design.

*Portland cement concrete (PCC)* pavement is the most common form of *rigid pavement* because of its excellent durability and long service life. Its raw materials are readily available and reasonably inexpensive; it is easily formed; it withstands exposure to water without deterioration; and it is recyclable. The primary disadvantages of PCC pavement are that it can lose its original nonskid surface over time; it must be used with an even subgrade and only where uniform settling is expected; and it may rise and fall (i.e., fault) at transverse joints.

PCC pavement is placed with *slip-form construction* methods. A stiff concrete is placed in front of a paving train that distributes, vibrates, screeds, and finishes the layer. Shoulders are usually constructed of asphalt pavement later, since shoulder traffic is much lower.

PCC pavement may be reinforced or nonreinforced, and joints may or may not be included. The four main types of concrete pavement are *plain jointed concrete pavement* (JCP), also known as *jointed plain concrete pavement* (JPCP); *jointed reinforced concrete pavement* (JRCP); *continuously reinforced concrete pavement* (CRCP); and *prestressed concrete pavement* (PCP). *Construction joints* are required in both reinforced and nonreinforced pavement. (See Sec. 77.10.)

Use of PCP is rare in the United States. The major advantage of prestressing is a reduction (up to 50%) in thickness, making it more applicable to airfield pavements, which are thicker. Initial testing seems to indicate a superior, stronger, longer lasting pavement, but with added cost and complexity. Although the AASHTO *GDPS* provides some design guidance, few state transportation departments, vendors, or contractors are available to promote the technology.

## 2. MIXTURE PROPORTIONING

The PCA describes how to proportion a PCC mixture using the *absolute volume method* (*solid volume method*). In this method, a trial batch of concrete is first prepared and tested for the desired outcome properties. After observing test results of the trial batch, the inputs (i.e.,

constraints of the concrete element and clear spacing between reinforcing; methods for concrete batching and placing; the service environment and associated durability requirements; and required concrete mechanical properties) are varied as necessary to obtain the desired outputs (i.e., the required characteristics for the concrete mixture and each ingredient).

The following steps constitute the PCA's absolute volume method for proportioning a PCC mixture.

- step 1:* Gather input information, including physical dimensions of the finished product, minimum clear space between rebar or minimum form dimension, environmental conditions, expected durability, workability requirements, and approximate slump.
- step 2:* Select the maximum aggregate size to be smaller than one-fifth of the narrowest form dimension, one-third of the slab depth, and three-fourths of the clear space between the rebar.
- step 3:* Select a trial water-cement ratio based on exposure as the lower of the two values for exposure from Table 77.1, and for strength from Table 77.2.
- step 4:* Estimate the mixing water and air void contents from Table 77.3.
- step 5:* Calculate the cement content by dividing the mixing water content by the water-cement ratio. Check against the minimum requirements of cementing materials using Table 77.4.

**Table 77.1** Maximum Water-Cement Ratios (based on exposure)

exposure category*	exposure condition	maximum water-cement material ratio by weight for normalweight concrete	minimum design compressive strength, $f'_c$ (lbf/in <sup>2</sup> (MPa))
F0, S0, P0, C0	concrete protected from exposure to freezing and thawing, or application of deicing chemicals	select water-cement ratio on basis of strength, workability, and finishing needs	select strength based on structural requirements
P1	concrete intended to have low permeability when exposed to water	0.50	4000 (28)
F1, F2, F3	concrete exposed to freezing and thawing in a moist condition, or to deicers	0.45	4500 (31)
C2	for corrosion protection of reinforced concrete exposed to chlorides from deicing salts, salt water, brackish water, seawater, or spray from these sources	0.40	5000 (35)

(Multiply lbf/in<sup>2</sup> by 0.0069 to obtain MPa.)

\*Exposure categories are adapted from ACI 318. The following four exposure categories determine durability requirements for concrete: (1) F-freezing and thawing; (2) S-sulfates; (3) P-permeability; (4) C-corrosion. Increasing numerical values represent increasingly severe exposure conditions.

**Table 77.2** Typical Relationship Between Water-Cement Ratio and Compressive Strength

compressive strength at 28 days (lbf/in <sup>2</sup> )	water-cement ratio by weight, <i>w/c</i>	
	non-air-entrained concrete	air-entrained concrete
7000	0.33	—
6000	0.41	0.32
5000	0.48	0.40
4000	0.57	0.48
3000	0.68	0.59
2000	0.82	0.74

(Multiply lbf/in<sup>2</sup> by 6.89 to obtain kPa.)

Reprinted with permission of the Portland Cement Association from the *Design and Control of Concrete Mixtures*, 15th ed., Table 12-3, copyright © 2011.

*step 6:* Estimate the coarse aggregate content from Table 77.5. This gives a ratio of the volume (including interstitial air gaps between particles) of coarse aggregate to the volume of concrete.

*step 7:* Estimate the fine aggregate content. Subtract the volumes of all other ingredients from the unit volume of the concrete to determine the unit volume of fine aggregate.

**Table 77.3** Approximate Mixing Water and Target Air Content Requirements for Different Slumps and Maximum Sizes of Aggregate

slump (in)	lbf/yd <sup>3</sup> of concrete for indicated maximum sizes of aggregate <sup>a</sup>							
	3/8 in	1/2 in	3/4 in	1 in	1 1/2 in	2 in <sup>b</sup>	3 in <sup>b</sup>	6 in
non-air-entrained concrete								
1–2	350	335	315	300	275	260	220	190
3–4	385	365	340	325	300	285	245	210
6–7	410	385	360	340	315	300	270	—
approximate percentage of entrapped air in non-air-entrained concrete	3	2.5	2	1.5	1	0.5	0.3	0.2
air-entrained concrete								
1–2	305	295	280	270	250	240	205	180
3–4	340	325	305	295	275	265	225	200
6–7	365	345	325	310	290	280	260	—
recommended average percentage of total air content for level of exposure: <sup>c</sup>								
mild exposure	4.5	4.0	3.5	3.0	2.5	2.0	1.5	1.0
moderate exposure (class F1)	6.0	5.5	5.0	4.5	4.5	3.5	3.5	3.0
severe exposure (classes F2 and F3)	7.5	7.0	6.0	6.0	5.5	5.0	4.5	4.0

(Multiply in by 25.4 to obtain mm.)

(Multiply lbf/yd<sup>3</sup> by 0.593 to obtain kg/m<sup>3</sup>.)

<sup>a</sup>These quantities of mixing water are for use in computing cement factors for trial batches. They are maximums for reasonably well-shaped angular coarse aggregates graded with limits of accepted specifications.

<sup>b</sup>The slump values for concrete containing aggregates larger than 1 1/2 in are based on slump tests made after removal of particles larger than 1 1/2 in by wet screening.

<sup>c</sup>The air content in job specifications should be specified to be delivered within –1 to +2 percentage points of the table target value for moderate and severe exposures.

Reprinted with permission of the Portland Cement Association from the *Design and Control of Concrete Mixtures*, 15th ed., Table 12-5, copyright © 2011.

**Example 77.1**

Design a concrete mixture for use in an exposed bridge pier. The bridge is located where exposure is severe (e.g., concrete exposed to chlorides from deicing salts), so air entrainment will be used. Specifications call for a 28-day compressive strength of 4000 lbf/in<sup>2</sup>. The rebar has a clear spacing of 1 in. The fine aggregate has a fineness modulus of 2.60, and the coarse aggregate has a dry-rod unit weight of 97 lbf/ft<sup>3</sup>. The coarse aggregate bulk specific gravity is 2.65, and the fine aggregate bulk specific gravity is 2.63. Cement has a specific gravity of 3.15. The maximum slump is 3 in.

*Solution*

*step 1:* Use the input information provided in the problem statement.

*step 2:* The maximum aggregate size is 3/4 of the clear spacing between rebar.

$$\left(\frac{3}{4}\right)(1 \text{ in}) = 3/4 \text{ in}$$

*step 3:* Determine a trial water/cement ratio. From Table 77.1, for exposure category C2, *w/c* = 0.40, and from Table 77.2, *w/c* = 0.48. Select the lower value of 0.40.

**Table 77.4** Minimum Requirements of Cementing Materials for Concrete Used in Flatwork

nominal maximum aggregate size (in)	cementing materials* (lbf/yd <sup>3</sup> )
1½	470
1	520
¾	540
½	590
⅜	610

(Multiply in by 25.4 to obtain mm.)

(Multiply lbf/yd<sup>3</sup> by 0.593 to obtain kg/m<sup>3</sup>.)

\*Cementing materials quantities may need to be greater for severe exposure.

Reprinted with permission of the Portland Cement Association from the *Design and Control of Concrete Mixtures*, 15th ed., Table 12-6, copyright © 2011.**Table 77.5** Bulk Volume of Coarse Aggregate per Unit Volume

nominal maximum size of aggregate (in)	bulk volume of dry-rodded coarse aggregate per unit volume of concrete for different fineness moduli of fine aggregate			
	2.40	2.60	2.80	3.00
⅜	0.50	0.48	0.46	0.44
½	0.59	0.57	0.55	0.53
¾	0.66	0.64	0.62	0.60
1	0.71	0.69	0.67	0.65

6	0.87	0.85	0.83	0.81

(Multiply in by 25.4 to obtain mm.)

Reprinted with permission of the Portland Cement Association from the *Design and Control of Concrete Mixtures*, 15th ed., Table 12-4, copyright © 2011.step 4: Select the mixing water and air content. From Table 77.3, mixing water is 305 lbf/yd<sup>3</sup> of concrete. The absolute volume of mixing water is

$$V_{\text{water}} = \frac{305 \frac{\text{lbf}}{\text{yd}^3}}{62.4 \frac{\text{lbf}}{\text{ft}^3}} = 4.89 \frac{\text{ft}^3}{\text{yd}^3}$$

From Table 77.3, the air content is 6.0%.

Therefore, the absolute volume of air in a cubic yard of concrete is

$$V_{\text{air}} = \left(27 \frac{\text{ft}^3}{\text{yd}^3}\right)(0.06) = 1.62 \frac{\text{ft}^3}{\text{yd}^3}$$

step 5: The cement per cubic yard of concrete is

$$W_{\text{cement}} = \frac{W_{\text{water}}}{\frac{w}{c}} = \frac{305 \frac{\text{lbf}}{\text{yd}^3}}{0.40} \\ = 762.5 \frac{\text{lbf}}{\text{yd}^3}$$

The absolute volume of cement required is

$$V_{\text{cement}} = \frac{W_{\text{cement}}}{(\text{SG})\gamma_w} = \frac{762.5 \frac{\text{lbf}}{\text{yd}^3}}{(3.15)\left(62.4 \frac{\text{lbf}}{\text{ft}^3}\right)} \\ = 3.88 \frac{\text{ft}^3}{\text{yd}^3}$$

step 6: Determine the coarse aggregate content. The volume fraction of dry-rodded coarse aggregate from Table 77.5 is 0.64. The dry-rodded volume (including interstitial air gaps between particles) of coarse aggregate per cubic yard is

$$V_{\text{coarse,rodded}} = (0.64) \left(27 \frac{\text{ft}^3}{\text{yd}^3}\right) = 17.28 \frac{\text{ft}^3}{\text{yd}^3}$$

The weight of coarse aggregate is

$$W_{\text{coarse,rodded}} = V_{\text{coarse}}\gamma_{\text{coarse}} = \left(17.28 \frac{\text{ft}^3}{\text{yd}^3}\right) \left(97 \frac{\text{lbf}}{\text{ft}^3}\right) \\ = 1676.2 \frac{\text{lbf}}{\text{yd}^3}$$

The absolute (solid) volume of coarse aggregate is

$$V_{\text{coarse,rodded}} = \frac{W_{\text{coarse,rodded}}}{(\text{SG})\gamma_w} = \frac{1676.2 \frac{\text{lbf}}{\text{yd}^3}}{(2.65)\left(62.4 \frac{\text{lbf}}{\text{ft}^3}\right)} \\ = 10.14 \frac{\text{ft}^3}{\text{yd}^3}$$

step 7: Determine the fine aggregate content. The fine aggregate takes up all space remaining after allowances have been made for the water, air, cement, and coarse aggregate.

$$V_{\text{fine}} = 27 \frac{\text{ft}^3}{\text{yd}^3} - 4.89 \frac{\text{ft}^3}{\text{yd}^3} - 1.62 \frac{\text{ft}^3}{\text{yd}^3} \\ - 3.88 \frac{\text{ft}^3}{\text{yd}^3} - 10.14 \frac{\text{ft}^3}{\text{yd}^3} \\ = 6.47 \frac{\text{ft}^3}{\text{yd}^3}$$

The weight of the fine aggregate is

$$\begin{aligned} W_{\text{fine}} &= V_{\text{fine}}(\text{SG})\gamma_w \\ &= \left(6.47 \frac{\text{ft}^3}{\text{yd}^3}\right)(2.63)\left(62.4 \frac{\text{lbf}}{\text{ft}^3}\right) \\ &= 1061.8 \text{ lbf/yd}^3 \end{aligned}$$

### 3. AASHTO METHOD OF RIGID PAVEMENT DESIGN

The 1993 AASHTO *GDPS* method of rigid pavement design is a common empirical method. It determines the required slab depth,  $D$ , by solving Eq. 77.1 [AASHTO *GDPS* Eq. 1.2.2]. This equation is widely incorporated into computerized methods. For the purpose of manual solutions and this chapter, nomographic methods are used.

$$\begin{aligned} \log_{10} w_{18} &= z_R S_o + 7.35 \log_{10}(D+1) - 0.06 \\ &+ \frac{\log_{10}\left(\frac{\Delta \text{PSI}}{4.5 - 1.5}\right)}{1 + \frac{1.624 \times 10^7}{(D+1)^{8.46}}} \\ &+ (4.22 - 0.32 p_t) \\ &\times \log_{10} \left( \frac{S'_c C_d (D^{0.75} - 1.132)}{215.63 J \left( D^{0.75} - \frac{18.42}{\left(\frac{E_c}{k}\right)^{0.25}} \right)} \right) \end{aligned} \quad 77.1$$

All four types of PCC rigid pavement may be designed using the AASHTO method. The AASHTO rigid pavement design concepts, terminology, and procedures are similar to those used by AASHTO for flexible pavement design. Similar and parallel concepts include the principal design variables (time, traffic, reliability, and environment), serviceability, load equivalency factors, truck factors, growth factors, layer coefficients, structural number concept, lane and directional distribution factors, and ESAL loading.

The primary differences include using the soil modulus of subgrade reaction,  $k$ ; concrete modulus of rupture,  $S'_c$ ; drainage coefficient,  $C_d$ ; joint  $J$ -value; friction factor,  $F$ ; and standard deviation,  $S_o$ .

Based on information obtained during the AASHTO Road Test, an appropriate overall standard deviation,  $S_o$ , for rigid pavements is 0.35. This is slightly different than for flexible pavements.

Equation 77.1 was developed from the early AASHO Road Tests, and accordingly, the road test conditions were not all-inclusive. As with any empirical equation, it is important to know the equation's basic assumptions and limitations. These test conditions include use of (a) AASHTO pavement materials and roadbed soil; (b) exposure to the local test environment; (c) an accelerated two-year study period without exposure to 20 years of environmental factors; (d) loading by identical axle loads and configurations, rather than by mixed traffic; (e) transverse, doweled joints at the same spacing throughout; and (f) uniform aggregate, cement, and PCC mix throughout.

In using Eq. 77.1, it is assumed that (1) the characterization of subgrade support may be extended to other subgrade soils by an abstract soil support scale; (2) loading can be applied to mixed traffic by use of ESALs; (3) material characterizations may be applied to other surfaces, bases, and subbases by assigning appropriate values; and (4) the accelerated testing done at the AASHO Road Test two-year period can be extended to longer design periods.

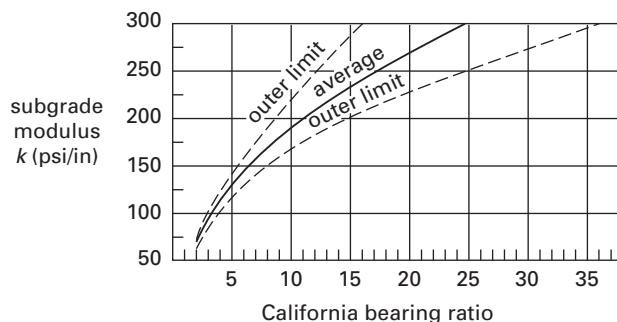

Due to the limitations of the original AASHO Road Tests, it was not unexpected that some pavements designed from its extensions performed poorly. An enhanced model was presented in the 1998 supplement to the 1993 AASHTO *GDPS*. Although the original 1993 model, as shown in Eq. 77.1, remains in publication and use, the newer supplemental model includes such enhancements as climate (temperature, wind speed, and precipitation) inputs, seasonally adjusted  $k$ -values, structural base course selection, improved subgrade  $k$ -value selection criteria, consideration of curling and warping, transverse joint spacing, slab width, shoulder type, consideration of slab/base friction, and faulting and corner break prediction. In other regards, the supplemental model uses many of the same inputs as the original model. However, using the model is greatly enhanced by computer implementations.

### 4. LAYER MATERIAL STRENGTHS

The material used for each pavement layer must be characterized. In the AASHTO method, the Westergaard *modulus of subgrade reaction*,  $k$  (also known as the  $k$ -value, and essentially the modulus of elasticity), is the primary performance factor for the soil. Its units are psi/in (i.e., pressure per unit length) or lbf/in<sup>3</sup> (N/m<sup>3</sup> or MPa/m). The resilient modulus concept can also be used, and the two moduli are linearly related. Correlations with other parameters are not generally exact, as Fig. 77.1 indicates. However, correlations with other subgrade parameters are often used because the plate-loading test used to determine  $k$  is both expensive and time consuming. Figure 77.1 and Table 77.6 are typical of such correlations.

$$k_{\text{lbf/in}^3} = \frac{M_{R,\text{lbf/in}^2}}{19.4} \quad 77.2$$

**Figure 77.1** Approximate Correlation Between CBR and Subgrade Modulus

**Table 77.6** Correlations of  $k$ -Values and Typical Subgrade Values

type of subgrade	amount of support	typical $k$ -values lb/in <sup>3</sup> (MPa/m)	California bearing ratio, CBR (%) <sup>a</sup>	resistance value, $R$ -value <sup>b</sup>
fine-grained, with high amounts of silt/clay	low	75–120 (20–34)	2.5–3.5	10–22
sand and sand-gravel, with moderate silt/clay	medium	130–170 (35–49)	4.5–7.5	29–41
sand and sand-gravel, with little or no silt/clay	high	180–220 (50–60)	8.5–12	45–52

<sup>a</sup>per ASTM D1183

<sup>b</sup>per ASTM D2844

Source: *Design of Concrete Pavement for Streets and Roads*, Table 10

The *effective slab support k-value* incorporates the support abilities of all the layers. AASHTO and PCA have published methods for incorporating the strength of all the layers. (See Table 77.7 and Table 77.8.)

Concrete's average *modulus of rupture* (flexural strength),  $S'_c$ , is found using a *third-point loading flexure test* at 28 days, as specified by AASHTO T97 or ASTM C78. The construction specification modulus of rupture should not be used, as it is too conservative since the average 28-day strength is often 10–15% or more higher than the acceptance criterion.

Concrete's compressive strength,  $f'_c$ , is routinely determined, and an approximate correlation exists between it and the modulus of rupture. In Eq. 77.3, the constant  $K$  varies from 7.5 to 10 for values of  $M_R$  and  $f'_c$  in lb/in<sup>2</sup>. (For values in MPa,  $K$  varies from 0.7 to 0.8.) Although concrete continues to strengthen with time, the average 28-day value of  $f'_c$  is used in Eq. 77.3.

$$M_R = K \sqrt{f'_c} \quad 77.3$$

**Table 77.7** Effective Slab Support (Subbase) Modulus with Untreated Subbase (lb/in<sup>3</sup>)

Concrete's *modulus of elasticity* is found using the ACI 318 relationship.

$$E_c = 57,000 \sqrt{f'_c} \quad [E_c \text{ and } f'_c \text{ in lb/in}^2] \quad 77.4$$

### Example 77.2

A subgrade has a California bearing ratio value of 10. A 6 in cement-treated subbase is to be used. What is the approximate effective subbase  $k$ -value?

*Solution*

From Fig. 77.1, the average subgrade  $k$ -value is 200 lb/in<sup>3</sup>. From Table 77.8, the effective subbase  $k$ -value is 640 lb/in<sup>3</sup>.

## 5. PAVEMENT DRAINAGE

The *drainage coefficient*,  $C_d$ , is a function of the drainage quality and presence of moisture. If the ground is saturated much of the time or the drainage is poor,  $C_d$  may be as low as 0.70. If the pavement is well-drained and conditions are dry,  $C_d$  may be as high as 1.25. In cases where the conditions are not specific,  $C_d = 1.00$  is assumed.

## 6. LOAD TRANSFER AND DOWELS

A *load transfer coefficient*,  $J$  (also known as the *J-value*), accounts for load distribution across joints and cracks. The  $J$ -value is affected by the use and placement of dowels, aggregate interlock, and tied shoulders. Approximate  $J$ -values for various conditions are

asphalt shoulders with dowels	$J = 3.2$
asphalt shoulders without dowels	$J = 4.0$
concrete shoulders with dowels	$J = 2.8$
concrete shoulders without dowels	$J = 3.8$

A rule of thumb for specifying the dowel diameter is the slab thickness divided by eight and then rounded up to the nearest standard bar size. Typical dowel spacing is 12 in (305 mm), and typical dowel length is 18 in (457 mm).

## 7. PAVEMENT DESIGN METHODOLOGY

Slab thickness is determined from Fig. 77.2 for each  $k$ -value, and then rounded to the nearest 0.5 in (13 mm). To use Fig. 77.2 to determine the slab thickness, the following variables are required: (a) effective  $k$ -value; (b) estimated future traffic in ESALs using the rigid pavement equivalency factors; (c) reliability level,  $R$ ; (d) overall standard deviation,  $S_o$ ; (e) design serviceability loss,  $\Delta\text{PSI}$ ; (f) concrete modulus of elasticity,  $E_c$ ; (g) concrete modulus of rupture,  $S'_c$ ; (h) load transfer coefficient,  $J$ ; and (i) drainage coefficient,  $C_d$ .

## 8. STEEL REINFORCING

Reinforcing steel for rigid pavements may consist of deformed reinforcing bar, smooth wire mesh, or deformed wire fabric. The purpose of the steel is not to add structural strength, but to hold cracks tightly together and restrain their growth. As the slab contracts, the contraction is resisted by friction with underlying material. Restraint of contraction causes tensile stresses to be at a maximum at mid-slab. When tensile stresses exceed the tensile strength of the concrete, cracks develop. Because transverse cracking is not expected in slabs less than 15 ft (4.2 m) long, reinforcement is not used in short slabs.

Although AASHTO provides a nomograph ("Reinforcement Design Chart for Jointed Reinforced Concrete Pavement," AASHTO *GDPS* Fig. 3.8), the percentage of reinforcing steel is easily calculated.

$$P_s = \frac{L_f F}{2f_{s,\text{lbf/in}^2}} \times 100\% \quad 77.5$$

The required reinforcement area is expressed as a percentage,  $P_s$ , of the cross-sectional area. The *slab length*,  $L$ , represents the distance between the free, or untied, joints and has a substantial effect on the maximum

concrete tensile stresses and the amount of steel required. *Steel working stress*,  $f_s$ , is assumed to be 75% of the steel yield strength. For example, grade 60 steel would be designed for 45 kips/in<sup>2</sup>.

The *friction factor*,  $F$ , represents the frictional resistance between the bottom of the slab and the top of the subbase or subgrade. Typical values of  $F$  are 0.9 for natural subgrade, 1.5 for crushed stone or gravel, 1.8 for stabilized material, and 2.2 for placement on another surface treatment [AASHTO *GDPS* Table 2.8].

To determine the amount of transverse reinforcement, Eq. 77.5 may still be used if  $L$  is taken as the side-to-side width of the slab. The transverse spacing between rebar,  $Y$ , is calculated from the cross-sectional area of the rebar,  $A_s$ ; the percent of transverse steel,  $P_t$ ; and the slab thickness,  $D$ .

$$P_t = \frac{A_s}{YD} \times 100\% \quad 77.6$$

*Tie bars* are dowels, usually deformed steel bars between 24 in and 40 in long, that are used to connect two abutting slabs (i.e., between two lanes poured at different times) to create a longitudinal joint. Figure 77.3 and Fig. 77.4 give tie bar spacing for 1/2 in and 5/8 in diameter deformed bars. To use these figures, the closest distance to a free edge, defined as any joint not having tie bars or as the distance between the edges of pavement, must be known. Tie bar spacing increases with decreases in the distance to a free edge since the steel tensile stress is maximum at the center of the slab. Spacing also increases with a decrease in slab thickness.

### Example 77.3

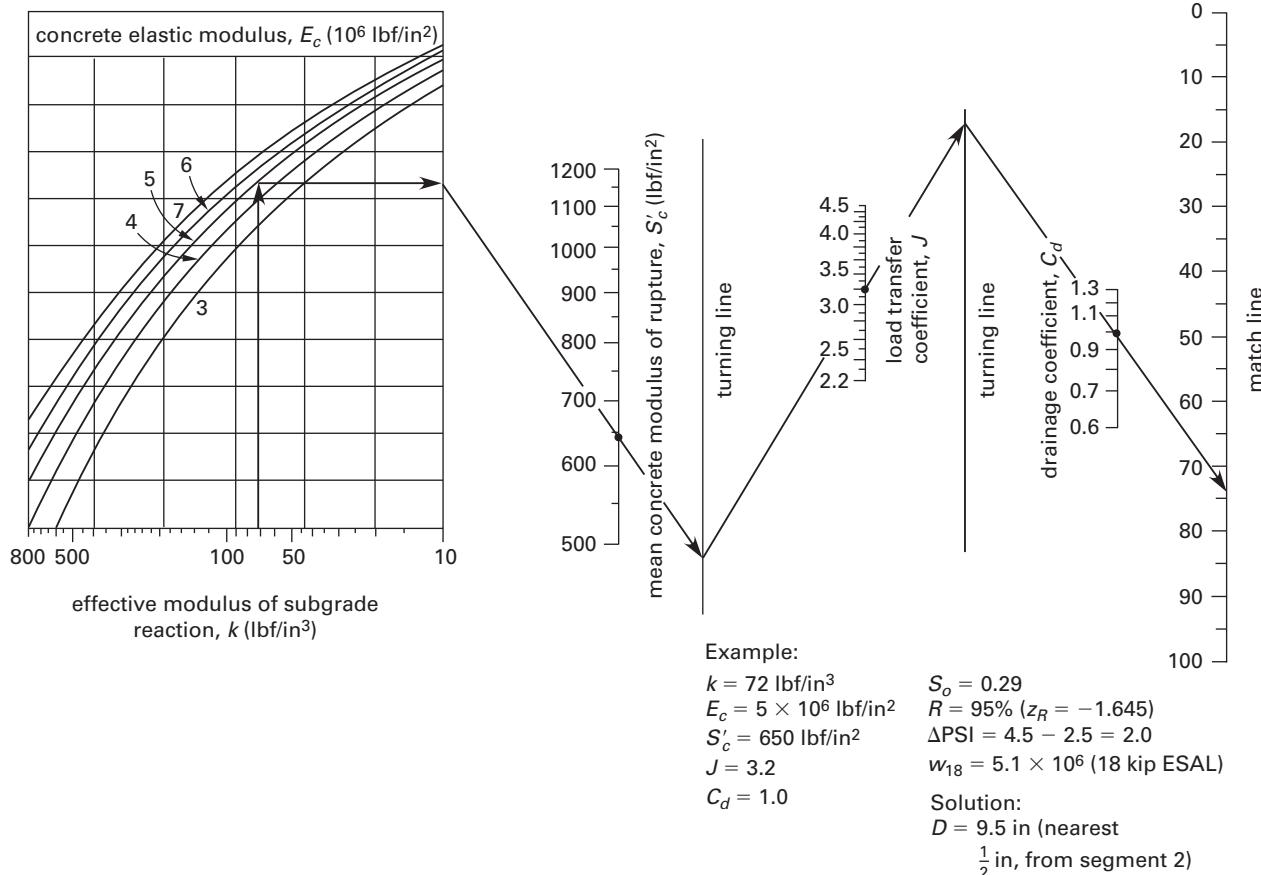

Design a jointed reinforced concrete pavement with a 60 ft slab length, two 12 ft lanes tied together, doweled joints, and doweled asphalt shoulders. Assume the pavement is placed in a wet location with poor drainage. The subgrade is very weak clay with a California bearing ratio of 3. The friction factor,  $F$ , is 1.8. The design reliability is 90%. The concrete has a compressive strength of 4000 lbf/in<sup>2</sup> and a modulus of rupture of 650 lbf/in<sup>2</sup>, both at 28 days. The traffic on the design lane is projected to be  $20 \times 10^6$  ESALs. An 8 in cement-treated subbase will be used. Grade 40 steel reinforcement and 1/2 in diameter tie bars will be used.

Determine the (a) slab thickness, (b) length and spacing of dowel bars, (c) longitudinal and transverse reinforcement, and (d) tie bars for use in the longitudinal joints.

### Solution

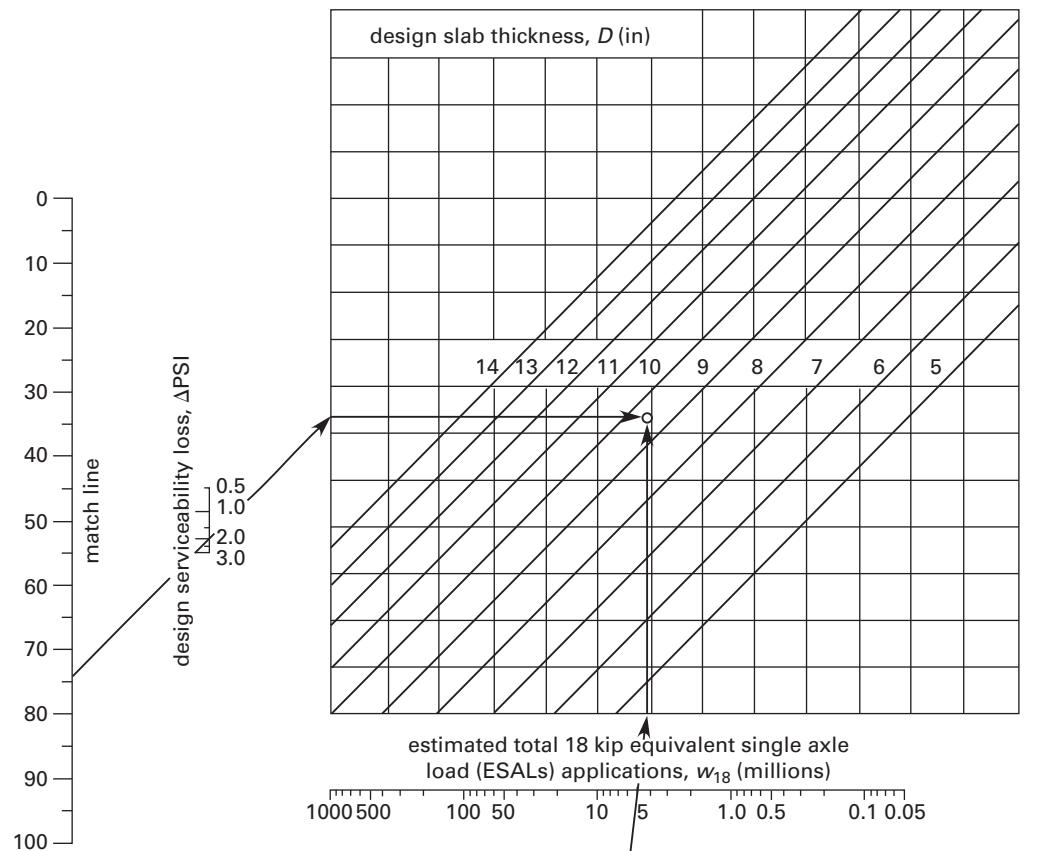

(a) From Fig. 77.1, the modulus of subgrade reaction is  $k = 100 \text{ lbf/in}^3$ . From Table 77.8 with the subbase, the effective subgrade modulus is  $k = 520 \text{ lbf/in}^3$ .

Figure 77.2 AASHTO Design Chart for Rigid Pavement\*

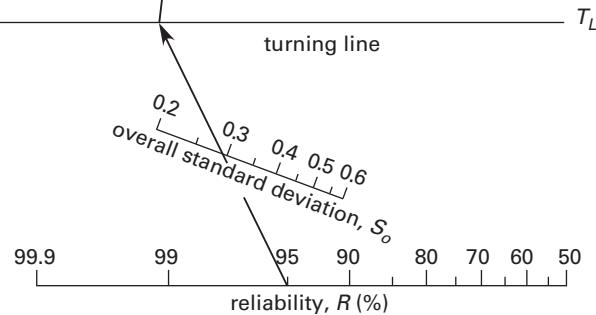

\*Based on mean value of each variable.

**NOTE:**

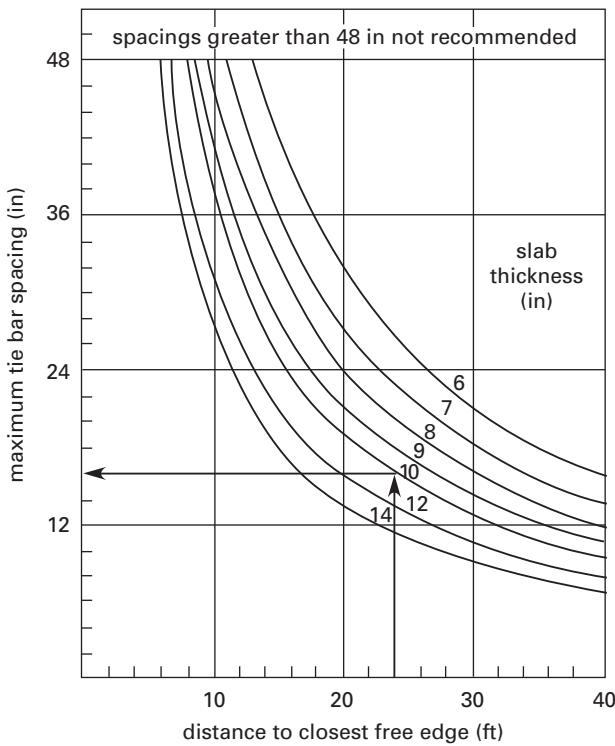

Application of reliability in this chart requires the use of mean values for all the input variables.

\*Based on mean value of each variable.

From AASHTO *Guide for Design of Pavement Structures*, Sec. II, p. II-45, Fig. 3.7, copyright © 1993 by the American Association of State Highway and Transportation Officials, Washington, D.C. Used by permission

**Figure 77.3** Recommended Maximum Tie Bar Spacing for PCC Pavement (1/2 in diameter tie bars, grade-40 steel, and subgrade friction factor of 1.5)

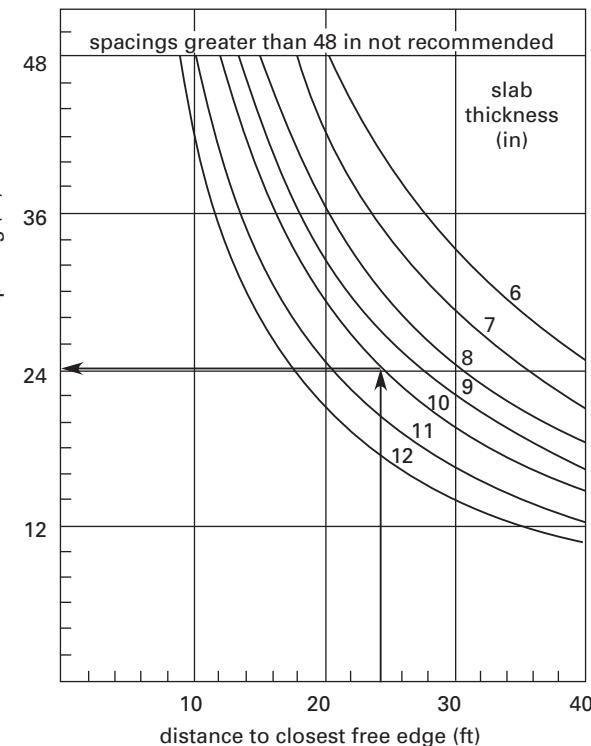

Example: distance from free edge: 24 ft

$$D = 10 \text{ in}$$

Answer: spacing = 16 in

From *AASHTO Guide for Design of Pavement Structures*, Part II, Fig. 3.13, copyright © 1993 by the American Association of State Highway and Transportation Officials, Washington, D.C. Used by permission.

**Figure 77.4** Recommended Maximum Tie Bar Spacing for PCC Pavement (5/8 in diameter tie bars, grade-40 steel, and subgrade friction factor of 1.5)

Example: distance from free edge: 24 ft

$$D = 10 \text{ in}$$

Answer: spacing = 24 in

From *AASHTO Guide for Design of Pavement Structures*, Part II, Fig. 3.14, copyright © 1993 by the American Association of State Highway and Transportation Officials, Washington, D.C. Used by permission.

Use Eq. 77.4 to estimate  $E_c$ .

$$E_c = 57,000\sqrt{f'_c} = 57,000\sqrt{4000 \frac{\text{lbf}}{\text{in}^2}} \\ = 3.6 \times 10^6 \text{ lbf/in}^2$$

From Sec. 77.6, the load transfer coefficient for asphalt shoulders with dowels is  $J = 3.2$ .

For poor draining, the drainage coefficient is  $C_d = 0.7$ .

Reliability,  $R$ , is given as 90%.

For PCC pavement, use an overall standard deviation,  $S_o$ , of 0.35.

Assume "normal" serviceability values of  $p_o = 4.5$  and  $p_t = 2.5$ .

$$\Delta \text{PSI} = 4.5 - 2.5 = 2.0$$

From Fig. 77.2, the slab thickness is 12.5 in.

(b) Use the rule of thumb for dowel bars.

$$\text{diameter} = \frac{\text{thickness}}{8} = \frac{12.5 \text{ in}}{8} \\ = 1.56 \text{ in} \quad [\text{use } 1\frac{5}{8} \text{ in}]$$

Use an average spacing of 12 in and a length of 18 in.

(c) Design the longitudinal and transverse reinforcement.

With grade 40 steel, the working stress is

$$f_s = 0.75f_y = (0.75)\left(40 \frac{\text{kips}}{\text{in}^2}\right) = 30 \text{ kips/in}^2$$

The friction factor is given as  $F = 1.8$ .

The percentage of longitudinal steel is given by Eq. 77.5.

$$P_s = \frac{LF}{2f_s} \times 100\% = \frac{(60 \text{ ft})(1.8)}{(2)(30,000 \frac{\text{lbf}}{\text{in}^2})} \times 100\% \\ = 0.18\%$$

Since the two lanes are tied together, both must be considered for horizontal steel. The width is 24 ft.

From Eq. 77.5, the area of transverse steel is

$$P_t = \frac{LF}{2f_s} \times 100\% = \frac{(24 \text{ ft})(1.8)}{(2)(30,000 \frac{\text{lbf}}{\text{in}^2})} \times 100\% \\ = 0.072\%$$

(d) Since  $\frac{1}{2}$  in diameter tie bars are used, Fig. 77.3 is applicable. The slab thickness is 12.5 in. The distance from the joint to a free edge is 12 ft. The tie bar spacing is read as approximately 26 in.

## 9. MECHANISTIC-EMPIRICAL DESIGN

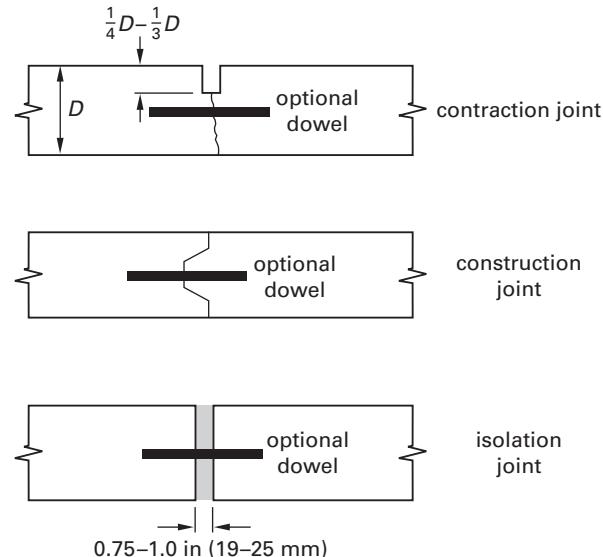

The overall process of *mechanistic-empirical* (ME) design is the same for PCC pavements as for hot mix asphalt (HMA) pavements. However, the ME design tests for layer characterizations are specific to PCC mixtures and include tests for the elastic modulus, modulus of rupture, water-cement ratio, air content, aggregate gradation, coefficient of thermal expansion, and cement type. The AASHTO *Mechanistic-Empirical Pavement Design Guide* (AASHTO MEPDG) lists more than 70 test protocols and standards covering laboratory materials and in-place materials tests, from which testing parameters can be selected, depending on the project. A trial design is tested using the AASHTO MEPDG software and uses additional inputs of traffic projections, axle loads, climate data, geographic location using longitude-latitude-elevation, weather patterns, properties of foundation soils, and overall condition of existing pavement (for rehabilitation projects). Trial designs that do not meet the initial criteria are revised and retested. When the criteria have been met, the trial designs become feasible.

## 10. PAVEMENT JOINTS

Figure 77.5 shows the three standard forms of joints used on a concrete pavement. *Contraction joints* (*control joints*, *weakened plane joints*, *dummy joints*) are usually sawn into the pavement to a depth of one-fourth (transverse joints) or one-third (longitudinal joints) of the slab thickness, but they can also be hand-formed while the concrete is wet or formed by pouring around inserts. The purpose of the joint is to create a thinner pavement section in one location (a weak line to encourage shrinkage cracking along that line). Contraction joints also relieve tensile stresses in the pavement. The uneven crack

joint provides for load transfer between the slab sections by aggregate interlock. To prevent deicing sand and water from infiltrating the joints, a hot pour or preformed joint sealer can be used in the joint.

**Figure 77.5** Types of Concrete Pavement Joints

With nonreinforced construction, contraction joints should be placed at regular intervals to allow for the shrinkage of the concrete during curing, drying, and thermal changes. Twenty-four times the thickness of the slab and a ratio of slab width to slab length  $\leq 1.25$  are typical rules of thumb used to select the distance between contraction joints for nonreinforced pavement.

The maximum spacing between transverse joints should not exceed 15 ft (4.6 m). Although climate, base types, and concrete properties factor into joint spacing decisions, Table 77.9 lists typical maximum joint spacing as a function of paving thickness. A value less than the maximum joint spacing is always preferred, as cracking and joint opening potential are reduced.

**Table 77.9** Recommended Maximum Transverse Joint Spacing for Plain Concrete Pavements

pavement thickness in (mm)	maximum joint spacing ft (m)
4 (100)	8 (2.4)
5 (125)	10 (3.0)
6 (150)	12 (3.7)
7 (175)	14 (4.3)
$\geq 8$ (200)	15 (4.6)

(Multiply in by 25.4 to obtain mm.)

(Multiply ft by 0.3 to obtain m.)

Source: Table 16 of the *Design of Concrete Pavements for Streets and Roads*, copyright © 2006, American Concrete Pavement Association, Skokie, IL.

Contraction joints can be placed at regular intervals and at  $90^\circ$  angles to the centerline. However, skewing the transverse joints and/or placing them at random

intervals minimizes the amount of faulting as well as noise and impact from vehicular traffic. State highway departments have standard joint patterns for spacing and standard skew angles.

The width of a saw cut is typically  $\frac{1}{8}$  in or  $\frac{1}{4}$  in (3 mm or 6 mm). To be effective, the depth of a cut should be at least one-quarter of the slab thickness when the cut is made after curing.<sup>1</sup> A cut depth of one-third of the slab layer is recommended for longitudinal joints and for transverse joints when the slab has been placed over a stabilized cement or asphalt subbase.

*Hinge joints*, also known as *warping joints*, are similar to contraction joints. However, hinge joints are longitudinal joints, generally placed along the centerline of a highway.

*Construction joints* are used transversely between construction periods and longitudinally between pavement lanes. Longitudinal joints are usually spaced to coincide with lane markings at 8 ft and 12 ft (2.4 m and 3.6 m) intervals, but spacing depends primarily on paver width. They are usually keyed, formed by attaching a metal or wooden keyway form at middepth. With slip-form pavers, the keyway is formed by the slipform as it advances. Dowels are not generally used with longitudinal joints.

*Isolation joints (expansion joints)* are used to relieve compressive (i.e., buckling) stresses in the pavement where it adjoins another structure. Expansion joints are placed where the pavement abuts bridges, at intersections, where concrete and asphalt pavements abut each other, and at end-of-day pours. Transverse joints are placed across the direction of roadway travel. Slab separation (and filler material) thickness should not exceed 1 in (25 mm).

Use of *dowel bars* in transverse joints depends on the service conditions. They are not needed in residential or other low-traffic streets, but they may be needed with heavy truck traffic. If one end of a dowel is lubricated, the slab will slip over the dowel as the slab expands and contracts, providing a good transfer of load. However, most dowels are inserted dry. Dowel insertion can be done automatically with modern paving train equipment, or they can be inserted manually.

## 11. SURFACE SEALING

Sealing of PCC surfaces is typically used to prevent chloride ions (from deicing salts) from penetrating the concrete and corroding reinforcing and supporting steel. Sealing is predominantly used to protect steel bridge decks. It is not commonly done on open roads.

In the past, natural linseed oil has traditionally been used. However, modern commercial formulations

include silane/siloxane-type sealers and alkali silicate-type sealers. Silane/siloxane sealers are classified as *penetrating sealers*, as they retain their properties after the upper surface layer of sealer has been worn away.

## 12. RECYCLING

Recycled PCC pavement material may be used as aggregate base, subbase, or aggregate for new pavement. Recycling is not only economically favorable; it also solves the problem of disposing of large amounts of PCC pavement. Recycled aggregate may actually be more durable than in the original state because it has already gone through multiple freeze-thaw cycles. Recycling can be used with lean concrete (*econocrete*) and slipform pavers.

In typical operation, diesel pile hammers, resonant pavement breakers, or drop hammers are used to break up the pre-existing concrete. A backhoe separates broken pavement and steel, and the steel is also recovered. The concrete is removed, crushed, screened, and reused. Most recycling is done on site.

## 13. PAVEMENT GROOVING

*Grooving* is a method of increasing skid resistance and reducing hydroplaning on all types of pavements. Grooves permit the water to escape under tires and prevent buildup of water on the surface. The recommended groove is  $\frac{1}{4}$  in wide and is  $\frac{1}{4}$  in deep (6 mm × 6 mm), with a center-to-center spacing of  $1\frac{1}{4}$  in (32 mm). So that the grooving does not weaken the pavement surface, the minimum spacing is approximately  $1\frac{1}{8}$  in (29 mm). To be effective in removing water, the maximum spacing is approximately 2 in (50 mm).

Grooving should be used only with structurally adequate pavements. If the pavement is in poor condition, it should be rehabilitated before grooving. Grooves should be continuous. In the case of special surfaces such as airfields where pavement widths exceed standard roadway widths, transverse rather than longitudinal grooves may be used.

## 14. FLY ASH CONCRETE PAVEMENT

Fly ash has been and is now widely used as a partial substitute for portland cement and as an additional component in concrete pavements. The performance characteristics of fly ash pavements depend on the type of fly ash and its proportion in the mixture. Fly ash comes in two main varieties: Class F, derived from anthracite and bituminous coals, and Class C, derived from lignite and other sub-bituminous coals. Both types exhibit *pozzolanic activity* (the ability of the silica and alumina components in fly ash to react with available calcium and/or magnesium hydration products from portland cement), but only Class C fly ash has substantial cementing properties.

<sup>1</sup>The cuts do not need to be as deep when early-entry saws are used.

When fly ash is used to partially replace portland cement, it is added at the rate of 1–1.5 times the weight of cement replaced. (Some reduction in fine aggregate is also typical to accommodate the increased volume of the lighter fly ash.) Class F fly ash is added to pavement mixes for up to 15–25% by weight of the total mixture; Class C can constitute 20–35% of the total mix weight.

In addition to generally reducing the cost of the mixture, other beneficial effects associated with using fly ash in concrete pavements include enhanced workability, reduced bleeding and lower water requirements, higher ultimate strength, reduced permeability and chloride ion penetration, lower heat of hydration, increased resistance to sulfate attack, increased resistance to alkali-aggregate reactivity, and reduced shrinkage while drying. Because of its contribution to increased resistance to road deicing salts, fly ash use is mandated by some northeastern states.

The possible detrimental effects include longer setting time and difficulty in controlling air entrainment. Strength may be slower to develop with Class F fly ash, but Class C fly ash may even enhance early strength development. There is some experimental evidence that using 30% or more Class C fly ash decreases abrasion resistance, while Class F fly ash does not exhibit such an effect. Other studies have validated fly ash concrete pavement performance in even higher proportions.

Due to contradictory performance studies, varying pozzolanic activity, mixing and proportioning concerns, and the difficulty in ensuring consistent as-delivered fly ash compositions and properties, mixture monitoring and performance testing are required.

## 15. ADVANCED, ALTERNATIVE, AND EXPERIMENTAL PAVEMENTS

*Dual-layer pavements* are claimed to yield quieter rides and reduced road noise. The paving machine lays down two layers of different concretes simultaneously—a lower, thicker layer containing large aggregate for economy, and an upper, thinner layer made up of smaller stones. The upper stones are subsequently exposed by washing away cement paste before hardening.

Until recently, few *thin-overlay* options were available. Delamination problems have been experienced with thin, *grout-bonded concrete* placed over existing concrete surfaces. Epoxy-bonded overlays have been more successful. Thin  $\frac{3}{4}$ –1 in (19–25 mm) *polymer concrete* overlays are successful and are becoming more common. Polyester-styrene polymer, a catalyst, aggregate smaller than  $\frac{1}{2}$  in (13 mm), and sand are used. Good bonding is obtained by abrasive blasting (e.g., shotblasting) followed by vacuuming to clean and roughen the original surface. The overlay sets up in less than half an hour.

*Rubcrete*, using ground-up rubber in place of some of the aggregate, is generally not applicable to structural applications, including upper pavement layers.

Various other innovations, including *latex-modified concrete* (LMC) and *steel fiber-reinforced concrete*, are available for special applications and adventurous contractors.

## 1. ERROR ANALYSIS: MEASUREMENTS OF EQUAL WEIGHT

There are still many opportunities for errors in surveying, although calculators and modern equipment have significantly reduced the magnitudes of most errors. The purpose of error analysis is not to eliminate errors but rather to estimate their magnitudes. In some cases, it is also appropriate to assign the errors to the appropriate measurements.

The *expected value* of a measurement, also known as the *most likely value* or *probable value*, is the value that has the highest probability of being correct. If a series of  $k$  measurements is taken, the most probable value,  $x_p$ , is the average (mean) of those measurements, as shown in Eq. 78.1. For related measurements whose sum should equal some known quantity, the most probable values are the observed values corrected by an equal part of the total error.

$$x_p = \frac{x_1 + x_2 + \cdots + x_k}{k} \quad 78.1$$

Measurements of a given quantity are assumed to be normally distributed. If a quantity has a mean  $\mu$  and a sample standard deviation  $s$ , the probability is 50% that a measurement of that quantity will fall within the range of  $\mu \pm 0.6745s$ . The quantity  $0.6745s$  is known as the *probable error*. The *probable ratio of precision* is  $\mu/0.6745s$ . The interval between the extremes is known as the 50% *confidence interval*. Other confidence limits are easily obtained from the normal tables. For example, for a 95% interval, replace 0.6745 with 1.96, and for a 99% interval, replace 0.6745 with 2.57.

The *probable error of the mean*,  $E_{\text{mean}}$ , of  $k$  observations is given by Eq. 78.2.

$$\begin{aligned} E_{\text{mean}} &= \frac{0.6745s}{\sqrt{k}} \\ &= \frac{E_{\text{total}, k \text{ measurements}}}{\sqrt{k}} \end{aligned} \quad 78.2$$

The lower and upper 50% confidence limits, LCL and UCL, are

$$\text{LCL}_{50\%} = x_p - E_{\text{mean}} \quad 78.3$$

$$\text{UCL}_{50\%} = x_p + E_{\text{mean}} \quad 78.4$$

### Example 78.1

The interior angles of a triangular traverse were measured as  $63^\circ$ ,  $77^\circ$ , and  $41^\circ$ . Each measurement was made once, and all angles were measured with the same precision. What are the most probable interior angles?

*Solution*

The sum of angles in a triangle should equal  $180^\circ$ . The error in measurement is

$$(63^\circ + 77^\circ + 41^\circ) - 180^\circ = +1^\circ$$

The correction required to make the sum total  $180^\circ$  is  $-1^\circ$ , which is proportioned equally among the three angles. The most probable values are then

$$63^\circ - \frac{+1^\circ}{3} = 62.67^\circ$$

$$77^\circ - \frac{+1^\circ}{3} = 76.67^\circ$$

$$41^\circ - \frac{+1^\circ}{3} = 40.67^\circ$$

### Example 78.2

A critical distance was measured 12 times. The mean value was 423.7 ft. The sample standard deviation,  $s$ , of the measurements is 0.31 ft. What are the 50% confidence limits for the distance?

*Solution*

From Eq. 78.2, the standard error of the mean value is

$$\begin{aligned} E_{\text{mean}} &= \frac{0.6745s}{\sqrt{k}} = \frac{(0.6745)(0.31 \text{ ft})}{\sqrt{12}} \\ &= 0.06 \text{ ft} \end{aligned}$$

The probability is 50% that the true distance is within the limits of  $423.7 \pm 0.06$  ft.

### Example 78.3

The true length of a tape is 100 ft. The most probable error of a measurement with this tape is 0.01 ft. What is the expected error if the tape is used to measure out a distance of 1 mi?

*Solution*

1 mi consists of 5280 ft. The number of individual measurements will be  $5280 \text{ ft}/100 \text{ ft} = 52.8$ , or 53 measurements. The most probable error is given by Eq. 78.2.

$$\begin{aligned} E_{\text{total}, k \text{ measurements}} &= E_{\text{mean}} \sqrt{k} = (0.01 \text{ ft}) \sqrt{53} \\ &= 0.073 \text{ ft} \end{aligned}$$

## 2. ERROR ANALYSIS: MEASUREMENTS OF UNEQUAL WEIGHT

Some measurements may be more reliable than others. It is reasonable to weight each measurement with its relative reliability. Such weights can be determined subjectively. More frequently, however, they are determined from relative frequencies of occurrence or from the relative inverse squares of the probable errors.

The probable error and 50% confidence interval for weighted observations can be found from Eq. 78.5.

$x_i$  represents the  $i$ th observation, and  $w_i$  represents its relative weight.

$$E_{p,\text{weighted}} = 0.6745 \sqrt{\frac{\sum (w_i(\bar{x} - x_i)^2)}{(k-1)\sum w_i}} \quad 78.5$$

For related weighted measurements whose sum should equal some known quantity, the most probable weighted values are corrected inversely to the relative frequency of observation. Weights can also be calculated when the probable errors are known. The weights are the relative squares of the probable errors.

#### Example 78.4

An angle was measured five times by five equally competent crews on similar days. Two of the crews obtained a value of  $39.77^\circ$ , and the remaining three crews obtained a value of  $39.74^\circ$ . What is the probable value of the angle?

*Solution*

Weight the values by the relative frequency of observation.

$$\begin{aligned}\theta &= \frac{(2)(39.77^\circ) + (3)(39.74^\circ)}{5} \\ &= 39.75^\circ\end{aligned}$$

#### Example 78.5

A distance has been measured by three different crews. The measurements' probable errors are given. What is the most probable value?

$$\begin{aligned}\text{crew 1: } &1206.40 \pm 0.03 \text{ ft} \\ \text{crew 2: } &1206.42 \pm 0.05 \text{ ft} \\ \text{crew 3: } &1206.37 \pm 0.07 \text{ ft}\end{aligned}$$

*Solution*

The sum of squared probable errors is

$$(0.03 \text{ ft})^2 + (0.05 \text{ ft})^2 + (0.07 \text{ ft})^2 = 0.0083 \text{ ft}^2$$

The weights to be applied to the three measurements are

$$\frac{0.0083 \text{ ft}^2}{(0.03 \text{ ft})^2} = 9.22$$

$$\frac{0.0083 \text{ ft}^2}{(0.05 \text{ ft})^2} = 3.32$$

$$\frac{0.0083 \text{ ft}^2}{(0.07 \text{ ft})^2} = 1.69$$

The most probable length is

$$\begin{aligned}(1206.40 \text{ ft})(9.22) \\ + (1206.42 \text{ ft})(3.32) \\ + (1206.37 \text{ ft})(1.69) \\ \hline 9.22 + 3.32 + 1.69 = 1206.40 \text{ ft}\end{aligned}$$

#### Example 78.6

What is the 50% confidence interval for the measured distance in Ex. 78.5?

*Solution*

Work with the decimal portion of the answer.

$$\bar{x} = \frac{0.40 + 0.42 + 0.37}{3} \approx 0.40$$

$i$	$x_i$	$\bar{x} - x_i$	$(\bar{x} - x_i)^2$	$w_i$	$w_i(\bar{x} - x_i)^2$
1	0.40	0	0	9.22	0
2	0.42	-0.02	0.0004	3.32	0.0013
3	0.37	0.03	0.0009	1.69	0.0015
		total		14.23	0.0028

Use Eq. 78.5.

$$\begin{aligned}E_{p,\text{weighted}} &= 0.6745 \sqrt{\frac{\sum (w_i(\bar{x} - x_i)^2)}{(k-1)\sum w_i}} \\ &= 0.6745 \sqrt{\frac{0.0028}{(3-1)(14.23)}} \\ &= 0.0067\end{aligned}$$

The 50% confidence interval is  $1206.40 \pm 0.0067$  ft.

#### Example 78.7

The interior angles of a triangular traverse were repeatedly measured. What is the probable value for angle 1?

angle	value	number of measurements
1	$63^\circ$	2
2	$77^\circ$	6
3	$41^\circ$	5

*Solution*

The total of the angles is

$$63^\circ + 77^\circ + 41^\circ = 181^\circ$$

So,  $-1^\circ$  must be divided among the three angles. These corrections are inversely proportional to the number of measurements. The sum of the measurement inverses is

$$\begin{aligned}\frac{1}{2} + \frac{1}{6} + \frac{1}{5} &= 0.5 + 0.167 + 0.2 \\ &= 0.867\end{aligned}$$

The most probable value of angle 1 is then

$$63^\circ + \frac{\left(\frac{1}{2}\right)(-1^\circ)}{0.867} = 62.42^\circ$$

### Example 78.8

The interior angles of a triangular traverse were measured. What is the most probable value of angle 1?

angle	value
1	$63^\circ \pm 0.01^\circ$
2	$77^\circ \pm 0.03^\circ$
3	$41^\circ \pm 0.02^\circ$

*Solution*

The total of the angles is

$$63^\circ + 77^\circ + 41^\circ = 181^\circ$$

So,  $-1^\circ$  must be divided among the three angles. The corrections are proportional to the square of the probable errors.

$$(0.01)^2 + (0.03)^2 + (0.02)^2 = 0.0014$$

The most probable value of angle 1 is

$$63^\circ + \frac{(0.01)^2(-1^\circ)}{0.0014} = 62.93^\circ$$

### 3. ERRORS IN COMPUTED QUANTITIES

When independent quantities with known errors are added or subtracted, the error of the result is given by Eq. 78.6. The squared terms under the radical are added regardless of whether the calculation is addition or subtraction.

$$E_{\text{sum}} = \sqrt{E_1^2 + E_2^2 + E_3^2 + \dots} \quad 78.6$$

The error in the product of two quantities,  $x_1$  and  $x_2$ , which have known errors,  $E_1$  and  $E_2$ , is given by Eq. 78.7.

$$E_{\text{product}} = \sqrt{x_1^2 E_2^2 + x_2^2 E_1^2} \quad 78.7$$

### Example 78.9

An electronic distance measurement (EDM) instrument manufacturer has indicated that the manufacturer's standard error with a particular instrument is  $\pm 0.04 \text{ ft} \pm 10 \text{ ppm}$ . The instrument is used to measure a distance of 3000 ft. (a) What is the precision of the measurement? (b) What is the expected error of the measurement in ppm?

*Solution*

(a) There are two independent errors here. The fixed error is  $\pm 0.04 \text{ ft}$ . The variable error is

$$E_{\text{variable}} = (3000 \text{ ft}) \left( \frac{10}{1,000,000} \right) = 0.03 \text{ ft}$$

The precision is  $\pm(0.04 \text{ ft} + 0.03 \text{ ft}) = \pm 0.07 \text{ ft}$ .

(b) The expected error is

$$E_{\text{expected}} = \frac{0.07 \text{ ft}}{3000 \text{ ft}} \times 10^6 = 233 \text{ ppm}$$

### Example 78.10

The sides of a rectangular section were determined to be  $1204.77 \text{ ft} \pm 0.09 \text{ ft}$  and  $765.31 \text{ ft} \pm 0.04 \text{ ft}$ , respectively. What is the probable error in area?

*Solution*

Use Eq. 78.7.

$$\begin{aligned} E_{\text{area}} &= \sqrt{x_1^2 E_2^2 + x_2^2 E_1^2} \\ &= \sqrt{(1204.77 \text{ ft})^2 (0.04 \text{ ft})^2 + (765.31 \text{ ft})^2 (0.09 \text{ ft})^2} \\ &= 84.06 \text{ ft}^2 \end{aligned}$$

### 4. ORDERS OF ACCURACY

The significance of a known measurement error can be quantified by a ratio of parts (e.g., 1 ft in 10,000 ft, or 1:10,000). A distance measurement error is divided by the distance measured. A traverse closure error is divided by the sum of all traverse leg lengths to determine the fractional error.

Survey accuracy is designated by its *order*, with *first order* being the most accurate. In the United States, standard accuracies have been established for horizontal and vertical control, as well as for closure and triangulation errors. Theoretically, any organization or agency could establish its own standards, but the phrase "order of accuracy" generally refers to standards specified by the Federal Geodetic Control Committee (FGCC). The American Land Title Association (ALTA) and the American Congress on Surveying and Mapping (ASCM) have also issued standards for land title surveys of small parcels.

There are three different national *orders* (i.e., *levels*) of *accuracy*: first, second, and third order. Some states include a fourth order of accuracy (less than 1:5000). There are two different classes of accuracy in second- and third-order surveys: Classes I and II. These are described in Table 78.1.

**Table 78.1** Federal Standards of Traverse Closure Errors

order of accuracy	maximum error	application
first	1:100,000	primary control nets; precise scientific studies
second		support for primary control; control for large engineering projects
class I	1:50,000	
class II	1:20,000	
third		small-scale engineering projects; large-scale mapping projects
class I	1:10,000	
class II	1:5000	

Increased use of precise GPS techniques has created a demand for greater control. The National Geodetic Survey (NGS) has established both order A (accuracy of 1:10,000,000) and order B (accuracy of 1:1,000,000) points.

For land title surveys of parcels using ALTA/ACSM specifications, the *degree of accuracy* should be based on the intended use of the land parcel, without regard to its present use, provided the intended use is known. Four general survey classes are defined using various state regulations and accepted practices.

**Class A, Urban Surveys:** Surveys of land lying within or adjoining a city or town. This also includes the surveys of commercial and industrial properties, condominiums, town houses, apartments, and other multiunit developments, regardless of geographic location.

**Class B, Suburban Surveys:** Surveys of land lying outside urban areas. This land is used almost exclusively for single-family residences or residential subdivisions.

**Class C, Rural Surveys:** Surveys of land such as farms and other undeveloped land outside the suburban areas that may have a potential for future development.

**Class D, Mountain and Marshland Surveys:** Surveys of land that normally lie in remote areas with difficult terrain and that usually have limited potential for development.

## 5. TYPES OF SURVEYS

*Plane surveys* disregard the curvature of the earth. A plane survey is appropriate if the area is small. This is true when the area is not more than approximately 12 mi (19 km) in any one direction. *Geodetic surveys* consider the curvature of the earth. *Zoned surveys*, as used in various *state plane coordinate systems* and in the *Universal Transverse Mercator (UTM)* system, allow computations to be performed as if on a plane while accommodating larger areas.

## 6. SURVEYING METHODS

A *stadia survey* requires the use of a transit, theodolite, or engineer's level, as well as a rod for reading elevation

differences and a tape for measuring horizontal distances. Stadia surveys are limited by the sighting capabilities of the instrument as well as by the terrain ruggedness.

In a *plane table survey*, a plane table is used in conjunction with a *telescopic instrument*. The plane table is a drawing board mounted on a tripod in such a way that the board can be leveled and rotated without disturbing the azimuth. The primary use of the combination of the plane table and telescope is in field compilation of maps, for which the plane table is much more versatile than the transit.

*Total station surveys* integrate theodolites, EDM, and data recorders, collecting vertical and horizontal data in a single operation. *Manual total stations* use conventional optical-reading theodolites. *Automatic total stations* use electronic theodolites. *Data collectors* work in conjunction with total stations to store data electronically. Previously determined data can be downloaded to the data recorders for use in the field to stake out or field-locate construction control points and boundaries.

*Triangulation* is a method of surveying in which the positions of survey points are determined by measuring the angles of triangles defined by the points. Each survey point or monument is at a corner of one or more triangles. The survey lines form a network of triangles. The three angles of each triangle are measured. Lengths of triangle sides are calculated from trigonometry. The positions of the points are established from the measured angles and the computed sides.

Triangulation is used primarily for geodetic surveys, such as those performed by the National Geodetic Survey (NGS). Most first- and second-order control points in the national control network have been established by triangulation procedures. The use of triangulation for transportation surveys is minimal. Generally, triangulation is limited to strengthening traverses for control surveys.

*Trilateration* is similar to triangulation in that the survey lines form triangles. In trilateration, however, the lengths of the triangles' sides are measured. The angles are calculated from the side lengths. Orientation of the survey is established by selected sides whose directions are known or measured. The positions of trilaterated points are determined from the measured distances and the computed angles.

*Photogrammetric surveys* are conducted using aerial photographs. The advantages of using photogrammetry are speed of compilation, reduction in the amount of surveying required to control the mapping, high accuracy, faithful reproduction of the configuration of the ground by continuously traced contour lines, and freedom from interference by adverse weather and inaccessible terrain. Disadvantages include difficulty in areas containing heavy ground cover, the high cost of mapping small areas, difficulty of locating contour lines in flat terrain, and the necessity for field editing and field completion. Photogrammetry works with ground control panels that are

three to four times farther apart than with conventional surveys. But a conventional survey is still required in order to establish control initially.

*Airborne LIDAR (Light Detection and Ranging)* units are aircraft-mounted laser systems designed to measure the 3D coordinates of a passive target. This is achieved by combining a laser with positioning and orientation measurements. The laser measures the distance to the ground surface or target, and when combined with the position and orientation of the sensors, yields the 3D position of the target. Unlike EDM, which uses phase shifts of a continuous laser beam, LIDAR measures the time of flight for a single laser pulse to make the round trip from the source to receiver. LIDAR systems typically use a single wavelength, either 1064 nm or 532 nm, corresponding to the infrared and green areas of the electronic spectrum, respectively. Time can be measured to approximately  $\frac{1}{3}$  ns, corresponding to a distance resolution of approximately 5 cm.

## 7. GLOBAL POSITIONING SYSTEM

The NAVSTAR (Navigation Satellite Timing and Ranging) *Global Positioning System* (GPS) is a one-way (satellite to receiver) ranging system. The advantages of GPS are speed and access, while the main disadvantage is dependence on satellite availability/visibility. The GPS system is functional with 24 satellites arranged in six planes of four, although approximately 32 satellites are in the system performing various functions. At any moment, a minimum of six satellites are visible from any point on the earth with an unobstructed view of the sky, and up to 12 satellites may occasionally be visible at one time in particular locations. Four satellites must be visible for 3D work, and an unobstructed view of the sky is needed.

GPS determines positions without reference to any other point. It has the advantage of allowing work to proceed day or night, rain or shine, in fair weather or foul. It is not necessary to have clear lines of sight between stations, or to provide mountaintop stations for *inversability*.

GPS uses precisely synchronized clocks on each end—atomic clocks in the satellites and quartz clocks in the receivers. Frequency shift (as predicted by the Doppler effect) data is used to determine positions. Accurate positions anywhere on the earth's surface can easily be determined.

GPS can be used in two modes. *Stand-alone navigational mode* yields positional accuracies of  $\pm 210$  m; *differential* or *relative positioning* yields centimeter accuracies. A *wide-area augmentation system (WAAS)* relies on several ground-based reference stations in the western hemisphere to correct the timing of satellite signals. The correction factors from the ground stations are rebroadcast by GPS satellites. Receivers with WAAS capability

are used primarily by aviation to deliver better than the WAAS specification of  $\pm 25$  ft (7.6 m) lateral and vertical accuracies.

In relative positioning, one GPS receiver is placed on a point whose coordinates have been established in the National Geodetic Reference System (NGRS), and one or more other receivers are placed at other points whose coordinates are to be determined. All receivers observe the same satellites at the same time for about an hour, more or less, depending on the accuracy required and the conditions of observation. A computer analysis (using proprietary software from the GPS equipment manufacturer) of the observed and recorded data determines the coordinates of the unknown points, the distance and elevation between the known point and each unknown point, and the direction (azimuth) from the known point to each unknown point. With relative positioning, the distance between points can be measured to 1–2 cm and better than 1 part in 100,000.

Terms used when discussing GPS accuracy are *GDOP*, *HDOP*, and *VDOP*, standing for *geodetic*, *horizontal*, and *vertical dilution of position*. These numbers are inversely proportional to the volume of a pyramid that is formed by the position of the receiver and the four satellites being observed. In effect, GDOP is a measure of the geometry of the solution. A low GDOP number provides the best geometry and the most accurate solution.

GPS receivers are generally used in a fixed (stationary) position, hence the term *static GPS surveying*. With *rapid static mode* using a more sophisticated receiver, occupation times can be reduced from 45–60 min to 10–15 min for short baselines.

Using a modified observation procedure known as *kinematic GPS surveying*, the coordinates of any point can be determined in 45–60 sec. Kinematic GPS uses one stationary receiver and one or more roving receivers. However, this method is procedurally demanding and very unforgiving. For example, if the “lock” on a satellite is lost, a previously observed point must be reoccupied to continue the survey.

*Pseudokinematic GPS surveying* is similar to kinematic GPS in field procedure but similar to static GPS in processing. Rover units occupy each point for approximately 10 min, then reoccupy the positions later during a reverse run of the route.

GPS is less suited to elevation measurements. It is used in conjunction with traditional surveying methods to determine accurate elevations. Inaccuracies in elevation derive from the difference between the *spheroid* (the mathematical model selected by the software to best fit the surface of the entire earth) and the *geoid* (the actual shape of the earth at sea level). Depending on location, this difference in surface elevation can be anywhere between 2 m and 35 m.

## 8. INERTIAL SURVEY SYSTEMS

*Inertial survey systems* (ISSs) determine a position on the earth by analyzing the movement of a transport vehicle, usually a light-duty truck or helicopter in which the equipment is installed. An ISS system consists of a precise clock, a computer, a recording device, sensitive accelerometers, and gyroscopes. The equipment measures the acceleration of the vehicle in all three axes and converts the acceleration into distance. The production rate is 8–10 mph when mounted in tired vehicles. Helicopter ISSs can proceed at 50–70 mph.

To reduce errors and achieve horizontal accuracies of 1 part in 10,000 or even 20,000, the circuit is “double run” in opposite directions. This cancels some instrumentation errors caused by the earth’s rotation and magnetic field. Vertical accuracies are less.

## 9. GEOGRAPHIC INFORMATION SYSTEMS

A *geographic information system* (GIS) is a computerized database management system used to capture, store, retrieve, analyze, and display spatial data in map and overlay form. GIS replaces rolls and piles of time-bleached paper prints stored in drawers.

The integrated database contains spatial information, literal information (e.g., descriptions), and characteristics (e.g., land cover and soil type). Users can pose questions involving both position and characteristics.

GIS can produce “intelligent super maps” at the touch of a button. Details (e.g., lines, features, text) on maps that are *vector images* can be individually addressed, edited, colored, moved, and so on. Maps that consist of *raster images*, on the other hand, can be edited on a pixel-by-pixel basis, but the individual details cannot be modified.

## 10. UNITS

In most of the United States, survey work is conducted using the foot and decimal parts for distance. The SI system, using meters to measure distance, is widely used throughout the world. In the United States, the SI system has been adopted by only some state highway departments.

In the United States, angles are measured and reported in the *sexagesimal system*, using degrees, minutes, and seconds, abbreviated as °, ', and ". 60 seconds make up a minute, and 60 minutes make up a degree. Depending on convention and convenience, angles may be measured and reported in decimal values, with tenths, hundredths, thousandths, etc., of degrees.

At one time, an effort was made in some nations to convert angular measurement to the *gradian* (*grade*, *grad*, or *gon*) unit. A circle is divided into 400 gradians, rather than 360 degrees. In the gradian system, a right angle would have a measure of 100 grads. Few applications using gradians remain.

## 11. POSITIONS

Modern equipment permits surveyors to obtain positioning information directly from the theodolite.

It is not necessary to make a series of distance and angle measurements in the field and then return to the office to perform calculations to determine an unknown position.

Two methods are used to specify positions: (a) by latitude and longitude, and (b) by rectangular (Cartesian) coordinates measured from a reference point. The *state plane coordinate systems* are rectangular systems that use a partial latitude/longitude system for baseline references.

## 12. BENCHMARKS

*Benchmark* is the common name given to permanent monuments of known vertical positions. Monuments with known horizontal positions are referred to as *control stations* or *triangulation stations*. A nail or hub in the pavement, the flange bolts of a fire hydrant, or the top of a concrete feature (e.g., curb) can be used as a *temporary benchmark*. The elevations of temporary benchmarks are generally found in field notes and local official filings.

*Official benchmarks* (monuments) installed by surveyors and engineers generally consist of a bronze (or other inert material) disk set in the top of a concrete post or pillar. (Bronze caps in iron pipes were once used, but these have limited lives due to corrosion.) Stainless steel pins and Invar rods are also used. Bronze disks and identification plates are stamped, at the minimum, with the name of the agency or the state registration number of the individual setting the benchmark. Official USGS benchmarks are stamped with a unique identification code. Official benchmarks may or may not have the elevations indicated. If not, an official directory can be consulted for the information.

First-order monuments are widely spaced, but they are more accurately located for use in large-area control. Within the first-order network are a number of more closely spaced second-order monuments, followed by third-order and fourth-order networks of ever smaller scopes. Each lower-order monument is referenced to a higher-order monument.

Vertical positions (i.e., elevations) are measured above a reference surface or *datum*, often taken as *mean sea level*. For small projects, a local datum on a temporary permanent benchmark can be used.

## 13. DISTANCE MEASUREMENT: TAPING

*Gunter's chain* (developed around 1620), also known as a *surveyor's chain*, consisted of 100 links totaling 66 ft. It was superseded by steel tape in the 1900s. However, steel tapes (i.e., “engineers' chains”) are still sometimes referred to as “chains,” and measuring distance with a

steel tape is still called "chaining." The earliest tapes were marked at each whole foot, with only the last foot being subdivided into hundredths, similar to a Gunter's chain. Tapes exactly 100 ft long were called *cut chains*. Other tapes were 101 ft long and were called *add chains*. Tapes are almost universally subdivided into hundreds along their entire lengths. In practice, this enables the rear chainman to hold the zero mark on the point being measured from, while the head chainman reads the distance directly off the face of the tape.

Tapes are relatively inexpensive and easy to use, but they are mainly used only when measuring or staking short distances. Low-coefficient tapes made from nickel-steel alloy known as *Invar* are fairly insensitive to temperature. The coefficient of thermal expansion,  $\alpha$ , of Invar is  $2\text{--}5.5 \times 10^{-7}$   $^{\circ}\text{F}$  ( $3.6\text{--}9.9 \times 10^{-7}$   $^{\circ}\text{C}$ ), and its modulus of elasticity,  $E$ , is  $2.1 \times 10^7$  lbf/in $^2$  (145 GPa). For steel tapes,  $\alpha$  is  $6.45 \times 10^{-6}$   $^{\circ}\text{F}$  ( $1.16 \times 10^{-5}$   $^{\circ}\text{C}$ ) and the modulus of elasticity,  $E$ , is  $2.9 \times 10^7$  lbf/in $^2$  (200 GPa). Some woven tapes (e.g., linen, Dacron) may have embedded copper fibers to provide strength. Other tapes are manufactured from fiberglass, which neither stretch excessively nor conduct electricity.

Tapes can be marked with customary U.S. units, SI units, or both (on either side). They come in a variety of lengths, up to 100 m, though 100 ft and 30 m tapes are the most common.

Tape readings are affected by temperature, tension, and sag. Correction equations are given in Eq. 78.8, Eq. 78.9, and Eq. 78.10 and are applied according to Table 78.2.  $L$  is the length of tape,  $\alpha$  is the coefficient of thermal expansion,  $T$  and  $P$  are the temperature and tension at which the measurement was made,  $T_s$  and  $P_s$  are the temperature and tension at which the tape was standardized,  $A$  is the cross-sectional area of the tape, and  $E$  is the modulus of elasticity of the tape.

$$C_T = L\alpha(T - T_s) \quad [\text{temperature}] \quad 78.8$$

$$C_P = \frac{(P - P_s)L}{AE} \quad [\text{tension}] \quad 78.9$$

$$C_s = \pm \frac{W^2 L^3}{24 P^2} \quad [\text{sag}] \quad 78.10$$

**Table 78.2** Correction for Surveyor's Tapes

	measured flat	measured suspended
standardized flat	none	subtract $C_s$
standardized suspended	add $C_s$	none

## 14. DISTANCE MEASUREMENT: TACHEOMETRY

*Tacheometric distance measurement* involves sighting through a small angle at a distant scale. The angle may be fixed and the length measured (*stadia method*), or the length may be fixed and the angle measured

(*European method*). Stadia measurement consists of observing the apparent locations of the horizontal cross-hairs on a distant stadia rod. (See Fig. 78.1.) The interval between the two rod readings is called the *stadia interval* or the *stadia reading*.

**Figure 78.1** Horizontal Stadia Measurement

The distance is directly related to the distance between the telescope and the rod. For rod readings  $R_1$  and  $R_2$  (both in ft), the distance from the instrument to the rod is found from Eq. 78.11. The *instrument factor*,  $C$ , is the sum of the focal length and the distance from the plumb bob (or center of the instrument) to the forward lens. It varies from 0.6 ft to 1.4 ft, but is typically set by the manufacturer at 1 ft.  $C$  is zero for internal focusing telescopes. The *stadia interval factor*,  $K$ , often has a value of 100.

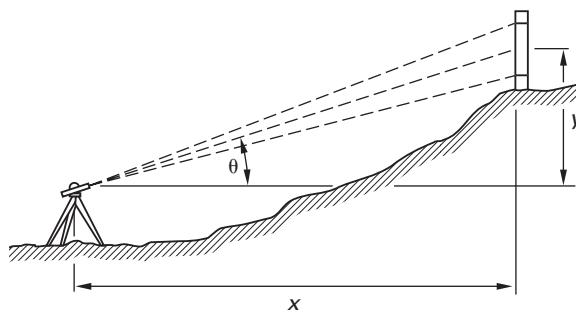

$$x = K(R_2 - R_1) + C \quad 78.11$$

If the sighting is inclined, as it is in Fig. 78.2, it is necessary to find both horizontal and vertical distances. These can be determined from Eq. 78.12 and Eq. 78.13, in which  $y$  is measured from the telescope to the sighting rod center. The height of the instrument above the ground must be known to calculate the elevation of the object above the ground.

$$x = K(R_2 - R_1)\cos^2 \theta + C \cos \theta \quad 78.12$$

$$y = \frac{1}{2}K(R_2 - R_1)\sin 2\theta + C \sin \theta \quad 78.13$$

**Figure 78.2** Inclined Stadia Measurement

## 15. DISTANCE MEASUREMENT: EDM

Long-range laser (infrared and microwave in older units) *electronic distance measurement* (EDM) equipment is capable of measuring lines up to 10 mi long in

less than 1 sec with an accuracy of better than  $\frac{1}{3}$  ft (100 mm). Shorter ranges are even more precise. EDM can measure lines 1 mi long in less than 5 sec with an accuracy of about 0.01 ft. Light beams are reflected back by glass *retroreflectors* (precisely ground trihedral prisms). Common EDM accuracy ranges up to 2 mi (3.2 km) are  $\pm 3\text{--}7$  mm and  $\pm 2\text{--}7$  ppm. Shorter distances yield even better accuracies.

An *optical plummet* allows the instrument or retroprism to be placed precisely over a point on the ground, in spite of winds that would make a string *plumb bob* swing.

## 16. STATIONING

In route surveying, lengths are divided into 100 ft or 100 m sections called *stations*. The word “station” can mean both a location and a distance. A station is a length of 100 ft or 100 m, and the unit of measure is frequently abbreviated “sta.” (30 m and 1000 m stationing are also used.) When a length is the intended meaning, the unit of measure will come after the numerical value; for example, “the length of curve is 4 sta.” When a location is the intended meaning, the unit of measure will come before the number. For example, “the point of intersection is at sta 4.” The location is actually a distance from the starting point. Therefore, the two meanings are similar and related.

Interval *stakes* along an established route are ordinarily laid down at *full station* intervals. If a marker stake is placed anywhere else along the line, it is called a *plus station* and labeled accordingly. A stake placed 825 ft (251 m) from station 0+00 is labeled “8+25” (2+51). Similarly, a stake placed 2896 ft (883 m) from a reference point at station 10+00 (10+00) is labeled “38+96” (18+83).

## 17. LEVELS

Automatic and self-leveling laser *levels* have all but replaced the optical level for leveling and horizontal alignment. A tripod-mounted laser can rotate and project a laser plane 300 ft to 2000 ft in diameter. A receiver mounted on a rod with visual and audible signals will alert the rodman to below-, at-, and above-grade conditions.

## 18. ELEVATION MEASUREMENT

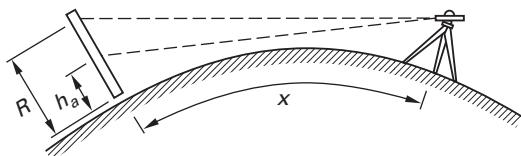

*Leveling* is the act of using an engineer’s level (or other leveling instrument) and rod to measure a vertical distance (*elevation*) from an arbitrary level surface.

If a level sighting is taken on an object with actual height  $h_a$ , the *curvature of the earth* will cause the object to appear taller by an amount  $h_c$ . (See Fig. 78.3.) In Eq. 78.14,  $x$  is measured in feet along the curved surface of the earth.

$$h_c = \left( 7.84 \times 10^{-8} \frac{1}{\text{m}} \right) x_m^2 \quad [\text{SI}] \quad 78.14(a)$$

$$h_c = \left( 2.39 \times 10^{-8} \frac{1}{\text{ft}} \right) x_{\text{ft}}^2 \quad [\text{U.S.}] \quad 78.14(b)$$

Figure 78.3 Curvature and Refraction Effects

*Atmospheric refraction* will make the object appear shorter by an amount  $h_r$ .

$$h_r = \left( 10.8 \times 10^{-9} \frac{1}{\text{m}} \right) x_m^2 \quad [\text{SI}] \quad 78.15(a)$$

$$h_r = \left( 3.3 \times 10^{-9} \frac{1}{\text{ft}} \right) x_{\text{ft}}^2 \quad [\text{U.S.}] \quad 78.15(b)$$

The effects of curvature and refraction are combined into a single correction,  $h_{rc}$ . As shown in Eq. 78.16, the correction is a positive by convention. Whether the correction increases or reduces a measured quantity depends on the nature of the quantity. To determine if rod readings, elevations at the rod base, and elevations at the instrument should be increased or decreased by  $h_{rc}$ , it is helpful to draw the geometry.

$$h_{rc,m} = |h_r - h_c| = \left( 6.75 \times 10^{-8} \frac{1}{\text{m}} \right) x_m^2 \quad [\text{SI}] \quad 78.16(a)$$

$$h_{rc,ft} = |h_r - h_c| = \left( 2.06 \times 10^{-8} \frac{1}{\text{ft}} \right) x_{\text{ft}}^2 \quad [\text{U.S.}] \quad 78.16(b)$$

The corrected rod reading (actual height) is

$$h_a = R_{\text{observed}} - h_{rc} \quad 78.17$$

## 19. ELEVATION MEASUREMENT: DIRECT LEVELING

A *telescope* is part of the sighting instrument. A *transit* or *theodolite* is often referred to as a “telescope” even though the telescope is only a part of the instrument. (Early telescoping theodolites were so long that it was not possible to invert, or “transit,” them, so the name “transit” is used for inverting telescopes.) An *engineer’s level* (*duffy level*) is a sighting device with a telescope rigidly attached to the level bar. A sensitive level vial is used to ensure level operation. The engineer’s level can be rotated, but in its basic form it cannot be elevated. An *alidade* consists of the base and telescopic part of the transit, but not the tripod or leveling equipment.

In a *semi-precise level*, also known as a *prism level*, the level vial is visible from the eyepiece end. In other respects, it is similar to the engineer's level. The *precise* or *geodetic level* has even better control of horizontal angles. The bubble vial is magnified for greater accuracy.

Transits and levels are used with rods. *Leveling rods* are used to measure the vertical distance between the line of sight and the point being observed. The *standard rod* is typically made of fiberglass and is extendable. It is sometimes referred to as a *Philadelphia rod*. *Precise rods*, made of wood-mounted Invar, are typically constructed in one piece and are spring-loaded in tension to avoid sagging.

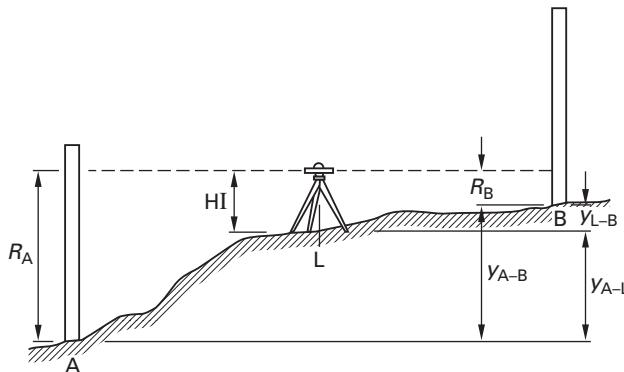

With *direct leveling*, a level is set up at a point approximately midway between the two points whose difference in elevation is desired. The vertical *backsight* (*plus sight*) and *foresight* (*minus sight*) are read directly from the rod. HI is the height of the instrument above the ground, and  $h_{rc}$  is the correction for refraction and curvature.

Referring to Fig. 78.4, and recalling that  $h_{rc}$  is positive,

$$y_{A-L} = R_A - h_{rc,A-L} - HI \quad 78.18$$

$$y_{L-B} = HI + h_{rc,L-B} - R_B \quad 78.19$$

**Figure 78.4** Direct Leveling

The difference in elevations between points A and B is

$$\begin{aligned} y_{A-B} &= y_{A-L} + y_{L-B} \\ &= R_A - R_B + h_{rc,L-B} - h_{rc,A-L} \end{aligned} \quad 78.20$$

If the backsight and foresight distances are equal (or approximately so), then the effects of refraction and curvature cancel.

$$y_{A-B} = R_A - R_B \quad 78.21$$

## 20. ELEVATION MEASUREMENT: DIFFERENTIAL LEVELING

*Differential leveling* is the consecutive application of direct leveling to the measurement of large differences in elevation. There is usually no attempt to balance the

foresights and backsights exactly. Therefore, there is no record made of the exact locations of the level positions. Furthermore, the path taken between points need not be along a straight line connecting them, as only the elevation differences are relevant. If greater accuracy is desired without having to balance the foresight and backsight distance pairs accurately, it is possible to eliminate most of the curvature and refraction error by balancing the sum of the foresights against the sum of the backsights.

The following abbreviations are used with differential leveling.

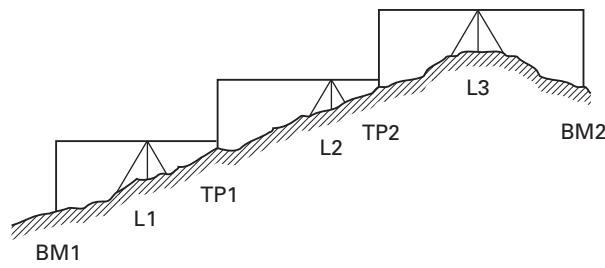

BM	benchmark or monument
TP	turning point
FS	foresight (also known as a minus sight)
BS	backsight (also known as a plus sight)
HI	height of the instrument
L	level position

HI (or H.I.) is the distance between the instrument axis and the datum. For differential leveling, the datum established for all elevations is used to define the HI. However, in stadia measurements, HI may be used (and recorded in the notes) to represent the height of the instrument axis above the ground.

### Example 78.11

The following readings were taken during a differential leveling survey between benchmarks 1 and 2. All values given are in feet. (a) What is the difference in elevations between these two benchmarks? (b) What are the elevations at station 1+00 and station 2+00?

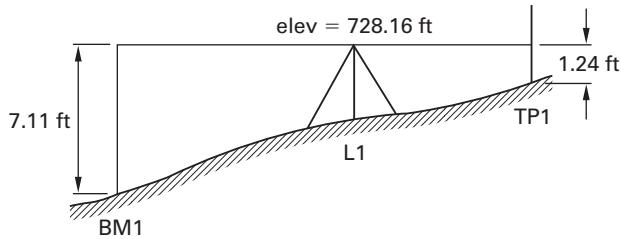

station	BS (ft)	FS (ft)	elevation (ft)
BM1	7.11		721.05
TP1	8.83	1.24	
TP2	11.72	1.11	
sta 1+00			2.92
sta 2+00			6.43
BM2			10.21

**Solution**

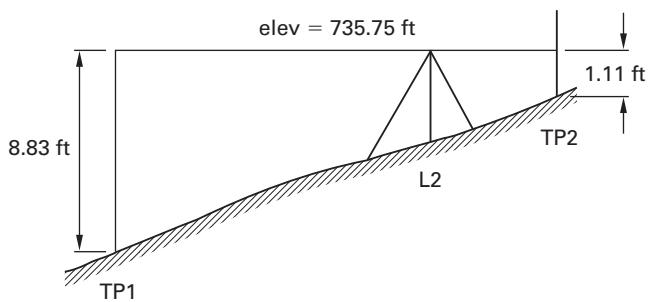

(a) The first measurement is shown in larger scale. The height of the instrument is

$$\begin{aligned} \text{HI1} &= \text{elev}_{\text{BM}} + \text{BS} = 721.05 \text{ ft} + 7.11 \text{ ft} \\ &= 728.16 \text{ ft} \end{aligned}$$

The height of the instrument at the second level position is

$$\begin{aligned} \text{HI2} &= \text{HI1} + \text{BS} - \text{FS} \\ &= 728.16 \text{ ft} + 8.83 \text{ ft} - 1.24 \text{ ft} \\ &= 735.75 \text{ ft} \end{aligned}$$

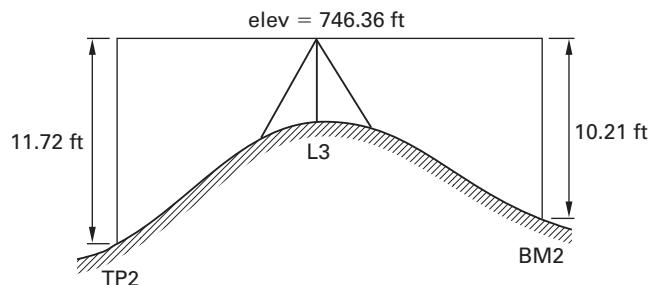

The height of the instrument at the third level position is

$$\begin{aligned} \text{HI3} &= \text{HI2} + \text{BS} - \text{FS} \\ &= 735.75 \text{ ft} + 11.72 \text{ ft} - 1.11 \text{ ft} \\ &= 746.36 \text{ ft} \end{aligned}$$

The elevation of BM2 is

$$\begin{aligned} \text{elev}_{\text{BM2}} &= \text{HI3} - \text{FS} \\ &= 746.36 \text{ ft} - 10.21 \text{ ft} \\ &= 736.15 \text{ ft} \end{aligned}$$

The difference in elevation is

$$\text{elev}_{\text{BM2}} - \text{elev}_{\text{BM1}} = 736.15 \text{ ft} - 721.05 \text{ ft} = 15.1 \text{ ft}$$

Check using the backsight and foresight sums.

The backsight sum is

$$7.11 \text{ ft} + 8.83 \text{ ft} + 11.72 \text{ ft} = 27.66 \text{ ft}$$

The foresight sum is

$$1.24 \text{ ft} + 1.11 \text{ ft} + 10.21 \text{ ft} = 12.56 \text{ ft}$$

The difference in elevation is

$$27.66 \text{ ft} - 12.56 \text{ ft} = 15.1 \text{ ft} \quad [\text{OK}]$$

(b) The elevation of sta 1+00 is

$$\begin{aligned} \text{elev}_{\text{sta } 1+00} &= \text{HI1} - \text{FS} = 728.16 \text{ ft} - 2.92 \text{ ft} \\ &= 743.44 \text{ ft} \end{aligned}$$

The elevation of sta 2+00 is

$$\begin{aligned} \text{elev}_{\text{sta } 2+00} &= \text{HI2} - \text{FS} \\ &= 735.75 \text{ ft} - 6.43 \text{ ft} \\ &= 739.32 \text{ ft} \end{aligned}$$

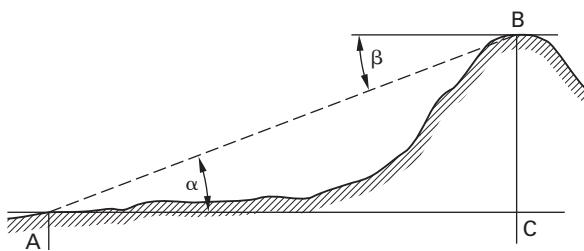

## 21. ELEVATION MEASUREMENT: INDIRECT LEVELING

*Indirect leveling*, illustrated in Fig. 78.5, does not require a backsight. (A backsight reading can still be taken to eliminate the effects of curvature and refraction.) In Fig. 78.5, distance AC has been determined. Within the limits of ordinary practice, angle ACB is 90°. Including the effects of curvature and refraction, the elevation difference between points A and B is

$$y_{A-B} = AC \tan \alpha + 2.1 \times 10^{-8}(AC)^2 \quad [\text{U.S.}] \quad 78.22$$

If a backsight is taken from B to A and angle  $\beta$  is measured, then

$$y_{A-B} = AC \tan \beta - 2.1 \times 10^{-8}(AC)^2 \quad [\text{U.S.}] \quad 78.23$$

**Figure 78.5** Indirect Leveling

Adding Eq. 78.22 and Eq. 78.23 and dividing by 2,

$$y_{A-B} = \frac{1}{2}AC(\tan \alpha + \tan \beta) \quad 78.24$$

## 22. EQUIPMENT AND METHODS USED TO MEASURE ANGLES

A *transit* is a telescope that measures vertical angles as well as horizontal angles. The conventional *engineer's transit* (*surveyor's transit*) used in the past had a  $6\frac{1}{4}$  in diameter metal circle and vernier. It could be clamped vertically and used as a level. Few instruments of this nature are still available.

With a *theodolite*, horizontal and vertical angles are measured by looking into viewpieces. There may be up to four viewpieces, one each for the sighting-in telescope, the compass, the horizontal and vertical angles, and the optical plummet. Theodolites may be scale-reading optical, micrometer-reading optical, or electronic. Angles read electronically interface with EDM equipment and data recorders.

## 23. DIRECTION SPECIFICATION

The direction of any line can be specified by an angle between it and some other reference line, known as a *meridian*. If the meridian is arbitrarily chosen, it is called an *assumed meridian*. If the meridian is a true north-to-south line passing through the true north pole, it is called a *true meridian*. If the meridian is parallel to the earth's magnetic field, it is known as a *magnetic meridian*. A rectangular grid may be drawn over a map with any arbitrary orientation. If so, the vertical lines are referred to as *grid meridians*.

A true meridian differs from a magnetic meridian by the *declination* (*magnetic declination* or *variation*). An *isogonic line* connects locations in a geographical region that have the same magnetic declination. If the north end of a compass points to the west of true meridian, the declination is referred to as a *west declination* or *minus declination*. Otherwise, it is referred to as an *east declination* or *plus declination*. Plus declinations are added to the magnetic compass azimuth to obtain the true azimuth. Minus declinations are subtracted from the magnetic compass azimuth.

A direction (i.e., the variation of a line from its meridian) may be specified in several ways. Directions are normally specified as either bearings or azimuths referenced to either north or south. In the United States, most control work is performed using directions stated as azimuths. Most construction projects and property surveys specify directions as bearings.

**Azimuth:** An azimuth is given as a clockwise angle from the reference direction, either "from the north" or "from the south" (e.g., "NAz 320°"). Azimuths may not exceed 360°.

**Deflection angle:** The angle between a line and the prolongation of a preceding line is a deflection angle. Such measurements must be labeled as "right" for clockwise angles and "left" for counterclockwise angles.

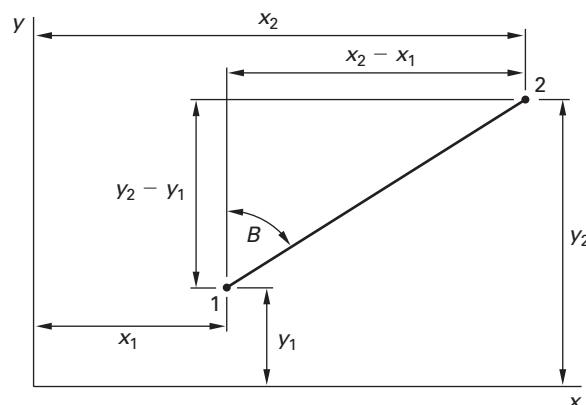

**Angle to the right:** An angle to the right is a clockwise deflection angle measured from the preceding to the following line.

**Azimuths from the back line:** Same as angle to the right.

**Bearing:** The bearing of a line is referenced to the quadrant in which the line falls and the angle that the line makes with the meridian in that quadrant. It is necessary to specify the two cardinal directions that define the quadrant in which the line is found. The north and south directions are always specified first. A bearing contains an angle and a direction from a reference line, either north or south (e.g., "N45°E"). A bearing may not have an angular component exceeding 90°.

Bearings and azimuths are calculated from trigonometric and geometric relationships. From Fig. 78.6, the tangent of the bearing angle  $B$  of the line between the two points is given by Eq. 78.25.

$$\tan B = \frac{x_2 - x_1}{y_2 - y_1} \quad 78.25$$

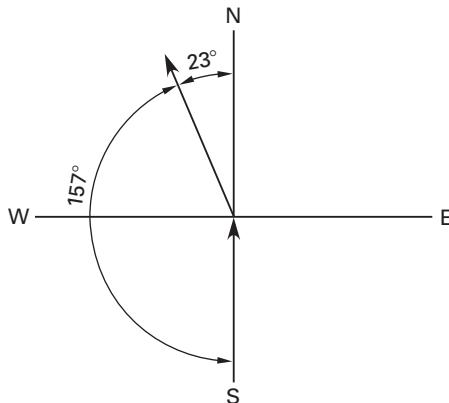

**Figure 78.6** Calculation of Bearing Angle

The distance,  $D$ , between the two points is given by Eq. 78.26.

$$D = \sqrt{(y_2 - y_1)^2 + (x_2 - x_1)^2} \quad 78.26$$

If the numerator in Eq. 78.25 is positive, the line from point 1 to 2 bears east. If the denominator is positive, the line bears north. Determining the bearing and length of a line from the coordinates of the two points is called *inversing the line*. (See Fig. 78.7 for equivalent angle measurements.)

**Figure 78.7** Equivalent Angle Measurements

azimuth from the south:  $157^\circ$   
azimuth from the north:  $337^\circ$   
deflection angle:  $23^\circ L$   
angle to the right:  $157^\circ$   
bearing:  $N23^\circ W$

The *azimuth*,  $A_N$ , of a line from point 1 to 2 measured from the north meridian is given by Eq. 78.27.

$$\tan A_N = \frac{x_2 - x_1}{y_2 - y_1} \quad 78.27$$

The azimuth,  $A_S$ , of the same line from point 1 to 2 measured from the south meridian is given by Eq. 78.28.

$$\tan A_S = \frac{x_1 - x_2}{y_1 - y_2} \quad 78.28$$

### Example 78.12

A group of hikers on the Pacific Crest Trail (easterly magnetic declination of  $+17^\circ$ ) uses a magnetic compass to sight in on a distant feature. What is the true azimuth if the observed compass angle is  $42^\circ$ ?

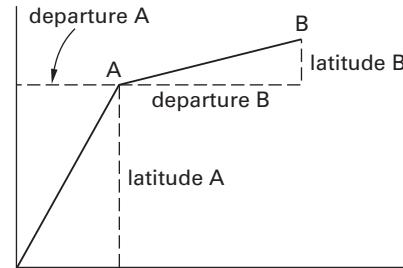

*Solution*

An easterly (plus) declination is added to the observed azimuth. Therefore, the true azimuth is  $42^\circ + 17^\circ = 59^\circ$ .

## 24. LATITUDES AND DEPARTURES

The *latitude* of a line is the distance that the line extends in a north or south direction. A line that runs toward the north has a positive latitude; a line that runs toward the south has a negative latitude. The *departure* of a line is the distance that the line extends in an east or west direction. A line that runs toward the east has a positive departure; a line that runs toward the west has a negative departure. (See Fig. 78.8.)

**Figure 78.8** Latitudes and Departures

If the  $x$ - and  $y$ -coordinates of two points are known, the latitude and departure of the line between the two points are determined by Eq. 78.29 and Eq. 78.30.

$$\text{latitude of line from point A to B: } y_B - y_A \quad 78.29$$

$$\text{departure of line from point A to B: } x_B - x_A \quad 78.30$$

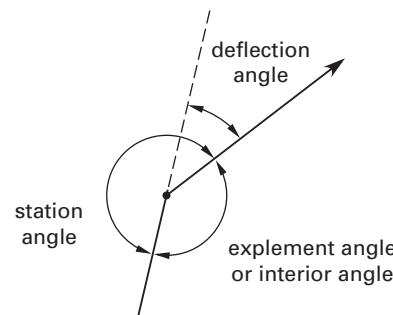

## 25. TRAVERSES

A *traverse* is a series of straight lines whose lengths and directions are known. A traverse that does not come back to its starting point is an *open traverse*. A traverse that comes back to its starting point is a *closed traverse*. The polygon that results from closing a traverse is governed by the following two geometric requirements.

1. The sum of the deflection angles is  $360^\circ$ .
2. The sum of the interior angles of a polygon with  $n$  sides is  $(n - 2)(180^\circ)$ .

There are three ways to specify angles in traverses: *deflection angles*, *interior angles* (also known as *explement angles*), and *station angles*. These are illustrated in Fig. 78.9.

**Figure 78.9** Angles Used in Defining Traverses

## 26. BALANCING

Refined field measurements are not the goal of measurement *balancing* (also known as *adjusting*). Balancing is used simply to accommodate the mathematical necessity of having a balanced column of figures. Balancing is considered inappropriate by some surveyors, since errors are not eliminated, only distributed to all of the measurements. Balancing does not make inaccurate measurements more accurate—it only makes inaccurate measurements more inaccurate. It is particularly inappropriate when a “blunder” (a measurement grossly in error that should be remeasured) is fixed by balancing.

## 27. BALANCING CLOSED TRAVERSE ANGLES

Due to measurement errors, variations in magnetic declination, and local magnetic attractions, it is likely that the sum of angles making up the interior angles will not exactly equal  $(n - 2)(180^\circ)$ . The following adjusting procedure can be used to distribute the angle error of closure among the angles.

- step 1:* Calculate the interior angle at each vertex from the observed bearings.
- step 2:* Subtract  $(n - 2)(180^\circ)$  from the sum of the interior angles.
- step 3:* Unless additional information in the form of numbers of observations or probable errors is available, assume the angle error of closure can be divided equally among all angles. Divide the error by the number of angles.
- step 4:* Find a line whose bearing is assumed correct; that is, find a line whose bearing appears unaffected by errors, variations in magnetic declination, and local attractions. Such a line may be chosen as one for which the forward and back bearings are the same. If there is no such line, take the line whose difference in forward and back bearings is the smallest.
- step 5:* Start with the assumed correct line and add (or subtract) the prorated error to each interior angle.
- step 6:* Correct all bearings except the one for the assumed correct line.

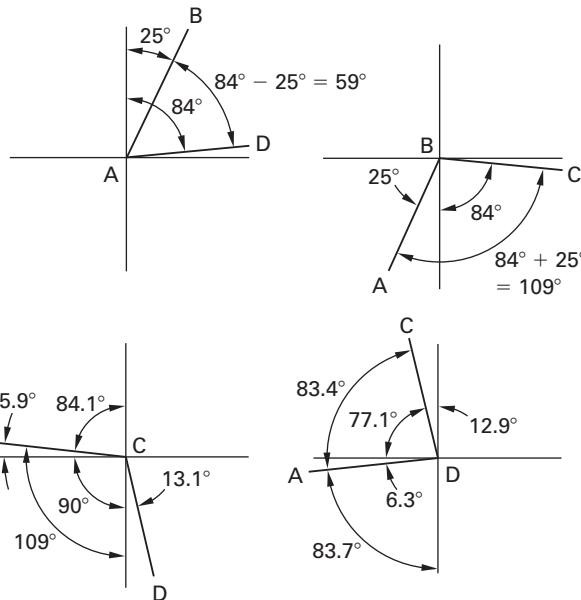

### Example 78.13

Balance the angles on the four-sided closed traverse whose magnetic foresights and backsights are as follows.

line	bearing
AB	N25°E
BA	S25°W
BC	S84°E
CB	N84.1°W
CD	S13.1°E
DC	N12.9°W
DA	S83.7°W
AD	N84°E

*Solution*

*step 1:* The interior angles are calculated from the bearings.

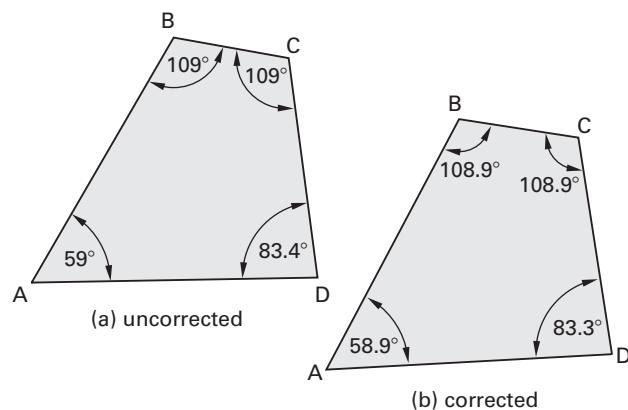

*step 2:* The sum of the angles is

$$59^\circ + 109^\circ + 109^\circ + 83.4^\circ = 360.4^\circ$$

For a four-sided traverse, the sum of interior angles should be  $(4 - 2)(180^\circ) = 360^\circ$ , so a correction of  $-0.4^\circ$  must be divided evenly among the four angles. Since the backsight and foresight bearings of line AB are the same, it is assumed that the  $25^\circ$  bearings are the most accurate. The remaining bearings are then adjusted to use the corrected angles.

line	bearing
AB	N25°E
BA	S25°W
BC	S83.9°E
CB	N83.9°W
CD	S12.8°E
DC	N12.8°W
DA	S83.9°W
AD	N83.9°E

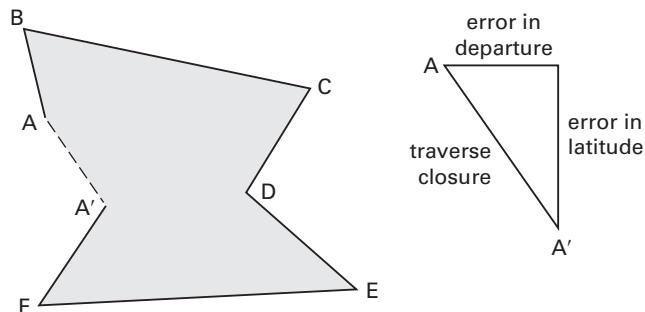

## 28. BALANCING CLOSED TRAVERSE DISTANCES

In a closed traverse, the algebraic sum of the latitudes should be zero. The algebraic sum of the departures should also be zero. The actual non-zero sums are called *closure in latitude* and *closure in departure*, respectively.

The *traverse closure* is the line that will exactly close the traverse. Since latitudes and departures are orthogonal, the closure in latitude and closure in departure can be considered as the rectangular coordinates and the traverse closure length calculated from the Pythagorean theorem. The coordinates will have signs opposite the closures in departure and latitude. That is, if the closure in departure is positive, point A will lie to the left of point A', as shown in Fig. 78.10.

**Figure 78.10** Traverse Closure

The length of a traverse closure is calculated from the Pythagorean theorem.

$$L = \sqrt{(closure \text{ in departure})^2 + (closure \text{ in latitude})^2} \quad 78.31$$

To balance a closed traverse, the traverse closure must be divided among the various legs of the traverse. (Of course, if it is known that one leg was poorly measured due to difficult terrain, all of the error may be given to that leg.) This correction requires that the latitudes and departures be known for each leg of the traverse.

Computer-assisted traverse balancing systems offer at least two balancing methods: compass rule, transit rule, Crandall method, and least squares. The use of one rule or the other is often arbitrary or a matter of convention.

The most common balancing method is the *compass rule*, also known as the *Bowditch method*: the ratio of a leg's correction to the total traverse correction is equal to the ratio of leg length to the total traverse length, with the signs reversed. The compass rule is used when the angles and distances in the traverse are considered equally precise.

$$\frac{\text{leg departure correction}}{\text{closure in departure}} = \frac{-\text{leg length}}{\text{total traverse length}} \quad 78.32$$

$$\frac{\text{leg latitude correction}}{\text{closure in latitude}} = \frac{-\text{leg length}}{\text{total traverse length}} \quad 78.33$$

If the angles are precise but the distances are less precise (such as when the distances have been determined by taping through rugged terrain), the *transit rule* is a preferred method of distributing the correction to the traverse legs. This rule distributes the closure error in proportion to the absolute values of the latitudes and departures.

$$\frac{\text{leg departure correction}}{\text{closure in departure}} = -\left(\frac{\text{leg departure}}{\text{sum of departure absolute values}}\right) \quad 78.34$$

$$\frac{\text{leg latitude correction}}{\text{closure in latitude}} = -\left(\frac{\text{leg latitude}}{\text{sum of latitude absolute values}}\right) \quad 78.35$$

With the *Crandall rule*, adjustments assume that the closing errors are random and normally distributed, and that angular error is negligible or has already been eliminated (i.e., adjusted out). The closure error is distributed throughout the traverse by adjusting only the traverse distances, not the angles. The adjustment made to each leg is such that the sum of the squares is a minimum. However, the Crandall rule is not the same as the method of least squares.

The *method of least squares* balancing has significant advantages over the other methods, although the computational burden makes it difficult to implement with manual calculations. This method reduces the sum of the squares of the differences between the unadjusted and adjusted measurements (angles and distances) to a minimum. Particularly when calculations are implemented in surveying equipment or analysis software, the least squares method accommodates weighting of measurements and the inclusion of redundant data to strengthen some measurements. With this method, adjusted coordinate positions are computed using estimated precisions of observations' coordinates to reconcile differences between observations and the inverses to their adjusted coordinates. The least squares method also produces adjustment statistics that indicate the strengths of computed locations. The strength of the computed location translates directly into measurement confidence and can also be helpful in detecting input or measurement errors.

### Example 78.14

A closed traverse consists of seven legs, the total of whose lengths is 2705.13 ft. Leg CD has a departure of 443.56 ft and a latitude of 219.87 ft. The total closure in departure for the traverse is +0.41 ft; the total closure in latitude is -0.29 ft. Use the compass rule to determine the corrected latitude and departure for leg CD.

**Solution**

The length of leg CD is

$$\begin{aligned} L_{CD} &= \sqrt{(443.56 \text{ ft})^2 + (219.87 \text{ ft})^2} \\ &= 495.06 \text{ ft} \end{aligned}$$

Use the compass rule, Eq. 78.33.

$$\frac{\text{latitude correction}}{-0.29 \text{ ft}} = -\frac{495.06 \text{ ft}}{2705.13 \text{ ft}}$$

$$\text{latitude correction} = 0.05 \text{ ft}$$

The corrected latitude is

$$\begin{aligned} 219.87 \text{ ft} + 0.05 \text{ ft} &= 219.92 \text{ ft} \\ \frac{\text{departure correction}}{+0.41 \text{ ft}} &= -\frac{495.06 \text{ ft}}{2705.13 \text{ ft}} \\ \text{departure correction} &= -0.08 \text{ ft} \end{aligned}$$

The corrected departure is

$$443.56 \text{ ft} - 0.08 \text{ ft} = 443.48 \text{ ft}$$

## 29. RECONSTRUCTING MISSING SIDES AND ANGLES

If one or more sides or angles of a traverse are missing or cannot be determined by measurement, they can sometimes be reconstructed from geometric and trigonometric principles.

The traverse shown in Fig. 78.11(a) has one leg missing. However, line EA can be reconstructed from its components EE' and E'A. These components are equal to the sum of the departures and the sum of the latitudes, respectively, with the signs changed. The angle can be determined from the ratio of the sides. The length EA can be found from Eq. 78.31.

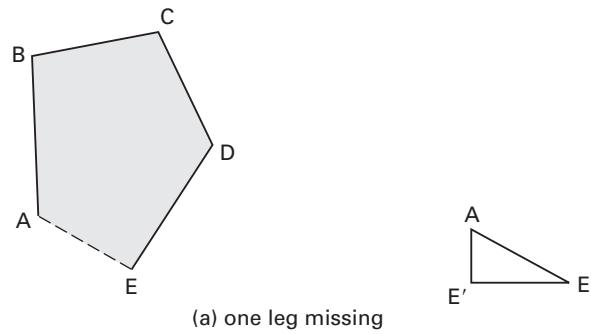

Figure 78.11(b) shows a traverse that has two adjacent legs missing. The traverse can be closed as long as some length/angle information is available. The technique is to close the traverse by using the same method for when one leg is missing. This will give the line DA. Then, the triangle EAD can be completed from other information.

Figure 78.11(c) shows a traverse with two nonadjacent legs missing. Since the latitudes and departures of two parallel lines are equal, this can be solved by closing the traverse and shifting one missing leg as a parallel leg, to be adjacent to the other missing leg. This reduces the problem to the case of two adjacent legs missing.

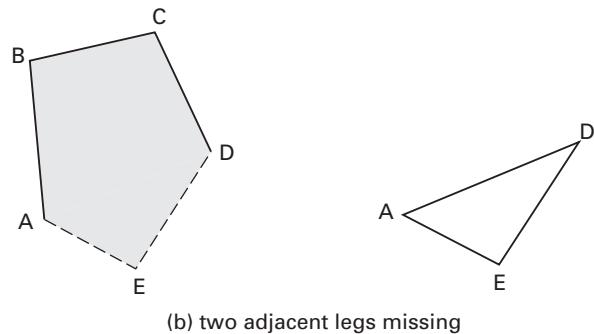

## 30. TRAVERSE AREA: METHOD OF COORDINATES

The area of a simple traverse can be found by dividing the traverse into a number of geometric shapes and summing their areas.

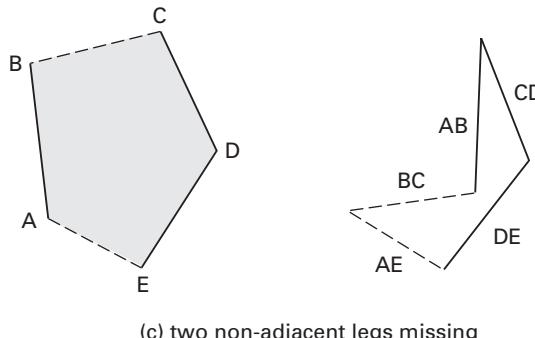

**Figure 78.11 Completing Partial Traverses**

(a) one leg missing

(b) two adjacent legs missing

(c) two non-adjacent legs missing

If the coordinates of the traverse leg end points are known, the *method of coordinates* can be used. The coordinates can be *x-y* coordinates referenced to some arbitrary set of axes, or they can be sets of departure and latitude. In Eq. 78.36,  $x_n$  is substituted for  $x_0$ . Similarly,  $x_1$  is substituted for  $x_{n+1}$ .

$$A = \frac{1}{2} \left| \sum_{i=1}^n y_i(x_{i-1} - x_{i+1}) \right| \quad 78.36$$

The area calculation is simplified if the coordinates are written in the following form.

$$\frac{x_1}{y_1} \times \frac{x_2}{y_2} \times \frac{x_3}{y_3} \times \frac{x_4}{y_4} \times \cdots \times \frac{x_1}{y_1}$$

The area is

$$A = \frac{1}{2} \left| \sum \text{of full line products} - \sum \text{of broken line products} \right| \quad 78.37$$

**Example 78.15**

Calculate the area of a triangle with  $x$ - $y$  coordinates of its corners given as (3, 1), (5, 1), and (5, 7).

$$\begin{array}{ccccccc} \frac{3}{1} & < & \frac{5}{1} & < & \frac{5}{7} & < & \frac{3}{1} \end{array}$$

*Solution*

Use Eq. 78.36.

$$\begin{aligned} A &= \left(\frac{1}{2}\right) ((3)(1) + (5)(7) + (5)(1) - (1)(5) \\ &\quad - (1)(5) - (7)(3)) \\ &= 6 \end{aligned}$$

**31. TRAVERSE AREA: DOUBLE MERIDIAN DISTANCE**

If the latitudes and departures are known, the *double meridian distance* (DMD) method can be used to calculate the area of a traverse. Equation 78.38 defines a double meridian distance for a leg.

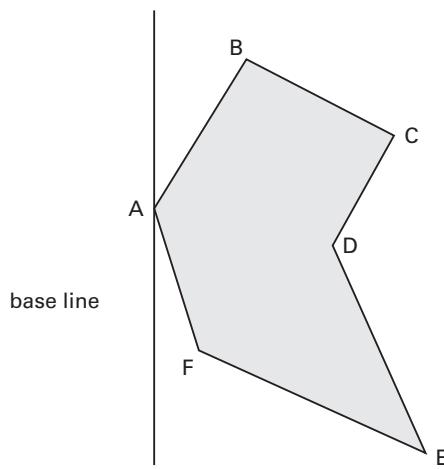

$$\begin{aligned} \text{DMD}_{\text{leg } i} &= \text{DMD}_{\text{leg } i-1} + \text{departure}_{\text{leg } i-1} \\ &\quad + \text{departure}_{\text{leg } i} \end{aligned} \quad 78.38$$

Special rules are required to handle the first and last legs. The DMD of the first course is defined as the departure of that course. The DMD of the last course is the negative of its own departure. The traverse area is calculated from Eq. 78.39. A tabular approach is the preferred manual method of using the DMD method.

$$A = \frac{1}{2} \left| \sum (\text{latitude}_{\text{leg } i} \times \text{DMD}_{\text{leg } i}) \right| \quad 78.39$$

**Example 78.16**

The latitudes and departures (in feet) of a six-leg traverse have been determined as given. Use the DMD method to calculate the traverse area.

leg	latitude (ft)	departure (ft)
AB	200	200
BC	-100	200
CD	-200	-100
DE	-300	200
EF	200	-400
FA	200	-100

*Solution*

By the special starting rule, the DMD of the first leg, AB, is the departure of leg AB. The DMD of leg BC is given by Eq. 78.38.

$$\begin{aligned} \text{DMD}_{\text{BC}} &= \text{DMD}_{\text{AB}} + \text{departure}_{\text{AB}} + \text{departure}_{\text{BC}} \\ &= 200 \text{ ft} + 200 \text{ ft} + 200 \text{ ft} \\ &= 600 \text{ ft} \end{aligned}$$

The other DMDs are calculated similarly.

leg	latitude (ft)	departure (ft)	DMD (ft)	lat. × DMD (ft <sup>2</sup> )
AB	200	200	200	40,000
BC	-100	200	600	-60,000
CD	-200	-100	700	-140,000
DE	-300	200	800	-240,000
EF	200	-400	600	120,000
FA	200	-100	100	20,000
			total	-260,000

The area is given by Eq. 78.39.

$$\begin{aligned} A &= \frac{1}{2} \left| \sum (\text{latitude}_{\text{leg } i} \times \text{DMD}_{\text{leg } i}) \right| = \left(\frac{1}{2}\right) (260,000 \text{ ft}^2) \\ &= 130,000 \text{ ft}^2 \end{aligned}$$

**32. AREAS BOUNDED BY IRREGULAR BOUNDARIES**

Areas of sections with irregular boundaries, such as creek banks, cannot be determined precisely, and approximation methods must be used. (See Fig. 78.12.) If the irregular side can be divided into a series of cells of width  $d$ , either the trapezoidal rule or Simpson's rule can be used. (If the coordinates of all legs in the irregular boundary are known, the DMD method can be used.)

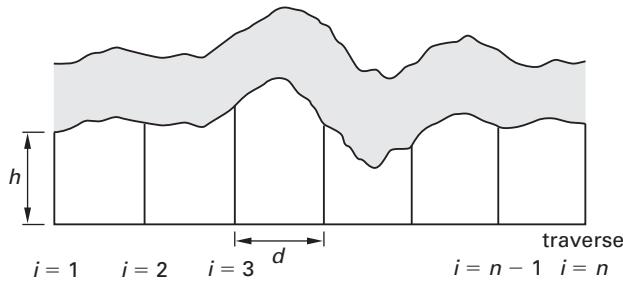

If the irregular side of each cell is fairly straight, the *trapezoidal rule* as given in Eq. 78.40 can be used.

$$A = d \left( \frac{h_1 + h_n}{2} + \sum_{i=2}^{n-1} h_i \right) \quad 78.40$$

If the irregular side of each cell is curved or parabolic, then *Simpson's rule* (sometimes referred to as *Simpson's 1/3 rule*) as given in Eq. 78.41 can be used.

$$\begin{aligned} A &= \frac{d}{3} \left( h_1 + h_n + 2 \sum_{\text{odd}} h_i + 4 \sum_{\text{even}} h_i \right) \\ &= \frac{d}{3} (h_1 + 4h_2 + 2h_3 + 4h_4 + \dots + h_n) \end{aligned} \quad 78.41$$

**Figure 78.12** Area Bounded by Irregular Areas

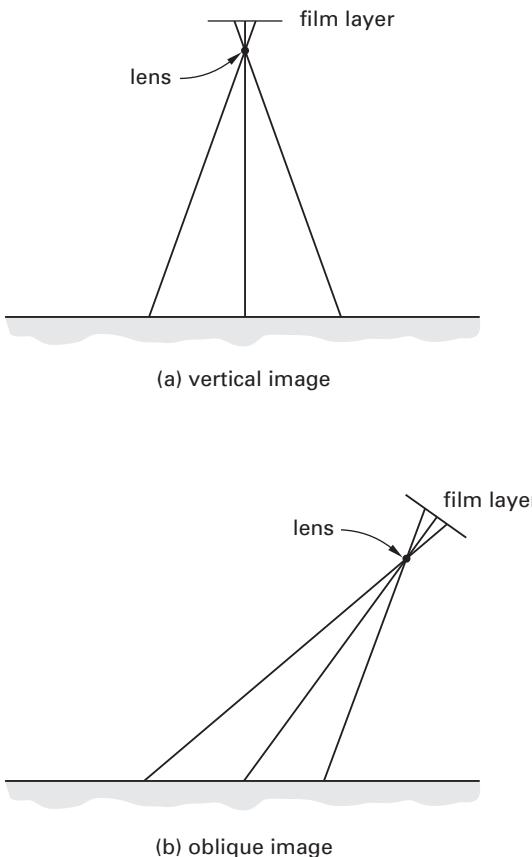

### 33. PHOTOGRAHMETRY

*Photogrammetry (aerial mapping)* uses photography to obtain distance measurements. Either vertical or oblique (inclined) photographs can be used, as shown in Fig. 78.13. The controlling dimensions are taken between large paint marks or flags set out on the ground that are visible in the aerial photographs. Adjacent photographs overlap by 60% or more, forming a "stereo pair." Stereo pair photographs enable the operator to see the ground in three dimensions so that elevations of the features can also be determined.

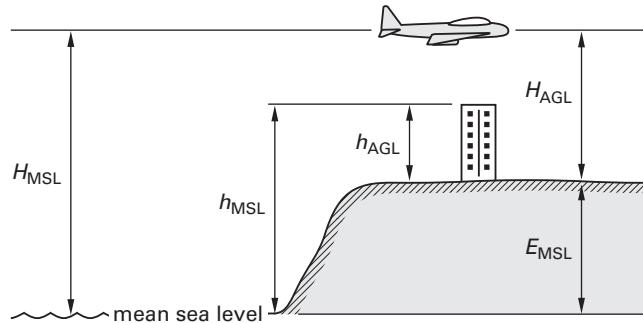

Aircraft flight altitudes,  $H$ , and heights of features,  $h$ , can be stated in two ways: (1) above sea level and (2) above the ground (level). Altitudes above mean sea level are designated MSL (e.g., 6000 ft MSL); and, altitudes above the ground (level) are designated AGL (e.g., 550 ft AGL). These values differ by the elevation,  $E$ , of the surrounding terrain. (See Fig. 78.14.)

The *scale*,  $S$ , of a photograph is the ratio of the dimension on the photo and the dimension on the ground. It is also the ratio of the focal length,  $f$ , and the flight altitude,  $H_{AGL}$ . Precise mappings use scales of 1 in = 50–500 ft, whereas more general mappings might use 1 in = 600–1300 ft. Scale is constantly changing, since the elevation above the ground level depends on the surface terrain. Also, the distance from the camera to the ground directly below the camera will be less than the distance from the camera to points on the outer fringes of the photograph. Therefore, an average distance from camera to ground level is used as the flight altitude. The number of photographs and the number

**Figure 78.13** Photogrammetric Images

**Figure 78.14** Photogrammetry Nomenclature

of flight paths required depend on the film size and lap percentages.

$$\begin{aligned} S &= \frac{f}{H_{AGL}} = \frac{f}{H_{MSL} - E_{MSL}} \\ &= \frac{\text{length in photograph}}{\text{true length}} \end{aligned} \quad 78.42$$

Photogrammetry recognizes three "centers." The *principal point* is the location in a camera where the optical axis of the lens intersects the imaging plane (i.e., the geometric center of the imaging plane). This generally

coincides with the geometric center of the printed photograph. The *nadir* is the (image of the) location on the ground immediately below the camera, regardless of camera tilt. The nadir is also known as the *plumb point* and *vertical point*. The *isocenter* is the midpoint of a line between the principal point and the nadir on the photograph. On a true vertical photograph, the principal point, nadir, and isocenter coincide at the geometric center of the photograph found at the intersection of straight lines drawn from diagonal corners of the photograph.

### Example 78.17

Aerial mapping is being used with a scale of 1 in:1000 ft. The film holder uses 8 in  $\times$  8 in film. The focal length of the camera is 6 in. The area to be mapped is square, 6 mi on each side. A side-lap from photo to photo of 30% is desired, as well as an end-lap from photo to photo of 60%. The plane travels at 150 mph.

- (a) What is the area covered by each photograph?
- (b) At what altitude should the plane fly while taking photographs?
- (c) How far apart will the flight paths be?
- (d) How many flight paths are required?
- (e) How many photographs are required per flight path?
- (f) How many photographs will be taken altogether?
- (g) How frequently should the photographs be taken?

*Solution*

- (a) The photograph area is

$$(8 \text{ in})(8 \text{ in}) = 64 \text{ in}^2$$

The area covered by each photograph is

$$(64 \text{ in}^2) \left( 1000 \frac{\text{ft}}{\text{in}} \right)^2 = 64,000,000 \text{ ft}^2$$

- (b) The flight altitude is calculated using Eq. 78.42.

$$\begin{aligned} H_{\text{AGL}} &= \frac{f}{S} = \frac{6 \text{ in}}{\frac{1 \text{ in}}{1000 \text{ ft}}} \\ &= 6000 \text{ ft} \end{aligned}$$

- (c) Each photograph covers 64,000,000 ft<sup>2</sup>, or an area 8000 ft on each side. With a 30% overlap, the distance between flight paths is calculated as

$$(1 - 0.30)(8000 \text{ ft}) = 5600 \text{ ft}$$

- (d) The number of flight paths is

$$\frac{(6 \text{ mi}) \left( 5280 \frac{\text{ft}}{\text{mi}} \right)}{5600 \text{ ft}} = 5.7 \quad [\text{use 6}]$$

- (e) With an end lap of 60%, the distance between photos along the flight path is

$$(8000 \text{ ft})(1 - 0.60) = 3200 \text{ ft}$$

The number of photographs per flight path is

$$\frac{(6 \text{ mi}) \left( 5280 \frac{\text{ft}}{\text{mi}} \right)}{3200 \text{ ft}} = 9.9 \quad [\text{use 10}]$$

- (f) The total number of photos will be  $(6)(10) = 60$ .

- (g) At 150 mph, the frequency of camera shots will be

$$\frac{(3200 \text{ ft}) \left( 3600 \frac{\text{sec}}{\text{hr}} \right)}{\left( 150 \frac{\text{mi}}{\text{hr}} \right) \left( 5280 \frac{\text{ft}}{\text{mi}} \right)} = 14.5 \text{ sec/photo}$$

### 34. DETERMINING OBJECT HEIGHT PHOTOGRAMMETRICALLY

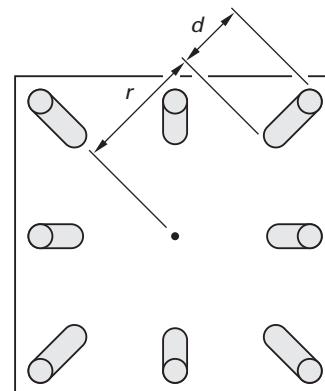

An object's height can be determined from the actual length of its shadow and the angle of the sun above the horizon. The true shadow length,  $l$ , would be determined from a photograph's measured length and scale.

$$h_{\text{AGL}} = l \tan \alpha \quad 78.43$$

If the camera is pointed directly downward (i.e., the *principal point* of the photograph is the nadir position), and if the top and bottom of a tall object near the edge of mono aerial photograph are clearly defined, the exaggerated displacement can be used to determine the height using the *displacement method*. When the image displacement,  $d$ , is great enough to be accurately measured on a photograph taken from a camera located a distance  $H_{\text{AGL}}$  above ground level, the height,  $h_{\text{AGL}}$ , above the ground of an object that is a distance  $r$  from the nadir can be determined from Eq. 78.44.  $h_{\text{AGL}}$  and  $H_{\text{AGL}}$  have the same units (e.g., feet or meters);  $d$  and  $r$  are measured from the photograph and have the same units, though different from  $h_{\text{AGL}}$  and  $H_{\text{AGL}}$ .

$$h_{\text{AGL}} = \frac{dH_{\text{AGL}}}{r} \quad 78.44$$

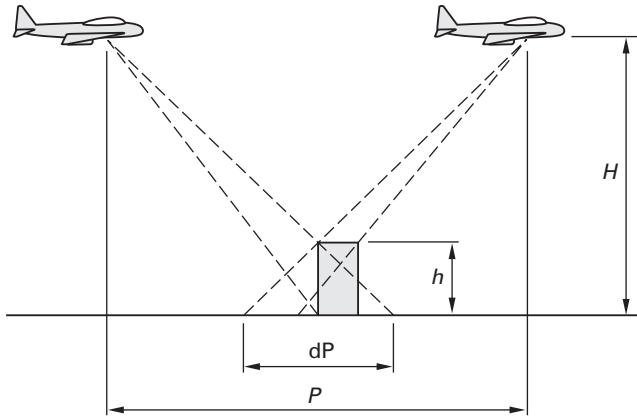

Figure 78.15 Radial Displacement Method

With *parallax height measurement*, a stereo pair of photographs is used. In Eq. 78.45,  $dP$  is the *differential parallax*, and  $P$  is the *absolute parallax* (i.e., the true distance between the nadirs of the two photographs, also known as the *photobase*).  $h_{AGL}$  and  $H_{AGL}$  have the same units (e.g., feet or meters).  $P$  and  $dP$  are measured from the photograph and have the same units, though different from  $h_{AGL}$  and  $H_{AGL}$ .

$$h_{AGL} = \frac{H_{AGL}(dP)}{P + dP} \quad 78.45$$

**Figure 78.16** Parallax Height Measurement

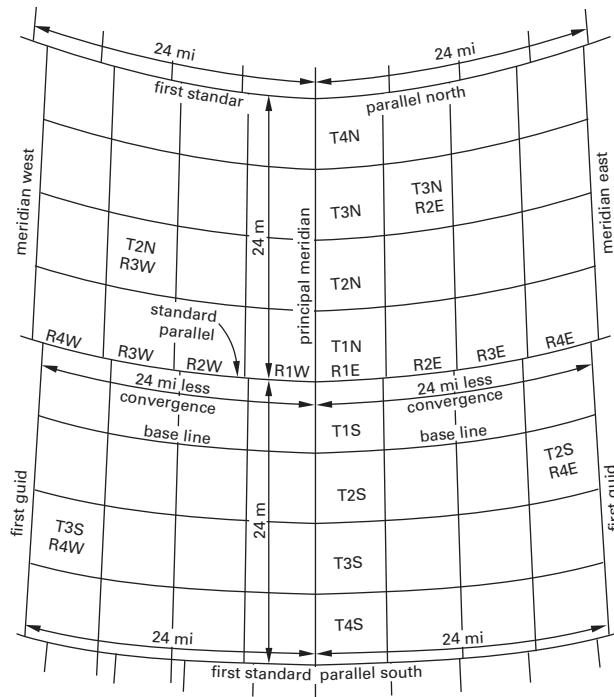

### 35. PUBLIC LAND SYSTEM

The *United States Rectangular Surveying System* was devised with the objective of locating, marking, and fixing subdivisions “for all time.” The land was divided into *tracts* approximately  $24\text{ mi} \times 24\text{ mi}$  by means of meridians and parallels of latitude. These tracts were then divided into 16 *townships*, which were approximately 6 mi on a side. The last step was to divide the township into 36 *sections*, each approximately 1 mi  $\times$  1 mi. Each township has an area of approximately  $36\text{ mi}^2$ , containing 36 sections, each  $1\text{ mi}^2$  in area. Sections were further divided into quarter sections.

Townships were labeled using a range and township number. The *township number* assigned to the parcel of land was determined according to its location relative to the standard parallel of latitude defining the northern and southern boundaries. The *range number* assigned to that parcel was determined according to its location relative to the principal meridian defining the eastern and western boundaries. For example, the parcel of land that is two rows south of the standard parallel and three rows east of the principal meridian bordering the township would be numbered “T2S, R3E.” Fig. 78.17 illustrates the identification of tracts.

**Figure 78.17** Standard Parallels and Guide Meridians

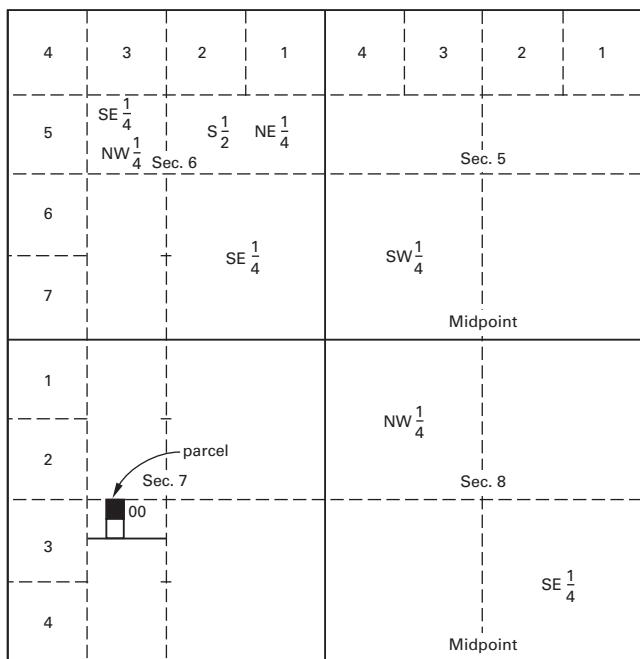

**Figure 78.18** Subdivision of Township into Sections

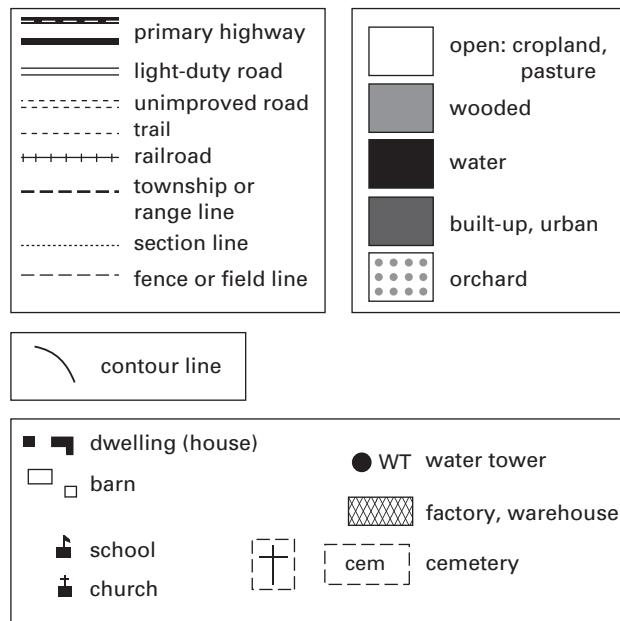

6	5	4	3	2	1
7	8	9	10	11	12
18	17	16	15	14	13
19	20	21	22	23	24
30	29	28	27	26	25
31	32	33	34	35	36

### Example 78.18

Give a legal description of the parcel of land shown, located in section 7 of T3N, R4E, of the 6 Principal Meridian, located in Jefferson County, Nebraska.

**Figure 78.19** Standard USGS Topographic Map Symbols

### *Solution*

Beginning with the smallest identifiable quarter section of land, the legal identification would be as follows.

The NE<sup>1/4</sup> of the NW<sup>1/4</sup> of the NE<sup>1/4</sup> of the SW<sup>1/4</sup> of section 7, T3N, R4E, of the 6 Principal Meridian, located in Jefferson County, Nebraska.

## **36. TOPOGRAPHIC MAPS**

*Topographic maps* are graphic representations of the surface of the earth. They contain a plan view of the land, scales to measure distance, bearings to indicate direction, coordinate systems to locate features, symbols of natural and artificial features, and contour lines to show elevation, slope, and relief of the landscape. Standard USGS mapping symbols are shown in Fig. 78.19.

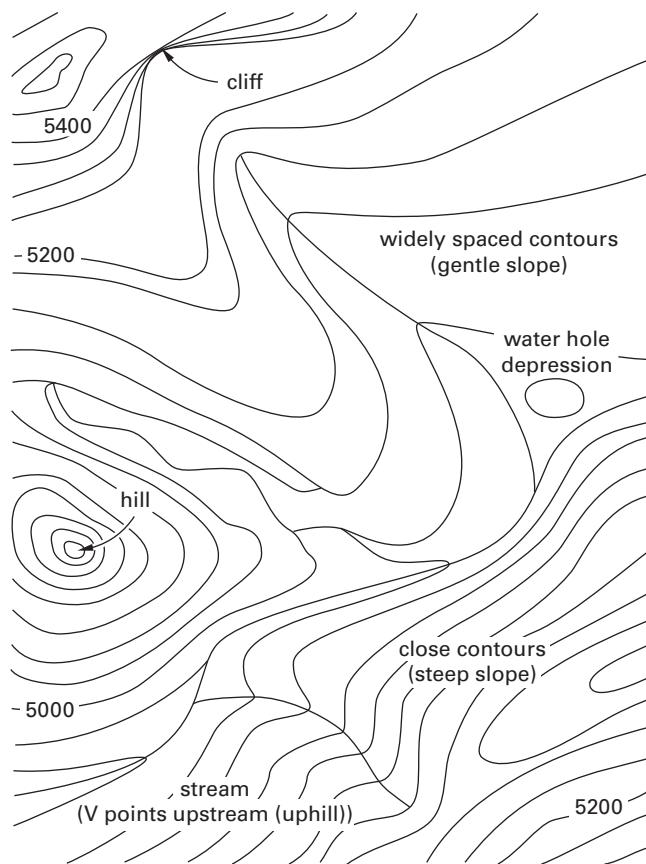

The *map scale* can be specified in several ways: a fractional scale (e.g., “1:50,000”) indicating that one unit of distance on the map corresponds to a number of the same units on the ground, an explicit verbal scale (e.g., “1 cm to 1 km”), and a graphic scale consisting of a calibrated bar or line.

The *vertical exaggeration* is the distortion of the vertical scale of a topographic profile used to emphasize relief and slope. The vertical exaggeration is calculated as the vertical scale divided by the horizontal scale.

Official USGS topographic maps, as shown in Fig. 78.20, can be selected by scale or coverage angle. Available scales include 1:24,000 or 1:25,000, 1:62,500, 1:100,000, and 1:250,000. Some 1:500,000 maps are also available.

The two most common coverage angles are (a)  $7.5'$  ( $\frac{1}{8}^\circ$ )

**Figure 78.20** Topographic Map

quadrangle maps, which extend 7.5' of latitude from north to south and 7.5' of longitude from east to west; and (b) 15' ( $1/4^\circ$ ) quadrangle maps, which extend 15' of latitude from north to south and 15' of longitude from east to west. North is always at the top of the map.

*Contour lines* are imaginary lines connecting points of equal elevation. They can be used to show elevation, relief (the difference in elevations between two points), and slope. The *contour interval* (e.g., 10 ft or 20 ft) is constant on any given map. Every fifth line is an *index contour*, drawn heavier and marked with the elevation for reference. When ground is level, no contours are shown. Closely spaced contours indicate a steep slope. Merged contours indicate a cliff.

Two types of coordinate systems are given on most topographic maps: (a) latitude and longitude and (b) township and range. The township and range coordinate system is used only in the western and southern United States, whereas the latitude and longitude coordinate system is used throughout the world.

The *Universal Transverse Mercator* (UTM) grid generally appears on topographic maps. A UTM coordinate is essentially the *x-y* coordinates on the map. The first half of the UTM digits are the *x*-coordinates; the second half are the *y*-coordinates. 4-, 6-, 8-, and 10-digit coordinates can be specified, with some interpolation on the map being required. For complete identification, the map number, zone, or other regional information must also be specified.

$x$	tangent distance

## 1. HORIZONTAL CURVES

A horizontal circular curve is a circular arc between two straight lines known as *tangents*. When traveling in a particular direction, the first tangent encountered is the

back tangent (approach tangent), and the second tangent encountered is the forward tangent (departure tangent or ahead tangent).

The geometric elements of a horizontal circular curve are shown in Fig. 79.1. Table 79.1 lists the standard terms and abbreviations used to describe the elements. Equation 79.1 through Eq. 79.7 describe the basic relationships between the elements. The *intersection angle* (*deflection angle*, *curve central angle*, or *interior angle*),  $I$ , has units of degrees unless indicated otherwise. (Equations that contain the *degree of curve* term,  $D$ , are only to be used with customary U.S. units.)

**Table 79.1** Horizontal Curves: Nomenclature and Abbreviations

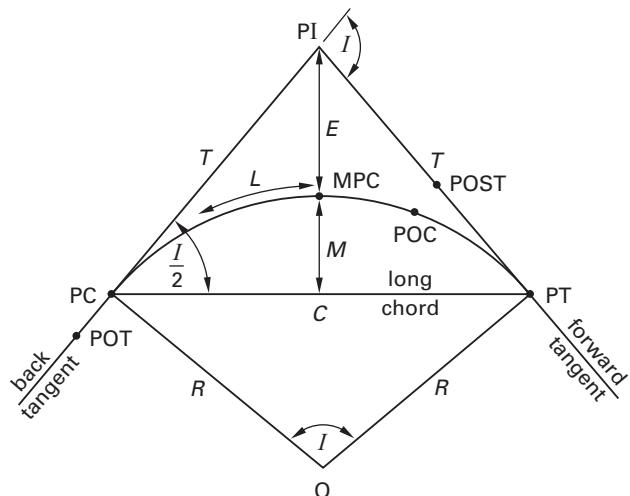

*preferred*

$c$	short chord (any straight distance from one point on the curve to another)
$C$	long chord (chord PC to PT); same as LC
$D$	degree of curve
$E$	external distance (the distance from the vertex to the midpoint of the curve)
$I$	intersection angle; central angle of curve; deflection angle between back and forward tangents; interior angle
$L$	length of the curve (the length of the curve from the PC to the PT)
LC	long chord (chord PC to PT); same as $C$
HSO	horizontal sightline offset (the distance from the centerline of the inside line to the midpoint of the long chord); same as $M$ at the obstacle location
$M$	middle ordinate (the distance from the midpoint of the curve to the long chord)
MPC	midpoint of curve
PC	point of curvature (the point where the back tangent ends and the curve begins)
PCC	point of continuing curve (the transition point between curves in a compound curve)
PI	point of intersection of back and forward tangents
POC	(any) point on the curve
POCT	point of curve tangent
POST	(any) point on the semitangent
POT	(any) point on the tangent
PT	point of tangency (the point where the curve ends and the forward tangent begins)
$R$	radius of the curve
RP	radius point (center of curve)
$T$	(semi-) tangent distance from V to PC or from V to PT
V	vertex of the tangent intersection point

*alternate*

BC	beginning of curve (same as PC and TC)
CT	change from curve to tangent (same as PT and EC)
EC	end of curve (same as PT and CT)
O	center of circle (same as RP)
PVI	point of vertical intersection (same as PI)
TC	a change from a tangent to a curve (same as BC and PC)
$\Delta$	intersection angle (same as $I$ )

**Figure 79.1** Horizontal Curve Elements

$$R = \frac{5729.578 \frac{\text{ft}}{\text{deg}}}{D} \quad [\text{U.S.; arc definition}] \quad 79.1$$

$$R = \frac{50 \frac{\text{ft}}{\text{deg}}}{\sin \frac{D}{2}} \quad [\text{U.S.; chord definition}] \quad 79.2$$

$$L = \frac{2\pi RI}{360^\circ} = RI_{\text{radians}} = \frac{(100 \frac{\text{ft}}{\text{deg}})I}{D} \quad [\text{U.S.}] \quad 79.3$$

$$T = R \tan \frac{I}{2} \quad 79.4$$

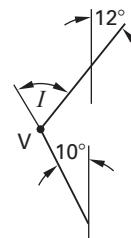

$$E = R \left( \sec \frac{I}{2} - 1 \right) = R \tan \frac{I}{2} \tan \frac{I}{4} \quad 79.5$$

$$M = R \left( 1 - \cos \frac{I}{2} \right) = \frac{C}{2} \tan \frac{I}{4} \quad 79.6$$

$$C = 2R \sin \frac{I}{2} = 2T \cos \frac{I}{2} \quad 79.7$$

### Example 79.1

Two tangents—the first entering a horizontal curve and the second leaving the horizontal curve—have bearings of  $N10^\circ W$  and  $N12^\circ E$ , respectively. The curve radius is 1300 ft. Determine the intersection angle.

**Solution**

Since the two tangents do not originate from a single point, the intersection angle is the deflection angle between the two tangents.

$$I = 10^\circ + 12^\circ = 22^\circ$$

**2. DEGREE OF CURVE**

In the United States, curvature of city streets, highways, and railway curves can be specified by either the radius,  $R$ , or the *degree of curve*,  $D$ . There is no parallel concept in metric highway design. Therefore, curves are only denoted by radius when using metric units.

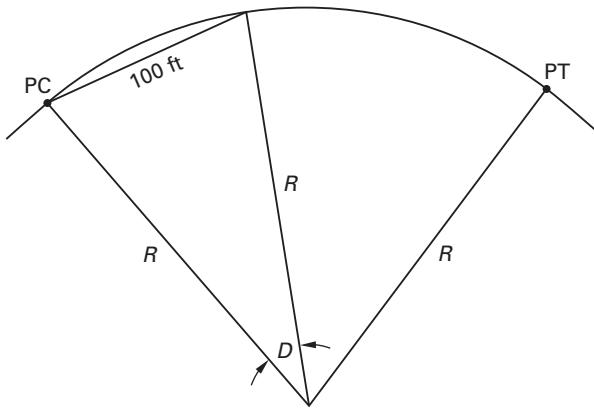

In most highway work, the *length of the curve* is understood to be the actual curved arc length, and the degree of the curve is the angle subtended by an arc of 100 ft. When the degree of curve is related to an arc of 100 ft, it is said to be calculated on an *arc basis*.

$$D = \frac{(360^\circ)(100 \text{ ft})}{2\pi R} = \frac{5729.578 \text{ ft}}{R} \quad [\text{arc basis}] \quad 79.8$$

Railway curves have very large radii. The radii are so large that short portions of the curves are essentially straight. In railroad surveys, the *chord basis* is used, and the degree of curve has a different definition. The railroad degree of curve is the angle subtended by a chord of 100 ft. (See Fig. 79.2.) In that case, the degree of curve and radius are related by Eq. 79.9. Once the radius is calculated, other arc-basis equations can be used. (See Eq. 79.1 through Eq. 79.7.)

$$\sin \frac{D}{2} = \frac{50}{R} \quad [\text{chord basis}] \quad 79.9$$

**Figure 79.2** Horizontal Railroad Curve (chord basis)

From *A Policy on Geometric Design of Highways and Streets*, Fig. 3-43, copyright © 2011 by the American Association of State Highway and Transportation Officials, Washington, D.C. Used by permission.

Where the radius is large ( $4^\circ$  curves or smaller), the difference between the arc length and the chord length is insignificant. Therefore, the length of the curve in railroad practice is equal to the number of 100 ft chords.

$$L \approx \left(\frac{I}{D}\right)(100 \text{ ft}) \quad [D \leq 4^\circ] \quad 79.10$$

**3. STATIONING ON A HORIZONTAL CURVE**

When the route is initially laid out between PIs, the curve is undefined. The “route” distance is measured from PI to PI. The route distance changes, though, when the curve is laid out. Stationing along the curve is continuous, as a vehicle’s odometer would record the distance. The PT station is equal to the PC station plus the curve length.

$$\text{sta PT} = \text{sta PC} + L \quad 79.11$$

$$\text{sta PC} = \text{sta PI} - T \quad 79.12$$

In route surveying, stationing is carried ahead continuously from a starting point or hub designated as station 0+00, and called *station zero plus zero zero*. The term *station* is applied to each subsequent 100 ft (or 100 m) length, where a stake is normally set. Also, the term *station* is applied to any point whose position is given by its total distance from the beginning hub. Thus, station 8+33.2 is a unique point 833.2 ft (or 833.2 m) from the starting point, measuring along the survey line. The partial length beyond the full station 8 is 33.2 ft (33.2 m) and is termed a *plus*. Moving or looking toward increasing stations is called *ahead stationing*. Moving or looking toward decreasing stations is called *back stationing*. Offsets from the centerline are either left or right looking ahead on stationing.

Normal curve layout follows the convention of showing increased stationing (ahead stationing) from left to right on the plan sheet, or from the bottom to the top of the sheet. Moving ahead on stationing, the first point of the curve is the *point of curvature* (PC). This point is alternatively called the *point of beginning of curve* (BC). Stationing is carried ahead along the arc of the curve to the end point of the curve, called the *point of tangency* (PT). This end point is alternatively called the *point of end of curve* (EC). The PI is stationed ahead from the PC. Therefore, the difference in stationing along the back curve tangent is the curve tangent length. The ahead tangent is rarely stationed to avoid the confusion of creating two stations for the PC.

**Example 79.2**

An interior angle of  $8.4^\circ$  is specified for a  $2^\circ$  (arc basis) horizontal curve. The forward PI station is 64+27.46. Locate the PC and PT stations.

*Solution*

Use Eq. 79.8.

$$R = \frac{(360^\circ)(100 \text{ ft})}{2\pi D} = \frac{(360^\circ)(100 \text{ ft})}{2\pi(2^\circ)} = 2864.79 \text{ ft}$$

Use Eq. 79.4 and Eq. 79.3.

$$T = R \tan \frac{I}{2} = (2864.79 \text{ ft}) \left( \tan \frac{8.4^\circ}{2} \right) = 210.38 \text{ ft}$$

$$L = RI \left( \frac{2\pi}{360^\circ} \right) = (2864.79 \text{ ft})(8.4^\circ) \left( \frac{2\pi}{360^\circ} \right) = 420.00 \text{ ft}$$

The PC and PT points are located at

$$\begin{aligned} \text{sta PC} &= \text{sta PI} - T = (\text{sta } 64+27.46) - 210.38 \text{ ft} \\ &= \text{sta } 62+17.08 \end{aligned}$$

$$\begin{aligned} \text{sta PT} &= \text{sta PC} + L = (\text{sta } 62+17.08) + 420.00 \text{ ft} \\ &= \text{sta } 66+37.08 \end{aligned}$$

#### 4. CURVE LAYOUT BY DEFLECTION ANGLE

Construction survey stakes should be placed at the PC, at the PT, and at all full stations. (In the United States, 100 ft stations are most common. Metric stationing may be 100 m or 1000 m, depending on the organization.) Stakes may also be required at quarter or half stations and at all other critical locations.

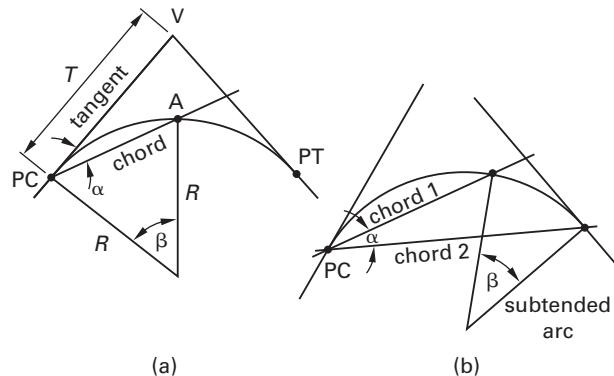

The *deflection angle method* is a common method used for staking out the curve. A *deflection angle* is the angle between the tangent and a chord. Deflection angles are related to corresponding arcs by the following principles.

1. The deflection angle between a tangent and a chord is half of the arc's subtended angle, as shown in Fig. 79.3(a).
2. The angle between two chords is half of the arc's subtended angle, as shown in Fig. 79.3(b).

In Fig. 79.3(a), angle V-PC-A is a deflection angle between a tangent and a chord. Using principle 1,

$$\alpha = \angle V-PC-A = \frac{\beta}{2} \quad 79.13$$

**Figure 79.3** Circular Curve Deflection Angle

Angle  $\beta$  can be found from the following relationships.

$$\frac{\beta}{360^\circ} = \frac{\text{arc length PC-A}}{2\pi R} \quad 79.14$$

$$\frac{\beta}{I} = \frac{\text{arc length PC-A}}{L} \quad 79.15$$

The chord distance PC-A is given by Eq. 79.16. The entire curve can be laid out from the PC by sighting the deflection angle V-PC-A and taping the chord distance PC-A.

$$C_{PC-A} = 2R \sin \alpha = 2R \sin \frac{\beta}{2} \quad 79.16$$

#### Example 79.3

A circular curve is to be constructed with a 225 ft radius and an intersection angle of  $55^\circ$ . The separation between the stakes along the arc is 50 ft. (a) Determine the chord lengths between stakes. (b) Assuming the curve is laid out from point to point, specify the first and last deflection angles. (c) Determine the length of the final (partial) chord.

*Customary U.S. Solution*

- (a) The central angle for an arc of 50 ft is given by Eq. 79.14.

$$\begin{aligned} \beta &= \frac{(360^\circ)(\text{arc length})}{2\pi r} \\ &= \frac{(360^\circ)(50 \text{ ft})}{2\pi(225 \text{ ft})} \\ &= 12.732^\circ \end{aligned}$$

From Eq. 79.16, the required chord length for full 50 ft arcs is

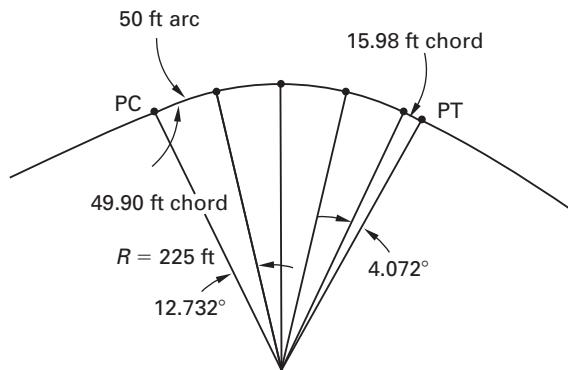

$$C = 2R \sin \frac{\beta}{2} = (2)(225 \text{ ft}) \left( \sin \frac{12.732^\circ}{2} \right) \\ = 49.90 \text{ ft}$$

(b) The first central angle is  $12.732^\circ$ . From principle 1, the first deflection angle is half of this or  $6.366^\circ$ .

$12.732^\circ$  goes into  $55^\circ$  four times with a remainder of  $4.072^\circ$ . The last deflection angle (sighting to the PT) is  $2.036^\circ$ .

(c) Use Eq. 79.16.

$$C = 2R \sin \frac{\beta}{2} = (2)(225 \text{ ft}) \left( \sin \frac{4.072^\circ}{2} \right) \\ = 15.99 \text{ ft}$$

## 5. TANGENT OFFSET

A *tangent offset*,  $y$ , is the perpendicular distance from an extended tangent line to the curve. A *tangent distance*,  $x$ , is the distance along the tangent to a perpendicular point. Tangent offsets for circular curves can be calculated from Eq. 79.17. (See Fig. 79.4.)

$$y = R(1 - \cos \beta) \\ = R - \sqrt{R^2 - x^2} \quad 79.17$$

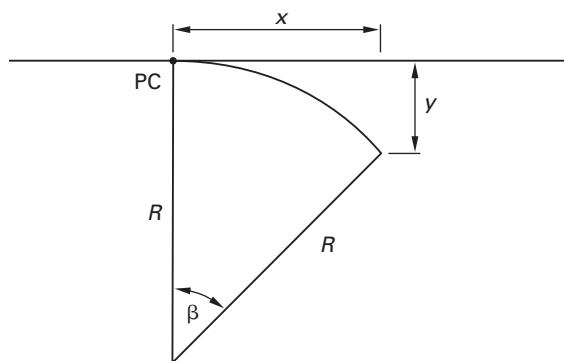

$$\beta = \arcsin \frac{x}{R} = \arccos \left( \frac{R - y}{R} \right) \quad 79.18$$

$$x = R \sin \beta = \sqrt{2Ry - y^2} \quad 79.19$$

Offsets from *parabolic curves* (*parabolic flares*, *parabolic tapers*, or *curb flares*) are calculated from Eq. 79.20.  $W$  is the maximum offset,  $L$  is the length of the flare (taper),  $x$  is the distance along the baseline, and  $y$  is the offset.

$$\frac{y}{W} = \frac{x^2}{L^2} \quad 79.20$$

Figure 79.4 Tangent Offset

## 6. CURVE LAYOUT BY TANGENT OFFSET

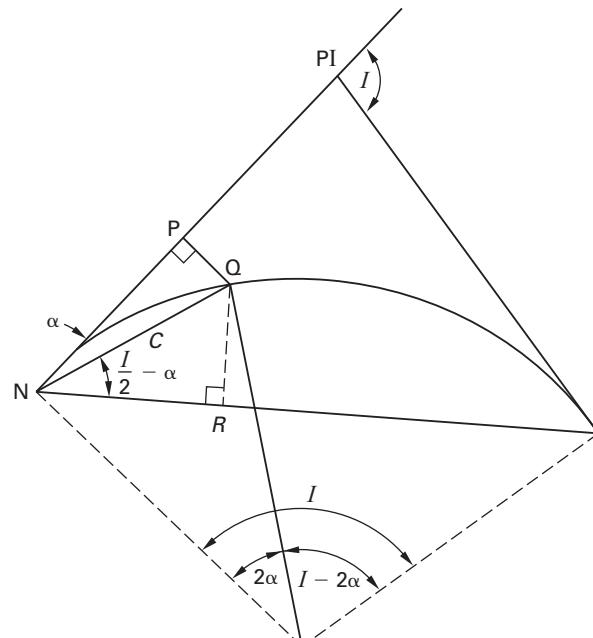

The *tangent offset method* (*station offset method*) can be used to lay out horizontal curves. This method is typically used on short curves. The method is named for the way in which the measurements are made, which is by measuring offsets from the tangent line.

Consider the two right triangles NPQ and NRQ in Fig. 79.5. Point Q is any point along the circular curve, and  $\alpha$  is the deflection angle between the tangent and NQ.

$$NP = \text{tangent distance} = NQ \cos \alpha \quad 79.21$$

$$PQ = \text{tangent offset} = NQ \sin \alpha \quad 79.22$$

Figure 79.5 Tangent and Chord Offset Geometry

The short chord distance is

$$NQ = C = 2R \sin \alpha \quad 79.23$$

$$\begin{aligned} NP &= (2R \sin \alpha) \cos \alpha \\ &= C \cos \alpha \end{aligned} \quad 79.24$$

$$\begin{aligned} PQ &= (2R \sin \alpha) \sin \alpha \\ &= 2R \sin^2 \alpha \end{aligned} \quad 79.25$$

## 7. CURVE LAYOUT BY CHORD OFFSET

The *chord offset method* is a third method for laying out horizontal curves. This method is also suitable for short curves. The method is named for the way in which the measurements are made, which is by measuring distances along the main chord from the instrument location at PC.

$$\begin{aligned} NR &= \text{chord distance} = NQ \cos\left(\frac{I}{2} - \alpha\right) \\ &= (2R \sin \alpha) \cos\left(\frac{I}{2} - \alpha\right) \\ &= C \cos\left(\frac{I}{2} - \alpha\right) \end{aligned} \quad 79.26$$

$$\begin{aligned} RQ &= \text{chord offset} = NQ \sin\left(\frac{I}{2} - \alpha\right) \\ &= (2R \sin \alpha) \sin\left(\frac{I}{2} - \alpha\right) \\ &= C \sin\left(\frac{I}{2} - \alpha\right) \end{aligned} \quad 79.27$$

## 8. HORIZONTAL CURVES THROUGH POINTS

Occasionally, it is necessary to design a horizontal curve to pass through a specific point. The following procedure can be used. (Refer to Fig. 79.6.)

*step 1:* Calculate  $\alpha$  and  $m$  from  $x$  and  $y$ . (If  $\alpha$  and  $m$  are known, skip this step.)

$$\alpha = \arctan \frac{y}{x} \quad 79.28$$

$$m = \sqrt{x^2 + y^2} \quad 79.29$$

*step 2:* Calculate  $\gamma$ . Since  $90^\circ + I/2 + \alpha + \gamma = 180^\circ$ ,

$$\gamma = 90^\circ - \frac{I}{2} - \alpha \quad 79.30$$

*step 3:* Calculate  $\phi$ .

$$\phi = 180^\circ - \arcsin \left( \frac{\sin \gamma}{\cos \frac{I}{2}} \right) \quad 79.31$$

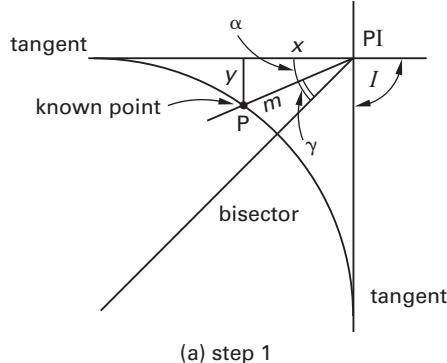

*step 4:* Calculate  $\theta$ .

$$\theta = 180^\circ - \gamma - \phi \quad 79.32$$

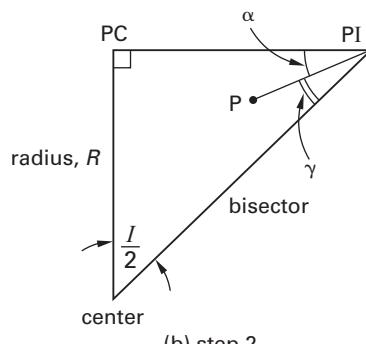

*step 5:* Calculate the curve radius,  $R$ , from the law of sines.

$$\frac{\sin \theta}{m} = \frac{\sin \phi \cos \frac{I}{2}}{R} \quad 79.33$$

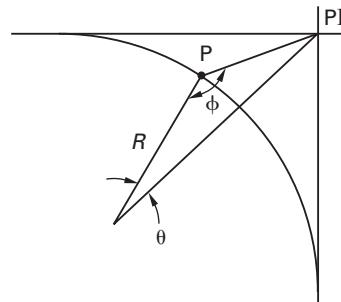

**Figure 79.6** Horizontal Curve Through a Known Point

(a) step 1

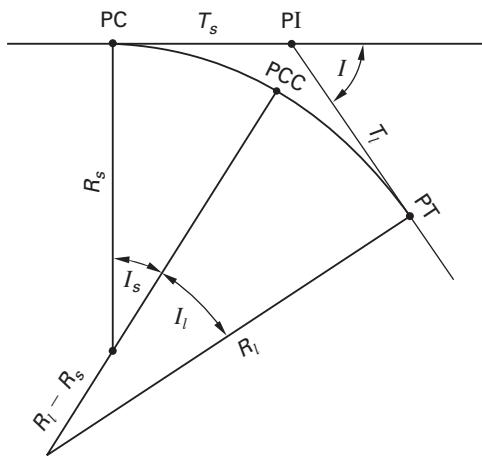

(b) step 2

(c) steps 3 and 4

## 9. COMPOUND HORIZONTAL CURVES

A *compound curve* comprises two or more curves of different radii that share a common tangent point, with their centers on the same side of the common tangent. The PT for the first curve and the PC for the second curve coincide. This point is the *point of continuing curve* (PCC). (See Fig. 79.7.)

**Figure 79.7** Compound Circular Curve

Compound curves are often used on low-speed roadways, such as on entrance or exit ramps. Their use is reserved for applications where design constraints, such as topography or high land cost, preclude the use of a circular or spiral curve. For safety, the radius of the larger curve should be less than or equal to four-thirds times the radius of the smaller curve (three-halves on interchanges).

## 10. SUPERELEVATION

(In this book, superelevation rate,  $e$ , is a decimal number. In the AASHTO *Green Book*, it is a percentage.)

If a vehicle travels in a circular path with instantaneous radius  $R$  and tangential velocity (i.e., speed)  $v_t$ , it will experience an apparent centrifugal force,  $F_c$ .

$$F_c = \frac{mv_t^2}{R} \quad [\text{SI}] \quad 79.34(a)$$

$$F_c = \frac{mv_t^2}{g_c R} \quad [\text{U.S.}] \quad 79.34(b)$$

The centrifugal force can be resisted by banking, friction, or a combination of the two. If it is intended that banking (no friction) alone will resist the centrifugal force, the banking angle,  $\phi$ , is given by Eq. 79.35. The elevation difference between the inside and outside edges of the curve is the *superelevation*. The transverse slope of the roadway has units of ft/ft (m/m), hence the synonymous name of *superelevation rate*,  $e$ , for slope. (However, runoff and transition “rates” are not the same.)

$$e = \tan \phi = \frac{v^2}{gR} \quad [\text{consistent units}] \quad 79.35$$

Some of the centrifugal force is usually resisted by *sideways friction*. (One-half of the theoretical superelevation rate is usually adequate.) The quantity  $1 - f \tan \phi$ , implicit in Eq. 72.31, is very nearly one in roadway work, leading to a simplified expression for roadway banking.

Equation 79.36 is the *simplified curve formula* (AASHTO *Green Book* Eq. 3-7), and it is used for determining the superelevation rate when friction is relied upon to counteract some of the centrifugal force. The sum,  $e + f_s$ , may be referred to as the *centrifugal factor*.

$$e = \tan \phi = \frac{v^2}{gR} - f_s \quad [\text{consistent units}] \quad 79.36$$

If the velocity,  $v$ , is expressed in common units, Eq. 79.36 becomes

$$e = \tan \phi = \frac{v_{\text{km/h}}^2}{127R} - f_s \quad [\text{SI}] \quad 79.37(a)$$

$$e = \tan \phi = \frac{v_{\text{mph}}^2}{15R} - f_s \quad [\text{U.S.}] \quad 79.37(b)$$

For very large values of  $R$ , Eq. 79.36 and Eq. 79.37 become negative. However, curves with very large radii do not need to be superelevated. The normal slopes of the terrain and crown limit the lower value of  $e$ .

Many studies have been performed to determine values of the *side friction factor*,  $f_s$ , and most departments of transportation have their own standards. One methodology is to assume the side friction factor to be 0.16 for speeds less than 30 mph (50 km/h). Equation 79.38 or Eq. 79.39 can be used for higher speeds.

$$f_s = 0.16 - \frac{0.01(v_{\text{mph}} - 30)}{10} \quad [< 50 \text{ mph}] \quad 79.38$$

$$f_s = 0.14 - \frac{0.02(v_{\text{mph}} - 50)}{10} \quad [50-70 \text{ mph}] \quad 79.39$$

Although the sophistication may be unwarranted, the friction factor for sideways slipping,  $f_s$ , can be differentiated from the straight-ahead friction factor. For sideways slipping, the friction factor may be referred to as the *side friction factor*, *lateral ratio*, *cornering ratio*, or *unbalanced centrifugal ratio*.

In general, a lower *banking angle* is used in urban areas than in rural areas. (For low-speed urban streets, use of superelevation is optional [AASHTO *Green Book*.] For arterial streets in downtown areas, the maximum superelevation rate is approximately 0.04–0.06. For arterial streets in suburban areas and on freeways where there is no snow or ice, the maximum superelevation rate is approximately 0.08–0.12. For arterial streets and freeways that experience snow and ice, the maximum should be 0.06–0.08.

Since the maximum superelevation rate is approximately 0.08 or 0.12, Eq. 79.35 can be used to calculate the minimum curve radius if the speed is known.

## 11. SUPERELEVATION TABLES

While theoretical superelevation can be calculated from the design speed and side friction factors, superelevation rate problems are almost always solved by using the AASHTO *Green Book* superelevation graphs (Fig. 3-9 through Fig. 3-13) and tables (Table 3-8 through Table 3-12). This is because by using the AASHTO graphs and tables, one can incorporate all the various considerations affecting superelevation design and eliminate common difficulties that accompany using the theoretical formulas (e.g., not knowing the maximum side friction factor and superelevation rates that become negative when the curve radius is large, leading to an erroneous conclusion that superelevation is not required and side friction alone should be used to resist the lateral force).

AASHTO *Green Book* Table 3-8 through Table 3-12 are used to determine the minimum radius (i.e., the sharpest curve) for any superelevation. When used to determine the sharpest curve that can be traveled without superelevation, the AASHTO tables incorporate an average cross slope rate of 1.5% (i.e., a normal cross slope).

However, in order to use the AASHTO graphs and tables, it is necessary to know the maximum superelevation,  $e_{\max}$ , that will be achieved in the circular curve.  $e_{\max}$  is typically limited by standards established by the transportation agency. The value selected takes into consideration local climate, road materials and conditions, terrain, adjacent land use, and nature of the traffic (e.g., fraction of tractors and other slow-moving vehicles).

Interpolation is not used with AASHTO *Green Book* Table 3-8 through Table 3-12. Instead, when entering the table with a known radius, a superelevation rate corresponding to the nearest smaller radius is used.

### Example 79.4

A low speed rural street has a design speed of 25 mph, a curve radius of 525 ft, and a maximum superelevation rate of 8%. What is the superelevation rate according to the AASHTO *Green Book*?

#### *Solution*

Use Table 3-10b. Enter from the top with a design speed of 25 mph, proceed down the 25 mph column to the closest lower curve radius (499 ft in the table), and read the superelevation of 5.0% in the left column.

## 12. TRANSITIONS TO SUPERELEVATION

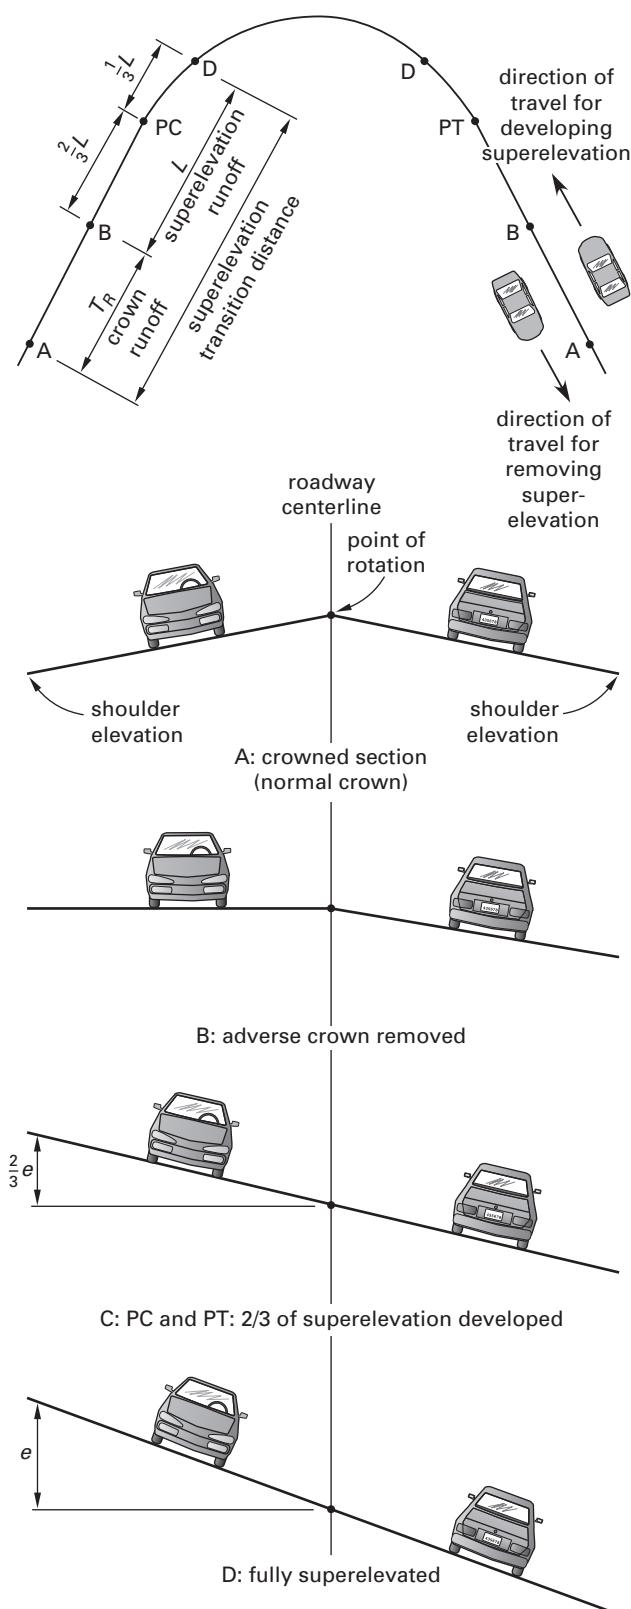

Transitions from crowned sections to superelevated sections should be gradual. When a curve is to be superelevated, it is first necessary to establish a rotational axis (often referred to as a “point”) on the cross section. This is the axis around which the pavement will be rotated (longitudinally) to gradually change to the specified superelevated cross slope. The rotational axis (“point”) is a

longitudinal axis parallel to the instantaneous direction of travel. The location of the rotational point varies with the basic characteristics of the typical section. The following guidelines can be used. (See Fig. 79.8.)

1. For two-lane and undivided highways, the axis of rotation is generally at (along) the original crown of the roadway. However, it may also be the edge of the outside or inside lane.
2. On divided highways with relatively wide depressed medians, the axis of rotation can be at the crown of each roadway or at the edge of the lane or shoulder nearest the median of each roadway. Placing the axis at the crown results in median edges at different elevations, but it reduces the elevation differential between extreme pavement edges. If it is likely that the highway will be widened in the future, it will be desirable to rotate the pavement cross-slope about the inside lane or shoulder.
3. On divided highways with narrow raised medians and moderate superelevation rates, the axis of rotation should be at the center of the median. If the combination of pavement width and superelevation rate results in substantial differences between pavement edge elevations, the axis of rotation should be at the edge of the lane or shoulder nearest the median of each roadway. If an at-grade crossing is located on the superelevated curve, the impact of intersecting traffic should be considered in selecting the axis of rotation.
4. On divided highways with concrete median barriers, the median elevation must be the same for both directions of travel. Rotation should occur at the barrier gutter.

For maximum comfort and safety, superelevation should be introduced and removed uniformly over a length adequate for the likely travel speeds. The total length of the *superelevation transition distance* is the sum of the tangent (crown) runout and the superelevation runoff. The following design factors should be considered in designing the superelevation transition distance.

1. *Tangent runout*,  $T_R$ , also known as *tangent runoff* and *crown runoff*, is a gradual change from a normal crowned section to a point where the *adverse cross slope* on the outside of the curve has been removed. When the adverse cross slope has been removed, the elevation of the outside pavement edge will be equal to the centerline elevation. The inside pavement edge will be unchanged. The rate of removal is usually the same as the superelevation runoff rate, SRR.
2. *Superelevation runoff*,  $L$ , is a gradual change from the end of the tangent runout to a cross section that is fully superelevated. The *superelevation runoff rate* (also known as the *transition rate*), SRR, is the rate at which the normal cross-slope of the roadway is transitioned to the superelevated cross-slope. The superelevation runoff rate is expressed in units of

**Figure 79.8** Roadway Profile Around Circular Curve

cross-slope elevation per unit width per unit length of traveled roadway.

For single lanes, a common superelevation runoff rate is 1 ft per foot of width for every 200 ft (60 m) length, expressed as 1:200. For speeds less than 50 mph, or if conditions are restrictive and if sufficient room is not available for a 1:200 transition rate, more abrupt rates may be used.

3. Tangent runoff and superelevation runoff distances may be calculated using Eq. 79.40 and Eq. 79.41.  $w$  is the lane width, and  $p$  is the rate of cross slope.

$$T_R = \frac{wp}{SRR} \quad 79.40$$

$$L = \frac{we}{SRR} \quad 79.41$$

4. Superelevation runoff rate on a curve may be determined by a *time rule* (e.g., "runoff shall be completed within 4 sec at the design speed") or by a *speed rule* (e.g., "3 ft of runoff for every mph of design speed"), regardless of the initial superelevation. Time and speed rules depend on the specifying agency.
5. On circular curves, the superelevation runoff should be developed 60–90% on the tangent and 40–10% on the curve, with a large majority of state highway agencies using a rule of two-thirds on the tangent and one-third on the curve. This results in two-thirds of the full superelevation at the beginning and ending of the curve. This is a compromise between placing the entire transition on the tangent section, where superelevation is not needed, and placing the transition on the curve, where full superelevation is needed. AASHTO *Green Book* Fig. 3-8 gives specific runoff recommendations based on speed and number of rotated lanes.
6. On spiral curves, the superelevation is developed entirely within the length of the spiral.
7. All shoulders should slope away from the traveled lanes. The angular breaks at the pavement edges of the superelevated roadways should be rounded by the insertion of vertical curves. The minimum curve length in feet should be approximately numerically equal to the design speed in miles per hour.

### Example 79.5

One end of a horizontal curve on a two-lane highway has 12 ft lanes and a crown cross-slope of 0.02 ft/ft. The PC is at sta 10+00. The transition rate is 1:400, and the required superelevation is 0.04. The  $\frac{2}{3}$ - $\frac{1}{3}$  rule is used to allocate the runoff to the curve. Calculate the stationing where (a) the superelevation runoff begins, (b) the tangent runoff begins, and (c) the curve is fully superelevated.

**Solution**

(a) Use Eq. 79.40 and Eq. 79.41.

$$T_R = \frac{wp}{SRR} = \frac{(12 \text{ ft})(0.02 \frac{\text{ft}}{\text{ft}})}{\frac{1}{400} \frac{\text{ft}}{\text{ft}}} = 96 \text{ ft}$$

$$L = \frac{we}{SRR} = \frac{(12 \text{ ft})(0.04 \frac{\text{ft}}{\text{ft}})}{\frac{1}{400} \frac{\text{ft}}{\text{ft}}} = 192 \text{ ft}$$

The superelevation should be developed two-thirds before the curve and one-third after. Therefore, the superelevation begins at  $\frac{2}{3}L$  before the PC.

$$\begin{aligned} \text{sta } 10+00 - \frac{2}{3}L &= \text{sta } 10+00 - \left(\frac{2}{3}\right)(192 \text{ ft}) \\ &= \text{sta } 10+00 - 128 \text{ ft} \\ &= \text{sta } 8+72 \end{aligned}$$

(b) The tangent runout begins at

$$\text{sta } 8+72 - 96 \text{ ft} = \text{sta } 7+76$$

(c) The pavement should be fully superelevated at  $\frac{1}{3}L$  after the PC, at station

$$\begin{aligned} \text{sta } 10+00 + \frac{1}{3}L &= \text{sta } 10+00 + \left(\frac{1}{3}\right)(192 \text{ ft}) \\ &= \text{sta } 10+00 + 64 \text{ ft} \\ &= \text{sta } 10+64 \end{aligned}$$

**13. SUPERELEVATION OF RAILROAD LINES**

The method of specifying superelevation for railroad lines is somewhat different than for roadways. The *equilibrium elevation*,  $E$ , of the outer rail relative to the inner rail is calculated from Eq. 79.42. The *effective gauge*,  $G_{\text{eff}}$ , is the center-to-center rail spacing. Superelevation may be referred to in railroad work as *cant*.

$$E = \frac{G_{\text{eff}} v^2}{gR} \quad [\text{railroads}] \quad 79.42$$

**14. STOPPING SIGHT DISTANCE**

The *stopping sight distance* is the distance required by a vehicle traveling at the design speed to stop before reaching a stationary object that has suddenly appeared in its path. Calculated stopping sight distances are the minimums that should be provided at any point on any roadway. Greater distances should be provided wherever possible.

Stopping sight distance is the sum of two distances: the distance traveled during driver perception and reaction time, and the distance traveled during brake application. The equations used to calculate sight distance assume that the driver's eyes are 3.5 ft (1080 mm) above the surface of the roadway. For stopping sight distances, it is assumed that the object being observed has a height of 2.0 ft (600 mm).

Equation 79.43 can be used to calculate the stopping sight distance,  $S$ , for straight-line travel on a constant grade. In Eq. 79.43, the grade,  $G$ , is in decimal form and is negative if the roadway is downhill. The coefficient of friction,  $f$ , is evaluated for a wet pavement. The perception-reaction time,  $t_p$ , often is taken as 2.5 sec for all but the most complex conditions. If the deceleration rate,  $a$ , is known, the friction factor,  $f$ , can be replaced with  $a/g$ , where  $g$  is the acceleration of gravity (9.81 m/s<sup>2</sup> for SI calculations and 32.2 ft/sec<sup>2</sup> for U.S. calculations).

$$S = \left( 0.278 \frac{\frac{\text{m}}{\text{s}}}{\frac{\text{km}}{\text{h}}} \right) t_p v_{\text{km/h}} + \frac{v_{\text{km/h}}^2}{254(f + G)} \quad [\text{SI}] \quad 79.43(a)$$

$$S = \left( 1.47 \frac{\frac{\text{ft}}{\text{sec}}}{\frac{\text{mi}}{\text{hr}}} \right) t_p v_{\text{mph}} + \frac{v_{\text{mph}}^2}{30(f + G)} \quad [\text{U.S.}] \quad 79.43(b)$$

Desirable values of stopping sight distance,  $S$ , are listed in Table 79.2 for various design speeds on level roadways.

**15. PASSING SIGHT DISTANCE**

The *passing sight distance* is the length of open roadway ahead necessary to pass without meeting an oncoming vehicle. Passing sight distance is applicable only to two-lane, two-way highways. Passing sight distance is not relevant on multilane highways.

Passing sight distances assume that the driver's eyes are 3.5 ft (1080 mm) above the surface of the roadway. The object being viewed is assumed to be at a height of 3.5 ft (1080 mm). AASHTO *Green Book* Table 3-4 tabulates passing sight distances for two-lane highways.

**16. MINIMUM HORIZONTAL CURVE LENGTH FOR STOPPING DISTANCE**

A horizontal circular curve is shown in Fig. 79.9. Obstructions along the inside of curves, such as retaining walls, cut slopes, trees, buildings, and bridge piers, can limit the available (chord) sight distance. Often, a curve must be designed that will simultaneously provide the required stopping sight distance while maintaining a clearance from a roadside obstruction.

**Table 79.2** AASHTO Minimum Stopping Sight Distances on Level Roadways (based on braking distance)<sup>a,b</sup>

design speed (mph)	(km/h)	brake reaction distance (ft)	(m)	braking distance on level		stopping sight distance		design (ft)	(m)
				(ft)	(m)	calculated (ft)	(m)

80		294.0		614.3		908.3		910	

(Multiply ft by 0.3048 to obtain m.)

(Multiply mph by 1.6093 to obtain km/h.)

<sup>a</sup>Brake reaction distance predicated on a time of 2.5 sec; deceleration rate of 11.2 ft/sec<sup>2</sup> (3.4 m/s<sup>2</sup>) used to determine calculated sight distance.<sup>b</sup>Use AASHTO Green Book Table 3-2 for roadways on grades.

Adapted from *A Policy on Geometric Design of Highways and Streets*, Table 3-1, copyright © 2011 by the American Association of Highway and Transportation Officials, Washington, D.C. Used by permission.

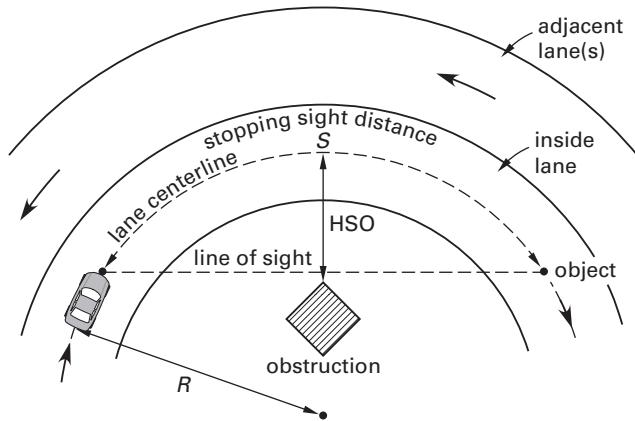

The sight distance is a chord of a curve segment with the chord midpoint at the obstruction itself. The stopping distance is the distance along the lane centerline, which will be slightly longer than the chord (i.e.,  $S + L$ ). This additional length gives a small margin of increased stopping distance for a given sight line, but the additional distance is so small that it is not usually considered. Instead, the sight distance is used as the needed distance. The offset of the obstruction from the centerline of the inside lane, called the *horizontal sightline offset* (HSO), is the *middle ordinate*,  $M$ , of the arc of the curve subtended by the sight distance chord. Substituting HSO for  $M$  in Eq. 79.6, HSO is related to the radius of the lane centerline curve, the deflection of the curve arc,  $\theta$ , and the sightline chord length by Eq. 79.44 and Eq. 79.45. The angle  $\theta$  is in degrees.

$$S = \left( \frac{R}{28.65} \right) \left( \arccos \frac{R - \text{HSO}}{R} \right) \quad 79.44$$

$$\begin{aligned} \text{HSO} &= R(1 - \cos \theta) = R \left( 1 - \cos \frac{DS}{200} \right) \\ &= R \left( 1 - \cos \frac{28.65S}{R} \right) \end{aligned} \quad 79.45$$

*Decision sight distance* should be added on a horizontal curve whenever a driver is confronted with additional information that may unduly complicate the highway information the driver must process. Ten seconds of decision time is considered to be the minimum for all but the most simple avoidance maneuvers.

The curve length methods presented in this section are based on horizontal tangent grades only. If a vertical

**Figure 79.9** Horizontal Circular Curve with Obstruction

grade occurs in conjunction with a circular curve, these methods cannot be used.

## 17. VERTICAL CURVES

Vertical curves are used to change the elevations of highways. Curves that approach higher elevations are known as *crest curves*. *Sag curves* approach lower elevations. Most vertical curves take the shape of an *equal-tangent parabola*. Such curves are symmetrical about the vertex. Since the grades are very small, the actual arc length of the curve is approximately equal to the chord length BVC-EVC. Vertical curves are measured as the horizontal distance between grade points, regardless of the slope of the grade. Table 79.3 lists the standard abbreviations used to describe geometric elements of vertical curves.

**Table 79.3** Vertical Curves: Abbreviations and Terms

preferred

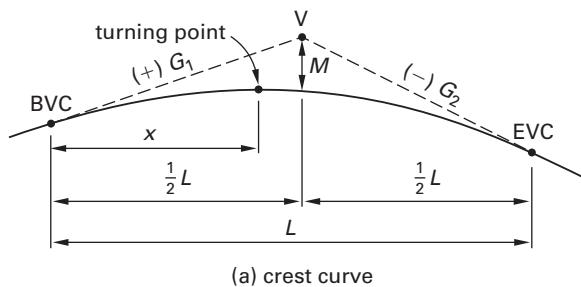

$A$	change in gradient, $ G_2 - G_1 $ [always positive]
BVC	beginning of the vertical curve
EVC	end of the vertical curve
$G_1$	grade from which the stationing starts, in percent
$G_2$	grade toward which the stationing heads, in percent
$L$	length of curve
$M$	middle ordinate
$R$	rate of change in grade per station
V	vertex (the intersection of the two tangents)
alternate	
$E$	tangent offset at V (same as $M$ )
EVT	end of vertical tangency (same as EVC and PVT)
PVC	same as BVC
PVI	same as V
PVT	same as EVC
VPI	vertical point of intersection (same as V)

A vertical parabolic curve is completely specified by the two grades and the curve length. Alternatively, the *rate of grade change per station*,  $R$ , can be used in place of curve length. The rate of grade change per station is given by Eq. 79.46. Units of %/sta are the same as ft/sta<sup>2</sup>.

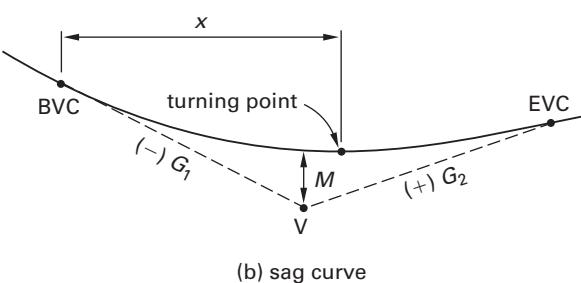

$$R = \frac{G_2 - G_1}{L} \quad [\text{may be negative}] \quad 79.46$$

Equation 79.47 defines an equal-tangent parabolic curve. (See Fig. 79.10.)  $x$  is the distance to any point on the curve, measured in stations beyond the BVC, and elevation is measured in feet. The same reference point is used to measure all elevations.

$$\text{elev}_x = \frac{Rx^2}{2} + G_1x + \text{elev}_{\text{BVC}} \quad 79.47$$

**Figure 79.10** Symmetrical Parabolic Vertical Curve

(a) crest curve

(b) sag curve

The maximum or minimum elevation will occur when the slope is equal to zero (the high point or low point, respectively), which is located as determined by Eq. 79.48. This point is known as the *turning point*. In sag vertical curves, the turning point (low point) is the location at which catch basins should be installed.

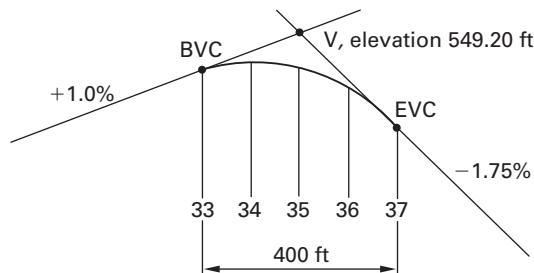

$$x_{\text{turning point}} = \frac{-G_1}{R} \quad [\text{in stations}] \quad 79.48$$

The *middle ordinate distance* is found from Eq. 79.49.

$$M_{\text{ft}} = \frac{AL_{\text{sta}}}{8} \quad 79.49$$

### Example 79.6

A crest vertical curve with a length of 400 ft connects grades of +1.0% and -1.75%. The vertex is located at station 35+00 and elevation 549.20 ft. What are the elevations of the (a) BVC, (b) EVC, and (c) all full stations on the curve?

*Solution*

The curve length is 4 stations (400 ft).

$$\begin{aligned} \text{(a)} \quad \text{elev}_{\text{BVC}} &= \text{elev}_V - G_1 \left( \frac{L}{2} \right) \\ &= 549.20 \text{ ft} - \left( 1 \frac{\text{ft}}{\text{sta}} \right) \left( \frac{4 \text{ sta}}{2} \right) \\ &= 547.20 \text{ ft} \end{aligned}$$

$$\begin{aligned} \text{(b)} \quad \text{elev}_{\text{EVC}} &= \text{elev}_V + G_2 \left( \frac{L}{2} \right) \\ &= 549.20 \text{ ft} + \left( -1.75 \frac{\text{ft}}{\text{sta}} \right) \left( \frac{4 \text{ sta}}{2} \right) \\ &= 545.70 \text{ ft} \end{aligned}$$

(c) Use Eq. 79.46.

$$\begin{aligned} R &= \frac{G_2 - G_1}{L} = \frac{-1.75\% - 1\%}{4 \text{ sta}} \\ &= -0.6875 \%/\text{sta} \\ \frac{R}{2} &= \frac{-0.6875 \frac{\%}{\text{sta}}}{2} \\ &= -0.3438 \%/\text{sta} \quad [\text{same as } -0.3438 \text{ ft/sta}^2] \end{aligned}$$

The equation of the curve is

$$\begin{aligned}\text{elev}_x &= \frac{Rx^2}{2} + G_1x + \text{elev}_{\text{BVC}} \\ &= -0.3438x^2 + \left(1 \frac{\text{ft}}{\text{sta}}\right)x + 547.20 \text{ ft}\end{aligned}$$

At sta 34+00,  $x = 34 \text{ sta} - 33 \text{ sta} = 1 \text{ sta}$ .

$$\begin{aligned}\text{elev}_{34+00} &= \left(-0.3438 \frac{\text{ft}}{\text{sta}^2}\right)(1 \text{ sta})^2 + 1 \text{ ft} + 547.20 \text{ ft} \\ &= 547.86 \text{ ft}\end{aligned}$$

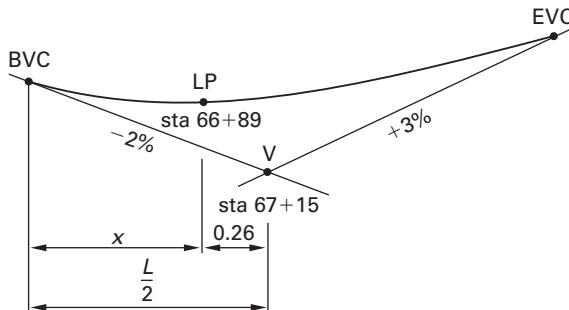

Similarly,

$$\begin{aligned}\text{elev}_{35+00} &= \left(-0.3438 \frac{\text{ft}}{\text{sta}^2}\right)(2 \text{ sta})^2 + 2 \text{ ft} + 547.20 \text{ ft} \\ &= 547.82 \text{ ft}\end{aligned}$$

$$\begin{aligned}\text{elev}_{36+00} &= \left(-0.3438 \frac{\text{ft}}{\text{sta}^2}\right)(3 \text{ sta})^2 + 3 \text{ ft} + 547.20 \text{ ft} \\ &= 547.11 \text{ ft}\end{aligned}$$

### Example 79.7

A vertical sag curve with vertex located at sta 67+15 has a low point at sta 66+89. The grade into the curve is  $-2\%$ , and the grade out of the curve is  $+3\%$ . What is the length of curve?

*Solution*

The location of the low point is defined by Eq. 79.46 and Eq. 79.48.

$$\begin{aligned}R &= \frac{G_2 - G_1}{L} = \frac{3 \frac{\%}{\text{sta}} - \left(-2 \frac{\%}{\text{sta}}\right)}{L} = \frac{5 \frac{\%}{\text{sta}}}{L} \\ x &= \frac{-G_1}{R} = \frac{-\left(-2 \frac{\%}{\text{sta}}\right)}{\frac{5 \frac{\%}{\text{sta}}}{L}} \\ &= 0.4L\end{aligned}$$

The distance between the low point and the vertex is  $(\text{sta } 67+15) - (\text{sta } 66+89) = 0.26 \text{ sta}$ . The distance between BVC and the vertex is

$$\frac{L}{2} = x + 0.26 \text{ sta}$$

Substituting  $x = 0.4L$ ,

$$\begin{aligned}\frac{L}{2} &= 0.4L + 0.26 \text{ sta} \\ L &= 2.6 \text{ sta} \quad (260 \text{ ft})\end{aligned}$$

### 18. VERTICAL CURVES THROUGH POINTS

If a curve is to have some minimum clearance from an obstruction, as shown in Fig. 79.11, the curve length generally will not be known in advance. If the station and elevation of the point,  $P$ , the station and elevation of the BVC or the vertex, and the gradient values  $G_1$  and  $G_2$  are known, the curve length can be determined explicitly.

*step 1:* Find the elevation of points E, F, and G.

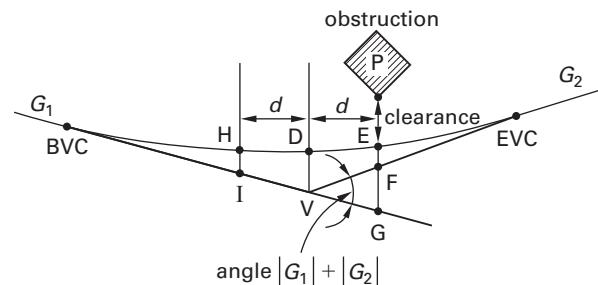

*step 2:* Calculate the constant (no physical significance)  $s$ .

$$s = \sqrt{\frac{\text{elev}_E - \text{elev}_G}{\text{elev}_E - \text{elev}_F}} \quad 79.50$$

*step 3:* Solve for  $L$  directly.

$$L = \frac{2d(s+1)}{s-1} \quad 79.51$$

Figure 79.11 Vertical Curve with an Obstruction

### Example 79.8

Determine the length of a sag vertical curve that passes through a point at elevation 614.00 ft and sta 17+00. The grades are  $G_1 = -4.2\%$  and  $G_2 = +1.6\%$ . The BVC is at sta 13+00, elevation = 624.53 ft.

*Solution*

The distance from the BVC to the point is

$$\begin{aligned}x &= 17 \text{ sta} - 13 \text{ sta} \\ &= 4 \text{ sta}\end{aligned}$$

At the given point for this curve,

$$\text{elev} = 614.00 \text{ ft}$$

$$R = \frac{G_2 - G_1}{L} = \frac{1.6 \frac{\%}{\text{sta}} - \left(-4.2 \frac{\%}{\text{sta}}\right)}{L} = (5.8 \frac{\%}{\text{sta}})/L$$

The equation of the curve is

$$\begin{aligned} \text{elev} &= \frac{Rx^2}{2} + G_1x + \text{elev}_{\text{BVC}} \\ &= \frac{\left(\frac{5.8 \frac{\%}{\text{sta}}}{L}\right)(4 \text{ sta})^2}{2} + \left(-4.2 \frac{\text{ft}}{\text{sta}}\right)(4 \text{ sta}) + 624.53 \text{ ft} \\ 614.00 \text{ ft} &= \frac{-10.53 \text{ ft}}{L} - 16.8 \text{ ft} \\ L &= 7.4 \text{ sta} \quad (740 \text{ ft}) \end{aligned}$$

## 19. VERTICAL CURVE TO PASS THROUGH TURNING POINT

Another common situation involving equal-tangent vertical curves is calculating the length of a sag or crest curve needed to pass through a turning point, TP, at a particular elevation. Equation 79.52 can be used to determine the curve length directly. Grades  $G_1$  and  $G_2$  and the elevations of the BVC or the PVI (point V) and the turning point must be known.

$$\begin{aligned} L &= \frac{2(G_2 - G_1)(\text{elev}_V - \text{elev}_{\text{TP}})}{G_1 G_2} \\ &= \frac{2(G_2 - G_1)(\text{elev}_{\text{BVC}} - \text{elev}_{\text{TP}})}{G_1^2} \end{aligned} \quad 79.52$$

## 20. MINIMUM VERTICAL CURVE LENGTH FOR SIGHT DISTANCES (CREST CURVES)

Crest curve lengths are generally determined based on stopping sight distances. (Headlight sight distance and rider comfort control the design of sag vertical curves.) The passing sight distance could also be used, except that the required length of the curve would be much greater than that based only on the stopping sight distance. Since the curve length determines the extent of the earthwork required, and it is easier (i.e., less expensive) to prohibit passing on crest curves than to perform the earthwork required to achieve the required passing sight distance, only the stopping sight distance is usually considered in designing the curve length.

Two factors affect the sight distance: the algebraic difference,  $A$ , between gradients of the intersecting tangents, and the length of the vertical curve,  $L$ . With a small algebraic difference in grades, the length of the vertical curve may be short. However, to obtain the same sight distance with a large algebraic difference in grades, a much longer vertical curve is needed.

Table 79.4 implies that the choice of a curve length is a simple selection of sight distance based on design speed. This is actually the case in simple curve length design problems where the design speed,  $v$ , and grades,  $G_1$  and  $G_2$ , are known. The required stopping distance is determined from Table 79.2 or calculated from Eq. 79.43 or Eq. 79.44. The required curve length,  $L$ , is calculated from the formulas in Table 79.4. Since it is initially unknown, curve length is calculated for both the  $S < L$  and  $S > L$  cases. The calculated curve length that is inconsistent with its assumption is discarded.

The constants in Table 79.4 are based on specific heights of objects and driver's eyes above the road surface. In general, the sight distance over the crest of a vertical curve is given by Eq. 79.53 and Eq. 79.54, where  $h_1$  is the height of the eyes of the driver and  $h_2$  is the height of the object sighted, both in feet.

$$L = \frac{AS^2}{200(\sqrt{h_1} + \sqrt{h_2})^2} \quad [S < L] \quad 79.53$$

$$L = 2S - \frac{200(\sqrt{h_1} + \sqrt{h_2})^2}{A} \quad [S > L] \quad 79.54$$

**Table 79.4** AASHTO Required Lengths of Curves on Grades<sup>a</sup>

	stopping sight distance <sup>b</sup> (crest curves)	passing sight distance <sup>c</sup> (crest curves)	stopping sight distance (sag curves)
<i>SI units</i>			
$S < L$	$L = \frac{AS^2}{658}$	$L = \frac{AS^2}{864}$	$L = \frac{AS^2}{120 + 3.5S}$
$S > L$	$L = 2S - \frac{658}{A}$	$L = 2S - \frac{864}{A}$	$L = 2S - \frac{120 + 3.5S}{A}$
<i>U.S. units</i>			
$S < L$	$L = \frac{AS^2}{2158}$	$L = \frac{AS^2}{2800}$	$L = \frac{AS^2}{400 + 3.5S}$
$S > L$	$L = 2S - \frac{2158}{A}$	$L = 2S - \frac{2800}{A}$	$L = 2S - \frac{400 + 3.5S}{A}$

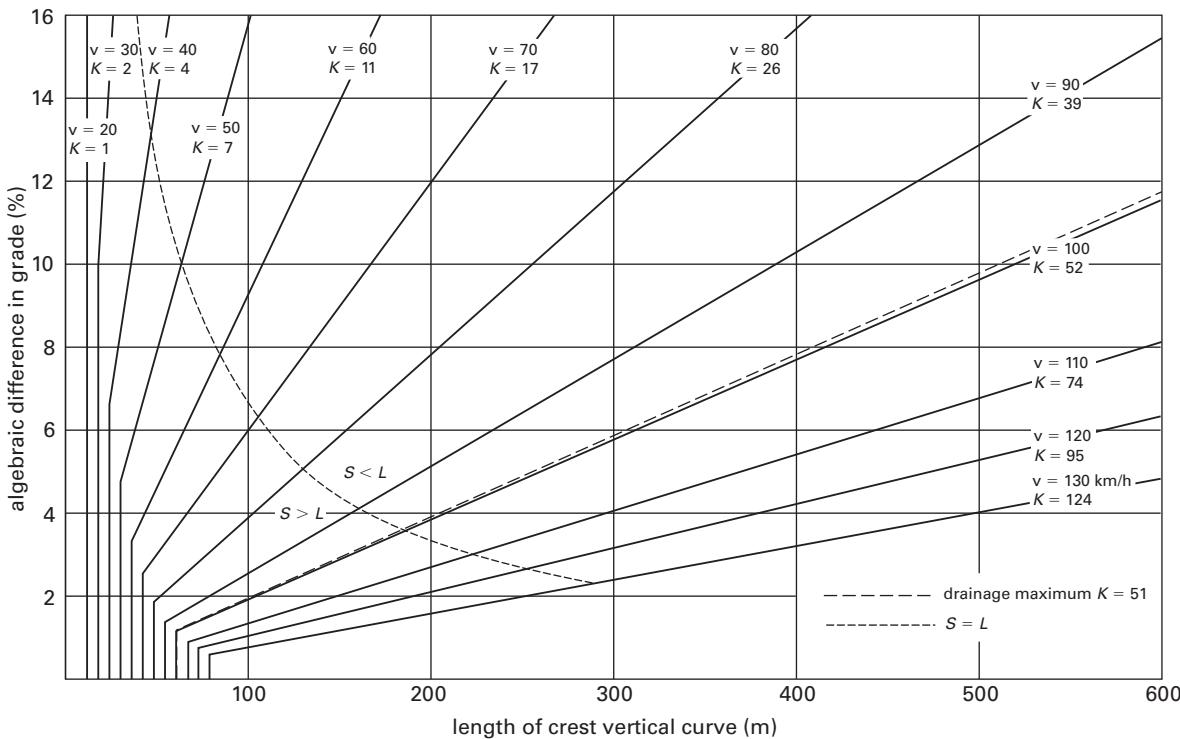

<sup>a</sup> $A = |G_2 - G_1|$ , absolute value of the algebraic difference in grades, in percent.

<sup>b</sup>The driver's eye is 3.5 ft (1080 mm) above road surface, viewing an object 2.0 ft (600 mm) high.

<sup>c</sup>The driver's eye is 3.5 ft (1080 mm) above road surface, viewing an object 3.5 ft (1080 mm) high.

**Figure 79.12** Design Controls for Crest Vertical Curves (SI units)

From *A Policy on Geometric Design of Highways and Streets*, Fig. 3-43, copyright © 2011 by the American Association of State Highway and Transportation Officials, Washington, D.C. Used by permission.

The sight distance under an overhead structure to see an object beyond a sag vertical curve is given by Eq. 79.55 and Eq. 79.56.  $C$  is the clearance between the road surface and the overhead structure. Various assumptions, including eye and taillight (object) heights and beam divergence, were made by AASHTO in developing the following equations.

$$L = \frac{AS^2}{800(C - 1.5)} \quad [S < L] \quad [\text{SI}] \quad 79.55(a)$$

$$L = \frac{AS^2}{800(C - 5)} \quad [S < L] \quad [\text{U.S.}] \quad 79.55(b)$$

$$L = 2S - \frac{800(C - 1.5)}{A} \quad [S > L] \quad [\text{SI}] \quad 79.56(a)$$

$$L = 2S - \frac{800(C - 5)}{A} \quad [S > L] \quad [\text{U.S.}] \quad 79.56(b)$$

grade difference,  $K$ , is the ratio of the curve length,  $L$ , to grade difference,  $A$ .

$$K = \frac{L}{A} = \frac{L}{|G_2 - G_1|} \quad [\text{always positive}] \quad 79.57$$

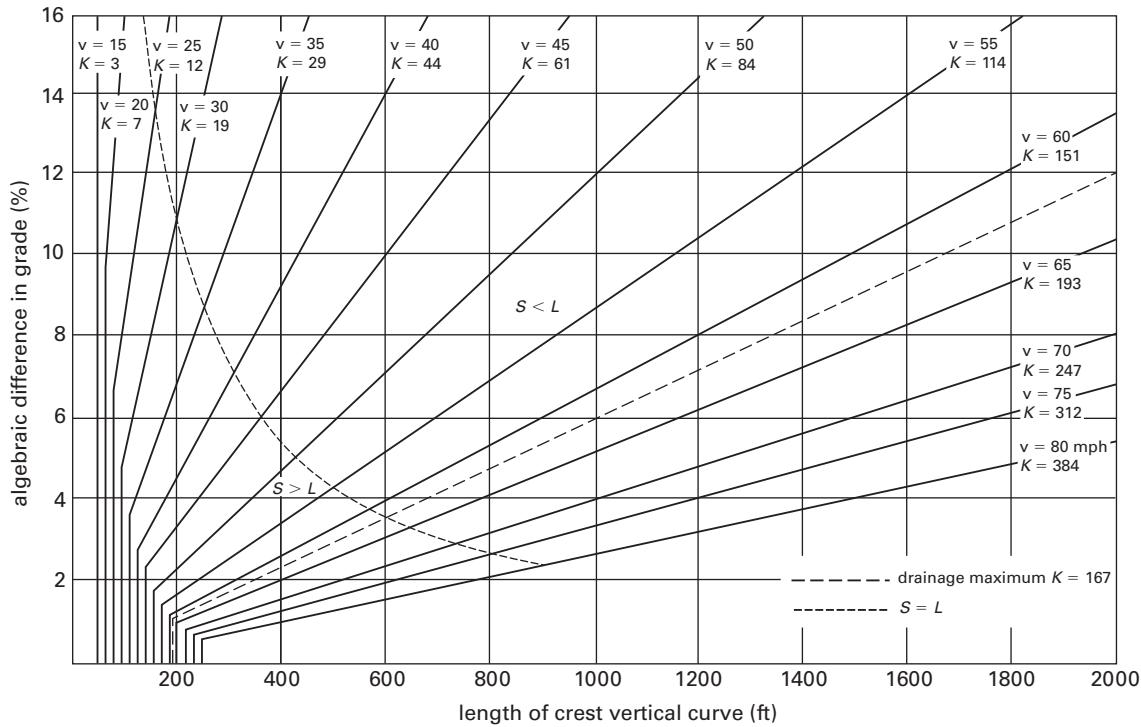

The  $L = KA$  relationship is conveniently linear. In order to facilitate rapid calculation of curve lengths, AASHTO has prepared several graphs. Figure 79.12 and Fig. 79.13 give minimum curve lengths for crest vertical curves. Since for a fixed grade difference the speed determines the stopping distance, every value of speed has a corresponding value of  $K$ . Thus, the curves in the figures are identified concurrently with the speed and the  $K$ -value. It is not necessary to specify both  $A$  and  $L$ , as knowing  $K$  is sufficient.

The simplified procedure is to select one of the curves based on the speed or the  $K$ -value, and then read the curve length that corresponds to the grade difference,  $A$ .  $K$ -values shown on the graphs have been rounded for design.

The minimum curve lengths in the AASHTO figures have been determined by other overriding factors, the most important of which are experience and state requirements. Curve lengths calculated from Table 79.4 for  $S > L$  often do not represent desirable design practice and are replaced by estimated values of three times the design speed (0.6 times the design speed in km/h). This is

## 21. DESIGN OF CREST CURVES USING K-VALUE

The *K-value method* of analysis used in the AASHTO *Green Book* is a simplified and more conservative method of choosing a stopping sight distance for a crest vertical curve. The length of vertical curve per percent

**Figure 79.13** Design Controls for Crest Vertical Curves (customary U.S. units)

From *A Policy on Geometric Design of Highways and Streets*, Fig. 3-43, copyright © 2011 by the American Association of State Highway and Transportation Officials, Washington, D.C. Used by permission.

consistent with the minimum curve lengths of 100–300 ft (30–90 m) prescribed by most states. The estimated solutions in the AASHTO figures are also justified on the basis that the longer curve lengths are obtained inexpensively when the difference in grades is small.

### Example 79.9

A car is traveling up a 1.25% grade of a crest curve with a design speed of 40 mph. The descending grade is  $-2.75\%$ . What is the required length of curve for minimum proper stopping sight distance?

*Solution*

Table 79.2 gives the minimum stopping sight distance at 40 mph as  $S = 305$  ft. Refer to Table 79.4. Assume  $S > L$ .

$$A = |G_2 - G_1| = |-2.75\% - 1.25\%| = 4.0\%$$

$$\begin{aligned} L &= 2S - \frac{2158}{A} = (2)(305 \text{ ft}) - \frac{2158}{4.0} \\ &= 70.5 \text{ ft} \quad [S > L \text{ verified}] \end{aligned}$$

Using Table 79.4 and assuming  $S < L$ ,

$$\begin{aligned} L &= \frac{AS^2}{2158} = \frac{(4.0)(305 \text{ ft})^2}{2158} \\ &= 172.4 \text{ ft} \quad [S < L \text{ not verified}] \end{aligned}$$

Since 305 ft is greater than 172.4 ft ( $S > L$ ), the second assumption is not valid. The required curve length by formula is 70.5 ft.

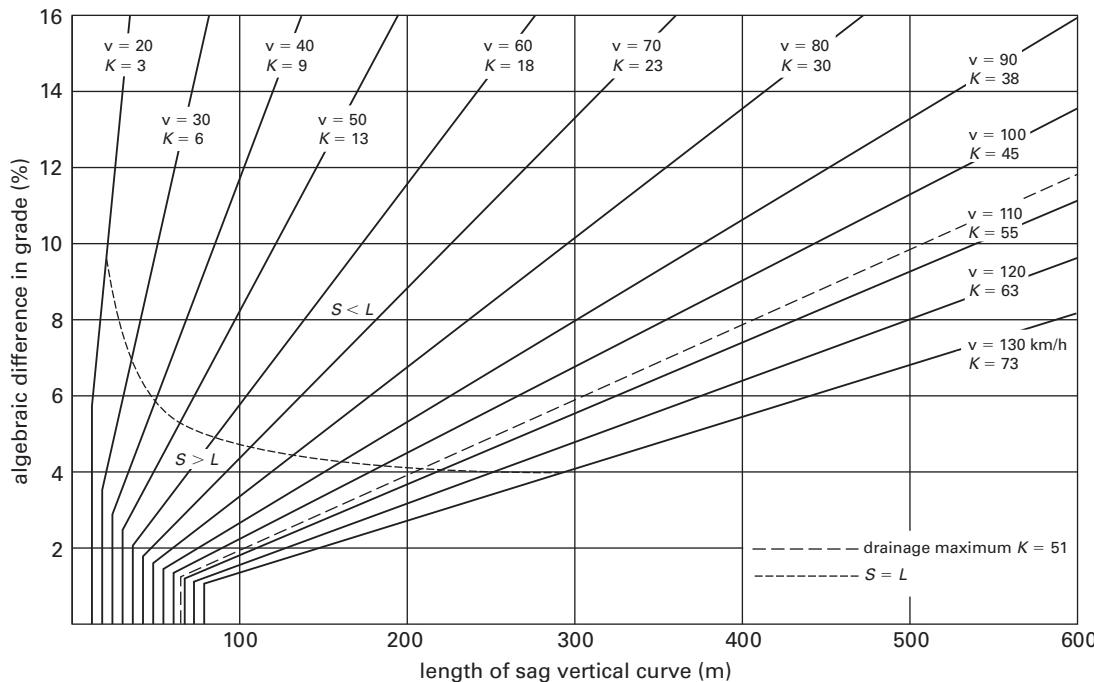

Since  $L < S$ , the curve length specifications will be affected by common usage and/or various state minimums. From Fig. 79.13, using the 40 mph line and  $A = 4$ , it is apparent that the operating condition is still in the sloped region to the left of the  $S = L$  line, so an arbitrary minimum value does not apply. However, the straight  $L = KA$  line will deviate from the formula significantly. Since  $K = 44$ , the required curve length is

$$L = KA = \left(44 \frac{\text{ft}}{\%}\right)(4\%) = 176 \text{ ft}$$

### 22. MINIMUM VERTICAL CURVE LENGTH FOR HEADLIGHT SIGHT DISTANCE: SAG CURVES

A *sag curve* should be designed so that a vehicle's headlights will illuminate a minimum distance of road ahead equal to the stopping sight distance. When full roadway lighting is available and anticipated to be available for the foreseeable future, designing for the *headlight sight distance* (also known as *light distance*) may not be necessary.

**Figure 79.14** Design Controls for Sag Vertical Curves (SI units)

From *A Policy on Geometric Design of Highways and Streets*, Fig. 3-44, copyright © 2011 by the American Association of State Highway and Transportation Officials, Washington, D.C. Used by permission.

### 23. MINIMUM VERTICAL CURVE LENGTH FOR COMFORT: SAG CURVES

In a sag curve, gravitational and centrifugal forces combine to simultaneously act on the driver and passengers and comfort becomes the design control. A formula for calculating the minimum length of curve to keep the added acceleration on passengers below 1 ft/sec<sup>2</sup> (0.3 m/s<sup>2</sup>) is given in Eq. 79.58. The curve length for comfort may be shorter or longer than the safe passing or stopping sight distances.

$$L_m = \frac{Av_{\text{km/h}}^2}{395} \quad [\text{SI}] \quad 79.58(a)$$

$$L_{\text{ft}} = \frac{Av_{\text{mph}}^2}{46.5} \quad [\text{U.S.}] \quad 79.58(b)$$

### 24. DESIGN OF SAG CURVES USING K-VALUE

The AASHTO *Green Book* contains a graphical method for determining the minimum lengths of sag vertical curves also. Factors taken into consideration are the headlight sight distance, rider comfort, drainage control, and rules of thumb. Figure 79.14 and Fig. 79.15 provide graphical methods of determining the lengths using the *K*-value concept. As with crest curves, the procedure is to select one of the curves based on the speed or the *K*-value

(from Eq. 79.57), and read the curve length that corresponds to the grade difference, *A*.

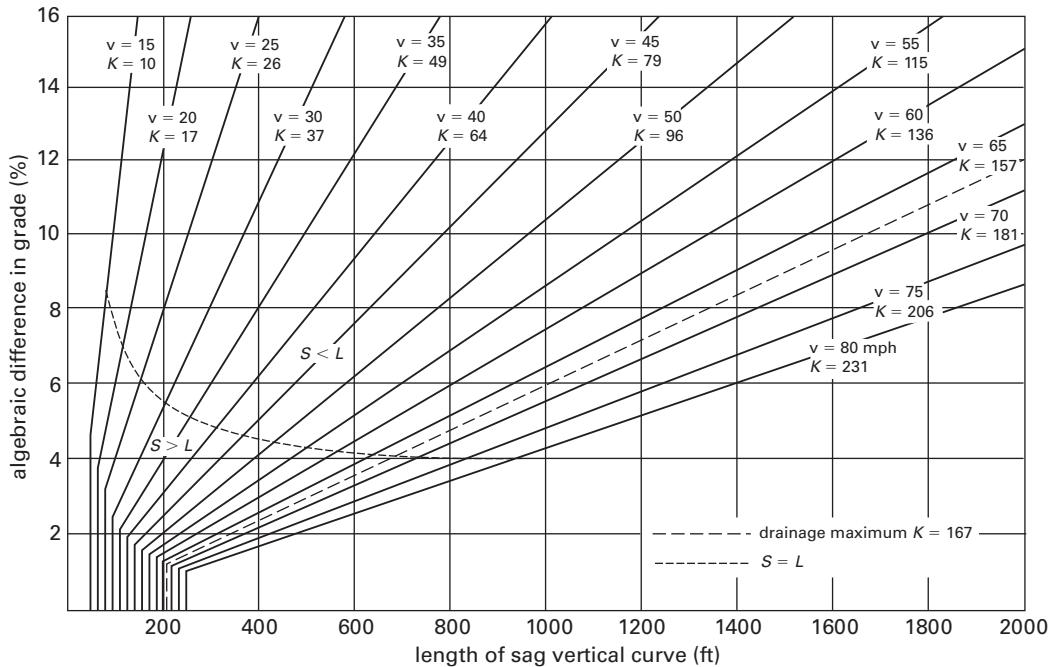

### 25. UNEQUAL TANGENT (UNSYMMETRICAL) VERTICAL CURVES

Not all vertical curves are symmetrical about their vertices. Figure 79.16 illustrates a curve in which the distance from the BVC to the vertex, *l*<sub>1</sub>, is not the same as the distance from the vertex to the EVC, *l*<sub>2</sub>. To evaluate the curve, a line, *v*<sub>1</sub>*v*<sub>2</sub>, is drawn parallel with AB such that *Av*<sub>1</sub> = *v*<sub>1</sub>*V* and *Vv*<sub>2</sub> = *v*<sub>2</sub>*B*. This line divides the curve into two halves of equal-tangent parabolic vertical curves: the first from A to K and the second from K to B. The elevation of *v*<sub>1</sub> is the average of that of A and V; the elevation of *v*<sub>2</sub> is the average of that of V and B. Therefore, CK = KV. The vertical distance, CV, is defined by Eq. 79.59.

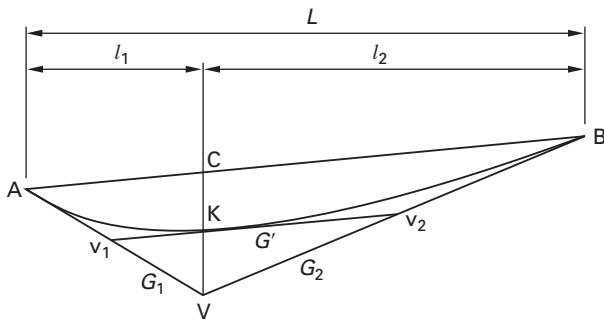

$$CV = \left( \frac{l_1 l_2}{L} \right) A \quad 79.59$$

In Eq. 79.59, *l*<sub>1</sub>, *l*<sub>2</sub>, and *L* are expressed in stations, and *A* is expressed in percent. Equation 79.60 can be used to solve for the distance CK.

$$CK = KV = \left( \frac{l_1 l_2}{2L} \right) A \quad 79.60$$

**Figure 79.15** Design Controls for Sag Vertical Curves (customary U.S. units)

From *A Policy on Geometric Design of Highways and Streets*, Fig. 3-44, copyright © 2011 by the American Association of State Highway and Transportation Officials, Washington, D.C. Used by permission.

**Figure 79.16** Unequal Tangent Vertical Curve

The grade,  $G'$ , of the line  $v_1v_2$  is the same as that of AB, found by Eq. 79.61.

$$G' = \frac{\text{elev}_B - \text{elev}_A}{L} \quad 79.61$$

## 26. SPIRAL CURVES

*Spiral curves* (also known as *transition curves* and *easement curves*) are used to produce a gradual transition from tangents to circular curves. A spiral curve is a curve of gradually changing radius and gradually changing degree of curvature. Figure 79.17 illustrates the geometry of spiral curves connecting tangents with a circular curve of radius  $R_c$  and degree of curvature  $D$ . The *entrance spiral* begins at the left at the TS (tangent

to spiral) and ends at the SC (spiral to curve). The circular curve begins at the SC and ends at the CS (curve to spiral). The *exit spiral* begins at the CS and ends at the ST (spiral to tangent). (See Table 79.5 for a list of spiral curve abbreviations.)

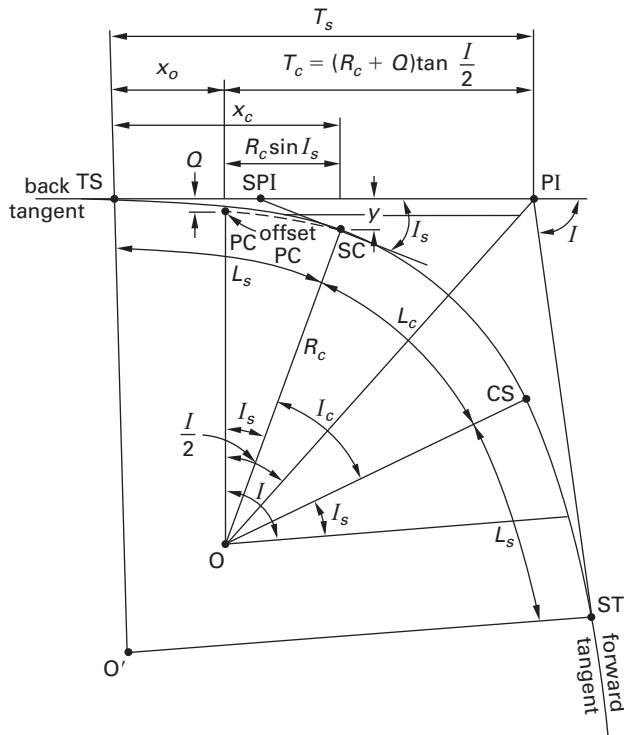

Entrance and exit spirals are geometrically identical. Their length,  $L_s$ , is the arc distance from the TS to the SC (or CS to ST). This length is selected to provide sufficient distance for introducing the curve's superelevation. The length of a spiral curve can be adjusted to between 75% and 200% of the theoretical value to meet other design criteria.

There are various ways of selecting the spiral length,  $L_s$ , including rules of thumb, tables, formulas, and codes. Equation 79.62 is the 1909 *Shortt equation*.

$$L_{s,m} \approx \frac{0.0214 v_{\text{km/h}}^3}{R_m C_{\text{m/s}^3}} \quad [\text{SI}] \quad 79.62(a)$$

$$L_{s,ft} \approx \frac{3.15 v_{\text{mph}}^3}{R_{ft} C_{\text{ft/sec}^3}} \quad [\text{U.S.}] \quad 79.62(b)$$

$C$  in Eq. 79.62 is the rate of increase of lateral (centripetal) acceleration and is selected by judgment. The value of  $C$  affects driver comfort and ease of staying in the lane. The original Shortt equation was developed for railroad use, and the corresponding railroad value of  $C$  is  $1 \text{ ft/sec}^3$  ( $0.3 \text{ m/s}^3$ ). However, transportation agencies

**Figure 79.17** Spiral Curve Geometry**Table 79.5** Spiral Curve Abbreviations

CS	curve to spiral point
$I_s$	spiral angle
$L_c$	curve length
$L_P$	distance to any point, P
$L_s$	length of spiral
$Q$	offset of ghost PC to new tangent (tangent shift)
$R_c$	radius of circular curve
SC	spiral to curve point
SPI	spiral to point of intersection
ST	spiral to tangent point
TS	tangent to spiral point

have used more aggressive values for roadways, ranging from 1 ft/sec<sup>3</sup> to 3 ft/sec<sup>3</sup> (0.3 m/s<sup>3</sup> to 0.9 m/s<sup>3</sup>), for various reasons, including the need to fit turns into smaller areas.

Transitions to and from superelevation logically affect the spiral curve length, and a few variations of Eq. 79.62 include a superelevation correction in order to reduce this length. However, the minimum spiral curve length is already effectively controlled by the distance needed for superelevation runoff, and for this reason, Eq. 79.62 is generally sufficient.

A tangent to the entrance spiral at the SC projected to the back tangent locates the SPI (spiral point of intersection). The angle at the SPI between the two tangents is the *spiral angle*,  $I_s$ . (As with circular curves, the symbols  $I$  and  $\Delta$  are both used for spiral angle.) The spiral's degree of curvature changes uniformly from 0°

at TS to  $D$  (the circular curve's degree) at SC. Since the change is uniform, the average degree of curve over the spiral's length is  $D/2$ . The spiral angle is given by Eq. 79.63.  $L_s$  is the length of spiral curve in ft, and  $I_s$ ,  $I_c$ , and  $D$  are in degrees. Since an oblique line intersects two parallel lines at the same skew angle, the angle between lines O-SC and O'-TS and the angle between O-SC and O-PC are the same.

$$I_s = \left( \frac{L_s}{100} \right) \left( \frac{D}{2} \right) = \frac{L_s D}{200} \quad 79.63$$

The *total deflection angle* is equal to the intersection angle,  $I$ , of the two intersecting tangents.

$$I = I_c + 2I_s \quad 79.64$$

The *total length of the curve system* is

$$L = L_c + 2L_s \quad 79.65$$

As with circular curves, spiral curves can be laid out using deflection angles or tangent offsets. The total deflection angle,  $\alpha_s$ , between lines TS-PI and TS-SC is

$$\alpha_s = \tan^{-1} \frac{y}{x} \approx \frac{y}{x} \approx \frac{I_s}{3} \quad [I_s < 20^\circ] \quad 79.66$$

At any other point, P, along the spiral curve, spiral angles,  $\alpha_P$ , are proportional to the square of the distance from the TS to the point.  $I_P$  is the central spiral angle at any point, P, whose distance from TS is  $L_P$ .

$$\frac{\alpha_P}{\alpha_s} = \frac{I_P}{I_s} = \left( \frac{L_P}{L_s} \right)^2 \quad 79.67$$

For any spiral curve length  $L$  up to  $L_s$ , the tangent offset is

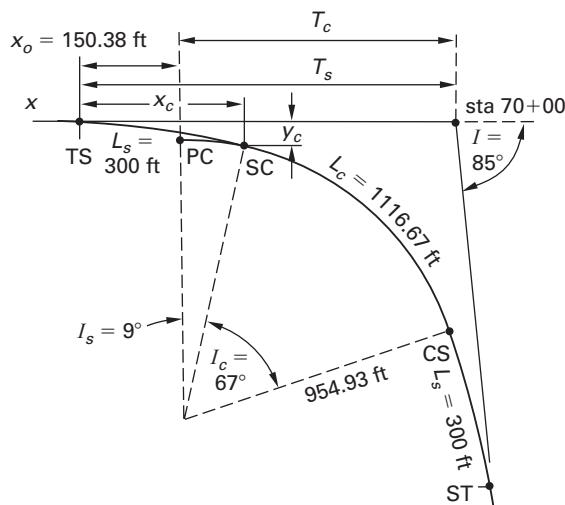

$$\begin{aligned} y &= x \tan \alpha_P \approx x \alpha_{P,\text{radians}} \\ &= \frac{x I_{s,\text{radians}}}{3} \\ &= \left( \frac{x L_s D_{\text{degrees}}}{(200)(3)} \right) \left( \frac{\pi}{180^\circ} \right) \\ &= \frac{x L_s}{6 R_c} \quad [I_s < 20^\circ] \end{aligned} \quad 79.68$$

$$T_c = (R_c + Q) \tan \frac{I}{2} \quad 79.69$$

$$\begin{aligned} Q &= y - R_c(1 - \cos I_s) \\ &= \frac{L_s^2}{6 R_c} - R_c(1 - \cos I_s) \end{aligned} \quad 79.70$$

### Example 79.10

A 300 ft long spiral curve is used as a transition to a 6° circular curve. The intersection angle of the tangents is 85°. The station of the PI is 70+00. Determine the stations of the (a) TS, (b) SC, (c) CS, and (d) ST.

*Solution*

Use Eq. 79.63.

$$I_s = \frac{L_s D}{200} = \frac{(300 \text{ ft})(6^\circ)}{200} = 9^\circ$$

The circular curve's subtended angle between the SC and CS is

$$I_c = I - 2I_s = 85^\circ - (2)(9^\circ) = 67^\circ$$

Use Eq. 79.1 to calculate the circular curve's radius.

$$R_c = \frac{5729.578 \text{ ft}}{D_c} = \frac{5729.578 \text{ ft}}{6^\circ} = 954.93 \text{ ft}$$

Use Eq. 79.10 to calculate the length of the circular curve.

$$L_c = \left( \frac{I_c}{D_c} \right) (100 \text{ ft}) = \left( \frac{67^\circ}{6^\circ} \right) (100 \text{ ft}) = 1116.67 \text{ ft}$$

Use Eq. 79.68 to calculate the offset from the tangent at the SC. At that point,  $x \approx L_s$ .

$$y = \frac{L_s^2}{6R_c} = \frac{(300 \text{ ft})^2}{(6)(954.93 \text{ ft})} = 15.71 \text{ ft}$$

Because  $9^\circ < 20^\circ$ , the tangent distance can be approximated as

$$x_c = \frac{y_c}{\tan \frac{I_s}{3}} = \frac{15.71 \text{ ft}}{\tan \frac{9^\circ}{3}} = 299.76 \text{ ft}$$

From Fig. 79.17,

$$\begin{aligned} x_o &= x_c - R_c \sin I_s = 299.76 \text{ ft} - (954.93 \text{ ft})(\sin 9^\circ) \\ &= 150.38 \text{ ft} \end{aligned}$$

Use Eq. 79.70.

$$\begin{aligned} Q &= \frac{L_s^2}{6R_c} - R_c(1 - \cos I_s) \\ &= \frac{(300 \text{ ft})^2}{(6)(954.93 \text{ ft})} - (954.93 \text{ ft})(1 - \cos 9^\circ) \\ &= 3.95 \text{ ft} \end{aligned}$$

Use Eq. 79.69.

$$\begin{aligned} T_c &= (R_c + Q)\tan \frac{I}{2} \\ &= (954.93 \text{ ft} + 3.95 \text{ ft})\left(\tan \frac{85^\circ}{2}\right) \\ &= 878.65 \text{ ft} \\ T_s &= x_o + T_c = 150.38 \text{ ft} + 878.65 \text{ ft} = 1029.03 \text{ ft} \end{aligned}$$

(a) Use Eq. 79.12.

$$\begin{aligned} \text{sta TS} &= \text{sta PI} - T_s = (\text{sta } 70+00) - 1029.03 \text{ ft} \\ &= \text{sta } 59+70.97 \end{aligned}$$

(b) Use Eq. 79.11.

$$\begin{aligned} \text{sta SC} &= \text{sta TS} + L_s = (\text{sta } 59+70.97) + 300 \text{ ft} \\ &= \text{sta } 62+70.97 \end{aligned}$$

(c) The station of CS is

$$\begin{aligned} \text{sta CS} &= \text{sta SC} + L_c = (\text{sta } 62+70.97) + 1116.67 \text{ ft} \\ &= \text{sta } 73+87.64 \end{aligned}$$

(d) The station of SI is

$$\begin{aligned} \text{sta ST} &= \text{sta CS} + L_s = (\text{sta } 73+87.64) + 300 \text{ ft} \\ &= \text{sta } 76+87.64 \end{aligned}$$

## 27. SPIRAL LENGTH TO PREVENT LANE ENCROACHMENT

Another consideration in determining spiral curve length is a driver's tendency to wander into an outer lane or onto the shoulder. A spiral curve that transitions too quickly may result in unsafe lane encroachment. Generally, the minimum curve length to prevent lane encroachment is less than the minimum curve lengths for comfort and superelevation. Nevertheless, the AASHTO *Green Book* provides two methods of calculating the minimum curve length based on encroachment prevention. The first method uses Eq. 79.62 with

a  $C$  value 4.0 ft/sec<sup>3</sup> (1.2 m/s<sup>3</sup>) [AASHTO *Green Book* Eq. 3-29].

The second method recognizes that most drivers are able to maintain their desired track only within 0.66 ft (0.20 m) of the desired direction in a spiral curve. This minimum shift (accuracy) is designated as the *minimum lateral offset between the tangent and the circular curve*,  $p_{\min}$ . The AASHTO *Green Book* Eq. 3-28 uses this parameter and the radius of the adjacent circular curve to calculate the minimum spiral curve length.

$$L_{s,\min,m} = \sqrt{24p_{\min,m}R_m} \quad [\text{SI}] \quad 79.71(a)$$

$$L_{s,\min,ft} = \sqrt{24p_{\min,ft}R_{ft}} \quad [\text{U.S.}] \quad 79.71(b)$$

Similar reasoning limits the maximum length of a spiral curve. That is, if a spiral curve is too long, the driver may be misled about the sharpness of the circular curve ahead. The maximum lateral shift that occurs with most drivers,  $p_{\max}$ , is designated as the *maximum lateral offset between the tangent and the circular curve*. The standard value for  $p_{\max}$  is 3.3 ft (1.0 m).

$$L_{s,\max,m} = \sqrt{24p_{\max,m}R_m} \quad [\text{SI}] \quad 79.72(a)$$

$$L_{s,\max,ft} = \sqrt{24p_{\max,ft}R_{ft}} \quad [\text{U.S.}] \quad 79.72(b)$$

## 28. MAXIMUM RADIUS FOR USE OF A SPIRAL

If a circular curve has a sufficiently large radius, a spiral curve may not be necessary. According to the AASHTO *Green Book*, only circular curves with radii less than a limiting maximum radius experience benefits of incorporating spiral curves. The limiting maximum radius will depend on design speed and is based on the desired maximum lateral (centripetal) acceleration, which varies between 1.3 ft/sec<sup>2</sup> and 4.25 ft/sec<sup>2</sup> (0.4 m/s<sup>2</sup> to 1.3 m/s<sup>2</sup>), depending on the specifying agency. AASHTO *Green Book* Table 3-20 lists the maximum radius based on a limit of 4.25 ft/sec<sup>2</sup> (1.3 m/s<sup>2</sup>), as calculated from Eq. 79.73.

$$R_{\max,m} = \frac{v^2}{a} = 0.0592v_{\text{km/h}}^2 \quad [\text{SI}] \quad 79.73(a)$$

$$R_{\max,ft} = \frac{v^2}{a} = 0.506v_{\text{mph}}^2 \quad [\text{U.S.}] \quad 79.73(b)$$

## 29. DESIRABLE SPIRAL CURVE LENGTH

The *desirable spiral curve length* is simply the distance that most drivers would naturally take to transition to a circular curve. AASHTO *Green Book* Table 3-21 lists the desirable length of spiral curve transitions. The values are based on the distance traveled by the driver in two seconds at the roadway's design speed, which

generally corresponds to the natural spiral paths taken by most drivers.

$$L_{s,\text{desirable},m} = 0.556v_{\text{km/h}} \quad [\text{SI}] \quad 79.74(a)$$

$$L_{s,\text{desirable},ft} = 2.93v_{\text{mph}} \quad [\text{U.S.}] \quad 79.74(b)$$

Deviations from the desirable spiral length are sometimes unavoidable. When shorter lengths are needed, they should never be less than  $L_{s,\min}$ . Larger lengths (up to twice the desirable spiral length) may be needed in order to develop proper superelevation. Keep in mind that deviations from the desirable spiral length will result in drivers allowing their vehicles to shift laterally into adjacent lanes or shoulders. Such encroachment can be accommodated by increasing the lane widths in the spiral curve.

## 30. GEOMETRIC DESIGN OF AIRPORTS

The primary document governing geometric design of airports is FAA advisory circular AC 150/5300-13, *Airport Design*. Chapters cover airport layout, runway and taxiway design, taxiway bridges, line of sight, gradients, wind analysis, and other topics. Size and performance data are provided for typical aircraft.

Gradient limitations in AC 150/5300-13 are specified according to an *aircraft approach category* according to *expected landing speed*,  $v_{\text{approach}}$ . The expected landing speed is calculated as 1.3 times the stall speed in a landing configuration (i.e., at the certificated maximum flap setting with landing gear down) and maximum landing weight at standard atmospheric conditions. In keeping with world-wide convention, aircraft speeds are listed in *knots* (kt, nautical miles per hour), where 1 *nautical mile* (nm), is approximately 1.15078 statute miles.

- category A:  $v_{\text{approach}} < 91 \text{ kt}$
- category B:  $91 \text{ kt} \leq v_{\text{approach}} < 121 \text{ kt}$
- category C:  $121 \text{ kt} \leq v_{\text{approach}} < 141 \text{ kt}$
- category D:  $141 \text{ kt} \leq v_{\text{approach}} < 166 \text{ kt}$
- category E:  $v_{\text{approach}} \geq 166 \text{ kt}$

Airports are often categorized as *utility airports* (roughly corresponding to airport approach categories A and B) and *transport airports* (roughly corresponding to airport approach categories C and D). Utility airports are designed to accommodate general aviation (i.e., small) aircraft and may be referred to as *general aviation airports*, while transport airports are designed to accommodate commercial passenger aircraft. Table 79.6 lists geometric characteristics of airport runways and taxiways.

## 31. GEOMETRIC DESIGN OF RAILWAYS

The geometric design of railways depends on the terrain, nature (freight, passenger, light rail, etc.), length, volume (number of vehicles per period), and speed of the rail traffic. The *Manual for Railway Engineering*,

**Table 79.6** Geometric Characteristics of Airport Runways and Taxiways\*

characteristic	airport approach category

minimum distance between points of intersection of two adjacent vertical curves	100 ft (30 m) times the sum of the two grade changes (in percent)	100 ft (30 m) times the sum of the two grade changes (in percent)

(Multiply ft by 0.3048 to obtain m.)

\*Values extracted from FAA advisory circular AC 150/5300-13, *Airport Design*, Chapter 5, "Surface Gradient and Line of Sight."

published by the American Railway Engineering and Maintenance-of-Way Association (AREMA), and the *Track Safety Standards Compliance Manual*, published by the U.S. Federal Railroad Administration (FRA), are standard resources. Although AREMA and FRA publications provide general guidance for alignment design, railways and transportation agencies usually have their own design standards. Accordingly, only the most general recommendations can be given. Table 79.7 lists general recommendations for maximum rates of grade change for vertical railroad curves.

**Table 79.7** Maximum Rate of Change of Gradient on Railroad Lines (percent per 100 ft station)

track line rating	curve type	
	sag	crest

## 1. DEFINITION

*Earthwork* is the excavation, hauling, and placing of soil, rock, gravel, or other material found below the surface of the earth. This definition also includes the measurement of such material in the field, the computation in the office of the volume of such material, and the determination of the most economical method of performing such work. The measurement of irregular areas on maps,

photographs, or illustrations using mechanical integration is in Chap. 2. Specific information about excavation analysis, bracing, bulkheads, and cofferdams is in Chap. 39.

## 2. UNIT OF MEASURE

In the United States, the *cubic yard* (i.e., the “yard”) is the unit of measure for earthwork. The cubic meter is used in metricated countries. However, the volume and density of earth changes under natural conditions and during the operations of excavation, hauling, and placing.

## 3. SWELL AND SHRINKAGE

The volume of a loose pile of excavated earth will be greater than the original, in-place natural volume. If the earth is compacted after it is placed, the volume may be less than its original volume.

The volume of the earth in its natural state is known as *bank-measure*. The volume during transport is known as *loose-measure*. The volume after compaction is known as *compacted-measure*. In the United States, the terms *bank cubic yards (BCY)*, *loose cubic yards (LCY)*, and *compacted cubic yards (CCY)* may be encountered.

When earth is excavated, it increases in volume because of an increase in voids. The change in volume of earth from its natural to loose state is known as *swell*. Swell is expressed as a percentage of the natural volume. A soil's *load factor*, *L*, in a particular excavation environment is the inverse of the *swell factor* (also known as the *bulking factor*), the sum of 1 and the decimal swell.

$$V_l = \left( \frac{100\% + \% \text{ swell}}{100\%} \right) V_b = \frac{V_b}{L} \quad 80.1$$

The decrease in volume of earth from its natural state to its compacted state is known as *shrinkage*. Shrinkage also is expressed as a percent decrease from the natural state.

$$V_c = \left( \frac{100\% - \% \text{ shrinkage}}{100\%} \right) V_b \quad 80.2$$

As an example, 1 yd<sup>3</sup> in the ground may become 1.2 yd<sup>3</sup> loose-measure and 0.85 yd<sup>3</sup> after compaction. The swell would be 20%, and the percent shrinkage would be 15%. Swell and shrinkage vary with soil types.

Table 80.1 provides a summary of excavation calculations, and Table 80.2 provides load factors and swell percentages for many different soil types.

#### 4. CLASSIFICATION OF MATERIALS

Excavated material is usually classified as *common excavation* or *rock excavation*. Common excavation is soil.

In highway construction, common road excavation is soil found in the roadway. *Common borrow* is soil found outside the roadway and brought in to the roadway. Borrow is necessary where there is not enough material in the roadway excavation to provide for the embankment.

#### 5. CUT AND FILL

Earthwork that is to be excavated is known as *cut*. Excavation that is placed in embankment is known as *fill*.

Payment for earthwork is normally either for cut and not for fill, or for fill and not for cut. In highway work, payment is usually for cut; in dam work, payment is usually for fill. To pay for both would require measuring two different volumes and paying for moving the same earth twice.

#### 6. FIELD MEASUREMENT

*Cut and fill volumes* can be computed from slope-stake notes, from plan cross sections, or by photogrammetric methods.

#### 7. CROSS SECTIONS

*Cross sections* are profiles of the earth taken at right angles to the centerline of an engineering project (such as a highway, canal, dam, or railroad). A cross section for a highway is shown in Fig. 80.1.

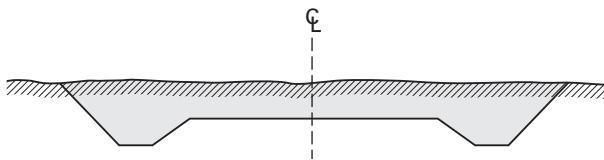

**Table 80.1** Summary of Excavation Soil Factors

quantity	symbol	example value or units	formulas		
swell factor; heaped factor [bank to loose]	SF	1.20	$\frac{LCY}{BCY}$	$\frac{1}{LF}$	$\frac{\gamma_{bank}}{\gamma_{loose}}$
shrinkage factor; shrink factor [bank to compacted]	DF	0.15	$1 - \frac{CCY}{BCY}$		$1 - \frac{\gamma_{bank}}{\gamma_{compacted}}$
load factor [loose to bank]	LF	0.83	$\frac{BCY}{LCY}$	$\frac{1}{SF}$	$\frac{\gamma_{loose}}{\gamma_{bank}}$
fill factor; dipper factor; fillability	FF	0.85	$\frac{\text{occupied volume}}{\text{solid capacity of bucket, dipper, or truck}}$		
operator factor	OF	0.93	$\frac{\text{actual production}}{\text{ideal production}}$		
loose volume; loose cubic yards	LCY	120 yd <sup>3</sup>	$SF \times BCY$	$\frac{BCY}{LF}$	$\frac{\gamma_{bank}}{\gamma_{loose}} \times BCY$
compacted volume; compacted cubic yards	CCY	85 yd <sup>3</sup>	$(1 - DF)BCY$	$\left(\frac{1 - DF}{SF}\right)LCY$	$\frac{\gamma_{bank}}{\gamma_{compacted}} \times BCY$
bank volume; bank cubic yards	BCY	100 yd <sup>3</sup>	$\frac{LCY}{SF}$	$\frac{CCY}{1 - DF}$	
swell	SWL	20 yd <sup>3</sup>	LCY - BCY (increase)	$(SF - 1)BCY$	$\frac{1 - LF}{LF} \times BCY$
		20%	$\frac{LCY - BCY}{BCY} \times 100\%$ (increase)	$(SF - 1) \times 100\%$	$\frac{1 - LF}{LF} \times 100\%$
shrinkage	SHR	15 yd <sup>3</sup>	BCY - CCY (decrease)	$DF \times BCY$	
		15%	$\frac{BCY - CCY}{BCY} \times 100\%$ (decrease)	$DF \times 100\%$

**Figure 80.1** Typical Highway Cross Section

## 8. ORIGINAL AND FINAL CROSS SECTIONS

To obtain volume measurement, cross sections are taken before construction begins and after it is completed. By plotting the cross section at a particular station both before and after construction, a sectional view of the change in the profile of the earth along a certain line is

**Figure 80.2** Typical Completed Section

obtained. The change along this line appears on the plan as an area. By using these areas at various intervals along the centerline, and by using distance between the areas, volume can be computed.

## 9. TYPICAL SECTIONS

**Typical sections** show the cross section view of the project as it will look on completion, including all dimensions. (See Fig. 80.2.) Highway projects usually show several typical sections including cut sections, fill sections, and sections showing both cut and fill. Interstate highway plans also show access-road sections and sections at ramps.

## 10. DISTANCE BETWEEN CROSS SECTIONS

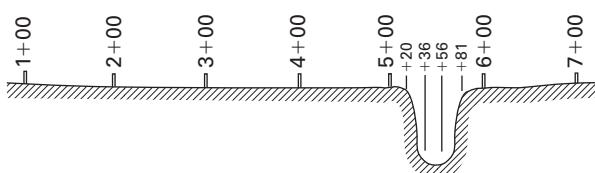

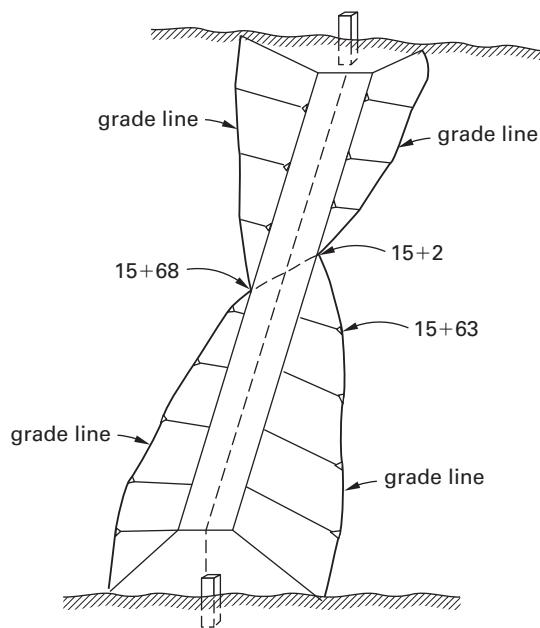

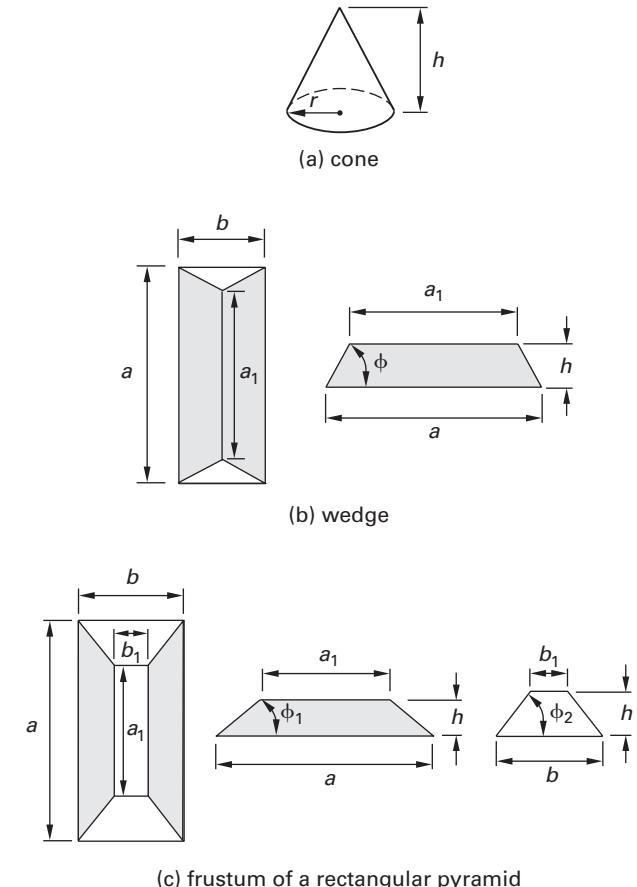

Cross sections are usually taken at each full station and at breaks in the ground along the centerline. In taking cross sections, the change in the earth's surface from one cross section to the next is assumed to be uniform, and a section halfway between the cross sections is taken as an average of the two. If the ground breaks appreciably between any two full-stations, one or more cross sections between full-stations must be taken. This is referred to as **taking sections at pluses**. Figure 80.3 shows eleven stations at which cross sections should be taken.

In rock excavation, or any other expensive operation, cross sections should be taken at intervals of 50 ft (15 m) or less. Cross sections should always be taken at the **PC** and **PT** of a curve. Plans should also show a section on each end of a project (where no construction is to take place) so that changes caused by construction will not be abrupt.

Where a cut section of a highway is to change to a fill section, several additional cross sections are needed. Such sections are shown in Fig. 80.4.

## 11. GRADE POINT

A point where a cut or fill section meets the natural ground (where a cut section begins) is known as the **grade point**. Similarly, a locus of grade points is known as a **grade line**.

**Figure 80.3** Cross-Section Locations

**Figure 80.4** Cut Changing to Fill

**Figure 80.5** Pile Shapes

## 12. VOLUMES OF PILES

The volumes of piles of soil, recycled pavement, and paving materials can be calculated if the pile shapes are assumed. (See Fig. 80.5.) The **angle of repose**,  $\phi$ , depends on the material, but it is approximately  $30^\circ$  for smooth gravel,  $40^\circ$  for sharp gravel,  $25\text{--}35^\circ$  for dry sand,  $30\text{--}45^\circ$  for moist sand,  $20\text{--}40^\circ$  for wet sand, and  $37^\circ$  for cement.

$$V = \left(\frac{h}{3}\right)\pi r^2 \quad [\text{cone}] \quad 80.3$$

$$V = \left(\frac{h}{6}\right)b(2a + a_1) = \frac{1}{6}hb\left(3a - \frac{2h}{\tan \phi}\right) \quad [\text{wedge}] \quad 80.4$$

$$\begin{aligned} V &= \left(\frac{h}{6}\right)(ab + (a + a_1)(b + b_1) + a_1b_1) \\ &= \left(\frac{h}{6}\right)\left(ab + 4\left(a - \frac{h}{\tan \phi_1}\right)\left(b - \frac{h}{\tan \phi_2}\right)\right. \\ &\quad \left.+ \left(a - \frac{2h}{\tan \phi_1}\right)\left(b - \frac{2h}{\tan \phi_2}\right)\right) \\ &\quad \left[\begin{array}{c} \text{frustum of a} \\ \text{rectangular pyramid} \end{array}\right] \quad 80.5 \end{aligned}$$

$$a_1 = a - \frac{2h}{\tan \phi_1} \quad 80.6$$

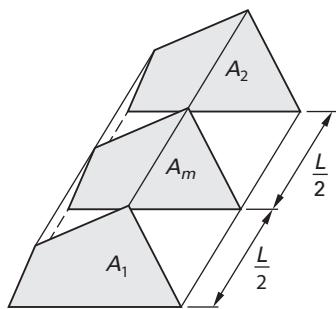

$$b_1 = b - \frac{2h}{\tan \phi_2} \quad 80.7$$

## 13. EARTHWORK VOLUMES

A three-dimensional soil volume between two points is known as a **soil prismoid** or **prism**. (See Fig. 80.6.) The prismoid (prismatic) volume must be calculated in order to estimate hauling requirements. Such volume is generally expressed in units of cubic yards ("yards") or cubic meters. There are two methods of calculating the prismoid volume: the **average end area method** and the **prismoidal formula method**.

## 14. AVERAGE END AREA METHOD

With the **average end area method**, the volume is calculated by averaging the two end areas and multiplying by the prism length. This disregards the slopes and orientations of the ends and sides, but is sufficiently accurate for most earthwork calculations. When the end area is complex, it may be necessary to use a planimeter or to

**Figure 80.6** Soil Prismoid

plot the area on fine grid paper and simply count the squares. The average end area method usually overestimates the actual soils volume, **favoring the contractor** in earthwork cost estimates.

$$V = \frac{L(A_1 + A_2)}{2} \quad 80.8$$

The precision obtained from the average end area method is generally sufficient unless one of the end areas is very small or zero. In that case, the volume should be computed as a pyramid or truncated pyramid.

$$V_{\text{pyramid}} = \frac{LA_{\text{base}}}{3} \quad 80.9$$

## 15. PRISMOIDAL FORMULA METHOD

The *prismoidal formula* is preferred when the two end areas differ greatly or when the ground surface is irregular. It generally produces a smaller volume than the average end area method and thus **favors the owner-developer** in earthwork cost estimating.

The prismoidal formula uses the mean area,  $A_m$ , midway between the two end sections. In the absence of actual observed measurements, the dimensions of the middle area can be found by averaging the similar dimensions of the two end areas. The middle area is not found by averaging the two end areas.

$$V = \left( \frac{L}{6} \right) (A_1 + 4A_m + A_2) \quad 80.10$$

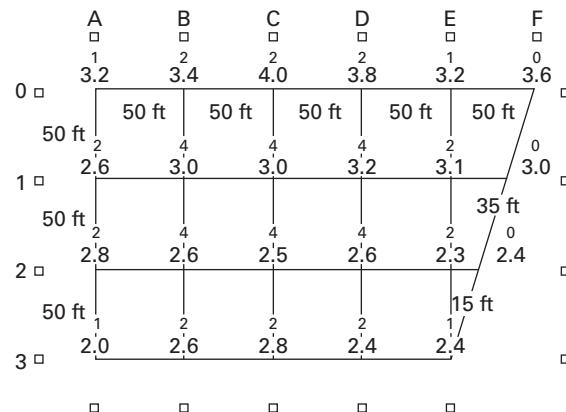

When using the prismoidal formula, the volume is not found as  $LA_m$ , although that quantity is usually sufficiently accurate for estimating purposes.

## 16. BORROW PIT GEOMETRY

It is often necessary to borrow earth from an adjacent area to construct embankments. Normally, the **borrow pit** area is laid out in a rectangular grid with 10 ft (3 m), 50 ft (15 m), or even 100 ft (30 m) squares. Elevations are determined at the corners of each square by leveling

before and after excavation so that the cut at each corner can be computed. (See Fig. 80.7.)

Points outside the cut area are established on the grid lines so that the lines can be reestablished after excavation is completed.

**Figure 80.7** Depth of Excavation (Cut) in a Borrow Pit Area

### Example 80.1

Excavation of a borrow pit has been surveyed and recorded as illustrated in Fig. 80.7. What are the volumes of excavation from prisms A0-B0-B1-A1 and E2-F2-E3?

*Solution*

Volumes are computed by multiplying the average cut by the area of the figure. The volume of the prism A0-B0-B1-A1 is

$$\begin{aligned} V &= \left( \frac{(50 \text{ ft})(50 \text{ ft})}{27 \frac{\text{ft}^3}{\text{yd}^3}} \right) \\ &\times \left( \frac{3.2 \text{ ft} + 3.4 \text{ ft} + 3.0 \text{ ft} + 2.6 \text{ ft}}{4} \right) \\ &= 282.4 \text{ yd}^3 \end{aligned}$$

The volume of the prism E2-F2-E3 is

$$\begin{aligned} V &= \left( \frac{(50 \text{ ft})(15 \text{ ft})}{(2)(27 \frac{\text{ft}^3}{\text{yd}^3})} \right) \left( \frac{2.3 \text{ ft} + 2.4 \text{ ft} + 2.4 \text{ ft}}{3} \right) \\ &= 32.9 \text{ yd}^3 \end{aligned}$$

Instead of computing volumes of prisms represented by squares separately, all square-based prisms can be computed collectively by multiplying the area of one square by the sum of the cut at each corner times the number of times that cut appears in any square, divided by 4. For instance, on the second line from the top in Fig. 80.7,

which is line 1, 2.6 appears in two squares, 3.0 appears in four squares, 3.0 appears in four squares, 3.2 appears in four squares, and 3.1 appears in two squares. In the figure, the small number above the cut indicates the number of times the cut is used in averaging the cuts for the square prisms.

### Example 80.2

Calculate the volume of earth excavated from the borrow pit shown in Fig. 80.7.

*Solution*

The volume of the squares is

$$V = \left( \frac{50 \text{ ft}}{\left( 27 \frac{\text{ft}^3}{\text{yd}^3} \right) (4)} \right) (50 \text{ ft}) \\ \times \left( \begin{array}{l} 3.2 \text{ ft} + (2)(3.4 \text{ ft}) + (2)(4.0 \text{ ft}) \\ + (2)(3.8 \text{ ft}) + 3.2 \text{ ft} + (2)(2.6 \text{ ft}) \\ + (4)(3.0 \text{ ft}) + (4)(3.0 \text{ ft}) + (4)(3.2 \text{ ft}) \\ + (2)(3.1 \text{ ft}) + (2)(2.8 \text{ ft}) + (4)(2.6 \text{ ft}) \\ + (4)(2.5 \text{ ft}) + (4)(2.6 \text{ ft}) + (2)(2.3 \text{ ft}) \\ + 2.0 \text{ ft} + (2)(2.6 \text{ ft}) + (2)(2.8 \text{ ft}) \\ + (2)(2.4 \text{ ft}) + 2.4 \text{ ft} \end{array} \right) \\ = 3194 \text{ yd}^3$$

The volume of the trapezoids is

$$V = \left( \frac{50 \text{ ft} + 35 \text{ ft}}{(2) \left( 27 \frac{\text{ft}^3}{\text{yd}^3} \right)} \right) (50 \text{ ft}) \\ \times \left( \frac{3.2 \text{ ft} + 3.6 \text{ ft} + 3.1 \text{ ft} + 3.0 \text{ ft}}{4} \right) \\ = 254 \text{ yd}^3$$

$$V = \left( \frac{35 \text{ ft} + 15 \text{ ft}}{(2) \left( 27 \frac{\text{ft}^3}{\text{yd}^3} \right)} \right) (50 \text{ ft}) \\ \times \left( \frac{3.1 \text{ ft} + 3.0 \text{ ft} + 2.3 \text{ ft} + 2.4 \text{ ft}}{4} \right) \\ = 125 \text{ yd}^3$$

The volume of the triangle is

$$V = \left( \frac{15 \text{ ft}}{(2) \left( 27 \frac{\text{ft}^3}{\text{yd}^3} \right)} \right) (50 \text{ ft}) \\ \times \left( \frac{2.3 \text{ ft} + 2.4 \text{ ft} + 2.4 \text{ ft}}{3} \right) \\ = 33 \text{ yd}^3$$

The total volume of earth excavated is

$$V = 3194 \text{ yd}^3 + 254 \text{ yd}^3 + 125 \text{ yd}^3 + 33 \text{ yd}^3 = 3606 \text{ yd}^3$$

## 17. MASS DIAGRAMS

A *profile diagram* is a cross section of the existing ground elevation along a route alignment. The elevation of the route is superimposed to identify the *grade points*, the points where the final grade coincides with the natural elevation.

A *mass diagram* is a record of the cumulative earthwork volume moved along an alignment, usually plotted below profile sections of the original ground and finished grade. The mass diagram can be used to establish a finished grade that balances cut-and-fill volumes and minimizes long hauls.

After volumes of cut and fill between stations have been computed, they are tabulated as shown in Table 80.3. The cuts and fills are then added, and the cumulative yardage at each station is recorded in the table. It is this cumulative yardage that is plotted as an ordinate. In Fig. 80.8, the *baseline*, also known as the *zero haulage line*, serves as the *x-axis* and cumulative yardage that has a plus sign is plotted above the baseline. Cumulative yardage that has a minus sign is plotted below the baseline. The scale is chosen for convenience. 1 in = 5 ft is typical, although 1 in = 10 ft or 20 ft can be used in steep terrain.

In Fig. 80.8, the mass diagram is plotted on the lower half of the sheet, and the centerline profile of the project is plotted on the upper half.

A rising line on the mass diagram represents areas of excavation; a falling line represents areas of embankment. The local minima and maxima on the mass diagram identify the grade points. Vertical distances on a mass diagram represent volumes of material (areas on the profile diagram). Areas in a mass diagram represent the product of volume and distance.

A *balance line* is a horizontal line drawn between two adjacent *balance points* in a crest or sag area. The volumes of excavation and embankment between the points are equal. Thus, a contractor can plan on using the earth volume from the excavation on one side of the grade point for the embankment on the other side of the grade point. In Fig. 80.9, a balance line has been drawn

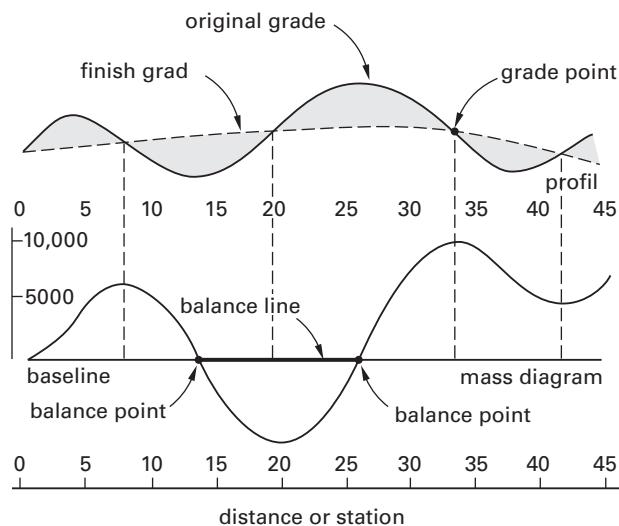

**Table 80.3** Typical Cut and Fill Calculations (all volumes are in cubic yards)

that intersects the mass diagram at two points. These points represent the inclusive stations for which the cut-and-fill volumes are equal. That is, the cut soil (area B) can be used for the fill soil (area A).

It is important in planning and construction to know the points along the centerline of a particular section of cut that will balance a particular section of fill. For example, assume that a cut section extends from

**Figure 80.8** Profile and Mass Diagrams

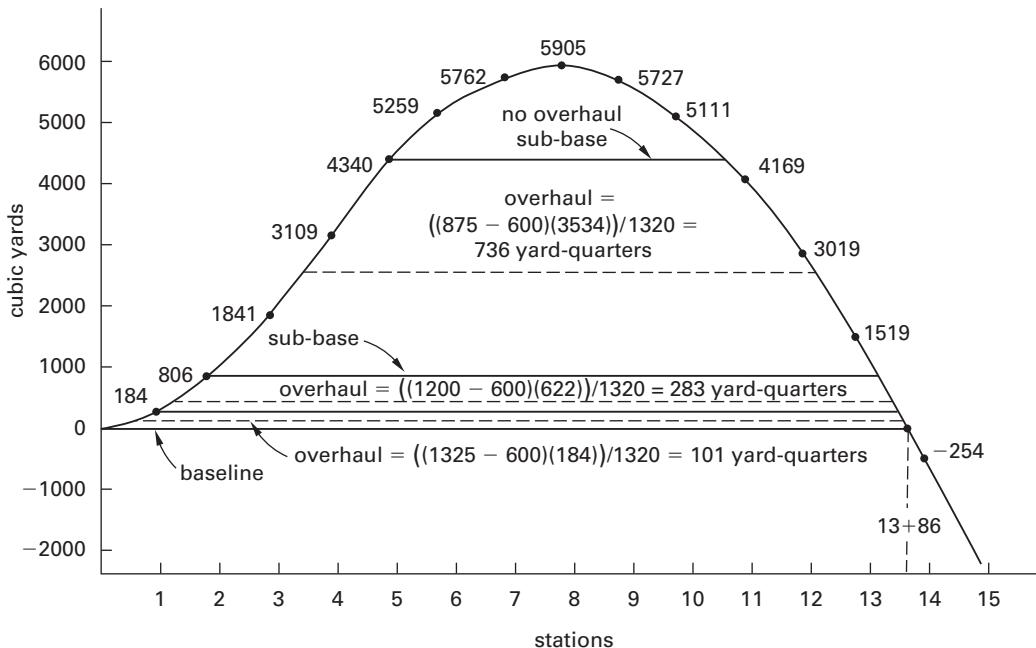

**Figure 80.9** Balance Line Between Two Points

sta 12+25 to sta 18+65, and a fill section extends from sta 18+65 to sta 26+80. Also, assume that the excavated material will exactly provide the material needed to make the embankment. Then, cut balances fill, and sta 12+25 and sta 26+80 are balance points.

A balance point occurs where the mass curve crosses the baseline. In Fig. 80.10, a balance point falls between sta 13 and 14. The ordinate of 13 is +1519; the ordinate of 14 is -254. Therefore, the curve fell  $1519 \text{ yd}^3 + 254 \text{ yd}^3 = 1773 \text{ yd}^3$  in 100 ft or  $17.73 \text{ yd}^3/\text{ft}$ . The curve crosses the baseline at a distance of  $1519 \text{ yd}^3 / (17.73 \text{ yd}^3/\text{ft}) = 86 \text{ ft}$  from sta 13 (13+86).

**Figure 80.10** Mass Diagram Showing Sub-Bases

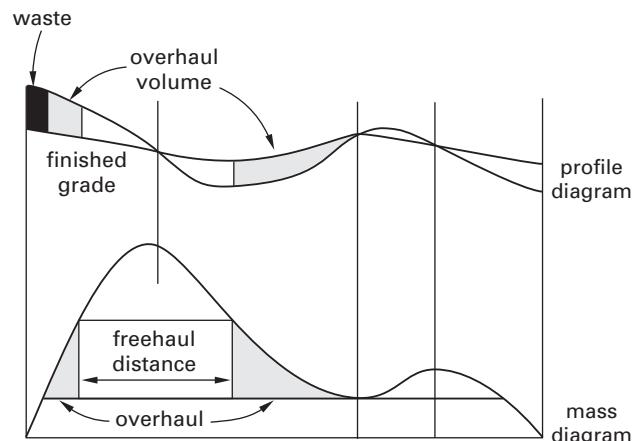

The average *haul distance* is the separation of the centroids of the excavation and embankment areas on the profile diagram. This distance is usually determined for each section of earthwork rather than for the entire mass of earthwork in a project.

The average haul can also be calculated from the mass diagram. For customary U.S. usage, the curve area under a balance line represents the total haul in *yard-stations*, which is the number of cubic yards moved in 100 ft (30 m). This figure can be used by the contractor to determine hauling costs. The height of the curve, or the distance between the balance line and the minimum or maximum, represents the *solidity* or the volume of the total haul. The average haul distance is found by dividing the curve area (area C) by the curve height, *h*.

The *freehaul distance* is the maximum distance, as specified in the construction contract, that the contractor is expected to transport earth without receiving additional payment. Typically, the freehaul distance is between 500 ft and 1000 ft (150 m and 300 m). Any soil transported more than the freehaul distance is known as *overhaul*. (See Fig. 80.11.)

Freehaul and overhaul can be determined from the mass diagram. The procedure begins by drawing a balance line equal in length to the freehaul distance. The enclosed area on the mass diagram represents material that will be hauled with no extra cost. The actual volume moved (the solidity) is the vertical distance between the balance line and the maximum or minimum.

The overhaul is found directly from the overhaul area on the mass diagram. It can also be calculated indirectly from the overhaul volume and overhaul distance. The

**Figure 80.11** Freehaul and Overhaul

overhaul volume is determined from the maximum height of the overhaul area on the mass diagram, or from the overhaul area on the profile diagram. The overhaul distance is found as the separation in overhaul centroids on the profile diagram.

*Sub-bases* are horizontal balance lines that divide an area of the mass diagram between two balance points into trapezoids for the purpose of more accurately computing overhaul. In Fig. 80.10, the top sub-base is less than 600 ft in length, the freehaul distance for this project. Therefore, the volume of earth represented by the area above this line will be hauled a distance less than the freehaul distance, and no payment will be made for overhaul. All the volume represented by the area below this top sub-base will receive payment for overhaul.

The area between two sub-bases is nearly trapezoidal. The average length of the bases of a trapezoid can be measured in feet, and the altitude of the trapezoid can be measured in cubic yards of earth. The product of these two quantities can be expressed in *yard-quarters*. A “yard-quarter” is a cubic yard of earthwork transported one quarter mile. If free haul is subtracted from the length, the quantity can be expressed as overhaul.

Sub-bases are drawn at distinct breaks in the mass curve. Distinct breaks in Fig. 80.10 can be seen at sta 1+00 ( $184 \text{ yd}^3$ ), sta 2+00 ( $806 \text{ yd}^3$ ), and sta 5+00 ( $4340 \text{ yd}^3$ ). After sub-bases are drawn, a horizontal line is drawn midway between the sub-bases. This line represents the average haul for the volume of earth between the two sub-bases. If a horizontal scale is used, the length of the average haul can be determined by scaling. This line, shown as a dashed line in Fig. 80.10, scales 875 ft for the area between the top sub-bases. The free haul is subtracted from this in Table 80.3.

The volume of earth between the two sub-bases is found by subtracting the ordinate of the lower sub-base from the ordinate of the upper sub-base. These ordinates are found in Table 80.3.

Multiplying average haul minus free haul in feet by volume of earth in cubic yards gives overhaul in yard-feet. Dividing by the number of feet in one-quarter mile, 1320 ft, gives yard-quarters.

When factors such as *shrinkage*, *swell*, *loss during transport*, and *subsidence* can be estimated, they are included in determining embankment volumes. A 5–15% excess is usually included in the calculations. This is achieved by increasing all fill volumes by the necessary percentage.

## 18. CAPACITIES OF EARTH-HANDLING EQUIPMENT

What equipment is used to excavate and transport earth depends on the expected volume of earth to be handled. Manual labor is an option for only the smallest jobs. Table 80.4 lists typical capacities of equipment commonly used on construction job sites. *Struck capacity* is the volume that can be held in a container filled just to its top (i.e., the *brimful capacity*). *Heaping capacity* includes material piled above the container edges. In the absence of specific information about the nature of the soil, 1  $\text{yd}^3$  of excavated soil can be assumed to weigh 1.4 tons (i.e., an excavated density of 100 lbm/ $\text{ft}^3$  ( $1600 \text{ kg/m}^3$ )).

## 19. COST OF EXCAVATION

The cost of excavation depends on many factors, including the volume and nature of the material to be excavated, the method used, the distance moved and disposition of the excavated material, and backfill considerations. Contractors will add overhead and profit to their direct cost estimates. Labor and rental equipment

**Table 80.4** Typical Capacities of Earth-Handling Methods

equipment	approximate capacity per cycle or load
<i>manual methods</i>	
shovel (no. 2 square point shovel), <sup>a</sup>	0.2–0.3 $\text{ft}^3$ per shovel
manual shoveling	
wheelbarrow, standard contractor's	6 $\text{ft}^3$ (fully loaded capacity) 3 $\text{ft}^3$ (soil loading)
<i>mechanized methods</i>	
bucket, clamshell	1–7½ $\text{yd}^3$
crane, truck-mounted	12–30 tons
crane, self-propelled	7–100 tons
dozer (bulldozer, crawler) (D9)	17.7 $\text{yd}^3$ (9 SU blade) 21.4 $\text{yd}^3$ (9 U blade) (varies widely)
excavator, self-propelled	0.5–12 $\text{yd}^3$
loader, backhoe	0.1–1.0 $\text{yd}^3$ typical (depends on scoop size and design)
loader (front-end loader, bucket loader)	½–1½ $\text{yd}^3$ typical (depends on bucket width and design)
loader, wheeled	½–8 $\text{yd}^3$
scraper	9–32 $\text{yd}^3$ (struck) 11–44 $\text{yd}^3$ (heaped)
shovel, drag	2–14 $\text{yd}^3$
trailer, dump	20–30 $\text{yd}^3$
trailer, standard semi-trailer (fifth wheel, single-axle group) <sup>b</sup>	10–15 $\text{yd}^3$
trailer, standard towed (aggregate trailer, B box) <sup>b,c</sup>	11 $\text{yd}^3$ (without bang boards)
trailer, water	2500–14,000 gal
truck, dump, single-axle <sup>b</sup>	5 $\text{yd}^3$
truck, dump, 10-wheel, double-axle <sup>b</sup>	10 $\text{yd}^3$ (12 tons)
truck, dump, triple-axle <sup>b</sup>	15–18 $\text{yd}^3$
truck, off-highway	28 $\text{yd}^3$ (struck) 40–100 tons (varies widely)
truck, pickup	3 $\text{yd}^3$ (heaping) 2 $\text{yd}^3$ (typical, full-size truck) 1½ $\text{yd}^3$ (typical, compact truck)

(Multiply  $\text{ft}^3$  by 0.0283 to obtain  $\text{m}^3$ .)

(Multiply  $\text{yd}^3$  by 0.765 to obtain  $\text{m}^3$ .)

(Multiply tons by 0.907 to obtain metric tons.)

<sup>a</sup>A common rule of thumb is that a cubic yard contains about 150 standard (no. 2) shovels of material.

<sup>b</sup>Typically limited by highway agencies to 20–40 tons loading on paved roads.

<sup>c</sup>A *transfer dump truck*, also known as a *slam-bang*, consists of a standard dump truck pulling a separate trailer.

costs vary with location and season. Materials (e.g., explosives), traffic control, dust mitigation, permits, worksite safety, and environmental protection costs must be considered. Excavation costs should always be preceded by test borings. Many unforeseen conditions can affect the actual expenses once work begins.

Excavation is usually priced by the cubic yard (cubic meter). Finding the excavation volume starts with the topographic map of the job site. The area whose soil is to remain undisturbed is bounded by a *neat line* (also known as a *net line*). When the ground is irregular, the work area should be divided into areas with similar elevations.

When calculating estimates, trenching (whether by hand or with equipment) should be kept separate from large areas of excavation due to difficulty in maneuvering in trenches. Excavations for walls and footings should include an allowance (e.g., a minimum of 1 ft (0.3 m)) on all sides for working room. For manual excavation, costs for picking (i.e., loosening the soil), throwing out, and wheeling away should be separated.

Considerable judgment is required to produce original estimates of excavation costs. For that reason, it is common to rely on "standard" values, such as *Building Construction Cost Data*, *Standard Site Work Cost Data*, and *Heavy Construction Cost Data*, all from R.S. Means, for costs and production capacities.

## 20. SLOPE AND EROSION CONTROL FEATURES

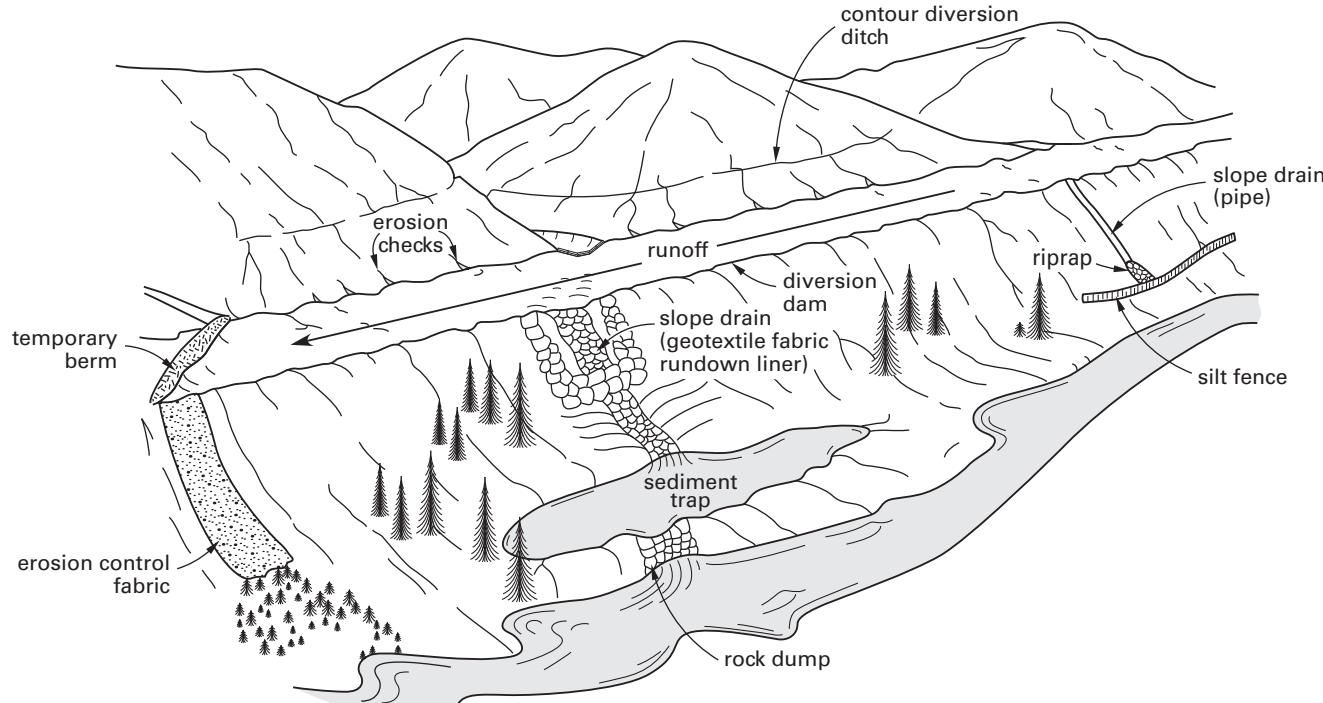

Almost all excavation requires temporary control measures to control erosion and water pollution of the construction job site and surrounding areas. These measures include berms, dikes, dams, sediment basins,

fiber mats, netting, mulches, grasses, slope drains, temporary silt fences, and other control devices. (See Fig. 80.12.) Construction details vary with agency and may be specified by contract.

A *temporary berm* is constructed of compacted soil, with or without a shallow ditch, at the top of fill slopes or transverse to centerline on fills. Berms are used temporarily at the top of newly constructed slopes to prevent excessive erosion until permanent controls are installed or slopes stabilized. A temporary berm is constructed of compacted soil, typically with a minimum width of 24 in (60 cm) at the top and a minimum height of 12 in (30 cm). Berms over which vehicles move may be wider. Temporary berms should drain to a compacted outlet through a slope drain. The area adjacent to the berm in the vicinity of the slope drain should be properly graded to enable this inlet to function efficiently and with minimum ponding in this area. Transverse berms required on the downstream side of a slope drain should extend across the grade to the highest point at approximately a 10° angle from the perpendicular to centerline.

A temporary *slope drain* is a feature consisting of stone gutters, fiber mats, plastic sheets, concrete or asphalt gutters, half-round pipe, metal pipe, plastic pipe, sod, or other material to carry water down slopes. The slope drain reduces erosion by carrying water accumulating in the cuts and on the fills down the slopes prior to the installation of permanent facilities or the growth of adequate ground cover on the slopes. Fiber matting and plastic sheeting should not be used on slopes steeper

**Figure 80.12** Temporary Control Measures

Source: Wyoming Department of Transportation.

than 4:1 V:H except for short distances of 20 ft (6 m) or less. Temporary slope drains must be anchored to the slope to prevent disruption by the force of the water flowing in the drains. The base for temporary slope drains should be compacted and concavely formed to channel the water or hold the slope drain in place. The inlet end should channel water into the temporary slope drain. Energy dissipaters (rock dumps or basins) are needed at the outlet ends of slope drains to prevent erosion downstream and to collect sediment.

A *sediment structure* is an energy-dissipating rock dump, basin, pond, and trap that catches and stores sediment from upstream erodible areas in order to protect properties and stream channels, including culverts and pipe structures, below the construction site from excessive siltation. Sediment structures should be at least twice as long as they are wide.

A *check dam* is a barrier composed of logs and poles, large stones, or other material placed across a natural or constructed drainway to retard stream flow and catch small sediment loads. A check dam should be keyed into the sides and bottom of the channel a minimum depth of 2 ft (0.6 m).

*Temporary seeding and mulching* are measures consisting of seeding, mulching, fertilizing, and matting utilized to reduce erosion. Typically, all cut and fill slopes, including waste sites and borrow pits, should be seeded. Mulch on slopes exceeding a 3:1 V:H ratio should be held in place by an erosion control fabric.

*Brush barriers* consist of brush, tree trimmings, shrubs, plants, and other refuse from the clearing and grubbing operation. Brush barriers should be placed on natural ground at the bottom of fill slopes (where the areas most likely to erode are located) to restrain sedimentation particles. Brush barriers should be constructed approximately parallel to original ground contour. A brush barrier should be compressed to an approximate height of 3–5 ft (0.9–1.5 m) and approximate width of 5–10 ft (1.5–3.0 m). An embankment should not be supported by brush barriers.

*Baled hay or straw erosion checks* are temporary measures to control erosion and prevent siltation. Bales may be either hay or straw containing 5 ft<sup>3</sup> (0.14 m<sup>3</sup>) or more of material. Baled hay or straw checks should be used where the existing ground slopes toward or away from the embankment along the toe of slopes, in ditches, or other areas where siltation erosion or water runoff is a problem. Hay or straw erosion checks should be embedded in the ground 4–6 in (10–15 cm) to prevent water flowing under them. The bales should also be anchored securely to the ground by wooden stakes driven through the bales into the ground.

*Temporary silt fences* are temporary measures utilizing woven wire (wire mesh) or other material attached to posts with *filter cloth* composed of burlap, plastic filter fabric, and so on. They are attached to the upstream side of the fence to retain the suspended silt particles in

the runoff water. Temporary silt fences should be placed on the natural ground, at the bottom of fill slopes, in ditches, or other areas where siltation is expected.

*Erosion control fabric* is used on steep slopes to prevent erosion of soil and mulch. Fabric should be unrolled and draped loosely, without stretching, so that continuous ground contact is maintained. In ditches, fabric should be unrolled and applied parallel to the flow direction. On slopes, fabric should normally be applied parallel to the slope direction. In ditches and on slopes, each fabric end (upslope and downslope) should be buried in a 4 in (10 cm) trench, stapled on 9 in (23 cm) centers, back-filled, and tamped. When splicing fabric longitudinally, the upslope piece should be brought over the end of the downslope roll so that there is a 12 in (30 cm) overlap placed in a 4 in (10 cm) trench, stapled on 9 in (23 cm) centers, backfilled, and tamped. On slopes with lateral overlaps of multiple widths, edges should be overlapped and stapled at 18–24 in (46–61 cm) intervals. The body of the fabric should be stapled in a rectangular grid pattern with a maximum staple spacing of 3 ft (1 m) each way.

Erosion of ditches can be prevented by using a *ditch lining fabric* (mat) fastened to the ground with stakes, U-staples, or wire. Ground fasteners should penetrate at least 8 in (20 cm) in the ground. Use of survey stakes is preferred when high velocity and/or large volumes of water are expected.

## 21. SITE DEWATERING

Some job sites must be dewatered prior to excavation. *Dewatering (unwatering)* is simply the removal of water from the job site, typically requiring a lowering of the water table. In some cases, the job site may be surrounded by waterproof barriers. Dewatering almost always involves the use of high-capacity wells with submersible pumps, or vacuum wellpoint methods. In addition to the cost of installation, operational costs are primarily a function of the volume of water removed.

Deep wells use submersible electric pumps to lower the water table, bringing the job site into the well's *cone of depression*. The soil's permeability and the pump's power determine the volume of water that can be removed. Typically, several deep wells surrounding or ringing the job site will be used. The *Dupuit equation* can be used to predict the steady-state drawdown and volumetric flow from a deep *penetrating well* (i.e., a well that penetrates all the way down to an impermeable layer). More advanced methods are required to predict the transient performance and the performance of a non-penetrating well.

Vacuum dewatering uses wellpoints to draw water up small-diameter (e.g., 2 in (50 mm)) tubes with side perforations (integral strainers) in the liquid water zone. Wellpoints are typically jetting into position. This method is typically used when the dewatering depth is less than about 15–20 ft (5–7 m), since the vertical lift is

limited by the practical vacuum achievable. Wellpoints can be installed throughout a job site; however, they are typically installed around its periphery. Individual wellpoints are connected with flexible hoses to a manifold (header pipe) which is connected to the wellpoint vacuum pump. The wellpoint pump is selected to handle the liquid water, as well as entrained gasses found in the water. Sites can be dewatered to depths greater than 15–20 ft (5–7 m) by using multiple wellpoint stages.

## Construction Staking and Layout

1. Staking ..... 81-1
2. Stake Markings ..... 81-1
3. Establishing Slope Stake Markings ..... 81-4

### Nomenclature

	d	distance	ft	m
	h	height	ft	m
HI	height of instrument		ft	m
s	side-slope ratio	—	—	—
w	width	ft	m	—

### 1. STAKING

Surveying markers are referred to as *construction stakes*, *alignment stakes*, *offset stakes*, *grade stakes*, or *slope stakes*, depending on their purpose. Stakes come in different sizes, including  $1 \times 2 \times 18$  markers,  $5/16 \times 1\frac{1}{2} \times 24$  *half-lath stakes*, and various lengths (usually 12 in or 18 in) of  $2 \times 2$  *hubs* and  $1 \times 1$  *guineas*. (All measurements are in inches.) Fill stakes can be ripped diagonally lengthwise to give them a characteristic shape. Pin flags, full-length lagging, or colored paint may be used to provide further identification and visibility.

Distances are measured in feet or meters, with precisions depending on the nature of the feature being documented. (See Table 81.1.) A precision of 0.1 ft (30 mm) vertically and 0.5 ft (150 mm) horizontally is considered standard with earthwork (e.g., setting slope stakes). A precision of 0.01 ft (3 mm) is considered standard for locating curb and alignment stake positions and elevations so that the feature can be built to within 0.1 ft (30 mm). Bridges and buildings are located with higher precision.

### 2. STAKE MARKINGS

Stake markings vary greatly from agency to agency. The abbreviations shown in Table 81.2 and the procedures listed in this chapter are typical but not universal.

The front (the side facing the construction) and back are marked permanently using pencil, carpenter's crayon, or permanent ink markers. Stakes are read from top to bottom. The front of the stake is marked with *header information* (e.g., RPSS, offset distance) and *cluster information* (e.g., horizontal and vertical measurements, slope ratio). The header is separated from the first cluster by a double horizontal line. Multiple clusters are separated by single horizontal lines. All

**Table 81.1** Typical Required Accuracy for Construction Survey Staking

feature	accuracy (ft)
route alignment: PC, POT, PI, PT, CP, and BM	0.01
building	0.01
bridge, stationing	0.01
highway intersection	0.01
hub, paving	0.01
staking, final (blue tops)	0.05
culvert, box, length	0.1
hub, line	0.1
road, country	0.1
staking, rough grade	0.1
staking, slope (vertical)	0.1
culvert, stationing	1.0
farmstead drive	1.0
field entrance	1.0
pipe, drainage (stationing and length)	1.0
pole: telephone or power	1.0
well, stationing	1.0

(Multiply ft by 0.3048 to obtain m.)

cluster information is measured in the same direction from the same point.

Words like "from" and "to" are understood and are seldom written on a stake. For example, "2.0 FC" and "4.3 FG" mean "2.0 ft from the face of the curb" and "4.3 ft above the finished grade," respectively.

Many times, measurements are taken from a *hub stake*, also referred to as a *ground stake* or *reference point stake*, which is driven flush with the ground. No markings are made on hub stakes, since such stakes are entirely below grade.

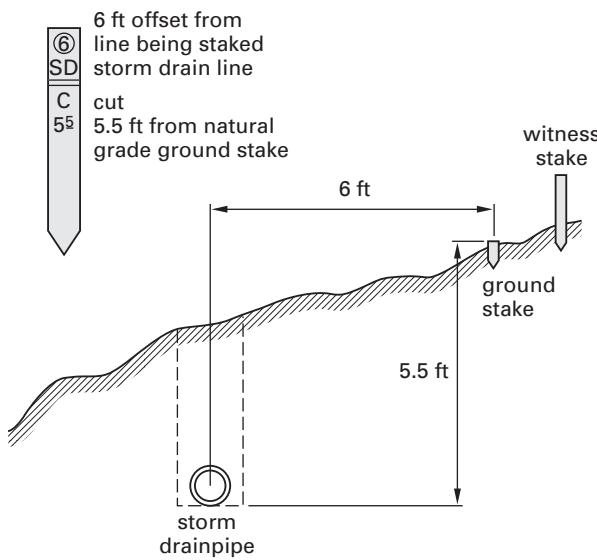

Hub stakes are located, identified, and protected by witness stakes or guard stakes. A *witness stake* calls attention to a hub stake but does not itself locate a specific point. A *guard stake* may be driven at an angle with its top over the flush-driven hub stake.

The back of a witness stake is used to record the station and other information, including literal descriptions (e.g., "at ramp"). Other information identifying the survey may also be included on the back. Actual elevations, when included, are marked on the thin edge of the stake. Figure 81.1 illustrates how a construction stake would be marked to identify a trench for a storm drain.

**Table 81.2** Common Stake Marking Abbreviations\*

@	from the	HP	hinge point
1/4SR	quarter point of slope rounding	INL	inlet
1/2SR	midpoint of slope rounding	INT	intersection

EW	end wall	STR	structure
F	fill	SW	sidewalk
FC	face of curb	TBC	top back of curb
FDN	foundation	TBM	temporary benchmark
FE	fence	TC	toe of curb or top of curve
FG	finish grade	TOE	toe
FGS	final grade stake	TOP	top
FH	fire hydrant	TP	turning point
FL	flow line or flared	TW	traveled way
FLC	flow line curb	VP	vent pipe
FTG	footing	WALL	wall
G	grade	WL	water line
GRT	grate	WM	water meter
GS	gutter slope	WV	water valve
GTR	gutter	WW	wingwall
GUT	gutter		

\*Compiled from various sources. Not intended to be exhaustive. Differences may exist from agency to agency.

**Figure 81.1** Construction Stake for Storm Drain

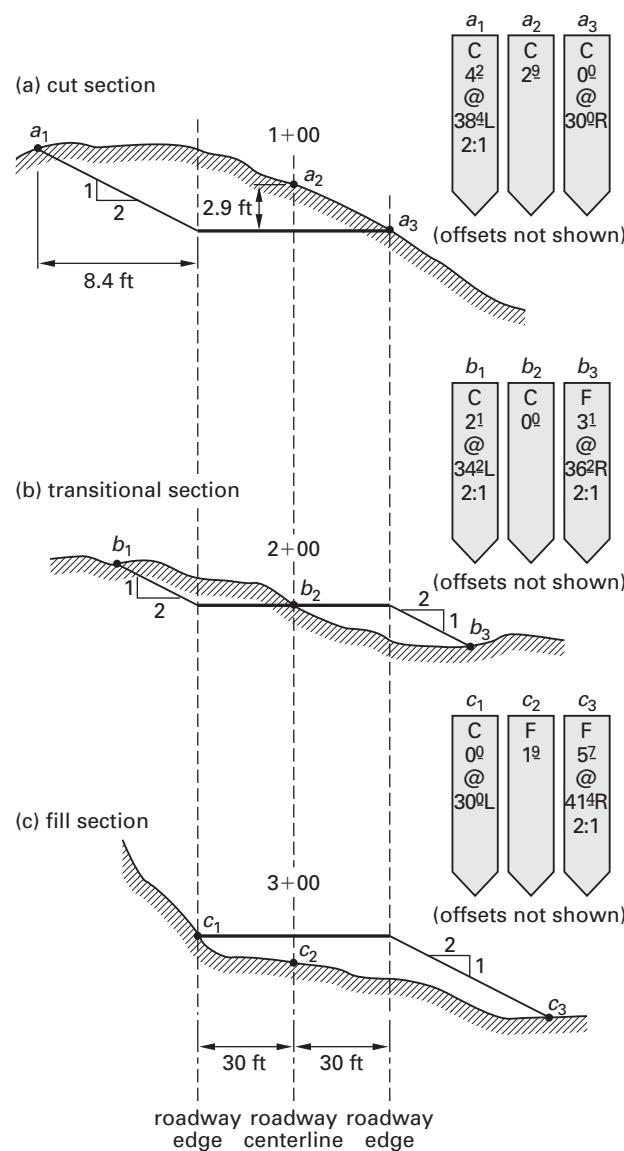

A stake both locates and identifies a specific point. A distance referenced on a stake **is measured from the natural ground surface at the point** where the stake is driven. Another system involves measuring from a tack or a reference mark on the stake itself. A *crow's foot*, which consists of a horizontal line drawn on the stake with a vertical arrow pointing to it, may be used. A crow's foot should be drawn on the edge of the stake.

**Alignment stakes** marked with the station indicate centerline alignment along a proposed roadway. They are placed every half, whole, or even-numbered station along tangents with uniform grade, and at every quarter or half station along horizontal and vertical curve alignments.

**Offset stakes** are used to mark excavations. Offset stakes are offset from the actual edge to protect the stakes from earthmoving and other construction equipment. The offset distance is circled on the stake and is separated from the subsequent data by a double line. For close-in work, the offset distance may be standardized, such as at 2 ft (61 cm). For highway work, offset stakes can be set at 25 ft, 50 ft, or 100 ft (8 m, 15 m, or 30 m) from the alignment centerline. Unless a separate ground stake or hub is used, distances (e.g., cuts, fills, and distances to centerline) marked on an offset stake refer to the point of insertion, not to the imaginary point located the offset distance away.

**Slope stakes** indicate **grade points**—points where the cuts and fills begin and the planned side slopes intersect the natural ground surface. Slope stakes are marked “SS” to indicate their purpose. Typically, they are placed with a 10 ft (3 m) offset. Figure 81.2 illustrates the use of slope stakes along three adjacent sections of a proposed highway.

In addition to indicating the grade point, the front of slope stakes are marked to indicate the nature of the earthwork (i.e., “C” for “cut” and “F” for “fill”), the offset

**Figure 81.2** Slope Stakes Along a Highway

distance, the type of line being staked, the distance from the centerline or control line, the slope to finished grade, and the elevation difference between the grade point and the finished grade. Distances from the centerline can be marked “L” or “R” to indicate whether the stake points are to the left or the right of centerline when looking up-station (i.e., ahead on stationing). The station is marked on the stake back.

For example, a stake’s front face markings, “C 4.2 FG @ 38.4L CL 2:1,” would be interpreted as “cut with 2:1 slope is required; stake set point is 4.2 ft above the finished grade; stake is 38.4 ft to the left of the centerline of the roadway.” The use of FG is optional.

Slope stakes can be driven vertically or at an angle, depending on convention. When driven at an angle, slope stakes slant outward, pointing away from the earthwork, when fill is required; and they slope inward,

toward the earthwork, when a cut is required. Stakes are set with the front face toward the construction.

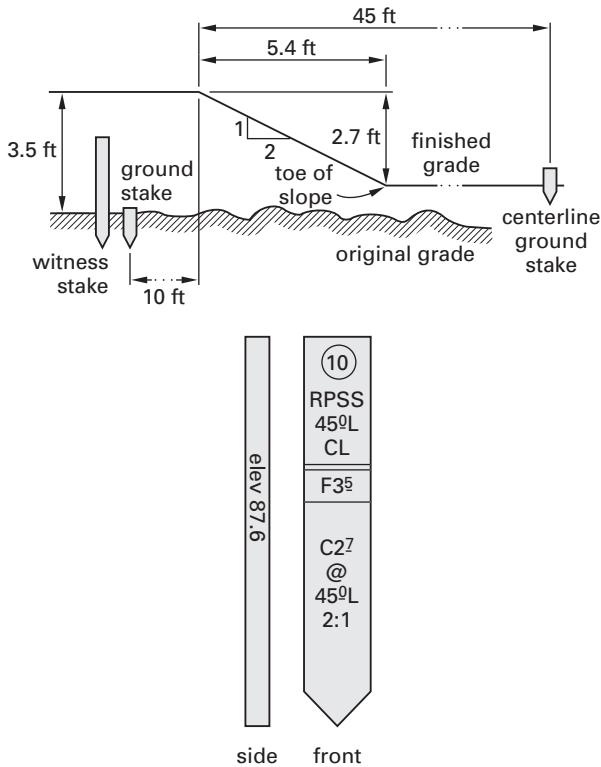

Hubs and other ground stakes without offsets are not used with fill stakes, since they would be covered during construction. For shallow and moderate fills, a fill stake alone is used. A crow's foot may be marked on the stake to indicate the approximate finished grade, or the top of the stake may be set to coincide with the approximate finished grade. For deeper fills, offset stakes are required.

Not all earthwork produces a straight slope. Some earthwork results in a smooth-curved ground surface between two lateral points. The points where the grading begins and ends are marked "BSR" (*begin slope rounding*) and "ESR" (*end slope rounding*), rather than the analogous grade point.

A line of stakes at adjacent grade or ESR points is known as a *daylight line*. Therefore, the term *daylight stake* can be used when referring to the stakes marking the grade or ESR points.

### Example 81.1

While checking the work of a surveying crew along a highway, you encounter the ground stake and its accompanying witness stake as shown. What is the elevation at the toe of the slope documented by the witness stake?

### Solution

The witness stake indicates that the ground stake is a reference point slope stake located 10 ft away from the point where excavation begins, 45.0 ft to the left of centerline when looking up-station. The elevation of the ground stake, marked on the side of the witness stake, is 87.6 ft. The earthwork starts out with a 3.5 ft fill. Then, the earth is cut away at a 2:1 slope until the finished grade is reached, 2.7 ft below.

The elevation at the toe of the slope is the same as the elevation of the finished grade.

$$\begin{aligned}\text{elev}_{\text{slope toe}} &= \text{elev}_{\text{ground stake}} + \text{fill} - \text{cut} \\ &= 87.6 \text{ ft} + 3.5 \text{ ft} - 2.7 \text{ ft} \\ &= 88.4 \text{ ft}\end{aligned}$$

### 3. ESTABLISHING SLOPE STAKE MARKINGS

The markings on a construction stake are determined from a survey of the natural ground surface. This survey requires two individuals: one, the *leveler* or *instrument person*, to work the instrument, and the other, the *rod person*, to hold the leveling rod. The elevation of the instrument (or the elevation of the ground at the instrument location) and the height of the instrument above the ground must be known if actual elevations are to be marked on a stake. The term "height of the instrument" (HI) is the elevation of the instrument above the reference datum.

$$\begin{aligned}\text{HI} &= \text{elev}_{\text{ground}} + \text{instrument height above the ground} \\ &= \text{elev}_{\text{ground}} + \text{ground rod}\end{aligned}\quad 81.1$$

The *rod reading*, or *ground rod*, is the sighting made through a leveling instrument at the rod held vertically at the grade point. The *grade rod*, short for *grade rod reading* and *rod reading for grade*, is the reading that would be observed on an imaginary rod held on the finished grade elevation. The grade rod is calculated from the planned grade elevation and the height of the instrument.

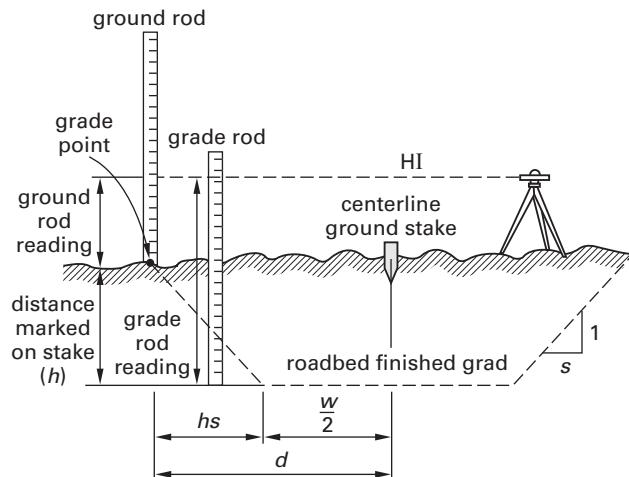

$$\text{grade rod} = \text{HI} - \text{elev}_{\text{grade}} \quad 81.2$$

The distance, *h*, marked on a construction stake, or the cut or fill, is the distance between natural and finished grade elevations and is easily calculated from the ground and grade rods. The cut or fill stake marking is the difference between grade and ground rod elevations. The actual steps taken to calculate the stake marking depend on whether the earthwork is a cut or a fill and whether the instrument is above or below the finished

grade. Drawing a diagram will clarify the algebraic steps and prevent sign errors. (See Fig. 81.3.)

$$h = \text{grade rod} - \text{ground rod} \quad 81.3$$

**Figure 81.3** Determining Stake Location

The distance from grade point to centerline or other control is also written on the stake. If  $w$  is the width of the finished surface,  $s$  is the side slope ratio (as horizontal:vertical), and  $h$  is the cut or fill at the grade point, then the horizontal distance,  $d$ , from the grade point to the centerline stake of the finished surface is calculated using Eq. 81.4. In the field, the stake location is found by trial and error.

$$d = \frac{w}{2} + hs \quad 81.4$$

## 1. INTRODUCTION

Local jurisdictions (including states) may write their own building codes, but in most cases, a model code is adopted into law by reference. A *model code* is one that has been written by a group comprised of experts knowledgeable in the field, without reference to any particular geographical area. Adopting a model code allows a city, county, or district to have a complete, workable building code without the difficulty and expense of writing its own. If certain provisions need to be added or changed to suit the particular requirements of a municipality, the model code is enacted with modification. Even when a city or state writes its own code, that code is usually based on a model code. Exceptions include some large cities, such as New York City, New York, and Chicago, Illinois, and a few states that have adopted the *NFPA 101: Life Safety Code* published by the *National Fire Protection Association (NFPA)*.

The primary model code is the *International Building Code (IBC)*, first published in 2000 by the *International Code Council (ICC)* and updated every three years. The IBC is an amalgam of the work of the three code-writing groups that previously published the three model codes in the United States. The IBC combines provisions of all three of the previous model codes and is organized in the same format that the three code-writing groups used in the most recent editions of their codes. Jurisdictions in all states have adopted one or more of the family of international codes and some states have adopted the IBC on a statewide level or have used it as a basis for writing their own codes.

The three legacy model codes previously published and still used by some jurisdictions in the United States include the following.

- the *Uniform Building Code (UBC)*, previously used in the western and central portions of the United States and published by the International Conference of Building Officials (ICBO)
- the *BOCA National Building Code (BOCA/NBC)*, previously used in the northeastern part of the United States and published by the Building Officials and Code Administrators International (BOCA)
- the *Standard Building Code (SBC)*, previously used in much of the southeastern United States and published by the Southern Building Code Congress International (SBCCI)

The *Comprehensive Consensus Codes*, also known as the *C3* set, is a competing code set authored by the 100+ year-old NFPA, in conjunction with the International Association of Plumbing and Mechanical Officials (IAPMO), Western Fire Chiefs Association (WFCA), and the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE).<sup>1</sup> The *C3* set arose out of contentious disagreement between the ICC and NFPA (and their respective supporters), which did not want their established model codes abandoned. The *C3* set is a comprehensive collection of model codes that include the *NFPA 5000* building construction and safety code, the *NFPA 1: Uniform Fire Code*, the *NFPA 101: Life Safety Code*, the *NFPA 70: National Electrical Code (NEC)*, the *Uniform Plumbing Code (UPC)*, and the *Uniform Mechanical Code (UMC)*. The *C3* set was first published in 2002 and is updated approximately every three years. Acceptance and adoption of the *C3* set has been scant, although the NEC continues to serve as the model standard for virtually all U.S. electrical design and construction. Although the ICC has written its own plumbing and mechanical codes (the *International Plumbing Code (IPC)* and the *International Mechanical Code (IMC)*), it has not written an electrical code. The IBC refers to the NEC and other NFPA publications for this purpose, albeit with amendments.

This book is based on the IBC exclusively.

<sup>1</sup>Most people refer to the *C3* set as *NFPA 5000*, using the name of the building construction and safety code provisions within it.

## 2. BUILDING REGULATIONS

Building codes are only one type of regulation affecting the design and construction of buildings. Additional requirements that may be applicable include legal and administrative regulations at the federal, state, and local levels. For example, a state may enforce environmental protection rules, while the building codes used in that state may not regulate environmental impact at all.

### State and Federal Regulations

Most states have agencies that regulate building in some way. In addition to a state building code, a state government may enforce energy codes, environmental regulations, fabric flammability standards, and specific rules relating to state government buildings, institutions, hospital buildings, housing, emergency services, and other facilities.

At the national level, several federal agencies may regulate a construction project, ranging from military construction to the building of federal prisons. Certain federal agencies may also regulate or issue rules covering a specific aspect of construction, such as the safety-glazing requirement issued by the Consumer Product Safety Commission (CPSC).

### Local Regulations

Local codes may include amendments to the model building code in use. These amendments usually pertain to specific concerns or needs of a geographical region or are provisions designed to alleviate local problems that are not addressed in the model codes. For example, a local amendment in a mountainous area might require a higher snow-load factor for roof design based on the local climate.

Local regulations may also affect the construction and operation of hospitals, nursing homes, restaurants, schools, and similar institutions, as well as police, fire, and emergency response agencies.

## 3. BUILDING CODES

The IBC and each of the three previously published model codes are prescriptive-based as opposed to performance-based. This means that the code describes specific materials and methods of construction, or how a building component or design must be designed, as opposed to how it is supposed to function. In most cases, the codes refer to nationally recognized standards of materials and testing, so that if a building component meets the test standard, it can be used. New or untested materials and construction methods can be used if they can pass the performance-based testing or if they can otherwise be shown to meet the requirements of the code.

Building codes are written to protect the health, safety, and welfare of the public, but they are based on the concept of the “least acceptable risk.” This is the

minimum level required for building and occupant safety (even though just “meeting the code” is not always the best construction for a given circumstance).

Building codes differ from zoning ordinances, easements, deed restrictions, and other regulations affecting the use and planning of land. Zoning ordinances, for example, deal with the use of a piece of property, the density of buildings within a district and on a lot, the locations of buildings on a property, floor-area ratio, building height, and parking.

### Legal Basis of Codes

In the United States, the authority for adopting and enforcing building codes is one of the powers reserved to the states by the Tenth Amendment to the United States Constitution. Each state, in turn, may retain those powers or delegate some of them to lower levels of government, such as counties or cities. Because of this division of power, the authority for adopting and enforcing building codes varies among the states.

**Building codes are usually adopted and enforced by local governments**, either by a municipality or, in the case of sparsely populated areas, a county or district. A few states write their own codes or adopt a model code statewide.

Codes are enacted as laws, just as any other local regulation would be. Before construction, a building code is enforced through the permit process, which requires that builders submit plans and specifications to the **authority having jurisdiction (AHJ)** for checking and approval before a building permit is issued. During construction, the AHJ conducts inspections to verify that building is proceeding according to the approved plans.

Even though **code enforcement is the responsibility of the local building department or the AHJ**, the architect and engineer are responsible for designing a building in conformance with all applicable codes and regulations. This is because an architect or engineer is required by registration laws to practice lawfully in order to protect the health, safety, and welfare of the public.

### Adjuncts to Building Codes

In addition to building codes, there are companion codes that govern other aspects of construction. The same groups that publish the model building codes publish these companion codes. For example, the ICC also publishes the *International Residential Code* (IRC), the *International Fire Code* (IFC), the *International Mechanical Code* (IMC), the *International Plumbing Code* (IPC), and the *International Zoning Code* (IZC), among others.

The electrical code used by all jurisdictions is the *National Electrical Code* (NEC), published by the NFPA. In order to maintain greater uniformity in building regulations, the ICC does not publish an electrical code, but relies on the NEC.

Model codes also make extensive use of industry standards that are developed by trade associations, such as the Gypsum Association (GA); government agencies; standards-writing organizations, such as ASTM International and the NFPA; and standards-approving groups, such as the American National Standards Institute (ANSI). Standards are adopted into a building code by reference name, number, and date of latest revision. For example, most codes adopt by reference the American National Standard ICC/ANSI A117.1, *Accessible and Usable Buildings and Facilities*. This standard was developed by the ICC based on previous ANSI accessibility standards and is approved by ANSI.

#### 4. TESTING AND MATERIAL STANDARDS

All approved materials and construction assemblies referred to in building codes are required to be manufactured according to accepted methods or tested by approved agencies according to standardized testing procedures, or both. There are hundreds of standardized tests and product standards for building materials and constructions. Some of the more common ones are listed in this section. Information about additional soils tests is included in Chap. 35 of this book, and concrete testing is included in Chap. 48 and Chap. 49 of this book.

As previously stated, standards are developed by trade associations, standards-writing organizations, and government agencies. By themselves, standards have no legal standing. Only when they are referred to in a building code and that code is adopted by a governmental jurisdiction do standards become enforceable.

##### Standards-Writing Organizations

ASTM International is one organization that publishes thousands of standards and test procedures that prescribe, in detail, such things as how the test apparatus must be set up, how materials must be prepared for the test, the length of the test, and other requirements. If a product manufacturer has one of its materials successfully tested, it will indicate in its product literature what tests the material has passed. Standards are developed through the work of committees of experts in a particular field. Although ASTM International does not actually perform tests, its procedures and standards are used by testing agencies.

The NFPA is another private, voluntary organization that develops standards related to the causes and prevention of destructive fires. The NFPA publishes hundreds of codes and standards in a multivolume set that covers the entire scope of fire prevention including sprinkler systems, fire extinguishers, hazardous materials, firefighting, and much more. As mentioned earlier in this chapter, the NFPA has published its own building code, *NFPA 5000*.

Other standards-writing organizations are typically industry trade groups that have an interest in a particular material, product, or field of expertise. Examples of

such trade groups include ASHRAE, the Illuminating Engineering Society (IES), the GA, the American Concrete Institute (ACI), the American Iron and Steel Institute (AISI), and the American Institute of Timber Construction (AITC), among others. There are hundreds of construction trade organizations such as these.

ANSI is a well-known organization, but unlike the other standards-writing groups, ANSI does not develop or write standards. Instead, it approves standards developed by other organizations and works to avoid duplications between different standards. The ANSI approval process ensures industry consensus for a standard and avoids duplication of standards. For example, ANSI 108, *American National Standard Specifications for the Installation of Ceramic Tile*, was developed by the Tile Council of America and reviewed by a large committee of widely varying industry representatives. Although the ANSI approval process does not necessarily represent unanimity among committee members, it requires much more than a simple majority and requires that all views and objections be considered, and that a concerted effort be made toward their resolution.

##### Testing Laboratories

When a standard describes a test procedure or requires one or more tests in its description of a material or product, a testing laboratory must perform the test. A standards-writing organization may also provide testing, but in most cases a Nationally Recognized Testing Laboratory (NRTL) must perform the test. An NRTL is an independent laboratory recognized by the Occupational Safety and Health Administration (OSHA) to test products to the specifications of applicable product safety standards.

One of the most well-known NRTLs is Underwriters Laboratories (UL). Among other activities, UL develops standards and tests products for safety. When a product successfully passes the prescribed test, it is given a UL label. There are several types of UL labels, and each means something different.

When a complete and total product is successfully tested, it is *listed*. This means that the product passed the safety test and is manufactured under the UL follow-up services program. Such a product receives a *listed label*.

Another type of label is the *classified label*. This means that samples of the product were tested for certain types of uses only. In addition to the classified label, the product must also carry a statement specifying which conditions were tested. This allows field inspectors and others to determine if the product is being used correctly.

One of the most common uses of UL testing procedures is for doors and other opening protections. For example, fire doors are required to be tested in accordance with UL 10B, *Fire Tests of Door Assemblies*, and to carry a UL

label. The results of UL tests and products that are listed are published in UL's *Building Materials Directory*.

### Types of Tests and Standards

There are hundreds of types of tests and standards for building materials and assemblies that examine a wide range of properties, from fire resistance to structural integrity to durability to stain resistance. Building codes indicate what tests or standards a particular type of material must satisfy in order to be considered acceptable for use.

ASTM International has established a number of standard soils tests, which are summarized in Chap. 35 of this book. Other materials testing procedures are summarized in Chap. 43 of this book.

### Destructive vs. Nondestructive Tests

Construction materials testing, a form of field quality control, helps to determine conformance to project specifications during construction, thus preventing costly damages resulting from substandard materials and/or unsatisfactory materials installation.

**Nondestructive testing (NDT)**, also called **nondestructive evaluation (NDE)** and **nondestructive inspection (NDI)**, is testing that does not destroy the test object. NDE is vital for constructing and maintaining all types of components and structures. To detect different defects such as cracking and corrosion, there are different **methods of testing** available.

- *Magnetic particle testing (MT)* identifies surface and near-surface discontinuities that are in ferromagnetic materials.
- *Dye penetrant testing (PT)* identifies surface discontinuities on alloy steel, aluminum, magnesium, brass, bronze, plastic, and glass objects using color contrast and fluorescence.
- *Radiographic inspection (RT)* identifies internal defects of a variety of materials using X-rays.
- *Ultrasonic testing (UT)* is a highly specialized field that is performed in both field and laboratory settings.

While destructive testing usually provides a more reliable assessment of the state of the test object, destruction of the test object usually makes this type of test more costly to the test object's owner than nondestructive testing. Destructive testing is also inappropriate in many circumstances, such as forensic investigation. That there is a trade-off between the cost of the test and its reliability favors a strategy in which most test objects are inspected nondestructively; destructive testing is performed on a sampling of test objects that are drawn randomly for the purpose of characterizing the testing reliability of the nondestructive test.

### 5. FIRE RESISTIVITY

The most important types of tests for building components are those that rate the ability of a construction assembly to prevent the passage of fire and smoke from one space to another, and tests that rate the degree of flammability of a finish material. The following summaries include common construction materials tests and fire testing for building products.

Three tests are commonly used for fire-resistant assembly ratings. These include ASTM E119, NFPA 252, and NFPA 257.

#### ASTM E119

One of the most commonly used tests for fire resistance of construction assemblies is ASTM E119, *Standard Test Methods for Fire Tests of Building Construction and Materials*. This test involves building a sample of the wall or floor/ceiling assembly in the laboratory and applying a standard fire on one side of it using controlled gas burners. Monitoring devices measure temperature and other aspects of the test as it proceeds.

There are two parts to the ASTM E119 test, the first of which measures heat transfer through the assembly. The goal of this test is to determine the temperature at which the surface or adjacent materials on the side of the assembly not exposed to the heat source will combust. The second is the "hose stream" test, which uses a high-pressure hose stream to simulate how well the assembly stands up to impacts from falling debris and the cooling and eroding effects of water. Overall, the test evaluates an assembly's ability to prevent the passage of fire, heat, and hot gases for a given amount of time. A similar test for doors is NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*.

Construction assemblies tested according to ASTM E119 are given a rating according to time. In general terms, this rating indicates the amount of time an assembly can resist a standard test fire without failing. The ratings are 1 hr, 2 hr, 3 hr, or 4 hr. Doors and other opening assemblies can also be given 20 min, 30 min, and 45 min ratings.

#### NFPA 252

NFPA 252, *Standard Methods of Fire Tests of Door Assemblies*, evaluates the ability of a door assembly to resist the passage of flame, heat, and gases. It establishes a time-based fire-endurance rating for the door assembly, and the hose stream part of the test determines if the door will stay within its frame when subjected to a standard blast from a fire hose after the door has been subjected to the fire-endurance part of the test. Similar tests include UL 10B and UL 10C.

#### NFPA 257

NFPA 257, *Standard on Fire Test for Window and Glass Block Assemblies*, prescribes specific fire and hose

stream test procedures to establish a degree of fire protection in units of time for window openings in fire-resistive walls. It determines the degree of protection to the spread of fire, including flame, heat, and hot gasses.

Flammability tests for building and finish materials determine the following.

- whether or not a material is flammable, and if so, whether it simply burns with applied heat or supports combustion (adds fuel to the fire)
- the degree of flammability (how fast fire spreads across it)
- how much smoke and toxic gas it produces when ignited

## 6. FIRE-RESISTANCE STANDARDS

Building codes recognize that there is no such thing as a fireproof building; **there are only degrees of fire resistance**. Because of this, **building codes specify requirements for two broad classifications of fire resistance** as mentioned in the previous section: **resistance of materials and assemblies, and surface burning characteristics of finish materials**. While architects would consider both in the design process, engineers are concerned primarily with the former.

### Construction Materials and Assemblies

In the first type of classification, the amount of fire resistance that a material or construction assembly must have is specified in terms of an hourly rating as determined by ASTM E119 for walls, ceiling/floor assemblies, columns, beam enclosures, and similar building elements. Codes also specify what time rating doors and glazing must have as determined by NFPA 252 or NFPA 257, respectively. For example, exit-access corridors are often required to have at least a 1 hr rating, and the door assemblies in such a corridor may be required to have a 20 min rating.

Building codes typically include tables indicating what kinds of construction meet various hourly ratings. Other sources of information for acceptable construction assemblies include UL's *Building Materials Directory*, manufacturers' proprietary product literature, and other reference sources.

Various building elements must be protected with the types of construction specified in IBC Table 601 and elsewhere in the code. (See Table 82.1.) When a fire-resistive barrier is built, any penetrations in the barrier must also be fire-rated. This includes doors, windows, and ducts. Duct penetrations are protected with fire dampers placed in line with the wall. If a fire occurs, a fusible link in the damper closes a louver that maintains the rating of the wall. The fire resistance ratings of

existing building components are important in determining the construction type of the building. This is discussed in more detail in a later section on classification based on construction type.

It is important to note that many materials by themselves do not create a fire-rated barrier. It is the construction assembly of which they are a part that is fire-resistant. A 1 hr rated suspended ceiling, for example, must use rated ceiling tile, but it is the assembly of tile, the suspension system, and the structural floor above that carries the 1 hr rating. In a similar way, a 1 hr rated partition may consist of a layer of  $\frac{5}{8}$  in (15.9 mm) Type X gypsum board, also known as drywall and plasterboard, attached to both sides of a wood or metal stud according to certain conditions. A single piece of gypsum board cannot have a fire-resistance rating by itself, except under special circumstances defined by the IBC.

## 7. ADMINISTRATIVE REQUIREMENTS OF BUILDING CODES

All building codes include a chapter dealing with the administration of the code itself. Provisions that are normally part of the administrative chapter include what codes apply, the duties and powers of the building official, the permit process, what information is required on construction documents, fees for services, how inspections are handled, and what kinds of inspections are required. Also included are the requirements for issuing a certificate of occupancy, instructions on how violations are handled, and the provisions for appealing the decisions of the building official concerning the application and interpretation of the code.

## 8. REQUIREMENTS BASED ON OCCUPANCY

*Occupancy* refers to the type of use of a building or interior space, such as an office, a restaurant, a private residence, or a school. Uses are grouped by occupancy based on similar life-safety characteristics, fire hazards, and combustible contents.

The idea behind occupancy classification is that some uses are more hazardous than others. For example, a building where flammable liquids are used is more dangerous than a single-family residence. Also, residents of a nursing home will have more trouble exiting than will young school children who have participated in fire drills. In order to achieve equivalent safety in building design, each occupancy group varies by fire protection requirements, area and height limitations, type of construction restrictions (as described in Sec. 82.9), and means of egress.

There are additional requirements for special occupancy types that include covered mall buildings, high-rise buildings, atriums, underground buildings, motor-vehicle-related occupancies, hazardous occupancies, and institutional occupancies, among others.

**Table 82.1** Fire-Resistance Rating Requirements for Building Elements (hours) [IBC Table 601]

building element	type I		type II		type III		type IV	type V	
	A	B	A <sup>d</sup>	B	A <sup>d</sup>	B		A <sup>d</sup>	B
primary structural frame <sup>g</sup> (see IBC Sec. 202)	3 <sup>a</sup>	2 <sup>a</sup>	1	0	1	0	HT	1	0
bearing walls									
exterior <sup>f,g</sup>	3	2	1	0	2	2	2	1	0
interior	3 <sup>a</sup>	2 <sup>a</sup>	1	0	1	0	1/HT	1	0
nonbearing walls and partitions							see IBC Table 602		
exterior									
nonbearing walls and partitions							see IBC Sec. 602.4.6	0	0
interior <sup>e</sup>	0	0	0	0	0	0			
floor construction and associated secondary members (see IBC Sec. 202)	2	2	1	0	1	0	HT	1	0
roof construction and associated secondary members (see IBC Sec. 202)		1½ <sup>b</sup>	1 <sup>b,c</sup>	1 <sup>b,c</sup>	0 <sup>c</sup>	1 <sup>b,c</sup>	0	HT	1 <sup>b,c</sup>
									0

For SI: 1 ft = 304.8 mm.

<sup>a</sup>Roof supports: Fire-resistance ratings of primary structural frame and bearing walls are permitted to be reduced by 1 hr where supporting a roof only.

<sup>b</sup>Except in Group F-1, H, M, and S-1 occupancies, fire protection of structural members shall not be required, including protection of roof framing and decking where every part of the roof construction is 20 ft or more above any floor immediately below. Fire-retardant-treated wood members shall be allowed to be used for such unprotected members.

<sup>c</sup>In all occupancies, heavy timber is allowed where a 1 hr or less fire-resistance rating is required.

<sup>d</sup>An approved automatic sprinkler system in accordance with IBC Sec. 903.3.1.1 shall be allowed to be substituted for 1 hr fire-resistance-rated construction, provided such a system is not otherwise required by other provisions of the code or used for an allowable area increase in accordance with IBC Sec. 506.3 or an allowable height increase in accordance with IBC Sec. 504.2. The 1 hr substitution for the fire resistance of exterior walls must not be permitted.

<sup>e</sup>Not less than the fire-resistance rating required by other sections of the IBC code.

<sup>f</sup>Not less than the fire-resistance rating based on fire separation distance (see IBC Table 602).

<sup>g</sup>Not less than the fire-resistance rating as referenced in IBC Sec. 704.10.

## Occupancy Groups

Every building or portion of a building is classified according to its use and is assigned an occupancy group. This is true of the IBC as well as Canadian model codes and the three former U.S. model codes still used in some jurisdictions. **The IBC classifies occupancies into 10 major groups.**

- **Group A (Assembly):** buildings such as churches, theaters, restaurants, stadiums, and community halls where people gather for entertainment, worship, or eating
- **Group B (Business):** buildings such as banks, offices, and government buildings where fewer people gather than in Group A buildings
- **Group E (Educational):** all educational institutions
- **Group F (Factory):** all buildings used for manufacturing or repairing products
- **Group H (High Hazard):** buildings where hazardous chemicals, explosives, or toxic materials are stored
- **Group I (Institutional):** buildings such as hospitals, nursing homes, and prisons where people live in a

supervised environment and where they may be physically unable to leave without external assistance

- **Group M (Mercantile):** buildings with significant public traffic and storage of merchandise such as supermarkets, department stores, and gas stations
- **Group R (Residential):** houses, apartment buildings, hotels, and motels
- **Group S (Storage):** all buildings whose main usage is storage, including parking garages
- **Group U (Utility):** buildings that do not fit into other groups, such as water towers and barns

Six of these groups are further divided into categories to distinguish subgroups that define the relative hazard of the occupancy. For example, in the assembly group, an A-1 occupancy includes assembly places, usually with fixed seats, used to view performing arts or motion pictures, while an A-2 occupancy includes places designed for food and/or drink consumption. Table 82.2 shows a brief summary of the occupancy groups and subgroups and gives some examples of each. This table is not complete, and the IBC should be consulted for specific requirements.

**Table 82.2** Occupancy Groups Summary\*

occupancy	description	examples
A-1	assembly with fixed seats for viewing of performances or movies	movie theaters, live performance theaters
A-2	assembly for food and drink consumption	bars, restaurants, clubs
A-3	assembly for worship, recreation, etc., not classified elsewhere	libraries, art museums, conference rooms with more than 50 occupants
A-4	assembly for viewing of indoor sports	arenas
A-5	assembly for outdoor sports	stadiums
B	business, for office or service transactions	offices, banks, educational institutions above the 12th grade, post offices
E	educational use by $\geq 6$ people through 12th grade	grade schools, high schools, day cares with more than 5 children, ages greater than 2.5 yr
F-1	factory, moderate hazard	see Code
F-2	factory, low hazard	see Code
H	hazardous—see Code	see Code
I-1	> 16 ambulatory people on 24 hr basis	assisted living, group home, convalescent facilities
I-2	medical care on 24 hr basis to > 5 people not capable of self-preservation	hospitals, skilled care nursing
I-3	> 5 people restrained	jails, prisons, reformatories
I-4	day care for > 5 adults or infants (< 2.5 yr)	day care for infants
M	mercantile	department stores, markets, retail stores, drug stores, sales rooms
R-1	residential, for transient lodging	hotels and motels
R-2	residential with 3 or more units	apartments, dormitories, condominiums, convents
R-3	1 or 2 dwelling units with attached uses or child care < 6, less than 24 hr care	bed and breakfast, small child care
R-4	residential assisted living where number of occupants > 5 but < 16	small assisted living
S	storage—see Code	see Code
U	utility—see Code	see Code
dwellings	must use <i>International Residential Code</i>	

\*This table briefly summarizes the groups and examples of occupancy groups. Refer to the IBC for a complete list or check with local building officials when a use is not clearly stated or described in the code.

Knowing the occupancy classification is important in determining other building requirements, such as the maximum area, the number of floors allowed, and how the building must be separated from other structures. The occupancy classification also affects the following.

- calculation of occupant load
- egress design
- interior finish requirements
- use of fire partitions and fire barriers
- fire detection and suppression systems

- ventilation and sanitation requirements
- other special restrictions particular to any given classification

### Mixed Occupancy and Occupancy Separation

When a building or area of a building contains two or more occupancies, it is considered to be of **mixed occupancy or mixed use**. This is quite common. For instance, the design of a large office space can include office occupancy (a B occupancy) adjacent to an auditorium used for training, which would be an assembly occupancy

(an A occupancy). Each occupancy must be separated from other occupancies with a fire barrier of the hourly rating (shown in Table 82.3) as defined by the particular code that applies. The idea is to

**Table 82.3** Incidental Uses [IBC Table 509]

room or area	separation and/or protection
furnace room where any piece of equipment is over 400,000 Btu/hr input	1 hr or provide automatic sprinkler system
rooms with boilers where the largest piece of equipment is over 15 psi and 10 horsepower	1 hr or provide automatic sprinkler system
refrigerant machinery room	1 hr or provide automatic sprinkler system
hydrogen cutoff rooms, not classified as Group H	1 hr in Group B, F, M, S, and U occupancies; 2 hr in Group A, E, I, and R occupancies
incinerator rooms	2 hr and automatic sprinkler system
paint shops, not classified as Group H, located in occupancies other than Group F	2 hr; or 1 hr and provide automatic sprinkler system
laboratories and vocational shops, not classified as Group H, located in Group E or I-2 occupancy	1 hr or provide automatic sprinkler system
laundry rooms over 100 ft <sup>2</sup>	1 hr or provide automatic sprinkler system
Group I-3 cells equipped with padded surfaces	1 hr
waste and linen collection rooms located in either Group I-2 occupancies or ambulatory care facilities	1 hr
waste and linen collection rooms over 100 ft <sup>2</sup>	1 hr or provide automatic sprinkler system
stationary storage battery systems having a liquid electrolyte capacity of more than 50 gal for flooded lead-acid, nickel cadmium, or VRLA, or more than 1000 lbm for lithium-ion and lithium metal polymer used for facility standby power, emergency power, or uninterrupted power supplies	1 hr in Group B, F, M, S, and U occupancies; 2 hr in Group A, E, I, and R occupancies

For SI: 1 ft<sup>2</sup> = 0.0929 m<sup>2</sup>, 1 lbf/in<sup>2</sup> = 6.9 kPa, 1 British thermal unit (Btu)/hr = 0.293 watts, 1 horsepower = 746 W, 1 gal = 3.785 L.

2012 International Building Code, International Code Council, Inc., Washington, D.C. Reproduced with permission. All rights reserved.  
www.iccsafe.org

increase the fire protection between occupancies as the relative hazard increases.

## 9. CLASSIFICATION BASED ON CONSTRUCTION TYPE

Every building is classified into one of five major types of construction based on the fire-resistance rating (protection) of its major construction components. The purpose of this classification is to protect the structural elements of a building from fire and collapse, and to divide the building into compartments so that a fire in one area will be contained long enough to allow people to evacuate the building and firefighters to arrive.

The major construction components, under the IBC, include the structural frame, bearing walls, nonbearing walls, exterior walls, floor construction, and roof construction. The five types of construction are Type I, II, III, IV, and V. Type I buildings are the most fire-resistant, while Type V are the least fire-resistant. Type I and II buildings are noncombustible, while Types III, IV, and V are considered combustible. The building type categories and fire-resistance rating requirements for each building element are shown in Table 82.1. The fire-resistance requirements for exterior, nonbearing walls are based on the distance from the building to the property line, the type of construction, and the occupancy group as shown in Table 82.4. Detailed requirements for the various construction types are contained in IBC Chap. 6.

In combination with occupancy groups, building type sets limits on the area and height of buildings. For example, Type I buildings of any occupancy (except certain hazardous occupancies) can be of unlimited area and height, while Type V buildings are limited to only a few thousand square feet in area and one to three stories in height, depending on their occupancy. The type and amount of combustibles due to the building's use and construction affect its safety. Limiting height and area based on construction type and occupancy recognizes that it becomes more difficult to fight fires, provide time for egress, and rescue people as buildings get larger and higher.

## 10. ALLOWABLE FLOOR AREA AND HEIGHTS OF BUILDINGS

IBC Chap. 5 sets forth the requirements for determining maximum height (in stories as well as feet or meters) and area of a building based on construction type. It also gives the allowed occupancy, and then presents conditions under which the height and area may be increased. The concept is that the more hazardous a building is the smaller it should be, making it easier to fight a fire and easier for occupants to exit in an emergency.

IBC Table 503 and similar tables in the other model codes give the maximum allowable area, per floor, of a

**Table 82.4** Fire-Resistance Rating Requirements for Exterior Walls Based on Fire Separation Distance<sup>a,e,h</sup> [IBC Table 602]

fire separation distance, $x$ (ft)	type of construction	occupancy Group H <sup>f</sup>	occupancy Group F-1, M, S-1 <sup>g</sup>	occupancy Group A, B, E, F-2, I, R, S-2 <sup>g</sup> , U <sup>b</sup>
$x < 5^c$	all	3	2	1
$5 \leq x < 10$	IA	3	2	1
	others	2	1	1
$10 \leq x < 30$	IA, IB	2	1	$1^d$
	IIB, VB	1	0	0
	others	1	1	$1^d$
$x \geq 30$	all	0	0	0

For SI: 1 ft = 304.8 mm.

<sup>a</sup>Load-bearing exterior walls shall also comply with the fire-resistance rating requirements of IBC Table 601.

<sup>b</sup>For special requirements for Group U occupancies, see IBC Sec. 406.3.

<sup>c</sup>For party walls, see IBC Sec. 706.1.1.

<sup>d</sup>Open parking garages complying with IBC Sec. 406 shall not be required to have a fire-resistance rating.

<sup>e</sup>The fire-resistance rating of an exterior wall is determined based upon the fire separation distance of the exterior wall and the story in which the wall is located.

<sup>f</sup>For special requirements for Group H occupancies, see IBC Sec. 415.5.

<sup>g</sup>For special requirements for Group S aircraft hangars, see IBC Sec. 412.4.1.

<sup>h</sup>Where IBC Table 705.8 permits nonbearing exterior walls with unlimited area of unprotective openings, the required fire-resistance rating for the exterior walls is 0 hr.

2012 International Building Code, International Code Council, Inc., Washington, D.C. Reproduced with permission. All rights reserved. www.iccsafe.org.

building. A portion of IBC Table 503 is reproduced here in Table 82.5. This basic area can be multiplied by the number of stories up to a maximum of three stories under the IBC and up to two stories under the UBC.

If the building is equipped throughout with an approved automatic sprinkler system, the area and height can be increased. For one-story buildings, the area can be tripled, and for multistory buildings, the area can be doubled. The maximum height can be increased by 20 ft (6 m), and the number of stories can be increased by one. Both area and height increases are allowed in combination.

If more than 25% of the building's perimeter is located on a public way or open space, the basic allowable area may be increased according to various formulas. Except for Group H, Divisions 1, 2, and 5 (hazardous occupancies), a Type I building may be of unlimited floor area and unlimited height, while other construction types are limited.

The basic allowable height and building area table (as shown in Table 82.5) can be used in one of two ways. If the occupancy and construction type are known, simply find the intersection of the row designating "occupancy"

and the column designating "type," read the permitted area or height, and then increase the areas according to the percentages allowed for sprinklers and perimeter open space. More often, the occupancy and required floor area are known from the building program and a determination must be made on the required construction type that will allow construction of a building that meets the client's size needs. This is typically part of the pre-design work of a project.

## 11. AMERICANS WITH DISABILITIES ACT

The *Americans with Disabilities Act* of 1990 (ADA) makes it illegal to discriminate against anyone who has a mental or physical disability in the United States in the area of employment, public services, transportation, public accommodations, and telecommunications. ADA provisions are integrated with all modern building and planning codes.

The ADA applies to people with substantial, as distinct from minor, impairments. *Substantial impairments* limit major life activities such as seeing, hearing, speaking, walking, breathing, performing manual tasks, learning, caring for oneself, and working. Examples of conditions representing substantial impairment include epilepsy, paralysis, substantial hearing or visual impairment, mental retardation, and learning disability. Minor, non-chronic conditions of short duration, such as sprains, infections, or broken limbs, generally do not qualify.

A *qualified individual* with a disability can meet legitimate skill, experience, education, or other requirements of employment, and that individual can perform the *essential functions* of the position with or without reasonable accommodation. It is not necessary for a qualified individual to be able to perform marginal, nonessential functions. The employer must consider whether an individual can perform these functions with a reasonable accommodation.

*Reasonable accommodation* is any modification or adjustment to a job or the work environment that will enable a qualified applicant or employee with a disability to perform essential job functions and to enjoy the same rights and privileges in employment as non-disabled employees.

The ADA comprises five titles. Title I prohibits employers with 15 or more employees, including public entities such as cities and towns, from discriminating against qualified job applicants and workers who are, or who become, disabled. The law covers all aspects of employment, including the application process and hiring, training, compensation, advancement, and any other employment term, condition, or privilege. Possible changes include restructuring jobs, altering the layout of workstations, and modifying equipment.

Title II prohibits public entities such as state and local governments from discriminating against disabled persons in their programs and activities, including public transportation services such as city buses and public rail

**Table 82.5** Allowable Building Heights and Areas<sup>a,b</sup> [IBC Table 503](Building height limitations shown in feet above grading plane. Story limitations shown as stories above grade plane. Building area limitations shown in ft<sup>2</sup>, as determined by the definition of "Area, building" per story.)

For SI: 1 ft = 304.8 mm, 1 ft<sup>2</sup> = 0.0929 m<sup>2</sup>; A = building area per story, S = stories above grade plane, UL = unlimited, NP = not permitted.<sup>a</sup>See the following sections for general exceptions to IBC Table 503.

1. IBC Sec. 504.2, Allowable building height and story increase due to automatic sprinkler system installation.

2. IBC Sec. 506.2, Allowable building area increase due to street frontage.

3. IBC Sec. 506.3, Allowable building area increase due to automatic sprinkler system installation.

4. IBC Sec. 507, Unlimited area buildings.

<sup>b</sup>See IBC Chap. 4 for specific exceptions to the allowable height and areas in IBC Chap. 5.

2012 International Building Code, International Code Council, Inc., Washington, D.C. Reproduced with permission. www.iccsafe.org.

buses, remanufacture existing buses in an accessible manner, and, except when it would result in an undue burden, provide *paratransit services*.

Title III prohibits private businesses that provide public accommodations and services from denying goods, services, and programs to people based on their disabilities. Title III also sets forth the applicable structural accessibility requirements for private entities. Such business include restaurants, retail stores, grocery stores, hotels, movie theaters, private schools, convention centers, doctors' offices, homeless shelters, transportation depots, zoos, funeral homes, day care centers, recreation facilities, including sports stadiums and fitness clubs, and privately owned transportation systems. All new construction and modifications must accommodate individuals with disabilities.

For existing facilities, barriers to services must be removed if readily achievable. This mandate includes removing barriers from existing buildings when it is readily achievable to do so. The ADA defines *readily achievable* as "easily accomplishable and able to be carried out without much difficulty or expense." For existing facilities, for example, *barrier removal* includes such activities as ramping a curb, widening an entrance door, installing visual alarms, and designating an accessible parking space. In an existing public toilet room, readily achievable activities include replacing round faucet handles with lever handles, lowering a paper towel dispenser, installing a full-length mirror or lowering the existing mirror, modifying the front of the counter to provide wheelchair access, and insulating exposed pipes under sinks to prevent burns.

Title IV makes available telecommunications (television and telephone) devices and services for the hearing and speech impaired. These regulations specify mandatory minimum standards applicable to common carriers (e.g., telephone companies). Telephone companies must have *Telecommunications Relay Service* (TRS) for individuals who use *telecommunications devices for the deaf* (TDDs), which are also known as *teletypewriters* (TTYs), available 24 hours a day, 7 days a week. TRS enables callers with hearing and speech disabilities and people with voice telephones to communicate with each other through a third-party communications assistant.

Title V includes miscellaneous provisions that relate to the format and application of the ADA, including alternative dispute resolution. Title V includes provisions prohibiting coercion, threats, and retaliation against the people asserting their rights under the ADA. It provides for recovery of legal fees for successful legal actions under the ADA.

## 12. BUILDING DEMOLITION REGULATIONS

Demolition activities are governed by various local, state, and federal regulations and codes addressing safety and environmental concerns. In addition to

obtaining a demolition permit, it is generally required to complete the following activities.

1. Secure the site with fencing and gates. Post warning signs.
2. Remove furnishings, carpets, personal effects, household waste, appliances, and electronics.
3. Shut off and cap all utilities, and notify the utility companies.
4. Purge and capture solid, liquid, and gaseous hazardous, flammable, and explosive chemicals from pipes, tanks, and equipment.
5. Remove sources of asbestos: insulation on pipes, boilers, and furnaces, fireproof doors, flooring (e.g., linoleum), steel beam and column fire protection, HVAC ductwork, and acoustic plaster and ceiling tiles. Mitigate in accordance with environmental regulations.
6. Remove sources of chlorofluorocarbons: fire extinguishers, air conditioners, coolers, refrigerators, heat pumps, and vending machines.
7. Remove sources of polychlorinated biphenyls (PCBs): transformers, lighting ballasts, and heat transfer equipment.
8. Remove sources of lead: lead pipes, painted surfaces, batteries, and flashings.
9. Remove sources of mercury: emergency lighting systems; fluorescent lights; HID lights; and HVAC, furnace, and boiler controls.
10. Remove hydraulic fluids and other hydrocarbon liquids.
11. Remove other hazardous substances that could become airborne dusts, including mold.
12. Exterminate rodents and other vermin.
13. Shore and brace structural deficiencies, including walls that support earth and adjoining structures.

## 13. CSI MASTERFORMAT

Construction projects involve many different kinds of products, activities, and installation methods. **MasterFormat**, a publication of the **Construction Specifications Institute (CSI)**, facilitates communication among engineers, architects, specifiers, contractors, and suppliers in the United States and Canada by standardizing information and terminology.<sup>2</sup> **MasterFormat** is not a building code or a regulation, but rather, a standardized list of titles and numbers used to organize construction documents (specifications) and other project information for most commercial building design and

<sup>2</sup>The *SpecsIntact* (*Specifications Kept Intact*), also known as *Master Text* and *Masters* standardization schemes used in projects involving the U.S. government or U.S. military, integrates MasterFormat.

construction projects in North America. It lists titles and section numbers for organizing data about construction requirements, products, and activities.

Prior to 2004, MasterFormat recognized 16 divisions. It has subsequently been reorganized into the 50 divisions of Table 82.6, although many are reserved for future use. **Each division is divided into up to four layers of subdivisions which are identified numerically.** For

example, the material specification 03 52 16.13 subdivision hierarchy is

NRR	noise reduction ratio	—	—
$R$	injury incidence rate	—	—
RWL	recommended weight limit	lbm	kg
$T_i$	reference duration	hr	h
TWA	time-weighted average	dB	dB
VM	vertical multiplier	—	—

## 1. INTRODUCTION

Common sense can go a long way in preventing many job site accidents. However, scheduling, economics, lack of concern, carelessness, and laxity are often more likely to guide actions than common sense. For that reason, the “science” of accident prevention is highly regulated. In the United States, workers’ safety is regulated by the federal Occupational Safety and Health Administration (OSHA). State divisions (e.g., Cal/OSHA) are charged with enforcing federal and state safety regulations.

Surface and underground mines, which share many hazards with the construction industry and which have others specific to them, are regulated by the federal Mine Safety and Health Act (MSHA). Other countries may have more restrictive standards.

All of the federal OSHA regulations are published in the **Code of Federal Regulations (CFR)**. The two main categories of standards are the “1910 standards,” which apply to general industry, and the “1926 standards,” which apply to the construction industry. Table 83.1 contains some of the major subjects covered by the general industry OSHA standards. Table 83.2 lists OSHA standards for the construction industry.

**Table 83.1** OSHA 1910 Subjects for General Industry

Safety and Health Programs
Recordkeeping
Hazard Communication
Exit Routes
Emergency Action Plans
Fire Prevention
Fire Detection and Protection
Electrical
Flammable and Combustible Liquids
Lockout/Tagout
Machine Guarding
Walking and Working Surfaces
Welding, Cutting, and Brazing
Material Handling
Ergonomics
Permit-Required Confined Spaces
Personal Protective Equipment (PPE)
Industrial Hygiene
Blood-Borne Pathogens
Hand and Portable Power Tools and Equipment

In addition to 1910 and 1926 regulations, other pertinent regulations include 1903 regulations about inspections, citations, and proposed penalties, and 1904 regulations about recording and reporting occupational injuries and illnesses.

This chapter covers only a minuscule portion of the standards and safety issues facing engineers and construction workers. Only the briefest descriptions of these complex issues and the regulations that govern them are provided.

Motor Vehicles

## 2. OCCUPATIONAL INJURIES AND ILLNESSES

Most companies with 10 or more employees must maintain injury records and report their incidents.<sup>1</sup> The OSHA criteria regarding *recordable incidents* are complex, and circumstances surrounding an injury complicate the classification. Recordable incidents include all work-related deaths, illnesses, and injuries that result in a loss of consciousness, restriction of work or motion, permanent transfer to another job within the company, or that require some type of medical treatment or first aid.

An *occupational injury* is an injury (including a fatality) that is the result of a single work-related incident or exposure. Such injuries include burns (thermal and chemical); amputations; broken, fractured, and crushed bones; cuts, abrasions, and punctures; respiratory irritations; and instantaneous hearing loss. An *occupational illness* is an abnormal condition or disorder (other than an injury) that is the result of work-related exposure through inhalation, absorption, or ingestion of, or direct contact to a biological, chemical, or physical agent. Occupational illnesses include dermatitis, asbestososis, acute congestion, poisoning, heatstroke, frostbite, and sunburn.

## 3. OSHA RECORDABLE INJURY INCIDENCE RATE

An *accident rate* is useful in monitoring the effects of safety measures and in comparing a company's safety performance against state and national averages. Different industries (also known as *business groups*) will have

different average rates.<sup>2</sup> OSHA uses a recordable *injury incidence rate* that represents the number of injuries per 200,000 hours—the equivalent of 100 employees working 40 hours per week, 50 weeks per year. The number of hours worked does not include paid nonwork time such as vacation, sick leave, and holidays. Only actual recordable nonfatal injuries and illnesses are included in the injury incidence rate calculation.

$$R = \frac{(\text{no. of injuries})(200,000 \text{ hr})}{\text{no. of hours worked}} \quad 83.1$$

Different names are given to the incidence rate depending on the types of incidents counted. The recordable injury incidence rate may be used to calculate the *total incidence rate*, the *lost time case rate* (based on lost time incidents), the *lost workday rate* (based on lost workdays), and the “Days Away, Restrictions, and Transfers” (*DART*) *rate*, which is based on days away, lost or restricted days, and job transfers.

For incidents that result in lost or restricted days, the *OSHA severity rate* is the ratio of lost days experienced compared to the number of recordable DART incidents.

## 4. GEOTECHNICAL SAFETY AND RISK MITIGATION

Geotechnical designs, sequencing, and construction methods can have significant unintended impacts on personnel, particularly those involved in construction. In addition to being needed for structural design, soil characteristics are used to evaluate the risks of soil stability and collapse during excavation and construction. Access points and depths of cuts, shoring and shields, slopes and benches, piles and storage, temporary stabilization, supervision and monitoring, access, and personal protective equipment are some of the subjects affected by soil characteristics. In the United States, in addition to state and local agencies, safety in the workplace is under or within the purview of the Occupational Safety and Health Administration.

## 5. SOIL CLASSIFICATION

Soils are classified into stable rock and types A, B, or C, with type C being the most unstable.

*Type A soils* are cohesive soils with an unconfined compressive strength of 1.5 tons per square foot (144 kPa) or greater. Examples of type A cohesive soils are clay, silty clay, sandy clay, clay loam, and in some cases, silty clay loam and sandy clay loam. No soil is type A if it is fissured, is subject to vibration of any type, has previously been disturbed, is part of a sloped, layered system where the layers dip into the excavation on a slope of four horizontal to one vertical or greater, or has seeping water.

<sup>1</sup>The types and numbers of injuries are recorded in an employer's *Log of Work-Related Injuries and Illnesses* (OSHA Form 300).

<sup>2</sup>The North American Industry Classification System (NAICS) is used.

**Type B soils** are cohesive soils with an unconfined compressive strength greater than 0.5 tons per square foot (48 kPa) but less than 1.5 (144 kPa). Examples of type B soils are angular gravel; silt; silt loam; previously disturbed soils unless otherwise classified as type C; soils that meet the unconfined compressive strength or cementation requirements of type A soils but are fissured or subject to vibration; dry unstable rock; and layered systems sloping into the trench at a slope less than four horizontal to one vertical (but only if the material would be classified as a type B soil).

**Type C soils** are cohesive soils with an unconfined compressive strength of 0.5 tons per square foot (48 kPa) or less. Type C soils include granular soils such as gravel, sand and loamy sand, submerged soil, soil from which water is freely seeping, and submerged rock that is not stable. Also included in this classification is material in a sloped, layered system where the layers dip into the excavation or have a slope of four horizontal to one vertical or greater.

*Layered geological strata* include soils that are configured in layers. Where a layered geologic structure exists, the soil must be classified on the basis of the soil classification of the weakest soil layer. Each layer may be classified individually if a more stable layer lies below a less stable layer (e.g., where a type C soil rests on top of stable rock).

OSHA 1926 App. A to Subpart P require that at least one visual and one manual method be used to classify the soil type as A, B, and C. (Tests are not necessary if type C soil is assumed and protection is provided for type C soil conditions.) Manual methods are the *thumb penetration*, *pocket penetrometer*, and *torvane shear vane tests*.

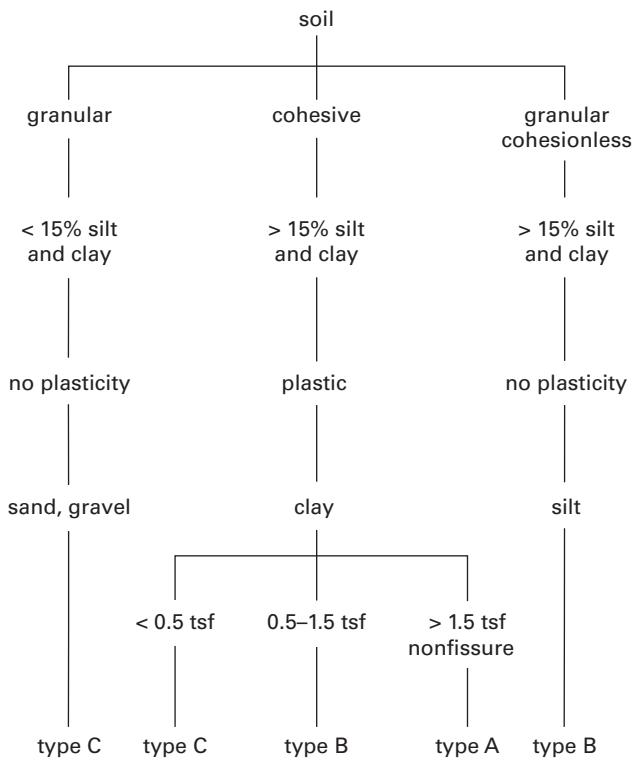

The thumb penetration test is subjective and the least accurate of the three methods. Only one method is required, and although penetrometer and shear vane tests are preferred because numerical readings can be recorded, the thumb penetration test is equally permissible.

The thumb penetration test should be conducted on an undisturbed soil sample, such as a large clump of soil, within five minutes after excavation to minimize moisture loss from drying. Using the thumb penetration test, soils that can be readily indented by the thumb (i.e., that have unconfined compressive strengths of at least 1.5 tsf), but can only be penetrated with great effort, are classified as type A soils. If the thumb penetrates no further than the length of the thumbnail, the soil is classified as type B. Type C soils (with unconfined strengths of 0.5 tsf or less) can be easily penetrated by the full length of the thumb and can be molded by light finger pressure. Figure 83.1 illustrates how the soil types correlate to other geotechnical qualities.

## 6. TRENCHING AND EXCAVATION

Except for excavations entirely in stable rock, excavations deeper than 5 ft (1.5 m) in all types of earth must be

**Figure 83.1** Soil Type by Geotechnical Qualities

protected from cave-in and collapse [OSHA 1926.652]. Excavations less than 5 ft (1.5 m) deep are usually exempt but may also need to be protected when inspection indicates that hazardous ground movement is possible.

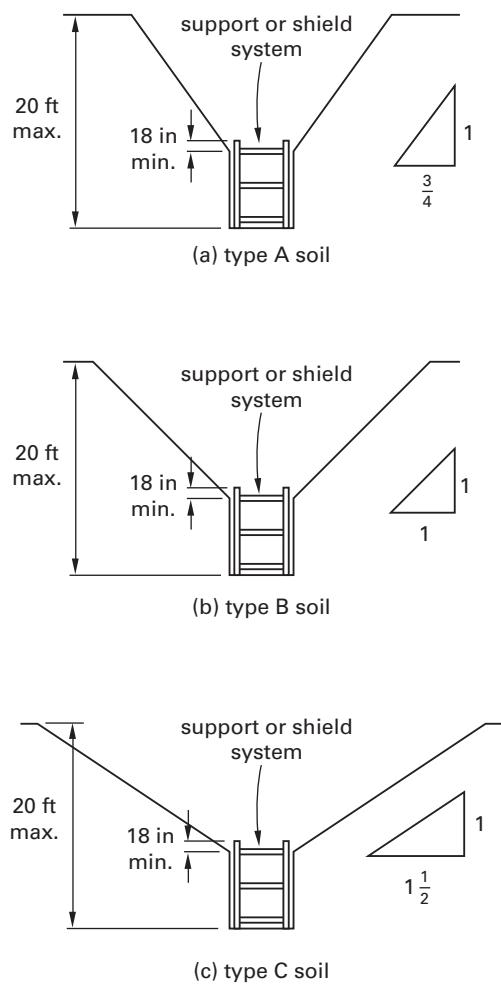

Timber and aluminum *shoring* (hydraulic, pneumatic, and screw jacked) and *trench shields* that meet the requirements of OSHA 1926.652 App. C to Subpart P, and App. D to Subpart P may be used in excavations up to 20 ft (6 m) deep. (See Fig. 83.2.)

*Sloping* and *benching* the trench walls may be substituted for shoring. Sloped walls in excavations deeper than 20 ft (6 m) must be designed by a professional engineer. Table 83.3 provides maximum slopes for excavations less than 20 ft deep. Greater slopes are permitted for short-term usage in excavations less than 12 ft (3.67 m) deep.

In trenches 4 ft (1.2 m) deep or more, ladders, stairways, or ramps are required so that no more than 25 ft (7.5 m) of lateral travel is required to reach an exit (i.e., with a maximum lateral spacing of 50 ft (15 m)) [OSHA 1926.651(c)(2)].

Spoils and other equipment that could fall into a trench or an excavation must be kept at least 2 ft (0.6 m) from the edge of a trench unless secured in some other fashion [OSHA 1926.651(j)(2)].

Examples of excavations by soil types A, B, and C are illustrated in Fig. 83.3. Figure 83.4 illustrates excavations in layered soils.

**Figure 83.2** Slope and Shield Configurations**Table 83.3** Maximum Allowable Slopes

soil or rock type	maximum allowable slopes (H:V) <sup>a</sup> for excavations less than 20 ft deep <sup>b</sup>
stable rock	vertical ( $90^\circ$ )
type A <sup>c</sup>	3/4:1 ( $53^\circ$ )
type B	1:1 ( $45^\circ$ )
type C <sup>d</sup>	1 1/2:1 ( $34^\circ$ )

<sup>a</sup>Numbers shown in parentheses next to maximum allowable slopes are angles expressed in degrees from the horizontal. Angles have been rounded off.

<sup>b</sup>Sloping or benching for excavations greater than 20 ft (6 m) deep must be designed by a registered professional engineer.

<sup>c</sup>A short-term maximum allowable slope of 1/2H:1V ( $63^\circ$ ) is allowed in excavations in type A soil that are 12 ft (3.67 m) or less in depth. Short-term maximum allowable slopes for excavations greater than 12 ft (3.67 m) in depth must be 3/4H:1V ( $53^\circ$ ).

<sup>d</sup>These slopes must be reduced 50% if the soil shows signs of distress.

Source: OSHA 1926.652 App. B

## 7. COMPETENT PERSON: SOIL EXCAVATIONS

OSHA requirements are effective when they are interpreted and implemented by competent individuals. For the purpose of determining the safety of soil excavations, OSHA defines a *competent person* as someone with (1) training, experience, and knowledge of soil analysis, use of protective systems, the OSHA regulations related to excavations (i.e., OSHA 1926 Subpart P); (2) the ability to detect conditions that could result in cave-ins, failures in protective systems, hazardous atmospheres, and other hazards including those associated with confined spaces; and (3) the authority to take prompt corrective measures to eliminate existing and predictable hazards and to stop work when required.

## 8. CHEMICAL HAZARDS

OSHA's Hazard Communication Standard [OSHA 1910.1200] requires that the dangers of all chemicals purchased, used, or manufactured be known to employees. The hazards are communicated in a variety of ways, including labeling containers, training employees, and providing ready access to *material safety data sheets* (MSDSs).

OSHA has suggested a nonmandatory standard form for the MSDS, but other forms are acceptable as long as they contain the same (or more) information. The information contained on an MSDS consists of the following categories.

*Chemical identity:* the identity of the substance as it appears on the label.

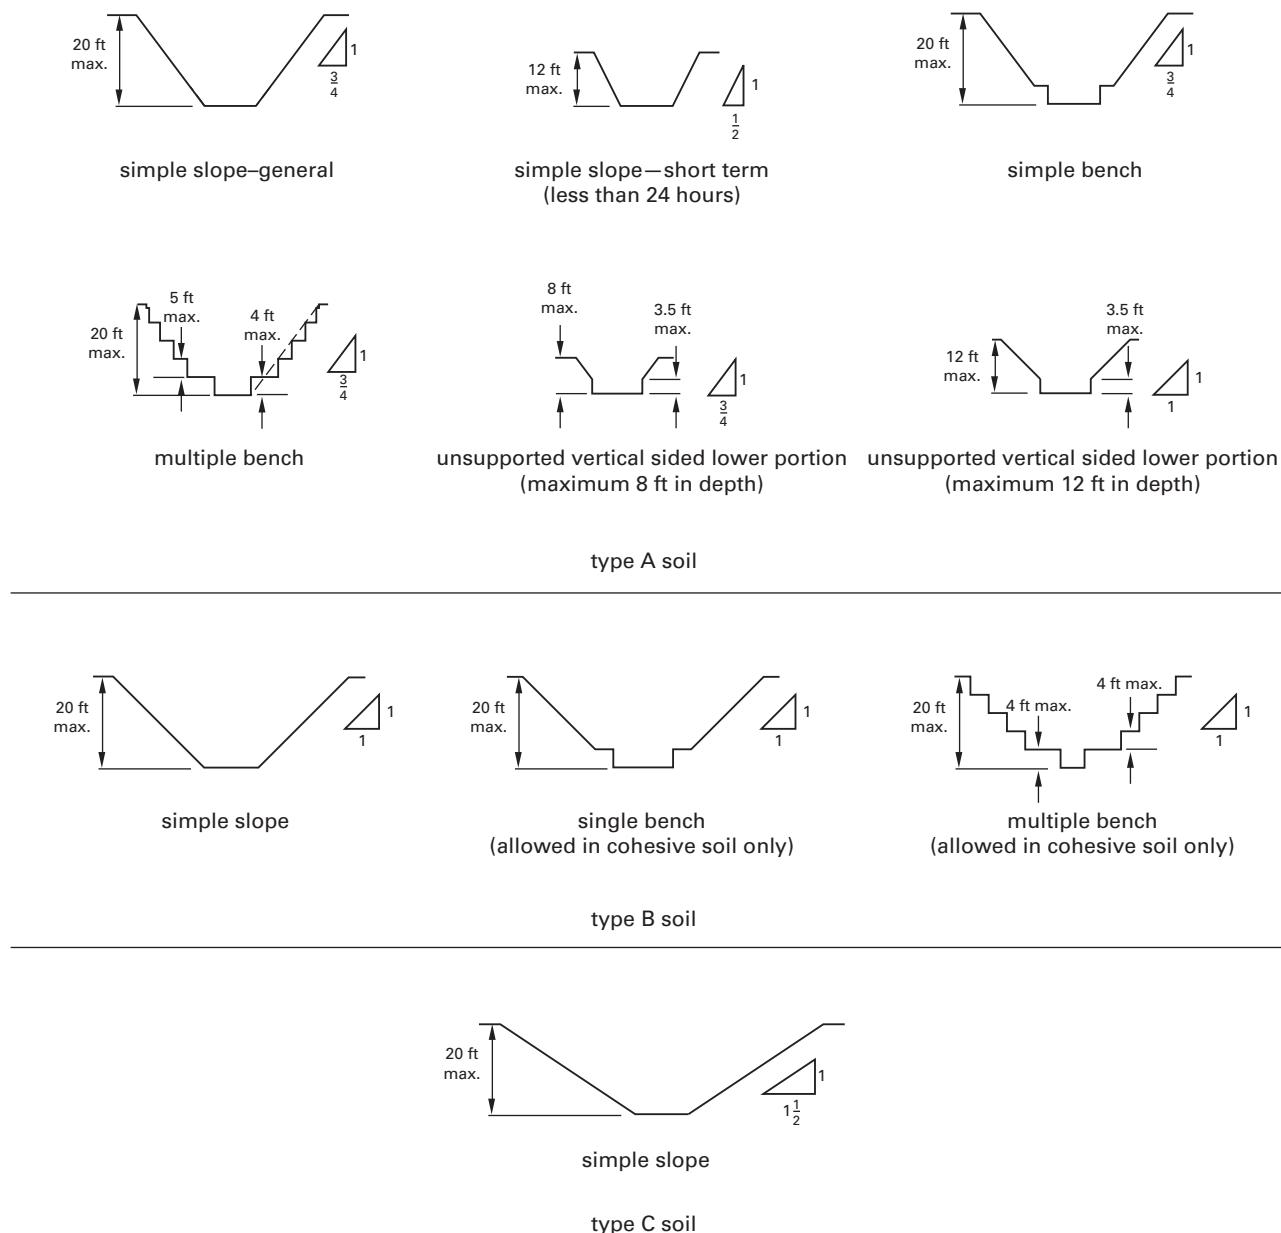

*Section I: Manufacturer's name and contact information:* manufacturer's name, address, telephone number, and emergency phone number; date the MSDS was prepared; and an optional signature of the preparer.

*Section II: Hazardous ingredients/identity information:* list of the hazardous components by chemical identity and other common names; OSHA permissible exposure limit (PEL), ACGIH threshold level value (TLV), and other recommended exposure limits; percentage listings of the hazardous components is optional.

*Section III: Physical/chemical characteristics:* boiling point, vapor pressure, vapor density, specific gravity, melting point, evaporation rate, solubility in water, physical appearance, and odor.

*Section IV: Fire and explosion hazard data:* flash point (and method used to determine it), flammability limits, extinguishing media, special firefighting procedures, and unusual fire and explosion hazards.

*Section V: Reactivity data:* stability, conditions to avoid, incompatibility (materials to avoid), hazardous decomposition or by-products, and hazardous polymerization (and conditions to avoid).

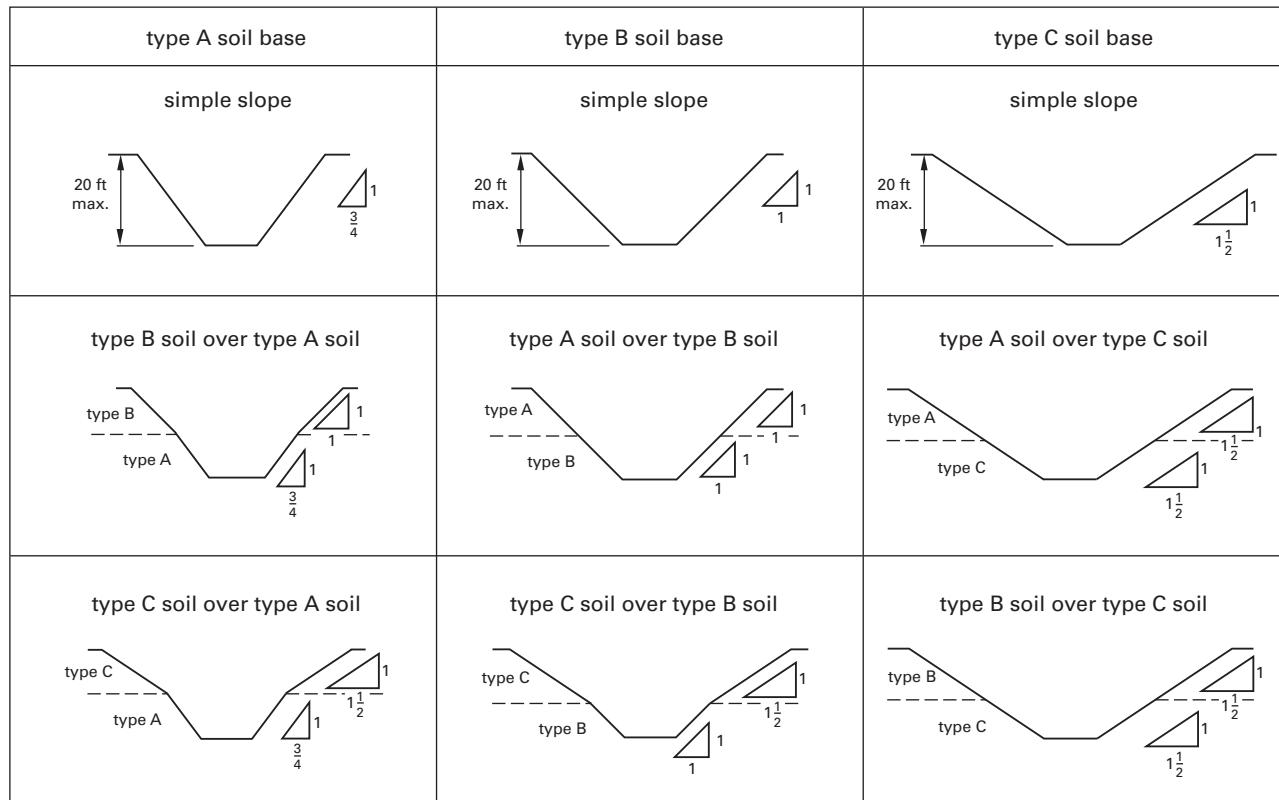

**Figure 83.3** Excavations by Soil Type

**Section VI: Health hazard data:** routes of entry into the body (inhalation, skin, ingestion), health hazards (*acute* = immediate, or *chronic* = builds up over time), carcinogenicity, signs and symptoms of exposure, medical conditions generally aggravated by exposure, and emergency and first-aid procedures.

**Section VII: Precautions for safe handling and use:** steps to be taken in case the material is released or spilled, waste disposal method, precautions to be taken in handling or storage, and other precautions.

**Section VIII: Control measures:** respiratory protection (type to be specified), ventilation (local, mechanical exhaust, special, or other), protective gloves, eye protection, other protective clothing or equipment, and work/hygienic practices.

**Section IX: Special precautions and comments:** safe storage and handling, types of labels or markings for containers, and Department of Transportation (DOT) policies for handling the material.

**Figure 83.4** Excavations in Layered Soils

## 9. CONFINED SPACES AND HAZARDOUS ATMOSPHERES

Employees entering confined spaces (e.g., excavations, sewers, tanks) must be properly trained, supervised, and equipped. Atmospheres in confined spaces must be monitored for oxygen content and other harmful contaminants. Oxygen content in confined spaces must be maintained at 19.5% or higher unless a breathing apparatus is provided [OSHA 1910.146]. Employees entering deep confined excavations must wear harnesses with lifelines [OSHA 1926.651].

## 10. ELECTRICAL SAFETY

Electrical safety hazards include shock, arc flash, explosion, and fire. Electrical safety programs must comply with state and federal requirements and are tailored to the specific needs of the workplace. Safety measures include overcurrent protection, such as circuit breakers, grounding, flame-resistant clothing, and insulated tools.

*Electrical shock*, when current runs through or across the body, is a hazard that can occur in nearly all industries and workplaces. Shock hazard is a function of current, commonly measured in millamps. Table 83.4 lists levels of current and their effects on a human body.

**Table 83.4** Effects of Current on Humans

current level	probable effect on human body
1 mA	Perception level. Slight tingling sensation. Still dangerous under certain conditions.
5 mA	Slight shock felt; not painful, but disturbing. Average individual can let go. However, strong involuntary reactions to shocks in this range may lead to injuries.
6–16 mA	Painful shock, begin to lose muscular control. Commonly referred to as the freezing current or “let go” range.
17–99 mA	Extreme pain, respiratory arrest, severe muscular contractions. Individual cannot let go. Death is possible.
100–2000 mA	Ventricular fibrillation (uneven, uncoordinated pumping of the heart). Muscular contraction and nerve damage begins to occur. Death is likely.
> 2000 mA	Cardiac arrest, internal organ damage, and severe burns. Death is probable.

## 11. POWER LINE HAZARDS

For general installations, repairs, and operations by personnel, OSHA 1926.403 specifies minimum working clearances and required space around electrical equipment and panels as functions of the voltage-to-ground and the number of sides of exposed equipment. Workers in mobile equipment and/or with movable components are covered by different provisions.

Employees operating cranes or other overhead material-handling equipment (e.g., concrete boom trucks, backhoe arms, and raised dump truck boxes) must be aware of the possibility of inadvertent power line contact. Prior to operation, the site must be thoroughly inspected for the danger of power line contact. OSHA provides specific minimum requirements for safe operating distances. For example, for lines of 50 kV or less, all parts of the equipment must be kept at least 10 ft (3 m) from the power line [OSHA 1926.1408(a)(2)(iii)]. A good rule of thumb for voltages greater than 50 kV is a clearance of 35 ft (10.5 m). However, the exact OSHA clearance requirement for voltages up to 1000 kV can be calculated from Eq. 83.2. Values should be rounded up to the nearest 5 ft (1.5 m).

$$\text{line clearance} = 3 \text{ m} + (10.2 \text{ mm})(V_{\text{kV}} - 50 \text{ kV})$$

[SI] 83.2(a)

$$\text{line clearance} = 10 \text{ ft} + (0.4 \text{ in})(V_{\text{kV}} - 50 \text{ kV})$$

[U.S.] 83.2(b)

## 12. FALL AND IMPACT PROTECTION

Fall protection can take the form of barricades, walkways, bridges (with guardrails), nets, and fall arrest systems. Personal *fall arrest systems* include lifelines, lanyards, and deceleration devices. Such equipment is attached to an anchorage at one end and to the body-belt or body harness at the other. All equipment is to be properly used, certified, and maintained. Employees are to be properly trained in the equipment's use and operation.

Employees must be protected from impalement hazards from exposed rebar [OSHA 1926.701(b)]. A widely used method for covering rebar ends has been plastic *mushroom caps*, often orange or yellow in color. However, OSHA no longer considers plastic caps adequate for anything more than scratch protection. Commercially available steel-reinforced caps and wooden troughs capable of withstanding a 250 lbm/10 ft drop test without breakthrough can still be used.

*Head protection*, usually in the form of a *helmet (hard hat)*, is part of a worker's *personal protective equipment (PPE)*. Head protection is required where there is a danger of head injuries from impact, flying or falling objects, electrical shock, or burns [OSHA 1910.132(a) and (c)]. Head protection should be nonconductive when there is electrical or thermal danger [OSHA 1910.335(a)(1)(iv)].

## 13. NIOSH LIFTING EQUATION

Low-back injuries are common in construction, because lifting conditions are rarely optimal. In 1993, the National Institute for Occupational Safety and Health (NIOSH) developed an evaluation tool called the NIOSH *lifting equation* that predicts the relative risk of the task.

The NIOSH lifting equation consists of two parts: (1) the calculation of a *lifting index (LI)*, and (2) the calculation of a *recommended weight limit (RWL)*. The lifting index is simply the ratio of the actual load to the recommended weight limit. Values of LI greater than 1.0 pose an increased risk for some workers, while values of LI greater than 3.0 expose most workers to a high risk of developing low-back pain and injury. The goal is to design lifting tasks so that  $LI \leq 1.0$ .

$$LI = \frac{L}{RWL} \quad 83.3$$

$$RWL = (LC)(HM)(VM)(DM)(AM)(FM)(CM) \quad 83.4$$

The recommended weight limit is calculated from a variety of factors, as shown in Eq. 83.4. LC is the *load constant*, which is the maximum recommended weight for lifting under optimal conditions. This value is taken as 51 lbm (23 kg). HM is the *horizontal multiplier*, which accounts for the distance between the load and the spine. VM is the *vertical multiplier*, which accounts for deviations from the best originating height of the load, and which is assumed to be 30 in (or 75 cm) above the floor. DM is the *distance multiplier*, which accounts for the vertical distance of lifting. AM is the *asymmetric multiplier*, which accounts for torso twisting during lifting. CM is the *coupling multiplier*, which accounts for the ease of holding the load. *Good coupling* occurs when a load has handles. *Fair coupling* occurs when a load has handles that are not easy to hold and lift. *Poor coupling* is where the loads are hard to grab and lift. FM is the *frequency multiplier*, which is affected by the lifting frequency.

The factors in the NIOSH lifting equation are based on the nature of the job and are determined from tables in DHHS/NIOSH publication 94-110, *Applications Manual for the Revised NIOSH Lifting Equation*. The various factors depend on characteristics of the lifting job, specifically, the horizontal distance between the hands lifting the load and the midpoint between the ankles,  $H$ ; the vertical distance of the hands from the floor,  $V$ ; the vertical travel distance between the origin and the destination of the lift,  $D$ ; the angle of symmetry,  $A$  (measured in degrees), which is the angle of torso twisting involved in lifting a load that is not directly in front of the person; and the average frequency of lifting,  $F$  (measured in lifts/min).

## 14. NOISE

OSHA sets maximum limits (*permissible exposure limit*, PEL) on daily sound exposure. The “all-day” eight-hour noise level limit is 90 dBA. This is higher than the maximum level permitted in most other countries (e.g., noise control threshold of 85 dBA in the United Kingdom, Germany, and Japan). In the United States, employees may not be exposed to steady sound levels above 115 dBA, regardless of the duration. Impact sound levels are limited to 140 dBA.

*Hearing protection*, educational programs, periodic examinations, and other actions are required for workers whose eight-hour exposure is more than 85 dBA or whose noise dose exceeds 50% of the *action levels*. (See Table 83.5.)

**Table 83.5** Typical Permissible Noise Exposure Levels\*

sound level (dBA)	exposure (hr/day)
90	8
92	6
95	4
97	3
100	2
102	1½
105	1
110	½
115	¼ or less

\* without hearing protection

Source: OSHA 1910.95, Table G-16

The parameter used in OSHA regulations to assess a worker's exposure is the time-weighted average (TWA). TWA represents a worker's noise exposure normalized to an eight-hour day, taking into account the average levels of noise and the time spent in each area. Determining the TWA starts with calculating the noise dose,  $D$ .  $C_i$  is the time in hours spent at each noise exposure level, and  $T_i$  is the reference duration calculated from the sound pressure level in dB for each exposure level. Since they are different representations of the same level, the OSHA action levels are based on either TWA or dose percent. These action levels are 85 dB (or 50% dose) and 90 dB (or 100% dose).

$$D = \sum \frac{C_i}{T_i} \times 100\% \quad 83.5$$

$$T_i = \frac{8 \text{ hr}}{2^{(L_i - 90)/5}} \quad 83.6$$

$$\text{TWA} = 90 + 16.61 \log_{10} \frac{D}{100\%} \quad 83.7$$

If engineering or administrative controls are ineffective or not feasible, *hearing protective devices* (HPDs), such as earmuffs and earplugs, can be used as a last resort. HPDs are labeled with a *noise reduction ratio* (NRR),

which is a manufacturer's claim of how much noise reduction (in dB) a hearing protective device provides. Theoretically, the entire NRR would be subtracted from the environmental noise level to obtain the noise level at the ear. However, since HPDs generally provide much less protection than their labels claim, OSHA (drawing on NIOSH standards) recommends in its field manual that inspectors calculate a more realistic measurement of effectiveness.

Since sound level meters have multiple scales, the calculation method depends on the measurement scale used to measure the environmental noise. For formable earplugs, when noise is measured in dBA (i.e., on the “A”-weighted scale), the OSHA formula subtracts 7 from the NRR and divides the result by 2. (Values for earmuffs and non-formable earplugs are calculated differently.)

$$\Delta L_{\text{dBA}} = \frac{\text{NRR} - 7}{2} \quad [\text{formable earplugs}] \quad 83.8$$

When noise is measured in dBC (i.e., on the “C”-weighted scale), the OSHA formula subtracts 7 from the NRR.

$$\Delta L_{\text{dBC}} = \text{NRR} - 7 \quad [\text{formable earplugs}] \quad 83.9$$

### Example 83.1

A construction worker leaves an 86 dB environment after 6 hrs and works in a 92 dB environment for 3 more hours. What are the (a) dose and (b) time-weighted average (TWA)?

*Solution*

Use Eq. 83.6.

$$\begin{aligned} T_1 &= \frac{8 \text{ hr}}{2^{(L_1 - 90)/5}} = \frac{8 \text{ hr}}{2^{(86 \text{ dB} - 90 \text{ dB})/5 \text{ dB}}} \\ &= 13.92 \text{ hr} \\ T_2 &= \frac{8 \text{ hr}}{2^{(L_2 - 90)/5}} = \frac{8 \text{ hr}}{2^{(92 \text{ dB} - 90 \text{ dB})/5 \text{ dB}}} \\ &= 6.06 \text{ hr} \end{aligned}$$

From Eq. 83.5, the noise dose is

$$\begin{aligned} D &= \sum \frac{C_i}{T_i} \times 100\% \\ &= \left( \frac{6 \text{ hr}}{13.92 \text{ hr}} + \frac{3 \text{ hr}}{6.06 \text{ hr}} \right) \times 100\% \\ &= 92.6\% \end{aligned}$$

From Eq. 83.7, the time-weighted average is

$$\begin{aligned} \text{TWA} &= 90 + 16.61 \log_{10} \frac{D}{100\%} \\ &= 90 \text{ dB} + 16.16 \log_{10} \frac{92.6\%}{100\%} \\ &= 89.46 \text{ dB} \end{aligned}$$

## 15. SCAFFOLDS

Scaffolds are any temporary elevated platform (supported or suspended) and its supporting structure (including points of anchorage) used for supporting employees, materials, or both. Construction and use of scaffolds are regulated in detail by OSHA 1926.451. A few of the regulations are summarized in the following paragraphs.

Each employee who performs work on a scaffold must be trained by a person qualified to recognize the hazards associated with the type of scaffold used and to understand the procedures to control or minimize those hazards. The training must include such topics as the nature of any electrical hazards, fall hazards, falling object hazards, the maintenance and disassembly of the fall protection systems, the use of the scaffold, handling of materials, the capacity, and the maximum intended load.

*Fall protection* (guardrail systems and personal fall arrest systems) must be provided for each employee on a scaffold more than 10 ft (3.1 m) above a lower level.<sup>3</sup>

Each scaffold and scaffold component must have the capacity to support its own weight and at least four times the maximum intended load applied or transmitted to it. Suspension ropes and connecting hardware must support six times the intended load. Scaffolds and scaffold components may not be loaded in excess of their maximum intended loads or rated capacities, whichever is less.

The scaffold platform must be planked or decked as fully as possible. It cannot deflect more than  $\frac{1}{60}$  of the span when loaded.

The work area for each scaffold platform and walkway must be at least 18 in (46 cm) wide. When the work area must be less than 18 in (46 cm) wide, guardrails and/or personal fall arrest systems must still be used.

Access must be provided when the scaffold platforms are more than 2 ft (0.6 m) above or below a point of access. Direct access is acceptable when the scaffold is not more than 14 in (36 cm) horizontally and not more than 24 in (61 cm) vertically from the other surfaces. Cross braces cannot be used as a means of access.

A competent person with the authority to require prompt corrective action is required to inspect the scaffold, scaffold components, and ropes on suspended scaffolds before each work shift and after any occurrence which could affect the structural integrity.

<sup>3</sup>OSHA prescribes in OSHA 1926 Subpart L (1926.451(g)(1)) a 10 ft (3 m) fall protection for scaffolds. This differs from the 6 ft (1.8 m) threshold for fall protection in OSHA 1926 Subpart M (1926.502(d)(16)(iii)) for other walking/working surfaces in construction, because scaffolds, unlike these other surfaces, are temporary structures erected to provide a work platform for employees who are constructing or demolishing other structures. The features that make scaffolds appropriate for short-term use in construction make them less amenable to the use of fall protection as the first level is being erected.

## 16. TEMPORARY STRUCTURES

*Temporary structures* are those that exist for only a period of time during construction and are removed prior to project completion. They include temporary buildings for occupancy and storage, shoring and underpinning, concrete formwork and slipforms, scaffolding, diaphragm and slurry walls, wharfs and docks, temporary fuel and water tanks, cofferdams, earth-retaining structures, bridge falsework, tunneling supports, roadway decking, and ramps and inclines. (See Sec. 83.15.)

While a persistent school of thought permits temporary structures to be installed and operated with lower factors of safety than permanent structures, just the opposite is required unless the expected loading is entirely predictable and manageable. Temporary structures may or may not require separate permits and/or drawings. Most temporary structures need ongoing inspection during their existence, since connections loosen and members get moved, weaken, deform, and/or fail. Temporary structures are often erected by a separate subcontractor, complicating the inspection tasks and responsibilities.

## 17. TRUCK AND TOWER CRANES

The main parts of a *hydraulic truck crane* are the boom, jib, rotex gear, outriggers, counterweights, wire rope, and hook. The *boom* is the arm that holds the load. Most hydraulic truck cranes have booms consisting of several telescoping sections. Some booms are equipped with a separate *jib*, which is a lattice structure that extends the boom's reach. Jibs may be fixed or luffing.<sup>4</sup> The free end of a *fixed jib* (*fixed-angle jib*) remains at a constant elevation above the ground. A *luffing jib* pivots where it attaches to the boom, allowing the free end to vary in elevation. ("Luffing" means "moving.") The *slewing platform* containing the operator's cab is mounted on a turntable bearing driven through the *rotex gear* by a bidirectional hydraulic motor.

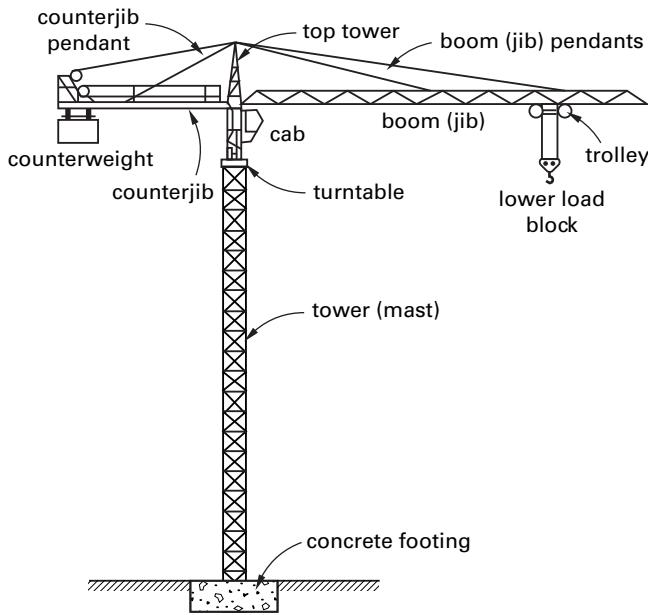

Tires do not offer the stability needed for the crane to achieve full capacity, so *outriggers* are used to lift the entire truck off the ground. Each outrigger consists of the beam (leg) and pad (foot). Wooden *floats* (blocks) may be placed under the pad to dissipate the outrigger down force over an area greater than the pad. To be effective, such blocks should have an area of at least three times the area of the outrigger pad. Detachable *counterweights* are placed on the back of the crane to prevent it from tipping during operation. The amount of counterweight needed for a particular lift is determined by the weight of the load, the radius of the boom, and the boom's angle during operation. Counterweights are used only during lifts and are removed when the crane is driven.

<sup>4</sup>To reach all the corners of a site, the jib has to *oversail* adjacent property. Following a legal ruling in the 1970s, permission for oversailing must be given by the adjacent owner. If oversailing is not permitted, the jib can be fixed in a nonoffending configuration.

Wire rope typically runs from a winch on pulleys up and over the boom and jib. The lines attach to a *load block* or metal ball that keeps the lines pulled taut when no load is attached to the hook. With *standard hoisting wire hoist rope*, which has an approximate mass of 2 lbm/ft (3 kg/m), each line can support an allowable *line pull* of 14,000 lbf (62 kN). However, crane capacities also depend on the *reeving*, the path of the wire rope as it comes off the hoist drum and wraps around the various upper and lower sheaves. The number of lines reeved on the main hoist block determines the capacity of the crane. As with simple pulleys, the lift capacity is proportional to the number of wire rope lines going to and coming from the hook. This number is known as *parts of the line* (*n-part line*, etc.).

*Tower cranes* consist of a *base*, often bolted to a concrete pad, that supports the crane, a *mast (tower)*, and a *slewing unit (turntable)* consisting of the gear and motor that allows the crane to rotate. (See Fig. 83.5.) Four parts are mounted on top of the slewing unit: (1) the *top tower* holds pulleys for the wire rope and bracing; (2) the horizontal *jib (boom or working arm)*, is the portion of the crane that carries the load on a *trolley*, which runs along the jib and moves the load in and out from the crane's center; (3) a shorter horizontal *machinery arm (counterjib)*, which contains the crane's motors and electronics as well as *counterweights*, and (4) the *operator's cab*.

**Figure 83.5** Tower Crane

## 18. CRANE USE AND SAFETY

OSHA federal crane safety regulations for general industry are covered in OSHA 1910.179 (*Overhead and Gantry Cranes*), OSHA 1910.180 (*Crawler Locomotive and Truck Cranes*), and OSHA 1917.45 (*Cranes and*

*Derricks*). Cranes used in construction are covered in OSHA 1926 Subpart CC (*Cranes and Derricks in Construction*). Some states have their own crane safety standards. In general, these regulations reference American National Standards Institute (ANSI)/American Society of Mechanical Engineers (ASME) Standards ASME B-30.1 through ASME B-30.6. Two ANSI/ASME standards delineate safe operation and maintenance practices for construction cranes: ASME B-30.3 (*Construction Tower Cranes*) and ASME B-30.5 (*Mobile and Locomotive Cranes*).

OSHA 1926.1412 (*Inspections*) makes a distinction between competent and qualified persons. A *qualified person* is defined as "a person who by possession of a recognized degree, certificate, or professional standing, or who by extensive knowledge, training, and experience, successfully demonstrates the ability to solve/resolve problems relating to the subject matter, the work, or the project." A *competent person* is defined as someone who is "capable of identifying existing and predictable hazards in the surroundings or working conditions which are unsanitary, hazardous, or dangerous to employees, and who has authorization to take prompt corrective measures to eliminate them."

Only a *qualified person* can conduct annual inspections of equipment; inspections of modified, repaired, and adjusted equipment; and inspections after equipment has been assembled. A *competent person* may conduct the work shift and monthly equipment inspections, as long as that person has been trained in the required elements of a shift inspection. The crane or derrick operator can be the inspector, but only if the operator meets the respective requirements for a qualified or competent person.

Crane safety is a function of crane inspection and maintenance, selection, rigging, loading, and use. While each crane will have its own specific requirements and limitations, some safe practices apply to all crane operations. Such safe practices include the following.

- The crane should be operated only by qualified and trained personnel.
- A "competent person" must inspect the crane and controls before it is used.
- The crane must be on a firm/stable surface and be level.
- During assembly and disassembly, pins should not be unlocked or removed unless the sections are blocked, secure, and stable.
- Outriggers should be fully extended.
- Areas inside the crane's swing radius should be barricaded.
- A clearance of at least 10 ft (2 m) from overhead electric power lines should be watched for and maintained.
- All rigging must be inspected prior to use.

- Rig properly. Do not wrap hoist lines around the load.
- The correct load chart for the crane's current configuration and setup, load weight, and lift path must be used.
- The load chart capacity must not be exceeded.
- Before delivering the load, raise the load a few inches, hold, verify capacity/balance, and test the brake system.
- Do not use the crane's lift angle indicator for loads exceeding 75% of the rated capacity.
- Do not move loads over workers.
- Remain in vocal and visual contact with observers and follow their signals.
- Observe the manufacturer's instructions and limitations.

## 19. CRANE LOAD CHARTS

Every crane has a **load chart** that specifies the crane's features, dimensions, and how its lifting capacity varies with configuration. A load chart actually consists of a set of tables of data organized in different ways. The chart includes data for operation with the outriggers extended, transport weight, and steering dimensions. The transport weight information, in turn, determines the trailer that would be required to transport the crane to the job site, how to load the crane on a trailer, the route to take, and what highway permits would be required. The load chart also specifies what counterweight is required and what the outrigger extension dimensions are.

Charts should be read conservatively. For example, when an angle is used that is not listed on the load chart, use the next lower boom angle noted on the load chart for determining the capacity of the crane. When using a particular radius that is not listed on the load chart, use the next larger radius measurement in the load chart for determining the capacity of the crane.

The chart's **lift capacity chart (lift table)** consists of a table of maximum loads. Each horizontal row of numbers corresponds to a particular radius from the center pin. This is the distance from the center pin to the center of the lifted load. Each vertical column corresponds to a boom extension length. Maximum capacity is always measured by the shortest lift, usually over the rear of the crane, and with the outriggers fully extended.

The chart's **lift range chart (range diagram or range table)** illustrates how much boom length is needed to pick up and lift a load at given distances and vertical lift heights. The range chart is generally a part of the load chart decaling, as well as being part of the operating manual.

With higher angles of lift, the maximum load capacity decreases. The chart's **lift angle chart** illustrates the maximum lift with luffing and fixed jibs. With a luffing jib, the angle can be automatically adjusted from the operators cab. With a fixed jib, the angle is fixed.

The crane's **crane in motion chart** defines the lift capacity for *pick and carry* operation. The chart lists total capacities able to be picked at a 360 degree angle while stationary on wheels, while slowly rolling with the load at a zero degree angle (creep), and while moving at a steady speed, usually 2.5 mi/hr (4 km/h). Each row corresponds to a particular radius. The maximum boom length that each weight can be carried at is also given.

Depending on how the load chart is organized, reductions in the gross capacity of a crane (as read from the load chart) may be required for the weights of the jib, block, ball, rigging, and lengths of the main and auxiliary ropes.

### Example 83.2

The load chart for a Series C13M crane with an 18 ft jib is shown in *Table for Ex. 83.2*. Loadline equipment deductions are downhaul weight, 90 lbf; one sheave block, 185 lbf; two sheave blocks, 355 lbf. The crane is configured with 60 lbf of rigging and one sheave block with two parts of line. What is the crane's net capacity at a radius of 35 ft when the main boom is extended to 45 ft?

#### *Solution*

Although the crane has an 18 ft jib, an extension of 45 ft does not require the jib's use. Therefore, use the main part of the load chart.

The boom is extended to 45 ft, which is between the 40 ft and 48 ft columns on the table. Use the larger column (48 ft). At a radius of 35.0 ft, the gross crane capacity is 2600 lbf. Deductions are 185 lbf for one sheave block and 60 lbf for the rigging. The net crane capacity is

$$\begin{aligned} \text{net capacity} &= \text{gross capacity} - \text{deductions} \\ &= 2600 \text{ lbf} - 185 \text{ lbf} - 60 \text{ lbf} \\ &= 2355 \text{ lbf} \end{aligned}$$

Table for Ex. 83.2

load radius (ft)	loaded boom angle (deg)	loaded boom boom (lbf)	loaded boom angle (deg)	loaded boom boom (lbf)	loaded boom angle (deg)	loaded boom boom (lbf)	loaded boom angle (deg)	loaded boom boom (lbf)	load radius (ft)	loaded boom angle (deg)	18 ft jib (lbf)
5	77.5	20,000									
6	74.5	17,300

# 84 Electrical Systems and Equipment

1. Electric Charge .....	84-2
2. Current .....	84-2
3. Voltage Sources .....	84-2
4. Resistivity and Resistance .....	84-2
5. Conductivity and Conductance .....	84-2
6. Ohm's Law .....	84-3
7. Power in DC Circuits .....	84-3
8. Electrical Circuit Symbols .....	84-3
9. Resistors in Combination .....	84-3
10. Simple Series Circuits .....	84-3
11. Simple Parallel Circuits .....	84-4
12. Voltage and Current Dividers .....	84-4
13. AC Voltage Sources .....	84-4
14. Maximum, Effective, and Average Values ..	84-4
15. Impedance .....	84-5
16. Reactance .....	84-5
17. Admittance, Conductance, and Susceptance .....	84-5
18. Resistors in AC Circuits .....	84-5
19. Capacitors .....	84-5
20. Inductors .....	84-6
21. Transformers .....	84-6
22. Ohm's Law for AC Circuits .....	84-6
23. AC Current and Phase Angle .....	84-6
24. Power in AC Circuits .....	84-6
25. Power Factor .....	84-7
26. Cost of Electrical Energy .....	84-7
27. Circuit Breaker Sizing .....	84-8
28. National Electrical Code .....	84-8
29. Power Factor Correction .....	84-9
30. Three-Phase Electricity .....	84-10
31. Three-Phase Loads .....	84-10
32. Line and Phase Values .....	84-11
33. Input Power in Three-Phase Systems .....	84-11
34. Rotating Machines .....	84-11
35. Regulation .....	84-11
36. Torque and Power .....	84-12
37. NEMA Motor Classifications .....	84-12
38. Nameplate Values .....	84-13
39. Service Factor .....	84-13
40. Duty Cycle .....	84-14
41. Induction Motors .....	84-14
42. Induction Motor Performance .....	84-15
43. Synchronous Motors .....	84-15
44. DC Machines .....	84-15
45. Choice of Motor Types .....	84-15
46. Losses in Rotating Machines .....	84-17
47. Efficiency of Rotating Machines .....	84-17
48. High-Efficiency Motors and Drives .....	84-18

## Nomenclature

<i>a</i>	turns ratio	—	—
<i>A</i>	area	ft <sup>2</sup>	m <sup>2</sup>
<i>B</i>	susceptance	S	S
<i>C</i>	capacitance	F	F
<i>d</i>	diameter	ft	m
<i>E</i>	energy usage (demand)	kW-hr	kW-h
<i>f</i>	linear frequency	Hz	Hz
<i>G</i>	conductance	S	S
<i>i</i>	varying current	A	A
<i>I</i>	constant current	A	A
<i>l</i>	length	ft	m
<i>L</i>	inductance	H	H
<i>n</i>	speed	rev/min	rev/min
<i>N</i>	number of turns	—	—
<i>p</i>	number of poles	—	—
<i>pf</i>	power factor	—	—
<i>P</i>	power	W	W
<i>Q</i>	charge	C	C
<i>Q</i>	reactive power	VAR	VAR
<i>R</i>	resistance	Ω	Ω
<i>s</i>	slip	—	—
<i>sf</i>	service factor	—	—
<i>S</i>	apparent power	VA	VA
<i>SR</i>	speed regulation	—	—
<i>t</i>	time	sec	s
<i>T</i>	period	sec	s
<i>T</i>	torque	ft-lbf	N·m
<i>v</i>	varying voltage	V	V
<i>V</i>	constant voltage	V	V
<i>VR</i>	voltage regulation	—	—
<i>X</i>	reactance	Ω	Ω
<i>Y</i>	admittance	S	S
<i>Z</i>	impedance	Ω	Ω

## Symbols

$\eta$	efficiency	—	—
$\theta$	phase angle	rad	rad
$\rho$	resistivity	Ω-ft	Ω·m
$\sigma$	conductivity	1/Ω-ft	1/Ω·m
$\phi$	impedance angle	rad	rad
$\omega$	angular frequency	rad/sec	rad/s

## Subscripts

<i>a</i>	armature
ave	average
<i>C</i>	capacitive
Cu	copper
<i>e</i>	equivalent

eff	effective
f	field
l	line
L	inductive
m	maximum
p	phase or primary
r	rated
R	resistive
s	secondary
t	total

## 1. ELECTRIC CHARGE

The charge on an electron is one *electrostatic unit* (esu). Since an esu is very small, electrostatic charges are more conveniently measured in *coulombs* (C). One coulomb is approximately  $6.242 \times 10^{18}$  esu. Another unit of charge, the *faraday*, is sometimes encountered in the description of ionic bonding and plating processes. One faraday is equal to one mole of electrons, approximately 96,485 C (96,485 A·s).

## 2. CURRENT

*Current*,  $I$ , is the movement of electrons. By historical convention, current moves in a direction opposite to the flow of electrons (i.e., current flows from the positive terminal to the negative terminal). Current is measured in *amperes* (A) and is the time rate change in charge.

$$I = \frac{dQ}{dt} \quad [\text{DC circuits}] \quad 84.1(a)$$

$$i(t) = \frac{dQ}{dt} \quad [\text{AC circuits}] \quad 84.1(b)$$

## 3. VOLTAGE SOURCES

A net *voltage*,  $V$ , causes electrons to move, hence the common synonym *electromotive force* (emf).<sup>1</sup> With *direct current* (DC) voltage sources, the voltage may vary in amplitude, but not in polarity. In simple problems where a battery serves as the voltage source, the magnitude is also constant.

With *alternating current* (AC) voltage sources, the magnitude and polarity both vary with time. Due to the method of generating electrical energy, AC voltages are typically sinusoidal.

## 4. RESISTIVITY AND RESISTANCE

*Resistance*,  $R$ , is the property of a *resistor* or resistive circuit to impede current flow.<sup>2</sup> A circuit with zero resistance is a *short circuit*, whereas an *open circuit* has infinite resistance. Adjustable resistors are known as *potentiometers*, *rheostats*, and *variable resistors*.

<sup>1</sup>The symbol  $E$  (derived from the name electromotive force) has been commonly used to represent voltage induced by electromagnetic induction.

<sup>2</sup>Resistance is not the same as *inductance*, which is the property of a device to impede a *change* in current flow. (See Sec. 84.20.)

Resistance of a circuit element depends on the *resistivity*,  $\rho$  (in  $\Omega\text{-in}$  or  $\Omega\text{-cm}$ ), and length,  $l$ , of the material and the geometry of the current path through the element. The area,  $A$ , of circular conductors is often measured in *circular mils*, abbreviated *cmils*, the area of a 0.001 in diameter circle.

$$R = \frac{\rho l}{A} \quad 84.2$$

$$A_{\text{cmils}} = \left( \frac{d_{\text{in}}}{0.001} \right)^2 \quad 84.3$$

$$A_{\text{in}^2} = (7.854 \times 10^{-7}) A_{\text{cmils}} \quad 84.4$$

Resistivity depends on temperature. For most conductors, resistivity increases linearly with temperature. The resistivity of standard *International Annealed Copper Standard* (IACS) copper wire at 20°C is approximately

$$\begin{aligned} \rho_{\text{IACS Cu}, 20^\circ\text{C}} &= 1.7241 \times 10^{-6} \Omega\text{-cm} \\ &= 1.7241 \times 10^{-8} \text{ m/S} \\ &= 0.67879 \times 10^{-6} \Omega\text{-in} \\ &= 10.371 \Omega\text{-cmil}/\text{ft} \end{aligned} \quad 84.5$$

### Example 84.1

What is the resistance of a parallelepiped (1 cm × 1 cm × 1 m long) of IACS copper if current flows between the two smaller faces?

*Solution*

From Eq. 84.2 and Eq. 84.5, the resistance is

$$\begin{aligned} R &= \frac{\rho l}{A} = \frac{(1.7241 \times 10^{-6} \Omega\text{-cm})(1 \text{ m}) \left( 100 \frac{\text{cm}}{\text{m}} \right)}{(1 \text{ cm})(1 \text{ cm})} \\ &= 1.724 \times 10^{-4} \Omega \end{aligned}$$

## 5. CONDUCTIVITY AND CONDUCTANCE

The reciprocals of resistivity and resistance are *conductivity*,  $\sigma$ , and *conductance*,  $G$ , respectively. The unit of conductance is the *siemens* (S).<sup>3</sup>

$$\sigma = \frac{1}{\rho} \quad 84.6$$

$$G = \frac{1}{R} \quad 84.7$$

*Percent conductivity* is the ratio of a substance's conductivity to the conductivity of standard IACS copper. (See Sec. 84.4.)

$$\begin{aligned} \% \text{ conductivity} &= \frac{\sigma}{\sigma_{\text{Cu}}} \times 100\% \\ &= \frac{\rho_{\text{Cu}}}{\rho} \times 100\% \end{aligned} \quad 84.8$$

<sup>3</sup>The siemens is the inverse of an ohm and is the same as the obsolete unit, the *mho*.

## 6. OHM'S LAW

The *voltage drop*, also known as the *IR drop*, across a circuit or circuit element with resistance,  $R$ , is given by *Ohm's law*.<sup>4</sup>

$$V = IR \quad [\text{DC circuits}] \quad 84.9$$

$$v(t) = i(t)R \quad [\text{AC circuits}] \quad 84.10$$

## 7. POWER IN DC CIRCUITS

The *power*,  $P$  (in watts), dissipated across two terminals with resistance,  $R$ , and voltage drop,  $V$ , is given by *Joule's law*, Eq. 84.11.

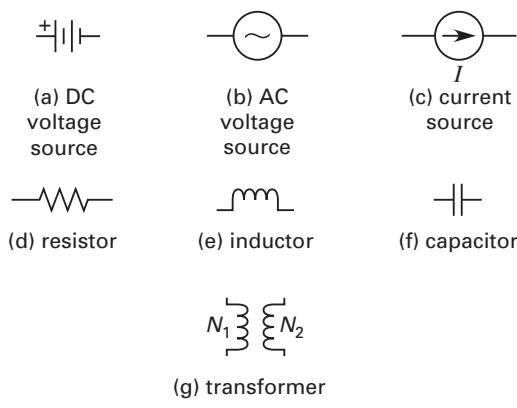

$$\begin{aligned} P &= IV = I^2 R = \frac{V^2}{R} \\ &= V^2 G \quad [\text{DC circuits}] \end{aligned} \quad 84.11$$

$$\begin{aligned} P(t) &= i(t)v(t) = i(t)^2 R = \frac{v(t)^2}{R} \\ &= v(t)^2 G \quad [\text{AC circuits}] \end{aligned} \quad 84.12$$

## 8. ELECTRICAL CIRCUIT SYMBOLS

Figure 84.1 illustrates symbols typically used to diagram electrical circuits in this book.

**Figure 84.1** Symbols for Electrical Circuit Elements

## 9. RESISTORS IN COMBINATION

Resistors in series are added to obtain the total (equivalent) resistance of a circuit.

$$R_e = R_1 + R_2 + R_3 + \dots \quad [\text{series}] \quad 84.13$$

Resistors in parallel are combined by adding their reciprocals. This is a direct result of the fact that conductances in parallel add.

$$G_e = G_1 + G_2 + G_3 + \dots \quad [\text{parallel}] \quad 84.14$$

$$\frac{1}{R_e} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \dots \quad [\text{parallel}] \quad 84.15$$

For two resistors in parallel, the equivalent resistance is

$$R_e = \frac{R_1 R_2}{R_1 + R_2} \quad [\text{two parallel resistors}] \quad 84.16$$

## 10. SIMPLE SERIES CIRCUITS

Figure 84.2 illustrates a simple series DC circuit and its equivalent circuit.

- The current is the same through all circuit elements.

$$I = I_{R_1} = I_{R_2} = I_{R_3} \quad 84.17$$

- The equivalent resistance is the sum of the individual resistances.

$$R_e = R_1 + R_2 + R_3 \quad 84.18$$

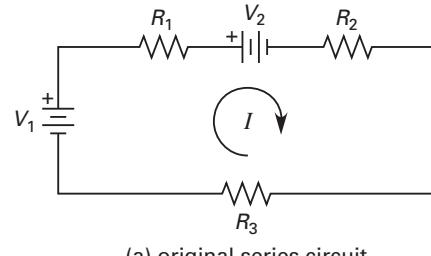

- The equivalent applied voltage is the sum of all voltage sources (polarities considered).

$$V_e = \pm V_1 \pm V_2 \quad 84.19$$

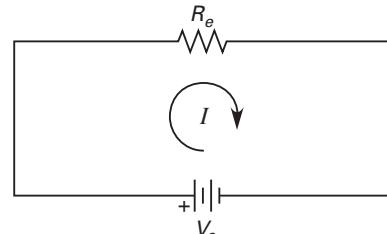

- The sum of all of the voltage drops across the components in the circuit (a *loop*) is equal to the equivalent applied voltage. This fact is known as *Kirchhoff's voltage law*.

$$V_e = \sum IR_j = I \sum R_j = IR_e \quad 84.20$$

**Figure 84.2** Simple Series DC Circuit and Its Equivalent

(a) original series circuit

(b) equivalent circuit

<sup>4</sup>This book uses the convention that uppercase letters represent fixed, maximum, or effective values, and lowercase letters represent values that change with time.

## 11. SIMPLE PARALLEL CIRCUITS

Figure 84.3 illustrates a simple parallel DC circuit with one voltage source and its equivalent circuit.

- The voltage drop is the same across all legs.

$$\begin{aligned} V &= V_{R_1} = V_{R_2} = V_{R_3} \\ &= I_1 R_1 = I_2 R_2 = I_3 R_3 \end{aligned} \quad 84.21$$

- The reciprocal of the equivalent resistance is the sum of the reciprocals of the individual resistances.

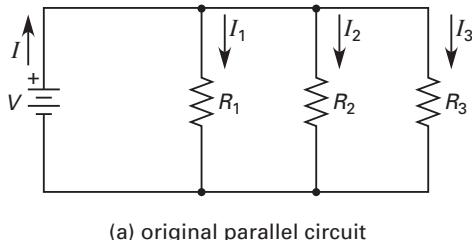

$$\frac{1}{R_e} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} \quad 84.22$$

$$G_e = G_1 + G_2 + G_3 \quad 84.23$$

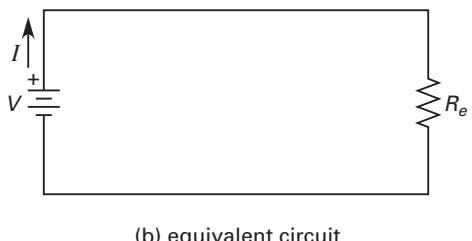

- The sum of all of the leg currents is equal to the total current. This fact is an extension of *Kirchhoff's current law*: The current flowing out of a connection (*node*) is equal to the current flowing into it.

$$\begin{aligned} I &= I_1 + I_2 + I_3 = \frac{V}{R_1} + \frac{V}{R_2} + \frac{V}{R_3} \\ &= V(G_1 + G_2 + G_3) \end{aligned} \quad 84.24$$

**Figure 84.3** Simple Parallel DC Circuit and Its Equivalent

(a) original parallel circuit

(b) equivalent circuit

## 12. VOLTAGE AND CURRENT DIVIDERS

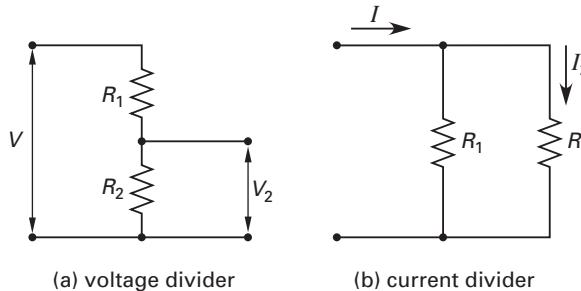

Figure 84.4(a) illustrates a *voltage divider circuit*. The voltage across resistor 2 is

$$V_2 = V \left( \frac{R_2}{R_1 + R_2} \right) \quad 84.25$$

Figure 84.4(b) illustrates a *current divider circuit*. The current through resistor 2 is

$$I_2 = I \left( \frac{R_1}{R_1 + R_2} \right) \quad 84.26$$

**Figure 84.4** Divider Circuits

## 13. AC VOLTAGE SOURCES

The term *alternating current* (AC) almost always means that the current is produced from the application of a voltage with sinusoidal waveform.<sup>5</sup> Sinusoidal variables can be specified without loss of generality as either sines or cosines. If a sine waveform is used, Eq. 84.27 gives the instantaneous voltage as a function of time.  $V_m$  is the *maximum value*, also known as the *amplitude*, of the sinusoid. If the time scale has been defined such that  $v(t)$  is not zero at  $t=0$ , a *phase angle*,  $\theta$ , must be included. In most cases, the voltage waveform is the reference, and  $\theta=0$ .

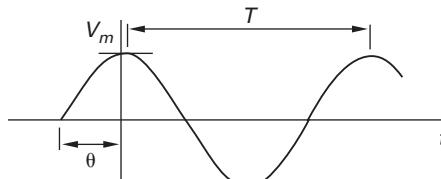

$$v(t) = V_m \sin(\omega t + \theta) \quad [\text{trigonometric form}] \quad 84.27$$

Figure 84.5 illustrates the *period*,  $T$ , of the waveform. The *frequency*,  $f$  (also known as *linear frequency*), of the sinusoid is the reciprocal of the period and is expressed in hertz (Hz).<sup>6</sup> *Angular frequency*,  $\omega$ , in radians per second (rad/s), can also be specified.

$$f = \frac{1}{T} = \frac{\omega}{2\pi} \quad 84.28$$

$$\omega = 2\pi f = \frac{2\pi}{T} \quad 84.29$$

**Figure 84.5** Sinusoidal Waveform

## 14. MAXIMUM, EFFECTIVE, AND AVERAGE VALUES

The *maximum value*,  $V_m$ , of a sinusoidal voltage is usually not specified in commercial and residential power systems. (See Fig. 84.5.) The *effective value*, also

<sup>5</sup>Other alternating waveforms commonly encountered in commercial applications are the square, triangular, and sawtooth waveforms.

<sup>6</sup>In the United States, the standard frequency is 60 Hz. The standard frequency is 50 Hz in Japan; the British Isles and Commonwealth nations; continental Europe; and some Mediterranean, Near Eastern, African, and South American countries.

known as the *root-mean-square (rms) value*, is usually specified when referring to single- and three-phase voltages.<sup>7</sup> A DC current equal in magnitude to the effective value of a sinusoidal AC current produces the same heating effect as the sinusoid. The scale reading of a typical AC current meter is proportional to the effective current.

$$V_{\text{eff}} = \frac{V_m}{\sqrt{2}} \approx 0.707 V_m \quad 84.30$$

The *average value* of a symmetrical sinusoidal waveform is zero. However, the average value of a rectified sinusoid (or the average value of a sinusoid taken over half of the cycle) is  $V_{\text{ave}} = 2V_m/\pi$ . A DC current equal to the average value of a *rectified AC current* has the same electrolytic action (e.g., capacitor charging, plating, and ion formation) as the rectified sinusoid.<sup>8</sup>

## 15. IMPEDANCE

Simple alternating current circuits can be composed of three different types of passive circuit components—resistors, inductors, and capacitors. Each type of component affects both the magnitude of the current flowing as well as the phase angle of the current. (See Sec. 84.23.) For both individual components and combinations of components, these two effects are quantified by the *impedance*,  $Z$ . Impedance is a complex quantity with a magnitude (in ohms) and an associated *impedance angle*,  $\phi$ . It is usually written in *phasor (polar) form* (e.g.,  $Z \equiv Z \angle \phi$ ).

Multiple impedances in a circuit combine in the same manner as resistances: impedances in series add; reciprocals of impedances in parallel add. However, the addition must use complex (i.e., vector) arithmetic.

## 16. REACTANCE

Impedance, like any complex quantity, can also be written in rectangular form. In this case, impedance is written as the complex sum of the resistive,  $R$ , and reactive,  $X$ , components, both having units of ohms. The resistive and reactive components combine trigonometrically in the impedance triangle. (See Fig. 84.6.) The reactive component,  $X$ , is known as the *reactance*.

$$Z \equiv R \pm jX \quad 84.31$$

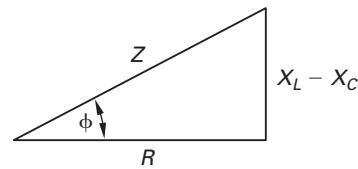

$$R = Z \cos \phi \quad [\text{resistive part}] \quad 84.32$$

$$X = Z \sin \phi \quad [\text{reactive part}] \quad 84.33$$

<sup>7</sup>The standard U.S. 110 V household voltage (also commonly referred to as 115 V, 117 V, and 120 V) is an effective value. This is sometimes referred to as the *nominal system voltage* or just *system voltage*. Other standard voltages used around the world, expressed as effective values, are 208 V, 220 V, 230 V, 240 V, 480 V, 550 V, 575 V, and 600 V.

<sup>8</sup>A *rectified waveform* has had all of its negative values converted to positive values of equal absolute value.

Figure 84.6 Impedance Triangle of a Complex Circuit

## 17. ADMITTANCE, CONDUCTANCE, AND SUSCEPTANCE

The reciprocal of impedance is the complex quantity *admittance*,  $Y$ . Admittance can be used to analyze parallel circuits, since admittances of parallel circuit elements add together.

$$Y = \frac{1}{Z} \equiv \frac{1}{Z} \angle -\phi \quad 84.34$$

The reciprocal of the resistive part of the impedance is the *conductance*,  $G$ , with units of siemens (S). The reciprocal of the reactive part of impedance is the *susceptance*,  $B$ .

$$G = \frac{1}{R} \quad 84.35$$

$$B = \frac{1}{X} \quad 84.36$$

## 18. RESISTORS IN AC CIRCUITS

An ideal resistor, with resistance  $R$ , has no inductance or capacitance. The magnitude of the impedance is equal to the resistance,  $R$  (in ohms,  $\Omega$ ). The impedance angle is zero. Therefore, current and voltage are in phase in a purely resistive circuit.

$$Z_R \equiv R \angle 0^\circ \equiv R + j0 \quad 84.37$$

## 19. CAPACITORS

A *capacitor* stores electrical charge. The charge on a capacitor is proportional to its *capacitance*,  $C$  (in farads, F), and voltage.<sup>9</sup>

$$Q = CV \quad 84.38$$

An ideal capacitor has no resistance or inductance. The magnitude of the impedance is the *capacitive reactance*,  $X_C$ , in ohms. The impedance angle is  $-\pi/2$  ( $-90^\circ$ ). Therefore, current leads the voltage by  $90^\circ$  in a purely capacitive circuit.

$$Z_C \equiv X_C \angle -90^\circ \equiv 0 - jX_C \quad 84.39$$

$$X_C = \frac{1}{\omega C} = \frac{1}{2\pi fC} \quad 84.40$$

<sup>9</sup>Since a farad is a very large unit of capacitance, most capacitors are measured in microfarads,  $\mu\text{F}$ .

## 20. INDUCTORS

An ideal *inductor*, with an *inductance*,  $L$  (in units of the henry, H), has no resistance or capacitance. The magnitude of the impedance is the *inductive reactance*,  $X_L$ , in ohms. The impedance angle is  $\pi/2$  ( $90^\circ$ ). Therefore, current lags the voltage by  $90^\circ$  in a purely inductive circuit.<sup>10</sup>

$$\mathbf{Z}_L \equiv X_L / 90^\circ \equiv 0 + jX_L \quad 84.41$$

$$X_L = \omega L = 2\pi f L \quad 84.42$$

## 21. TRANSFORMERS

Transformers are used to change voltages, isolate circuits, and match impedances. Transformers usually consist of two coils of wire wound on magnetically permeable cores. One coil, designated as the *primary coil*, serves as the input; the other coil, the *secondary coil*, is the output. The primary current produces a magnetic flux in the core; the magnetic flux, in turn, induces a voltage in the secondary coil. In an *ideal transformer* (*lossless transformer* or *100% efficient transformer*), the coils have no electrical resistance, and all magnetic flux lines pass through both coils.

The ratio of the numbers,  $N$ , of primary to secondary coil windings is the *turns ratio (ratio of transformation)*,  $a$ . If the turns ratio is greater than 1.0, the transformer decreases voltage and is a *step-down transformer*. If the turns ratio is less than 1.0, the transformer increases voltage and is a *step-up transformer*.

$$a = \frac{N_p}{N_s} \quad 84.43$$

In an ideal transformer, the power transferred from the primary side equals the power received by the secondary side.

$$P = I_p V_p = I_s V_s \quad 84.44$$

$$a = \frac{V_p}{V_s} = \frac{I_s}{I_p} = \sqrt{\frac{Z_p}{Z_s}} \quad 84.45$$

## 22. OHM'S LAW FOR AC CIRCUITS

Ohm's law can be written in phasor (polar) form. (See Sec. 84.6.) Voltage and current can be represented by their maximum, effective (rms), or average values. However, both must be represented in the same manner.

$$\mathbf{V} = \mathbf{I}\mathbf{Z} \quad 84.46$$

$$V = IZ \quad [\text{magnitudes only}] \quad 84.47$$

$$\phi_V = \phi_I + \phi_Z \quad [\text{angles only}] \quad 84.48$$

<sup>10</sup>Use the memory aid "ELI the ICE man" to remember that current (I) comes after voltage (electromagnetic force, E) in inductive (L) circuits. In capacitive (C) circuits, current leads voltage.

## 23. AC CURRENT AND PHASE ANGLE

The current and current phase angle of a circuit are determined by using Ohm's law in phasor form. The current *phase angle*,  $\phi_I$ , is the angular difference between when the current and voltage waveforms peak.

$$\mathbf{I} = \frac{\mathbf{V}}{\mathbf{Z}} \quad 84.49$$

$$I = \frac{V}{Z} \quad [\text{magnitudes only}] \quad 84.50$$

$$\phi_I = \phi_V - \phi_Z \quad [\text{angles only}] \quad 84.51$$

### Example 84.2

An inventor's black box is connected across standard household voltage (110 V rms). The current drawn is 1.7 A with a lagging phase angle of  $14^\circ$  with respect to the voltage. What is the impedance of the black box?

*Solution*

From Eq. 84.49,

$$\begin{aligned} \mathbf{Z} &= \frac{\mathbf{V}}{\mathbf{I}} = \frac{110 \text{ V}/0^\circ}{1.7 \text{ A}/14^\circ} \\ &= 64.71 \Omega/-14^\circ \end{aligned}$$

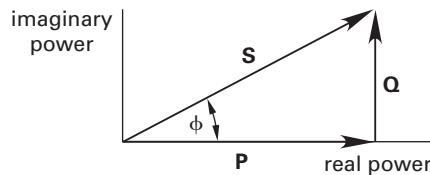

## 24. POWER IN AC CIRCUITS

In a purely resistive circuit, all of the current drawn contributes to dissipated energy. The flow of current causes resistors to increase in temperature, and heat is transferred to the environment.

In a typical AC circuit containing inductors and capacitors as well as resistors, some of the current drawn does not cause heating.<sup>11</sup> Rather, the current charges capacitors and creates magnetic fields in inductors. Since the voltage alternates in polarity, capacitors alternately charge and discharge. Energy is repeatedly drawn and returned by capacitors. Similarly, energy is repeatedly drawn and returned by inductors as their magnetic fields form and collapse.

Current through resistors in AC circuits causes heating, just as in DC circuits. The power dissipated is represented by the *real power* vector,  $\mathbf{P}$ . Current through capacitors and inductors contributes to reactive power, represented by the *reactive power* vector,  $\mathbf{Q}$ . Reactive power does not contribute to heating. For convenience, both real and reactive power are considered to be complex (vector) quantities, with magnitudes and associated angles. Real and reactive power combine as vectors into the *complex power* vector,  $\mathbf{S}$ , as shown in Fig. 84.7. The angle,  $\phi$ , is the *impedance angle*.

<sup>11</sup>The notable exception is a *resonant circuit* in which the inductive and capacitive reactances are equal. In that case, the circuit is purely resistive in nature.

**Figure 84.7** Complex Power Triangle (lagging)

The magnitude of real power is known as the *average power*,  $P$ , and is measured in watts. The magnitude of the reactive power vector is known as *reactive power*,  $Q$ , and is measured in VARs (volt-amps reactive). The magnitude of the complex power vector is the *apparent power*,  $S$ , measured in VAs (volt-amps). The apparent power is easily calculated from measurements of the line current and line voltage.

$$S = I_{\text{eff}} V_{\text{eff}} = \frac{1}{2} I_m V_m \quad 84.52$$

## 25. POWER FACTOR

The complex power triangle shown in Fig. 84.7 is congruent to the impedance triangle, and the *power angle*,  $\phi$ , is identical to the overall impedance angle. (See Fig. 84.6.)

$$S^2 = P^2 + Q^2 \quad 84.53$$

$$P = S \cos \phi \quad 84.54$$

$$Q = S \sin \phi \quad 84.55$$

$$\phi = \arctan \frac{Q}{P} \quad 84.56$$

The *power factor*, pf (also occasionally referred to as the *phase factor*), for a sinusoidal voltage is  $\cos \phi$ . By convention, the power factor is usually given in percent rather than by its equivalent decimal value. For a purely resistive circuit, pf = 100%; for a purely reactive circuit, pf = 0%.

$$\text{pf} = \frac{P}{S} \quad 84.57$$

Since the cosine is positive for both positive and negative angles, the terms “leading” and “lagging” are used to describe the nature of the circuit. In a circuit with a *leading power factor* (i.e., in a *leading circuit*), the load is primarily capacitive in nature. In a circuit with a *lagging power factor* (i.e., in a *lagging circuit*), the load is primarily inductive in nature.

## 26. COST OF ELECTRICAL ENERGY

Except for large industrial users, electrical meters at service locations usually measure and record real power only. Electrical utilities charge on the basis of the total energy used. Energy usage, commonly referred to as the *usage* or *demand*, is measured in kilowatt-hours, abbreviated kWh or kW-hr.

$$\text{cost} = (\text{cost per kW-hr}) \times E_{\text{kW-hr}} \quad 84.58$$

The cost per kW-hr may not be a single value but may be tiered so that cost varies with cumulative usage. The lowest rate is the *baseline rate*.<sup>12</sup> To encourage conservation, the incremental cost of energy increases with increases in monthly usage.<sup>13</sup> To encourage cutbacks during the day, the cost may also increase during periods of peak demand.<sup>14</sup> The increase in cost for usage during peak demand may be accomplished by varying the rate, additively, or by use of a *peak demand multiplier*. There may also be different rates for summer and winter usage.

Although only real power is dissipated, reactive power contributes to total current. (Reactive power results from the current drawn in supplying the magnetization energy in motors and charges on capacitors.) The distribution system (wires, transformers, etc.) must be sized to carry the total current, not just the current supplying the heating effect. When real power alone is measured at the service location, the power factor is routinely monitored and its effect is built into the charge per kW-hr. This has the equivalent effect of charging the user for apparent power usage.

### Example 84.3

A small office normally uses 700 kWh per month of electrical energy. The company adds a 1.5 kW heater (to be used at the rate of 1000 kWh/month) and a 5 hp motor with a mechanical efficiency of 90% (to be used at a rate of 240 hr/mo). What is the incremental cost of adding the heater and motor? The tiered rate structure is

electrical usage (kW-hr)	rate (\$/kW-hr)
less than 350	0.1255
350–999	0.1427
1000–3999	0.1693

<sup>12</sup>There might also be a *lifeline rate* for low-income individuals with very low usage.

<sup>13</sup>There are different rate structures for different categories of users. While increased use within certain categories of users (e.g., residential) results in a higher cost per kWh, larger users in another category may pay substantially less per kWh due to their volume “buying power.”

<sup>14</sup>The day may be divided into *peak periods*, *partial-peak periods*, and *off-peak periods*.

**Solution**

Motors are rated by their real power output, which is less than their real power demand. The incremental electrical usage per month is

$$\frac{(5 \text{ hp}) \left( 0.7457 \frac{\text{kW}}{\text{hp}} \right) (240 \text{ hr})}{1000 \text{ kW}\cdot\text{hr} + \frac{0.90}{}} = 1994 \text{ kW}\cdot\text{hr}$$

The cumulative monthly electrical usage is

$$700 \text{ kW}\cdot\text{hr} + 1994 \text{ kW}\cdot\text{hr} = 2694 \text{ kW}\cdot\text{hr}$$

The company was originally in the second tier. The new usage will be billed partially at the second and third tier rates.

The incremental cost is

$$(999 \text{ kW}\cdot\text{hr} - 700 \text{ kW}\cdot\text{hr}) \left( 0.1427 \frac{\$}{\text{kW}\cdot\text{hr}} \right) + (2694 \text{ kW}\cdot\text{hr} - 999 \text{ kW}\cdot\text{hr}) \left( 0.1693 \frac{\$}{\text{kW}\cdot\text{hr}} \right) = \$329.63$$

## 27. CIRCUIT BREAKER SIZING

The purpose of a circuit breaker (“breaker”) is to protect the wiring insulation from overheating. Breakers operate as heat-activated switches. Overloads, short circuits, and faulty equipment result in large current draws. Extended currents in excess of a breaker’s rating will cause it to trip.

A breaker should be sized based on the average expected electrical load for that circuit. *Dedicated circuits* are easily sized based on the amperage of the equipment served, taken either from the nameplate current or calculated from the nameplate power as  $I = P/V$ . For general purpose circuits, reasonable judgment is required to estimate how many of the outlets will be in use simultaneously, and what equipment will be plugged in. Although circuit breakers are designed to operate at their rated loads for at least three hours, breakers should be sized for about 1.25 times the expected maximum load, not to exceed the capacity of the wire.

## 28. NATIONAL ELECTRICAL CODE

While a circuit breaker can be simplistically sized by calculating the maximum current from the known loads, unless the practitioner is a licensed electrician or electrical power engineer, a little knowledge of

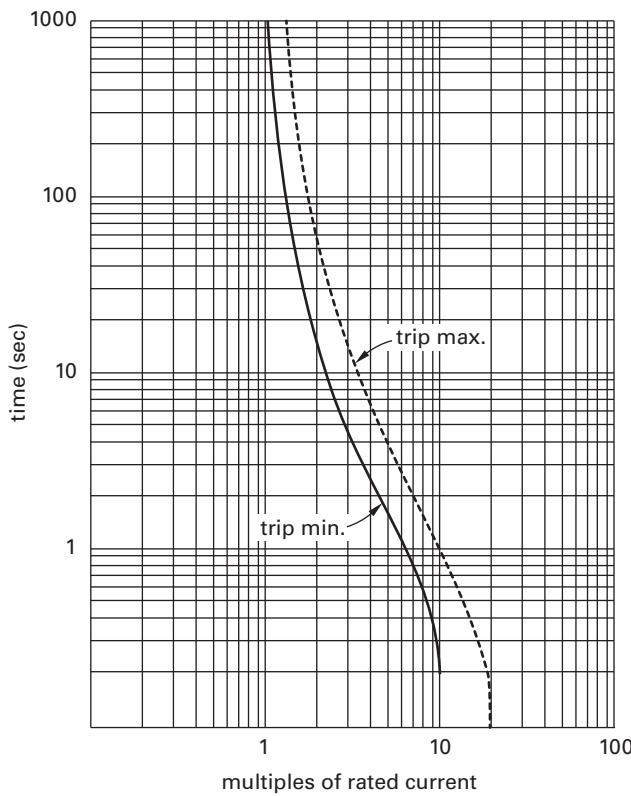

circuit breaker operation and the *National Electrical Code* (NEC) can greatly complicate the analysis. For this reason, most engineers should stop after calculating the maximum current, and they should leave the actual device selection to another trade. Selecting protection for standby generator circuits is particularly complex.

In the United States, the NEC specifies circuit breaker size as a function of the wire size. The wire is measured in American wire gauge and is abbreviated AWG or just GA. (Numerical wire size gauge decreases as the physical size increases.) Typical wire sizes and maximum currents (*ampacity*) for copper wire are 14 AWG (used for lighting and light-duty circuits up to 15 A), 12 AWG (for power outlets, kitchen microwaves, and lighting circuits up to 20 A), 10 AWG (30 A), 8 AWG (40 A), 6 AWG (50 A or 60 A), 4 AWG (75 A), and 3 AWG (100 A). For aluminum wires, the wire size should be one gauge larger. Common household circuit breaker sizes are 15 A, 20 A, and 30 A, although specialty sizes are also available in 5 A increments. Industrial sizes are readily available through 800 A, and larger breakers can handle thousands of amps.

The NEC refers to circuit breakers as *overcurrent protection devices* (OCPD). The NEC permits a circuit breaker to run essentially continuously at 100% of its *rated current*,  $I_r$ . This ability is intrinsic to the circuit breaker design, as Fig. 84.8 shows. When the current is greater than the rated current, the circuit breaker will open (i.e., “clear the circuit”) if the exposure duration is between the minimum and maximum curve times. The range of times between vertically adjacent points on the two curves represents the maximum delay for the breaker for that current, although exact values should not be expected. The lower minimum curve anticipates tripping due to thermal action; the upper maximum curve anticipates tripping due to magnetic action (i.e., short circuits).

Figure 84.8 shows that this particular curve allows circuit breakers to pass currents as large as 10 times their rated values, albeit for no more than a second, and twice their rated currents for up to 10 seconds. This overcurrent must be considered when selecting breakers with rated currents significantly in excess of the calculated maximum circuit current.

Allowing a circuit breaker to run continuously at its rated value is based on ideal testing conditions, such as mounting in free air, no enclosure, and constant 104°F (40°C) air temperature. For typical installations with heating from adjacent breakers in an enclosure, the NEC requires continuously operated breakers to be derated to 80% of rated capacities. This derating should be applied with continuous operation, which NEC Art. 100 defines as operation that exceeds three hours in duration. Interior office lighting would be considered continuous, while electrical kitchen appliances normally would not be. Most electrical heating for vessels, pipes, and deicing is considered continuous.

**Figure 84.8** Typical Thermal-Magnetic Breaker Trip Curve\*

\*Typical curve with Underwriters Laboratories (UL) specifications for use in the United States, 104°F (40°C). International Electrotechnical Commission trip curves (IEC 947-2) for other countries are similar in shape but differ in specific values from UL curves.

NEC Sec. 210.19(A)(1) and Sec. 210.20(A) specify the required OCPD (i.e., breaker) size as Eq. 84.59, which is sometimes referred to as the *80% rule*, since the reciprocal of 0.80 is 1.25.

$$\text{required rated capacity} = \frac{100\% \text{ of noncontinuous load}}{+ 125\% \text{ of continuous load}} \quad 84.59$$

Circuit breakers are subject to heating from adjacent breakers in an enclosure regardless of whether their loads are continuous or noncontinuous. This does not mean that all circuit breakers in an enclosure must be derated. *Standard circuit breakers*, also known as *80% rated circuit breakers* and *non-100% rated circuit breakers*, have been tested and certified to function properly with noncontinuous loads in enclosures, so Eq. 84.59 can be used with confidence. Unfortunately, there is also a class of *100% rated circuit breakers* (including solid state devices that do not generate thermal energy), which have been tested and certified to function properly with continuous loads within enclosures. The 125% multiplier does not need to be applied to 100% rated circuit breakers. Clearly, the specification of actual OCPDs should be left to the experts.

### Example 84.4

A 120 V (rms) circuit supplies 6 kW of office lighting and 125 A to one phase of a three-phase elevator induction motor. 175 A, 200 A, 225 A, and 250 A standard breakers are available. Which breaker should be specified?

*Solution*

The elevator motor is a noncontinuous load. The office lighting draws a continuous current of

$$I = \frac{P}{V} = \frac{(6 \text{ kW})(1000 \frac{\text{W}}{\text{kW}})}{120 \text{ V}} = 50 \text{ A}$$

Since a standard (i.e., 80% rated) circuit breaker is called for, use Eq. 84.59.

$$\begin{aligned} \text{required rated capacity} &= \frac{100\% \text{ of noncontinuous load}}{+ 125\% \text{ of continuous load}} \\ &= (1.0)(125 \text{ A}) + (1.25)(50 \text{ A}) \\ &= 187.5 \text{ A} \end{aligned}$$

The 200 A circuit breaker should be specified.

## 29. POWER FACTOR CORRECTION

Inasmuch as apparent power is paid for but only real power is used to drive motors or provide light and heating, it may be possible to reduce electrical utility charges by reducing the power angle without changing the real power. This strategy, known as *power factor correction*, is routinely accomplished by changing the circuit reactance in order to reduce the reactive power. The change in reactive power needed to change the power angle from  $\phi_1$  to  $\phi_2$  is

$$\Delta Q = P(\tan \phi_1 - \tan \phi_2) \quad 84.60$$

When a circuit is capacitive (i.e., leading), induction motors can be connected across the line to improve the power factor. (See Sec. 84.41.) In the more common situation, when a circuit is inductive (i.e., lagging), capacitors or synchronous capacitors can be added across the line. (See Sec. 84.43.) The size (in farads) of capacitor required is

$$C = \frac{\Delta Q}{\pi f V_m^2} \quad [V_m \text{ maximum}] \quad 84.61$$

$$C = \frac{\Delta Q}{2\pi f V_{\text{eff}}^2} \quad [V_{\text{eff}} \text{ effective}] \quad 84.62$$

Capacitors for power factor correction are generally rated in kVA. Equation 84.60 can be used to find that rating.

**Example 84.5**

A 60 Hz, 5 hp induction motor draws 53 A (rms) at 117 V (rms) with a 78.5% electrical-to-mechanical energy conversion efficiency. What capacitance should be connected across the line to increase the power factor to 92%?

*Solution*

The apparent power is found from the observed voltage and the current. Use Eq. 84.52.

$$S = IV = \frac{(53 \text{ A})(117 \text{ V})}{1000 \frac{\text{VA}}{\text{kVA}}} = 6.201 \text{ kVA}$$

The real power drawn from the line is calculated from the real work done by the motor. Use Eq. 84.72.

$$P_{\text{electrical}} = \frac{P_{\text{out}}}{\eta} = \frac{(5 \text{ hp}) \left( 0.7457 \frac{\text{kW}}{\text{hp}} \right)}{0.785} = 4.750 \text{ kW}$$

The reactive power and power angle are calculated from the real and apparent powers. From Eq. 84.53,

$$Q_1 = \sqrt{S^2 - P^2} = \sqrt{(6.201 \text{ kVA})^2 - (4.750 \text{ kW})^2} = 3.986 \text{ kVAR}$$

From Eq. 84.54,

$$\phi_1 = \arccos \frac{P}{S} = \arccos \frac{4.750 \text{ kW}}{6.201 \text{ kVA}} = 40.00^\circ$$

The desired power factor angle is

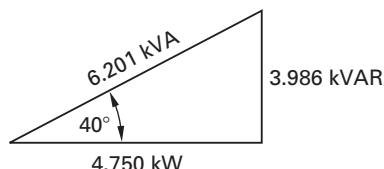

$$\phi_2 = \arccos 0.92 = 23.07^\circ$$

The reactive power after the capacitor is installed is given by Eq. 84.56.

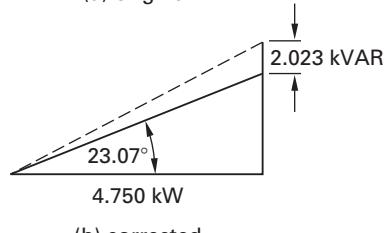

$$Q_2 = P \tan \phi_2 = (4.750 \text{ kW})(\tan 23.07^\circ) = 2.023 \text{ kVAR}$$

The required capacitance is found from Eq. 84.62.

$$C = \frac{\Delta Q}{2\pi f V_{\text{eff}}^2} = \frac{(3.986 \text{ kVAR} - 2.023 \text{ kVAR}) \left( 1000 \frac{\text{VAR}}{\text{kVAR}} \right)}{(2\pi)(60 \text{ Hz})(117 \text{ V})^2} = 3.8 \times 10^{-4} \text{ F} \quad (380 \mu\text{F})$$

(a) original

(b) corrected

**30. THREE-PHASE ELECTRICITY**

Smaller electric loads, such as household loads, are served by single-phase power. The power company delivers a sinusoidal voltage of fixed frequency and amplitude connected between two wires—a phase wire and a neutral wire. Large electric loads, large buildings, and industrial plants are served by three-phase power. Three voltage signals are connected between three phase wires and a single neutral wire. The phases have equal frequency and amplitude, but they are out of phase by 120° (electrical) with each other. Such *three-phase systems* use smaller conductors to distribute electricity.<sup>15</sup> For the same delivered power, three-phase distribution systems have lower losses and are more efficient.

Three-phase motors provide a more uniform torque than do single-phase motors whose torque production pulsates.<sup>16</sup> Three-phase induction motors require no additional starting windings or associated switches. When rectified, three-phase voltage has a smoother waveform. (See Fig. 84.9.)

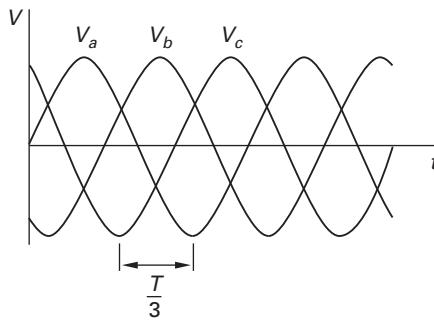

**31. THREE-PHASE LOADS**

Three impedances are required to load a three-phase voltage source fully. In three-phase motors and other devices, these impedances are three separate motor windings. Similarly, three-phase transformers have three separate sets of primary and secondary windings.

The impedances in a three-phase system are said to be *balanced loads* when they are identical in magnitude and angle. The voltages, line currents, and real, apparent, and reactive powers are all identical in a balanced system. Also, the power factor is the same for each phase. Therefore, only one phase of a balanced system needs to be analyzed (i.e., a *one-line analysis*).

<sup>15</sup>The uppercase Greek letter phi is often used as an abbreviation for the word “phase.” For example, “3Φ” would be interpreted as “three-phase.”

<sup>16</sup>Single-phase motors require auxiliary windings for starting, since one phase alone cannot get the magnetic field rotating.

**Figure 84.9** Three-Phase Voltage

### 32. LINE AND PHASE VALUES

The *line current*,  $I_l$ , is the current carried by the distribution lines (wires). The *phase current*,  $I_p$ , is the current flowing through each of the three separate loads (i.e., the phase) in the motor or device. Line and phase currents are both vector quantities.

Depending on how the motor or device is internally wired, the line and phase currents may or may not be the same. Figure 84.10 illustrates delta- and wye-connected loads. For balanced *wye-connected loads*, the line and phase currents are the same. For balanced *delta-connected loads*, they are not.

$$I_p = I_l \quad [\text{wye}] \quad 84.63$$

$$I_p = \frac{I_l}{\sqrt{3}} \quad [\text{delta}] \quad 84.64$$

Similarly, the *line voltage*,  $V_l$  (same as *line-to-line voltage*, commonly referred to as the *terminal voltage*), and *phase voltage*,  $V_p$ , may not be the same. With balanced delta-connected loads, the full line voltage appears across each phase. With balanced wye-connected loads, the line voltage appears across two loads.

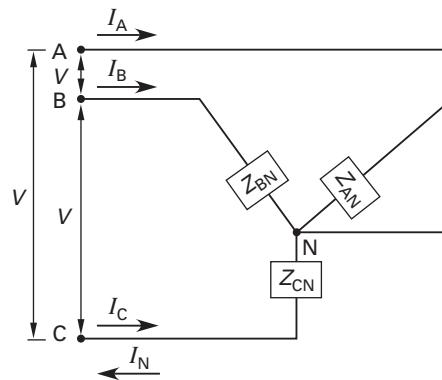

$$V_p = \frac{V_l}{\sqrt{3}} \quad [\text{wye}] \quad 84.65$$

$$V_p = V_l \quad [\text{delta}] \quad 84.66$$

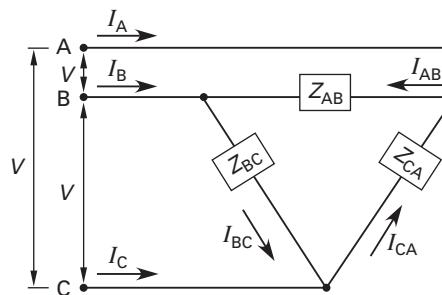

### 33. INPUT POWER IN THREE-PHASE SYSTEMS

Each impedance in a balanced system dissipates the same real *phase power*,  $P_p$ . The power dissipated in a balanced three-phase system is three times the phase power and is calculated in the same manner for both delta- and wye-connected loads.

$$\begin{aligned} P_t &= 3P_p = 3V_p I_p \cos \phi \\ &= \sqrt{3} V_l I_l \cos \phi \end{aligned} \quad 84.67$$

**Figure 84.10** Wye- and Delta-Connected Loads

(a) wye-connected loads

(b) delta-connected loads

The real power component is sometimes referred to as "power in kW." Apparent power is sometimes referred to as "kVA value" or "power in kVA."

$$\begin{aligned} S_t &= 3S_p = 3V_p I_p \\ &= \sqrt{3} V_l I_l \end{aligned} \quad 84.68$$

### 34. ROTATING MACHINES

Rotating machines are categorized as AC and DC machines. Both categories include machines that use electrical power (i.e., motors) and those that generate electrical power (alternators and generators).<sup>17</sup> Machines can be constructed in either single-phase or polyphase configurations, although single-phase machines may be inferior in terms of economics and efficiency. (See Sec. 84.30.)

Large AC motors are almost always three-phase. However, since the phases are balanced, it is necessary to analyze only one phase of the motor. Torque and power are divided evenly among the three phases.

### 35. REGULATION

Rotating machines (motors and alternators), as well as power supplies, are characterized by changes in

<sup>17</sup>An *alternator* produces AC potential. A *generator* produces DC potential.

voltage and speed under load. *Voltage regulation*, VR, is defined as

$$VR = \frac{\text{no-load voltage} - \text{full-load voltage}}{\text{full-load voltage}} \times 100\% \quad 84.69$$

*Speed regulation*, SR, is defined as

$$SR = \frac{\text{no-load speed} - \text{full-load speed}}{\text{full-load speed}} \times 100\% \quad 84.70$$

### 36. TORQUE AND POWER

For rotating machines, torque and power are basic operational parameters. It takes mechanical power to turn an alternator or generator. A motor converts electrical power into mechanical power. In SI units, power is given in watts (W) and kilowatts (kW). One horsepower (hp) is equivalent to 0.7457 kilowatts. The relationship between torque and power is

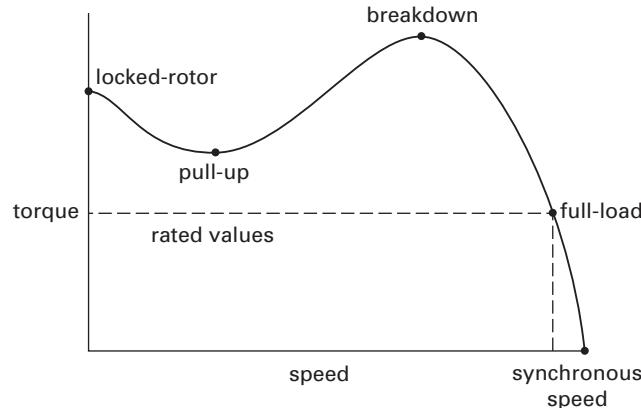

$$T_{\text{N.m}} = \frac{9549P_{\text{kW}}}{n_{\text{rpm}}} \quad [\text{SI}] \quad 84.71(a)$$

$$T_{\text{ft-lbf}} = \frac{5252P_{\text{horsepower}}}{n_{\text{rpm}}} \quad [\text{U.S.}] \quad 84.71(b)$$

There are many important torque parameters for motors. (See Fig. 84.11.) The *starting torque* (also known as *static torque*, *breakaway torque*, and *locked-rotor torque*) is the turning effort exerted by the motor when starting from rest. *Pull-up torque (acceleration torque)* is the minimum torque developed during the period of acceleration from rest to full speed. *Pull-in torque* (as developed in synchronous motors) is the maximum torque that brings the motor back to synchronous speed. (See Sec. 84.41.) *Nominal pull-in torque* is the torque that is developed at 95% of synchronous speed.

The *full-load torque (steady-state torque)* occurs at the rated speed and horsepower. Full-load torque is supplied to the load on a continuous basis. The full-load torque

**Figure 84.11** Induction Motor Torque-Speed Characteristic (typical of design B frames)

establishes the temperature increase that the motor must be able to withstand without deterioration. The *rated torque* is developed at rated speed and rated horsepower. The maximum torque that the motor can develop at its synchronous speed is the *pull-out torque*. *Breakdown torque* is the maximum torque that the motor can develop without stalling (i.e., without coming rapidly to a complete stop).

Motors are rated according to their output power (*rated power* or *brake power*). A 5 hp motor will normally deliver a full five horsepower when running at its rated speed. While the rated power is not affected by the motor's energy conversion efficiency,  $\eta$ , the electrical power input to the motor is

$$P_{\text{electrical}} = \frac{P_{\text{rated}}}{\eta} \quad 84.72$$

Table 84.1 lists standard motor sizes by rated horsepower.<sup>18</sup> The rated horsepower should be greater than the calculated brake power requirements. Since the rated power is the power actually produced, motors are not selected on the basis of their efficiency or electrical power input. The smaller motors listed in Table 84.1 are generally single-phase motors. The larger motors listed are three-phase motors.

**Table 84.1** Typical Standard Motor Sizes (horsepower)\*

$\frac{1}{8}$	$\frac{1}{6}$	$\frac{1}{4}$	$\frac{1}{3}$	$\frac{1}{2}$	$\frac{3}{4}$
1	$1\frac{1}{2}$	2	3	5	$7\frac{1}{2}$
10	15	20	25	30	40
50	60	75	100	125	150
200	250				

(Multiply hp by 0.7457 to obtain kW.)

\*1/8 hp and 1/6 hp motors are less common.

### 37. NEMA MOTOR CLASSIFICATIONS

Motors are classified by their NEMA design type—A, B, C, D, and F.<sup>19,20</sup> These designs are collectively referred to as *NEMA frame motors*. All NEMA motors of a given frame size are interchangeable as to bolt holes, shaft diameter, height, length, and various other dimensions.

- Frame design A: three-phase, squirrel-cage motor with high locked-rotor (starting) current but also higher breakdown torques; capable of handling intermittent overloads without stalling; 1–3% slip at full load.
- Frame design B: three-phase, squirrel-cage motor capable of withstanding full-voltage starting; locked-rotor and breakdown torques suitable for most applications; 1–3% slip at full load; often

<sup>18</sup>For economics, standard motor sizes should be specified.

<sup>19</sup>NEMA stands for the National Electrical Manufacturers Association.

<sup>20</sup>There is no type E.

designated for “normal” usage; the most common design.<sup>21</sup>

- Frame design C: three-phase, squirrel-cage motor capable of withstanding full-voltage starting; high locked-rotor torque for special applications (e.g., conveyors and compressors); 1–3% slip at full load.
- Frame design D: three-phase, squirrel-cage motor capable of withstanding full-voltage starting; develops 275% locked-rotor torque for special applications; high breakdown torque; depending on design, 5–13% slip at full load; commonly known as a *high-slip motor*; used for cranes, hoists, oil well pump jacks, and valve actuators.
- Frame design F: three-phase, squirrel-cage motor with low starting current and low starting torque; used to meet applicable regulations regarding starting current; limited availability.

### 38. NAMEPLATE VALUES

A *nameplate* is permanently affixed to each motor’s housing or frame. This nameplate is embossed or engraved with the *rated values* of the motor (*nameplate values* or *full-load values*). Nameplate information may include some or all of the following: voltage,<sup>22</sup> frequency,<sup>23</sup> number of phases, rated power (output power), running speed, duty cycle, locked-rotor and breakdown torques, starting current, current drawn at rated load (in kVA/hp), ambient temperature, temperature rise at rated load, temperature rise at service factor, insulation rating, power factor, efficiency, frame size, and enclosure type. (See Sec. 84.40 for more on duty cycle, and see Sec. 84.39 for more on temperature rise at service factor.)

It is important to recognize that the rated power of the motor is the actual output power (i.e., power delivered to the load), not the input power. Only the electrical power input is affected by the motor efficiency. (See Eq. 84.72.)

Nameplates are also provided on transformers. Transformer nameplate information includes the two winding voltages (either of which can be the primary winding), frequency, and kVA rating. Apparent power in kVA, not real power, is used in the rating because heating is proportional to the square of the supply current. As with motors, continuous operation at the rated values will not result in excessive heat buildup.

<sup>21</sup>Design B is estimated to be used in 90% of all applications.

<sup>22</sup>Standard NEMA nameplate voltages (effective) are 200 V, 230 V, 460 V, and 575 V. The NEMA motor voltage rating assumes that there will be a voltage drop from the network to the motor terminals. A 200 V motor is appropriate for a 208 V network, a 230 V motor on a 240 V network, and so on. NEMA motors are capable of operating in a range of only ±10% of their rated voltages. Thus, 230 V rated motors should not be used on 208 V systems.

<sup>23</sup>While some 60 Hz motors (notably those intended for 230 V operation) can be used at 50 Hz, most others (e.g., those intended for 200 V operation) are generally not suitable for use at 50 Hz.

### 39. SERVICE FACTOR

The horsepower and torque ratings listed on the nameplate of an AC motor can be maintained on a continuous basis without overheating. However, motors can be operated at slightly higher loads without exceeding a safe temperature rise.<sup>24</sup> The ratio of the safe to rated loads (horsepower or torque) is the *service factor*, sf, usually expressed as a decimal.

$$sf = \frac{\text{maximum safe load}}{\text{nameplate load}} \quad 84.73$$

Service factors vary from 1.15 to 1.4, with the lower values being applicable to the larger, more efficient motors. Typical values of service factor are 1.4 (up to 1/8 hp motors), 1.35 (1/6–1/3 hp motors), 1.25 (1/2–1 hp motors), and 1.15 (1 or 1 1/2 to 200 hp).

When running above the rated load, the motor speed, temperature, power factor, full-load current, and efficiency will differ from the nameplate values. However, the locked-rotor and breakdown torques will remain the same, as will the starting current.

*Active current* is proportional to torque and therefore, is proportional to the horsepower developed. (See Eq. 84.75.) The active current (line or phase) drawn is also proportional to the service factor. The current drawn per phase is given by Eq. 84.75.<sup>25</sup>

$$I_{\text{active}} = I_l(\text{pf}) \quad 84.74$$

$$\begin{aligned} I_{\text{actual},p} &= \frac{(sf)P_{\text{rated},p}}{V_p\eta(\text{pf})} \\ &= \frac{P_{\text{actual},p}}{V_p\eta(\text{pf})} \quad [\text{per phase; } P \text{ in watts}] \end{aligned} \quad 84.75$$

Equation 84.75 can also be used when a motor is developing less than its rated power. In this case, the service factor can be considered as the fraction of the rated power being developed.

#### Example 84.6

What is the approximate phase current drawn by a 98% efficient, three-phase, 75 hp, 230 V (rms) motor that is running at 88% power factor and at its rated load?

<sup>24</sup>Higher temperatures have a deteriorating effect on the winding insulation. A general rule of thumb is that a motor loses two or three hours of useful life for each hour run at the service factor load.

<sup>25</sup>It is important to recognize the difference between the rated (i.e., nameplate) power and the actual power developed. The actual power should not be combined with the service factor, since the actual power developed is the product of the rated power and the service factor.

**Solution**

The service factor is 1.00 because the motor is running at its rated load. From Eq. 84.75, the approximate phase current is

$$I_p = \frac{(sf)P_p}{V_p\eta(\text{pf})}$$

$$= \frac{(1.00)\left(\frac{75 \text{ hp}}{3 \text{ phases}}\right)\left(0.7457 \frac{\text{kW}}{\text{hp}}\right)\left(1000 \frac{\text{W}}{\text{kW}}\right)}{(230 \text{ V})(0.98)(0.88)}$$

$$= 93.99 \text{ A} \quad [\text{per phase}]$$

**40. DUTY CYCLE**

Motors are categorized according to their *duty cycle*: *continuous duty* (24 hr/day); *intermittent or short-time duty* (15 min to 30 min); and *special duty* (application specific). Duty cycle is the amount of time a motor can be operated out of every hour without overheating the winding insulation. The idle time is required to allow the motor to cool.

**41. INDUCTION MOTORS**

The three-phase induction motor is by far the most frequently used motor in industry. In an induction motor, the magnetic field rotates at the synchronous speed. The *synchronous speed* can be calculated from the number of poles and frequency. The frequency,  $f$ , is either 60 Hz (in the United States) or 50 Hz (in Europe and other locations). The number of poles,  $p$ , must be even.<sup>26</sup> The most common motors have 2, 4, or 6 poles.

$$n_{\text{synchronous}} = \frac{120f}{p} \quad [\text{rpm}] \quad 84.76$$

Due to rotor circuit resistance and other factors, rotors (and the motor shafts) in induction motors run slightly slower than their synchronous speeds. The percentage difference is known as the *slip*,  $s$ . Slip is seldom greater than 10%, and it is usually much less than that. 4% is a typical value.

$$s = \frac{n_{\text{synchronous}} - n_{\text{actual}}}{n_{\text{synchronous}}} \quad 84.77$$

<sup>26</sup>There are various forms of Eq. 84.76. As written, the speed is given in rpm, and the number of poles,  $p$ , is twice the number of *pole pairs*. When the synchronous speed is specified as  $f/p$ , it is understood that the speed is in revolutions per second (rps) and  $p$  is the number of pole pairs.

The rotor's actual speed is<sup>27</sup>

$$n_{\text{actual}} = (1 - s)n_{\text{synchronous}} \quad 84.78$$

Induction motors are usually specified in terms of the *kVA ratings*. The kVA rating is not the same as the motor power in kilowatts, although one can be calculated from the other if the motor's power factor is known. The power factor generally varies from 0.8 to 0.9 depending on the motor size.

$$\text{kVA rating} = \frac{P_{\text{kW}}}{\text{pf}} \quad 84.79$$

$$P_{\text{kW}} = 0.7457 P_{\text{mechanical,hp}} \quad 84.80$$

Induction motors can differ in the manner in which their rotors are constructed. A *wound rotor* is similar to an armature winding in a dynamo. Wound rotors have high-torque and soft-starting capabilities. There are no wire windings at all in a *squirrel-cage* rotor. Most motors use squirrel-cage rotors. Typical torque-speed characteristics of a design B induction motor are shown in Fig. 84.11.

**Example 84.7**

A pump is driven by a three-phase induction motor running at its rated values. The motor's nameplate lists the following rated values: 50 hp, 440 V, 92% lagging power factor, 90% efficiency, 60 Hz, and 4 poles. The motor's windings are delta-connected. The pump efficiency is 80%. When running under the pump load, the slip is 4%. What are the (a) total torque developed, (b) torque developed per phase, and (c) line current?

**Solution**

(a) The synchronous speed is given by Eq. 84.76.

$$n_{\text{synchronous}} = \frac{120f}{p} = \frac{(120)(60 \text{ Hz})}{4} = 1800 \text{ rpm}$$

From Eq. 84.78, the rotor speed is

$$n_{\text{actual}} = (1 - s)n_{\text{synchronous}} = (1 - 0.04)(1800 \text{ rpm}) = 1728 \text{ rpm}$$

Since the motor is running at its rated values, the motor delivers 50 hp to the pump. The pump's efficiency is

<sup>27</sup>Some motors (i.e., *integral gear motors*) are manufactured with integral speed reducers. Common standard output speeds are 37 rpm, 45 rpm, 56 rpm, 68 rpm, 84 rpm, 100 rpm, 125 rpm, 155 rpm, 180 rpm, 230 rpm, 280 rpm, 350 rpm, 420 rpm, 520 rpm, and 640 rpm. While the integral gear motor is more compact, lower in initial cost, and easier to install than a separate motor with belt drive, coupling, and guard, the separate motor and reducer combination may nevertheless be preferred for its flexibility, especially in replacing and maintaining the motor.

irrelevant. From Eq. 84.71, the total torque developed by all three phases is

$$T_t = \frac{5252 P_{\text{horsepower}}}{n_{\text{rpm}}} = \frac{\left(5252 \frac{\text{ft-lbf}}{\text{hp-min}}\right)(50 \text{ hp})}{1728 \text{ rpm}} \\ = 152.0 \text{ ft-lbf} \quad [\text{total}]$$

(b) The torque developed per phase is one-third of the total torque developed.

$$T_p = \frac{T_t}{3} = \frac{152.0 \text{ ft-lbf}}{3 \text{ phases}} \\ = 50.67 \text{ ft-lbf} \quad [\text{per phase}]$$

(c) The total electrical input power is given by Eq. 84.72.

$$P_{\text{electrical}} = \frac{P_{\text{rated}}}{\eta} = \frac{(50 \text{ hp})\left(0.7457 \frac{\text{kW}}{\text{hp}}\right)}{0.90} \\ = 41.43 \text{ kW} \quad [\text{total}]$$

Since the power factor is less than 1.0, more current is being drawn than is being converted into useful work. From Eq. 84.79, the apparent power in kVA per phase is

$$S_{\text{kVA}} = \frac{P_{\text{kW}}}{\text{pf}} = \frac{41.43 \text{ kW}}{(3)(0.92)} \\ = 15.01 \text{ kVA} \quad [\text{per phase}]$$

The phase current is given by Eq. 84.52.

$$I = \frac{S}{V} = \frac{(15.01 \text{ kVA})\left(1000 \frac{\text{VA}}{\text{kVA}}\right)}{440 \text{ V}} \\ = 34.11 \text{ A}$$

Since the motor's windings are delta-connected across the three lines, the line current is found from Eq. 84.64.

$$I_l = \sqrt{3} I_p = (\sqrt{3})(34.11 \text{ A}) \\ = 59.08 \text{ A}$$

## 42. INDUCTION MOTOR PERFORMANCE

The following rules of thumb can be used for initial estimates of induction motor performance.

- At 1800 rpm, a motor will develop a torque of 3 ft-lbf/hp.
- At 1200 rpm, a motor will develop a torque of 4.5 ft-lbf/hp.
- At 550 V, a three-phase motor will draw 1 A/hp.
- At 440 V, a three-phase motor will draw 1.25 A/hp.
- At 220 V, a three-phase motor will draw 2.5 A/hp.

- At 220 V, a single-phase motor will draw 5 A/hp.
- At 110 V, a single-phase motor will draw 10 A/hp.

## 43. SYNCHRONOUS MOTORS

*Synchronous motors* are essentially dynamo alternators operating in reverse. The stator field frequency is fixed, so regardless of load, the motor runs only at a single speed—the synchronous speed given by Eq. 84.76. Stalling occurs when the motor's counter-torque is exceeded. For some equipment that must be driven at constant speed, such as large air or gas compressors, the additional complexity of synchronous motors is justified.

Power factor can be adjusted manually by varying the field current. With *normal excitation* field current, the power factor is 1.0. With *over-excitation*, the power factor is leading, and the field current is greater than normal. With *under-excitation*, the power factor is lagging, and the field current is less than normal.

Since a synchronous motor can be adjusted to draw leading current, it can be used for power factor correction. A synchronous motor used purely for power factor correction is referred to as a *synchronous capacitor* or *synchronous condenser*. A power factor of 80% is often specified or used with synchronous capacitors.

## 44. DC MACHINES

DC motors and generators can be wired in one of three ways: series, shunt, and compound. Operational characteristics are listed in Table 84.2. Equation 84.71 can be used to calculate torque and power.

## 45. CHOICE OF MOTOR TYPES

Squirrel-cage induction motors are commonly chosen because of their simple construction, low maintenance, and excellent efficiencies.<sup>28</sup> A wound-rotor induction motor should be used only if it is necessary to achieve a low starting kVA, controllable kVA, controllable torque, or variable speed.<sup>29</sup>

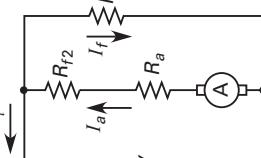

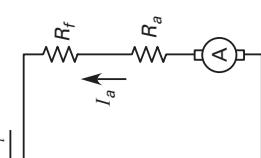

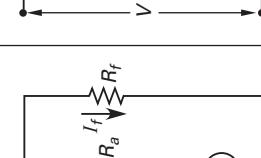

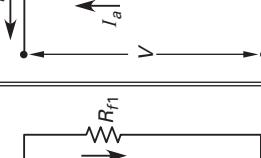

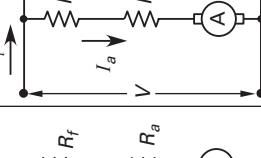

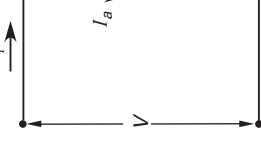

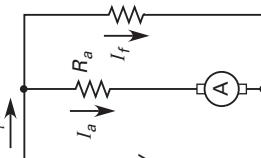

While induction motors are commonly used, synchronous motors are suitable for many applications normally handled by a NEMA design B squirrel-cage motor. They have adjustable power factors and higher efficiency. Their initial cost may also be less.

Selecting a motor type is greatly dependent on the power, torque, and speed requirements of the rotating load. Table 84.3, Fig. 84.12, App. 84.A, and App. 84.B can be used as starting points in the selection process.

<sup>28</sup>The larger the motor and the higher the speed, the higher the efficiency. Large 3600 rpm induction motors have excellent performance.

<sup>29</sup>A constant-speed motor with a slip coupling could also be used.

## 46. LOSSES IN ROTATING MACHINES

Losses in rotating machines are typically divided into the following categories: armature copper losses, field copper losses, mechanical losses (including friction and windage), core losses (including hysteresis losses, eddy current losses, and brush resistance losses), and stray losses.

Copper losses (also known as  $I^2R$  losses, impedance losses, heating losses, and real losses) are real power losses due to wire and winding resistance heating.

$$P_{Cu} = \sum I^2 R \quad 84.81$$

Core losses (also known as iron losses) are constant losses that are independent of the load and, for that reason, are also known as open-circuit and no-load losses.

Mechanical losses (also known as rotational losses) include brush and bearing friction and windage (air friction). (Windage is a no-load loss but is not an electrical core loss.) Mechanical losses are determined by measuring the power input at the rated speed and with no load.

Stray losses are due to nonuniform current distribution in the conductors. Stray losses are approximately 1% for DC machines and zero for AC machines.

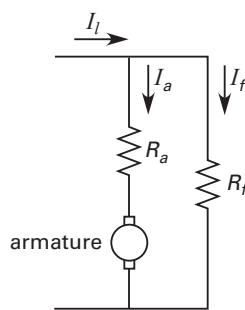

## 47. EFFICIENCY OF ROTATING MACHINES

Only real power is used to compute the efficiency of a rotating machine. This efficiency is sometimes referred to as overall efficiency and commercial efficiency.

$$\begin{aligned} \eta &= \frac{\text{output power}}{\text{input power}} \\ &= \frac{\text{output power}}{\text{output power} + \text{power losses}} \\ &= \frac{\text{input power} - \text{power losses}}{\text{input power}} \end{aligned} \quad 84.82$$

### Example 84.8

A DC shunt motor draws 40 A at 112 V when fully loaded. When running without a load at the same speed, it draws only 3 A at 106 V. The field resistance is 100  $\Omega$ , and the armature resistance is 0.125  $\Omega$ . (a) What is the efficiency of the motor? (b) What power (in hp) does the motor deliver at full load?

*Solution*

(a) The field current is given by Eq. 84.9.

$$\begin{aligned} I_f &= \frac{V}{R_f} = \frac{112 \text{ V}}{100 \Omega} \\ &= 1.12 \text{ A} \end{aligned}$$

The total full-load line current is known to be 40 A. The full-load armature current is

$$\begin{aligned} I_a &= I_l - I_f = 40 \text{ A} - 1.12 \text{ A} \\ &= 38.88 \text{ A} \end{aligned}$$

The field copper loss is given by Eq. 84.11.

$$\begin{aligned} P_{Cu,f} &= I_f^2 R_f = (1.12 \text{ A})^2 (100 \Omega) \\ &= 125.4 \text{ W} \end{aligned}$$

The armature copper loss is given by Eq. 84.11.

$$\begin{aligned} P_{Cu,a} &= I_a^2 R_a = (38.88 \text{ A})^2 (0.125 \Omega) \\ &= 189.0 \text{ W} \end{aligned}$$

The total copper loss is

$$\begin{aligned} P_{Cu,t} &= P_{Cu,f} + P_{Cu,a} = 125.4 \text{ W} + 189.0 \text{ W} \\ &= 314.4 \text{ W} \end{aligned}$$

Stray power is determined from the no-load conditions. At no load, the field current is given by Eq. 84.9.

$$\begin{aligned} I_f &= \frac{V}{R_f} = \frac{106 \text{ V}}{100 \Omega} \\ &= 1.06 \text{ A} \end{aligned}$$

At no load, the armature current is

$$\begin{aligned} I_a &= I_l - I_f = 3 \text{ A} - 1.06 \text{ A} \\ &= 1.94 \text{ A} \end{aligned}$$

The stray power loss is

$$\begin{aligned} P_{stray} &= V_l I_a - I_a^2 R_a \\ &= (106 \text{ V})(1.94 \text{ A}) - (1.94 \text{ A})^2 (0.125 \Omega) \\ &= 205.2 \text{ W} \end{aligned}$$

The stray power loss is assumed to be independent of the load. The total losses at full load are

$$\begin{aligned} P_{loss} &= P_{Cu,t} + P_{stray} = 314.4 \text{ W} + 205.2 \text{ W} \\ &= 519.6 \text{ W} \end{aligned}$$

The power input to the motor when fully loaded is

$$P_{input} = I_l V_l = (40 \text{ A})(112 \text{ V}) = 4480 \text{ W}$$

The efficiency is

$$\begin{aligned} \eta &= \frac{\text{input power} - \text{power losses}}{\text{input power}} \\ &= \frac{4480 \text{ W} - 519.6 \text{ W}}{4480 \text{ W}} \\ &= 0.884 \quad (88.4\%) \end{aligned}$$

(b) The real power (in hp) delivered at full load is

$$\begin{aligned} P_{real} &= \text{input power} - \text{power losses} \\ &= \frac{4480 \text{ W} - 519.6 \text{ W}}{\left(1000 \frac{\text{W}}{\text{kW}}\right) \left(0.7457 \frac{\text{kW}}{\text{hp}}\right)} \\ &= 5.3 \text{ hp} \end{aligned}$$

## 48. HIGH-EFFICIENCY MOTORS AND DRIVES

A premium, energy-efficient motor will have approximately 50% of the losses of a conventional motor. Due to the relatively high overall efficiency enjoyed by all motors, however, this translates into only a 5% increase in overall efficiency.

High-efficiency motors are often combined with *variable-frequency drives* (VFDs) to achieve continuous-variable speed control.<sup>30</sup> VFDs can substantially reduce the power drawn by the process. For example, with a motor-driven pump or fan, the motor can be slowed down instead of closing a valve or damper when the flow requirements decrease. Since the required motor horsepower varies with the cube root of the speed, for processes that do not always run at full-flow (fluid pumping, metering, flow control, etc.), the energy savings can be substantial.

A VFD uses an electronic controller to produce a variable-frequency signal that is not an ideal sine wave. This results in additional heating (e.g., an increase of 20–40%) from copper and core losses in the motor. In pumping applications, though, the process load drops off faster than additional heat is produced. Thus, the process power savings dominate.

Most low- and medium-power motors implement VFD with DC voltage intermediate circuits, a technique known as *voltage-source inversion*. Voltage-source inversion is further subdivided into *pulse width modulation* (PWM) and *pulse amplitude modulation* (PAM).

Under VFD control, the motor torque is approximately proportional to the applied voltage and drawn current but inversely proportional to the applied frequency.

$$T \propto \frac{VI}{f} \quad 84.83$$

<sup>30</sup>Prior to VFDs, there were two common ways to change the speed of an induction motor: (a) increasing the slip, and (b) changing the number of pole pairs. Increasing the slip was accomplished by under-magnetizing the motor so that it received less input voltage than it was built for. Dropping or adding the number of active poles resulted in the speed changing by a factor of 2 (or  $1/2$ ).

## 1. ACCURACY

A measurement is said to be *accurate* if it is substantially unaffected by (i.e., is insensitive to) all variation outside of the measurer's control.

For example, suppose a rifle is aimed at a point on a distant target and several shots are fired. The target point represents the "true value" of a measurement—the value that should be obtained. The impact points represent the measured values—what is obtained. The

distance from the centroid of the points of impact to the target point is a measure of the alignment accuracy between the barrel and the sights. This difference between the true and measured values is known as the measurement *bias*.

## 2. PRECISION

*Precision* is not synonymous with *accuracy*. Precision is concerned with the repeatability of the measured results. If a measurement is repeated with identical results, the experiment is said to be precise. The average distance of each impact from the centroid of the impact group is a measure of precision. Therefore, it is possible to take highly precise measurements and still be inaccurate (i.e., have a large bias).

Most measurement techniques (e.g., taking multiple measurements and refining the measurement methods or procedures) that are intended to improve accuracy actually increase the precision.

Sometimes the term *reliability* is used with regard to the precision of a measurement. A *reliable measurement* is the same as a *precise estimate*.

## 3. STABILITY

*Stability* and *insensitivity* are synonymous terms. (Conversely, *instability* and *sensitivity* are synonymous.) A stable measurement is insensitive to minor changes in the measurement process.

### Example 85.1

At 65°F (18°C), the centroid of an impact group on a rifle target is 2.1 in (5.3 cm) from the sight-in point. At 80°F (27°C), the distance is 2.3 in (5.8 cm). What is the sensitivity to temperature?

*SI Solution*

$$\begin{aligned}\text{sensitivity to temperature} &= \frac{\Delta \text{ measurement}}{\Delta \text{ temperature}} \\ &= \frac{5.8 \text{ cm} - 5.3 \text{ cm}}{27^\circ\text{C} - 18^\circ\text{C}} \\ &= 0.0556 \text{ cm}/^\circ\text{C}\end{aligned}$$

*Customary U.S. Solution*

$$\begin{aligned}\text{sensitivity to temperature} &= \frac{\Delta \text{ measurement}}{\Delta \text{ temperature}} \\ &= \frac{2.3 \text{ in} - 2.1 \text{ in}}{80^\circ\text{F} - 65^\circ\text{F}} \\ &= 0.0133 \text{ in}/^\circ\text{F}\end{aligned}$$

## 4. CALIBRATION

*Calibration* is used to determine or verify the scale of the measurement device. In order to calibrate a measurement device, one or more known values of the quantity to be measured (temperature, force, torque, etc.) are applied to the device and the behavior of the device is noted. (If the measurement device is linear, it may be adequate to use just a single calibration value. This is known as *single-point calibration*.)

Once a measurement device has been calibrated, the calibration signal should be reapplied as often as necessary to prove the reliability of the measurements. In some electronic measurement equipment, the calibration signal is applied continuously.

## 5. ERROR TYPES

Measurement errors can be categorized as *systematic (fixed) errors*, *random (accidental) errors*, *illegitimate errors*, and *chaotic errors*.

*Systematic errors*, such as improper calibration, use of the wrong scale, and incorrect (though consistent) technique, are essentially constant or similar in nature over time. *Loading errors* are systematic errors and occur when the act of measuring alters the true value.<sup>1</sup> Some *human errors*, if present in each repetition of the measurement, are also systematic. Systematic errors can be reduced or eliminated by refinement of the experimental method.

*Random errors* are caused by random and irregular influences generally outside the control of the measurer. Such errors are introduced by fluctuations in the environment, changes in the experimental method, and variations in materials and equipment operation. Since the occurrence of these errors is irregular, their effects can be reduced or eliminated by multiple repetitions of the experiment.

There is no reason to expect or tolerate *illegitimate errors* (e.g., errors in computations and other blunders). These are essentially mistakes that can be avoided through proper care and attention.

*Chaotic errors*, such as resonance, vibration, or experimental “noise,” essentially mask or entirely invalidate the experimental results. Unlike the random errors previously mentioned, chaotic disturbances can be sufficiently large to reduce the experimental results to meaninglessness.<sup>2</sup> Chaotic errors must be eliminated.

<sup>1</sup>For example, inserting an air probe into a duct will change the flow pattern and velocity around the probe.

<sup>2</sup>Much has been written about *chaos theory*. This theory holds that, for many processes, the ending state is dependent on imperceptible differences in the starting state. Future weather conditions and the landing orientation of a finely balanced spinning top are often used as examples of states that are greatly affected by their starting conditions.

## 6. ERROR MAGNITUDES

If a single measurement is taken of some quantity whose true value is known, the *error* is simply the difference between the true and measured values. However, the true value is never known in an experiment, and measurements are usually taken several times, not just once. Therefore, many conventions exist for estimating the unknown error.

When most experimental quantities are measured, the measurements tend to cluster around some “average value.” The measurements will be distributed according to some distribution, such as linear, normal, Poisson, and so on. The measurements can be graphed in a *histogram* and the distribution inferred. Usually the data will be normally distributed.<sup>3</sup>

Certain error terms used with normally distributed data have been standardized. These are listed in Table 85.1.

**Table 85.1** Normal Distribution Error Terms

term	number of standard deviations	percent certainty	approximate odds of being incorrect
probable error	0.6745	50	1 in 2
mean deviation	0.6745	50	1 in 2
standard deviation	1.000	68.3	1 in 3
one-sigma error	1.000	68.3	1 in 3
90% error	1.6449	90	1 in 10
two-sigma error	2.000	95	1 in 20
three-sigma error	3.000	99.7	1 in 370
maximum error*	3.29	99.9+	1 in 1000

\*The true maximum error is theoretically infinite.

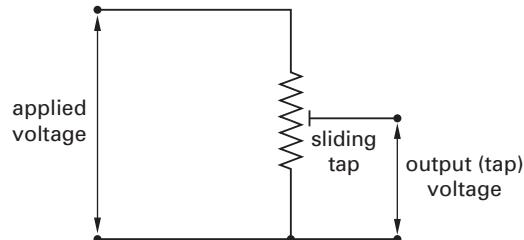

## 7. POTENTIOMETERS

A *potentiometer* (*potentiometer transducer, variable resistor*) is a resistor with a sliding third contact. It converts linear or rotary motion into a variable resistance (voltage).<sup>4</sup> It consists of a resistance oriented in a linear or angular manner and a variable-position contact point known as the *tap*. A voltage is applied across the entire resistance, causing current to flow through the resistance. The voltage at the tap will vary with tap position. (See Fig. 85.1.)

<sup>3</sup>The results of all numerical experiments are not automatically normally distributed. The throw of a die (one of two dice) is linearly distributed. Emissive power of a heated radiator is skewed with respect to wavelength. However, the means of sets of experimental data generally will be normally distributed, even if the raw measurements are not.

<sup>4</sup>There is a voltage-balancing device that shares the name *potentiometer* (*potentiometer circuit*). An unknown voltage source can be measured by adjusting a calibrated voltage until a null reading is obtained on a voltage meter. The applications are sufficiently different that no confusion occurs when the “pot is adjusted.”

**Figure 85.1** Potentiometer Circuit Diagram

## 8. TRANSDUCERS

Physical quantities are often measured with transducers (*detector-transducers*). A *transducer* converts one variable into another. For example, a Bourdon tube pressure gauge converts pressure to angular displacement; a strain gauge converts stress to resistance change. Transducers are primarily mechanical in nature (e.g., pitot tube, spring devices, Bourdon tube pressure gauge) or electrical in nature (e.g., thermocouple, strain gauge, moving-core transformer).

## 9. SENSORS

While the term “transducer” is commonly used for devices that respond to mechanical input (force, pressure, torque, etc.), the term *sensor* is commonly applied to devices that respond to varying chemical conditions.<sup>5</sup> For example, an electrochemical sensor might respond to a specific gas, compound, or ion (known as a *target substance* or *species*). Two types of electrochemical sensors are in use today: potentiometric and amperometric.

*Potentiometric sensors* generate a measurable voltage at their terminals. In electrochemical sensors taking advantage of half-cell reactions at electrodes, the generated voltage is proportional to the absolute temperature, *T*, and is inversely proportional to the number of electrons, *n*, taking part in the chemical reaction at the half-cell. In Eq. 85.1, *p*<sub>1</sub> is the partial pressure of the target substance at the measurement electrode; *p*<sub>2</sub> is the partial pressure of the target substance at the reference electrode.

$$V \propto \left( \frac{T_{\text{absolute}}}{n} \right) \ln \frac{p_1}{p_2} \quad 85.1$$

*Amperometric sensors* (also known as *voltammetric sensors*) generate a measurable current at their terminals. In the conventional electrochemical sensors known as *diffusion-controlled cells*, a high-conductivity acid or alkaline liquid electrolyte is used with a gas-permeable membrane that transmits ions from the outside to the inside of the sensor. A reference voltage is applied to two terminals within the electrolyte, and the current generated at a (third) sensing electrode is measured.

<sup>5</sup>The categorization is common but not universal. The terms “transducer,” “sensor,” “sending unit,” and “pickup” are often used loosely.

The maximum current generated is known as the *limiting current*. Current is proportional to the concentration,  $C$ , of the target substance; the permeability,  $P$ ; the exposed sensor (membrane) area,  $A$ ; and the number of electrons transferred per molecule detected,  $n$ . The current is inversely proportional to the membrane thickness,  $t$ .

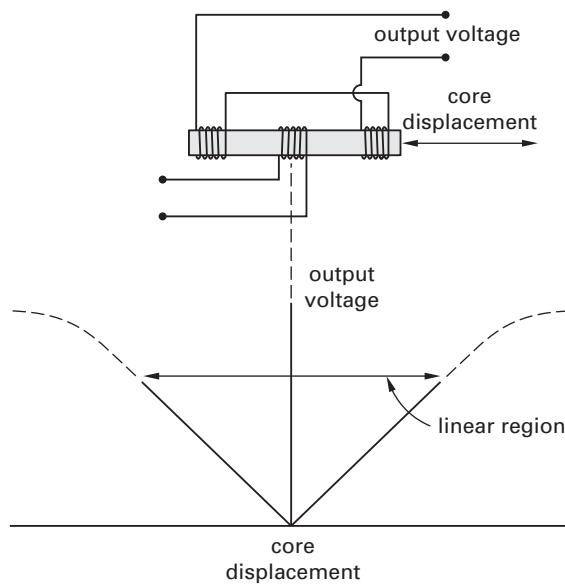

$$I \propto \frac{nPCA}{t} \quad 85.2$$

## 10. VARIABLE-INDUCTANCE TRANSDUCERS

*Inductive transducers* contain a wire coil and a moving permeable *core*.<sup>6</sup> As the core moves, the flux linkage through the coil changes. The change in inductance affects the overall impedance of the detector circuit.

The *differential transformer* or *linear variable differential transformer* (LVDT) is an important type of *variable-inductance transducer*. (See Fig. 85.2.) It converts linear motion into a change in voltage. The transformer is supplied with a low AC voltage. When the core is centered between the two secondary windings, the LVDT is said to be in its *null position*.

**Figure 85.2** Linear Variable Differential Transformer Schematic and Performance Characteristic

Movement of the core changes the magnetic flux linkage between the primary and secondary windings. Over a reasonable displacement range, the output voltage is proportional to the displacement of the core from the null position, hence the "linear" designation. The voltage changes phase (by 180°) as the core passes through the null position.

<sup>6</sup>The term *core* is used even if the cross sections of the coil and core are not circular.

Sensitivity of an LVDT is measured in mV/in (mV/cm) of core movement. The sensitivity and output voltage depend on the frequency of the applied voltage (i.e., the *carrier frequency*) and are directly proportional to the magnitude of the applied voltage.

## 11. VARIABLE-RELUCTANCE TRANSDUCERS

A *variable-reluctance transducer* (*pickup*) is essentially a permanent magnet and a coil in the vicinity of the process being monitored.<sup>7</sup> There are no moving parts in this type of transducer. However, some of the magnet's magnetic flux passes through the surroundings, and the presence or absence of the process changes the coil voltage. Two typical applications of variable-reluctance pickups are measuring liquid levels and determining the rotational speed of a gear.

## 12. VARIABLE-CAPACITANCE TRANSDUCERS

In *variable-capacitance transducers*, the capacitance of a device can be modified by changing the plate separation, plate area, or dielectric constant of the medium separating the plates.

## 13. OTHER ELECTRICAL TRANSDUCERS

The *piezoelectric effect* is the name given to the generation of an electrical voltage when placed under stress.<sup>8</sup> *Piezoelectric transducers* generate a small voltage when stressed (strained). Since voltage is developed during the application of changing strain but not while strain is constant, piezoelectric transducers are limited to dynamic applications. Piezoelectric transducers may suffer from low voltage output, instability, and limited ranges in operating temperature and humidity.

The *photoelectric effect* is the generation of an electrical voltage when a material is exposed to light.<sup>9</sup> Devices using this effect are known as *photocells*, *photovoltaic cells*, *photosensors*, or *light-sensitive detectors*, depending on the applications. The sensitivity can be to radiation outside of the visible spectrum. Photoelectric detectors can be made that respond to infrared and ultraviolet radiation. The magnitude of the voltage (or of the current in an attached circuit) will depend on the

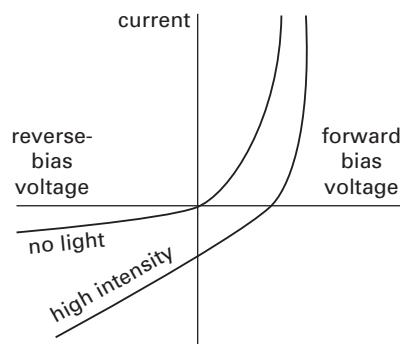

<sup>7</sup>Reluctance depends on the area, length, and permeability of the medium through which the magnetic flux passes.

<sup>8</sup>Quartz, table sugar, potassium sodium tartarate (Rochelle salt), and barium titanate are examples of piezoelectric materials. Quartz is commonly used to provide a stable frequency in electronic oscillators. Barium titanate is used in some ultrasonic cleaners and sonar-like equipment.

<sup>9</sup>While the *photogenerative* (*photovoltaic*) definition is the most common definition, the term "photoelectric" can also be used with *photoconductive devices* (those whose resistance changes with light) and *photoemissive devices* (those that emit light when a voltage is applied).

amount of illumination. If the cell is reverse-biased by an external battery, its operation is similar to a constant-current source.<sup>10</sup> (See Fig. 85.3.)

**Figure 85.3** Photovoltaic Device Characteristic Curves

## 14. PHOTOSENSITIVE CONDUCTORS

*Cadmium sulfide* and *cadmium selenide* are two compounds that decrease in resistance when exposed to light. Cadmium sulfide is most sensitive to light in the 5000–6000 Å (0.5–0.6 μm) range, while cadmium selenide shows peak sensitivities in the 7000–8000 Å (0.7–0.8 μm) range. These compounds are used in *photosensitive conductors*. Due to hysteresis, photosensitive conductors do not react instantaneously to changes in intensity.<sup>11</sup> High-speed operation requires high light intensities and careful design.

## 15. RESISTANCE TEMPERATURE DETECTORS

*Resistance temperature detectors* (RTDs), also known as *resistance thermometers*, make use of changes in their resistance to determine changes in temperature. A fine wire is wrapped around a form and protected with glass or a ceramic coating. Nickel and copper are commonly used for industrial RTDs. Type D 100 Ω and type M 1000 Ω platinum are used when precision resistance thermometry is required. RTDs are connected through resistance bridges (see Sec. 85.19) to compensate for lead resistance. RTDs are categorized by their precision (tolerance). Class A RTDs are precise to within ±0.06% at 0°C, while class B RTDs are precise to within ±0.12% at 0°C. Tolerance varies with temperature, hence the need to specify a reference temperature.

Resistance in most conductors increases with temperature. The resistance at a given temperature can be calculated from the *coefficients of thermal resistance*,  $\alpha$  and  $\beta$ .<sup>12</sup> Positive values of  $\alpha$  are known as *positive temperature coefficients* (PTCs); negative values are known as *negative temperature coefficients* (NTCs). Although PTC platinum RTDs are most prevalent, RTDs can be constructed using materials with either positive or negative characteristics. The variation of resistance with temperature is nonlinear, though  $\beta$  is small and is often insignificant over short temperature ranges. Therefore, a linear relationship is often assumed and only  $\alpha$  is used. In Eq. 85.3,  $R_{\text{ref}}$  is the resistance at the reference temperature,  $T_{\text{ref}}$ , usually 100 Ω at 32°F (0°C).

$$R_T \approx R_{\text{ref}} (1 + \alpha \Delta T + \beta \Delta T^2) \quad 85.3$$

$$\Delta T = T - T_{\text{ref}} \quad 85.4$$

In commercial RTDs,  $\alpha$  is referred to by the literal term *alpha-value*. There are two applicable alpha values for platinum, depending on the purity. Commercial platinum RTDs produced in the United States generally have alpha values of 0.00391 1/°C, while RTDs produced in Europe and other countries generally have alpha values of 0.00385 1/°C.

Equation 85.3 and values of  $\alpha$  and  $\beta$  are of academic interest. In practice, an equation similar in appearance using the actual temperature,  $T$  (not  $\Delta T$ ), is used. Equation 85.5 and Eq. 85.6 constitute a very accurate correlation of resistance and temperature for platinum. The correlation is known as the *Callendar-Van Dusen equation*.  $R_0$  is the resistance of the RTD at 0°C, typically 100 Ω or 1000 Ω for commercial platinum RTDs, which are also referred to as *platinum resistance thermometers* (PRTs).

$$R_T = R_0 (1 + AT + BT^2 + CT^3 (T - 100^\circ\text{C})) \quad [-200^\circ\text{C} < T < 0^\circ\text{C}] \quad 85.5$$

$$R_T = R_0 (1 + AT + BT^2) \quad [0^\circ\text{C} < T < 850^\circ\text{C}] \quad 85.6$$

Values of  $A$ ,  $B$ , and  $C$  can be calculated from the  $\alpha$  and  $\beta$  values, if needed. For platinum RTDs with  $\alpha = 0.00385$  1/°C, these values are

- $A = 3.9083 \times 10^{-3}$  1/°C
- $B = -5.775 \times 10^{-7}$  1/°C<sup>2</sup>
- $C = -4.183 \times 10^{-12}$  1/°C<sup>4</sup>

Table 85.2 gives resistances for standard Pt100 RTDs.

## 16. THERMISTORS

*Thermistors* are temperature-sensitive semiconductors constructed from oxides of manganese, nickel, and cobalt, and from sulfides of iron, aluminum, and copper.

<sup>10</sup>A semiconductor device is *reverse-biased* when a negative battery terminal is connected to a p-type semiconductor material in the device, or when a positive battery terminal is connected to an n-type semiconductor material.

<sup>11</sup>*Hysteresis* is the tendency for the transducer to continue to respond (i.e., indicate) when the load is removed. Alternatively, hysteresis is the difference in transducer outputs when a specific load is approached from above and from below. Hysteresis is usually expressed in percent of the full-load reading during any single calibration cycle.

<sup>12</sup>Higher-order terms (third, fourth, etc.) are used when extreme accuracy is required.

**Table 85.2** Resistance of Standard Pt100 RTDs\*

T (°C)	R (Ω)	T (°C)	R (Ω)	T (°C)	R (Ω)
-50	80.31	10	103.90	70	127.07
-45	82.29	15	105.85	75	128.98
-40	84.27	20	107.79	80	130.89
-35	86.25	25	109.73	85	132.80
-30	88.22	30	111.67	90	134.70
-25	90.19	35	113.61	95	136.60
-20	92.16	40	115.54	100	138.50
-15	94.12	45	117.47	105	140.39
-10	96.09	50	119.40	110	142.29
-5	98.04	55	121.32	150	157.31
0	100.00	60	123.24	200	175.84
5	101.95	65	125.16		

(Multiply tabulated resistances by 10 for Pt1000 RTDs.)

\*Per DIN International Electrotechnical Commission (IEC) Standard 751

Thermistor materials are encapsulated in glass or ceramic materials to prevent penetration of moisture. Unlike RTDs, the resistance of thermistors decreases as the temperature increases.

Thermistor temperature-resistance characteristics are exponential. Depending on the brand, material, and construction,  $\beta$  typically varies between 3400K and 3900K.

$$R = R_o e^k \quad 85.7$$

$$k = \beta \left( \frac{1}{T} - \frac{1}{T_o} \right) \quad [T \text{ in K}] \quad 85.8$$

Thermistors can be connected to measurement circuits with copper wire and soldered connections. Compensation of lead wire effects is not required because resistance of thermistors is very large, far greater than the resistance of the leads. Since the negative temperature characteristic makes it difficult to design customized detection circuits, some thermistor and instrumentation standardization has occurred. The most common thermistors have resistances of  $2252 \Omega$  at  $77^\circ\text{F}$  ( $25^\circ\text{C}$ ), and most instrumentation is compatible with them. Other standardized resistances are  $3000 \Omega$ ,  $5000 \Omega$ ,  $10,000 \Omega$ , and  $30,000 \Omega$  at  $77^\circ\text{F}$  ( $25^\circ\text{C}$ ). (See Table 85.3.)

Thermistors typically are less precise and more unpredictable than metallic resistors. Since resistance varies exponentially, most thermistors are suitable for use only up to approximately  $550^\circ\text{F}$  ( $290^\circ\text{C}$ ).

## 17. THERMOCOUPLES

A *thermocouple* consists of two wires of dissimilar metals joined at both ends.<sup>13</sup> One set of ends, typically called a *junction*, is kept at a known reference

<sup>13</sup>The joint may be made by simply twisting the ends together. However, to achieve a higher mechanical strength and a better electrical connection, the ends should be soldered, brazed, or welded.

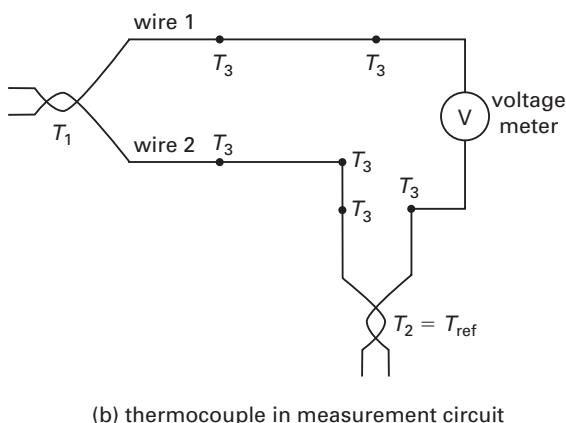

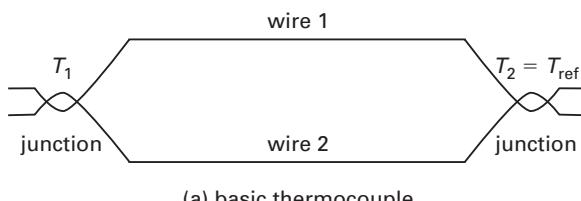

**Table 85.3** Typical Resistivities and Coefficients of Thermal Resistance<sup>a</sup>

conductor	resistivity <sup>b</sup> (Ω·cm)	$\alpha^c$ ( $1/\text{°C}$ )

tungsten (drawn)	$5.8 \times 10^{-6}$	0.0045 @ $70^\circ\text{F}$ ( $21^\circ\text{C}$ )

(Multiply  $1/\text{°C}$  by  $5/9$  to obtain  $1/\text{°F}$ .)(Multiply ppm/ $^\circ\text{F}$  by  $1.8 \times 10^{-6}$  to obtain  $1/\text{°C}$ .)<sup>a</sup>Compiled from various sources. Data is not to be taken too literally, as values depend on composition and cold working.<sup>b</sup>At  $20^\circ\text{C}$  ( $68^\circ\text{F}$ )<sup>c</sup>Values vary with temperature. Common values given when no temperature is specified.<sup>d</sup>Trade name for 94% Ni, 2.5% Mn, 2% Al, 1% Si, 0.5% Fe (TM of Hoskins Manufacturing Co.)<sup>e</sup>60% Cu, 40% Ni, also known by trade names *Advance*, *Eureka*, and *Ideal*.<sup>f</sup>Constantan is also the name given to the composition 55% Cu and 45% Ni, an alloy with slightly different properties.<sup>g</sup>Trade name for 90% Ni, 10% Cr (TM of Hoskins Manufacturing Co.)<sup>h</sup>36% Ni, 8% Cr, 0.5% Mo, remainder Fe<sup>i</sup>9% to 18% Mn, 11% to 4% Ni, remainder Cu<sup>j</sup>33% Cu, 67% Ni<sup>k</sup>75% Ni, 12% Fe, 11% Cr, 2% Mn<sup>l</sup>95% Pt, 5% Ir<sup>m</sup>90% Pt, 10% Rh

temperature while the other junction is exposed to the unknown temperature.<sup>14</sup> (See Fig. 85.4.) In a laboratory, the reference junction is often maintained at the *ice point*,  $32^\circ\text{F}$  ( $0^\circ\text{C}$ ), in an ice/water bath for convenience

<sup>14</sup>The *ice point* is the temperature at which liquid water and ice are in equilibrium. Other standardized temperature references are: *oxygen point*,  $-297.346^\circ\text{F}$  ( $90.19^\circ\text{C}$ ); *steam point*,  $212.0^\circ\text{F}$  ( $373.16^\circ\text{K}$ ); *sulfur point*,  $832.28^\circ\text{F}$  ( $717.76^\circ\text{K}$ ); *silver point*,  $1761.4^\circ\text{F}$  ( $1233.96^\circ\text{K}$ ); and *gold point*,  $1945.4^\circ\text{F}$  ( $1336.16^\circ\text{K}$ ).

**Figure 85.4** Thermocouple Circuits

in later analysis. In commercial applications, the reference temperature can be any value, with appropriate compensation being made.

Thermocouple materials, standard ANSI designations, and approximate useful temperature ranges are given in Table 85.4.<sup>15</sup> The “functional” temperature range can be much larger than the useful range. The most significant factors limiting the useful temperature range, sometimes referred to as the *error limits range*, are linearity, the rate at which the material will erode due to oxidation at higher temperatures, irreversible magnetic effects above magnetic critical points, and longer stabilization periods at higher temperatures.

A voltage is generated when the temperatures of the two junctions are different. This phenomenon is known as the *Seebeck effect*.<sup>16</sup> Referring to the polarities of the voltage generated, one metal is known as the *positive element* while the other is the *negative element*. The generated voltage is small, and thermocouples are calibrated in  $\mu\text{V}/^\circ\text{F}$  or  $\mu\text{V}/^\circ\text{C}$ . An amplifier may be required to provide usable signal levels, although thermocouples can be connected in series (a *thermopile*) to

<sup>15</sup>It is not uncommon to list the two thermocouple materials with “vs.” (as in *versus*). For example, a copper/constantan thermocouple might be designated as “copper vs. constantan.”

<sup>16</sup>The inverse of the Seebeck effect, that current flowing through a junction of dissimilar metals will cause either heating or cooling, is the *Peltier effect*, though the term is generally used in regard to cooling applications. An extension of the Peltier effect, known as the *Thompson effect*, is that heat will be carried along the conductor. Both the Peltier and Thompson effects occur simultaneously with the Seebeck effect. However, the Peltier and Thompson effects are so minuscule that they can be disregarded.

**Table 85.4** Typical Temperature Ranges of Thermocouple Materials<sup>a</sup>

materials	ANSI designation	useful range ( $^\circ\text{F}$ ( $^\circ\text{C}$ ))
copper-constantan	T	-300 to 700 (-180 to 370)
chromel-constantan	E	32 to 1600 (0 to 870)

constantan		
nichrome-alumel	-	to 2200 <sup>c</sup> (1200)

<sup>a</sup>Actual values will depend on wire gauge, atmosphere (oxidizing or reducing), use (continuous or intermittent), and manufacturer.

<sup>b</sup>Nonoxidizing atmospheres only.

<sup>c</sup>Approximate usable temperature range. Error limit range is less.

increase the value.<sup>17</sup> The accuracy (referred to as the *calibration*) of thermocouples is approximately  $1/2$ – $3/4$ %, though manufacturers produce thermocouples with various guaranteed accuracies.

The voltage generated by a thermocouple is given by Eq. 85.9. Since the *thermoelectric constant*,  $k_T$ , varies with temperature, thermocouple problems can be solved with published tables of total generated voltage versus temperature. (See App. 85.A.)

$$V = k_T(T - T_{\text{ref}}) \quad 85.9$$

Generation of thermocouple voltage in a measurement circuit is governed by three laws. The *law of homogeneous circuits* states that the temperature distribution along one or both of the thermocouple leads is irrelevant. Only the junction temperatures contribute to the generated voltage.

The *law of intermediate metals* states that an intermediate length of wire placed within one leg or at the junction of the thermocouple circuit will not affect the voltage generated as long as the two new junctions are at the same temperature. This law permits the use of a measuring device, soldered connections, and extension leads.

<sup>17</sup>There is no special name for a combination of thermocouples connected in parallel.

The *law of intermediate temperatures* states that if a thermocouple generates voltage  $V_1$  when its junctions are at  $T_1$  and  $T_2$ , and it generates voltage  $V_2$  when its junctions are at  $T_2$  and  $T_3$ , then it will generate voltage  $V_1 + V_2$  when its junctions are at  $T_1$  and  $T_3$ .

### Example 85.2

A type-K (chromel-alumel) thermocouple produces a voltage of 10.79 mV. The “cold” junction is kept at 32°F (0°C) by an ice bath. What is the temperature of the hot junction?

*Solution*

Since the cold junction temperature corresponds to the reference temperature, the hot junction temperature is read directly from App. 85.A as 510°F.

### Example 85.3

A type-K (chromel-alumel) thermocouple produces a voltage of 10.87 mV. The “cold” junction is at 70°F. What is the temperature of the hot junction?

*Solution*

Use the law of intermediate temperatures. From App. 85.A, the thermoelectric constant for 70°F is 0.84 mV. If the cold junction had been at 32°C, the generated voltage would have been higher. The corrected reading is

$$10.87 \text{ mV} + 0.84 \text{ mV} = 11.71 \text{ mV}$$

The temperature corresponding to this voltage is 550°F.

### Example 85.4

A type-T (copper-constantan) thermocouple is connected directly to a voltage meter. The temperature of the meter's screw-terminals is measured by a nearby thermometer as 70°F. The thermocouple generates 5.262 mV. What is the temperature of its hot junction?

*Solution*

There are two connections at the meter. However, both connections are at the same temperature, so the meter can be considered to be a length of different wire, and the law of intermediate metals applies. Since the meter connections are not at 32°F, the law of intermediate temperatures applies. The corrected voltage is

$$5.262 \text{ mV} + 0.832 \text{ mV} = 6.094 \text{ mV}$$

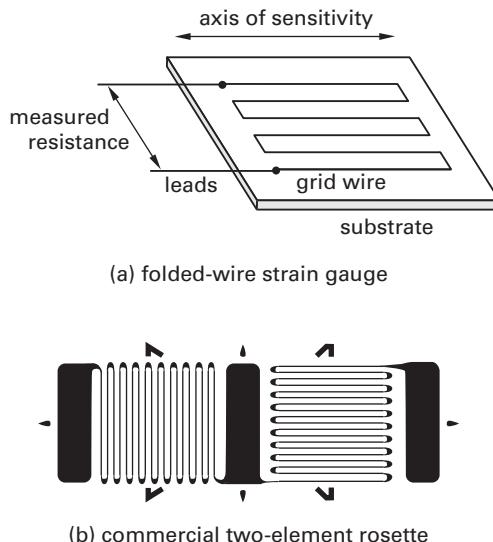

From App. 85.A, 6.094 mV corresponds to 280°F.

## 18. STRAIN GAUGES

A *bonded strain gauge* is a metallic resistance device that is cemented to the surface of the unstressed member.<sup>18</sup> The gauge consists of a metallic conductor (known as the *grid*) on a backing (known as the *substrate*).<sup>19</sup> The substrate and grid experience the same strain as the surface of the member. The resistance of the gauge changes as the member is stressed due to changes in conductor cross section and intrinsic changes in resistivity with strain. Temperature effects must be compensated for by the circuitry or by using a second unstrained gauge as part of the bridge measurement system. (See Sec. 85.19.)

When simultaneous strain measurements in two or more directions are needed, it is convenient to use a commercial *rosette strain gauge*. A rosette consists of two or more *grids* properly oriented for application as a single unit. (See Fig. 85.5.)

Figure 85.5 Strain Gauge

The *gage factor (strain sensitivity factor)*, GF, is the ratio of the fractional change in resistance to the fractional change in length (strain) along the detecting axis of the gauge. The higher the gage factor, the greater the sensitivity of the gauge. The gage factor is a function of the gauge material. It can be calculated from the grid

<sup>18</sup>A *bonded strain gauge* is constructed by bonding the conductor to the surface of the member. An *unbonded strain gauge* is constructed by wrapping the conductor tightly around the member or between two points on the member.

Strain gauges on rotating shafts are usually connected through *slip rings* to the measurement circuitry.

<sup>19</sup>The grids of strain gauges were originally of the folded-wire variety. For example, nichrome wire with a total resistance under 1000 Ω was commonly used. Modern strain gauges are generally of the foil type manufactured by printed circuit techniques. Semiconductor gauges are also used when extreme sensitivity (i.e., gage factors in excess of 100) is required. However, semiconductor gauges are extremely temperature-sensitive.

material's properties and configuration. From a practical standpoint, however, the gage factor and gage resistance are provided by the gauge manufacturer. Only the change in resistance is measured. (See Table 85.5.)

$$GF = 1 + 2\nu + \frac{\frac{\Delta\rho}{\rho_o}}{\frac{\Delta L}{L_o}} = \frac{\frac{\Delta R_g}{R_g}}{\frac{\Delta L}{L_o}} = \frac{\frac{\Delta R_g}{R_g}}{\frac{L_o}{\epsilon}} \quad 85.10$$

**Table 85.5** Approximate Gage Factors<sup>a</sup>

material	GF
constantan	2.0
iron, soft	4.2
isoelastic	3.5
manganin	0.47
monel	1.9
nichrome	2.0
nickel	-12 <sup>b</sup>
platinum	4.8
platinum-iridium	5.1

<sup>a</sup>Other properties of strain gauge materials are listed in Table 85.3.

<sup>b</sup>Value depends on amount of preprocessing and cold working.

Constantan and isoelastic wires, along with metal foil with gage factors of approximately 2 and initial resistances of less than 1000  $\Omega$  (typically 120  $\Omega$ , 350  $\Omega$ , 600  $\Omega$ , and 700  $\Omega$ ) are commonly used. In practice, the gage factor and initial gage resistance,  $R_g$ , are specified by the manufacturer of the gauge. Once the strain sensitivity factor is known, the strain,  $\epsilon$ , can be determined from the change in resistance. Strain is often reported in units of  $\mu\text{in/in}$  ( $\mu\text{m/m}$ ) and is given the name *microstrain*.

$$\epsilon = \frac{\Delta R_g}{(GF)R_g} \quad 85.11$$

Theoretically, a strain gauge should not respond to strain in its transverse direction. However, the turn-around end-loops are also made of strain-sensitive material, and the end-loop material contributes to a nonzero sensitivity to strain in the transverse direction. Equation 85.12 defines the *transverse sensitivity factor*,  $K_t$ , which is of academic interest in most problems. The transverse sensitivity factor is seldom greater than 2%.

$$K_t = \frac{(GF)_{\text{transverse}}}{(GF)_{\text{longitudinal}}} \quad 85.12$$

### Example 85.5

A strain gauge with a nominal resistance of 120  $\Omega$  and gage factor of 2.0 is used to measure a strain of 1  $\mu\text{in/in}$ . What is the change in resistance?

### Solution

From Eq. 85.11,

$$\begin{aligned} \Delta R_g &= (GF)R_g\epsilon = (2.0)(120 \Omega)\left(1 \times 10^{-6} \frac{\text{in}}{\text{in}}\right) \\ &= 2.4 \times 10^{-4} \Omega \end{aligned}$$

## 19. WHEATSTONE BRIDGES

The *Wheatstone bridge*, shown in Fig. 85.6, is one type of *resistance bridge*.<sup>20</sup> The bridge can be used to determine the unknown resistance of a resistance transducer (e.g., thermistor or resistance-type strain gauge), say  $R_1$  in Fig. 85.6. The potentiometer is adjusted (i.e., the bridge is “balanced”) until no current flows through the meter or until there is no voltage across the meter (hence the name *null indicator*).<sup>21,22</sup> When the bridge is balanced and no current flows through the meter leg, Eq. 85.13 through Eq. 85.16 are applicable.

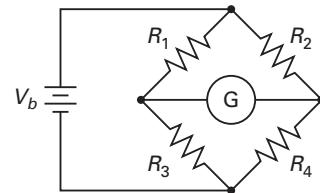

$$I_2 = I_4 \quad [\text{balanced}] \quad 85.13$$

$$I_1 = I_3 \quad [\text{balanced}] \quad 85.14$$

$$V_1 + V_3 = V_2 + V_4 \quad [\text{balanced}] \quad 85.15$$

$$\frac{R_1}{R_2} = \frac{R_3}{R_4} \quad [\text{balanced}] \quad 85.16$$

**Figure 85.6** Wheatstone Bridge

Since any one of the four resistances can be the unknown, up to three of the remaining resistances can be fixed or adjustable, and the battery and meter can be connected to either of two diagonal corners, it is sometimes confusing to apply Eq. 85.16 literally. However, the following bridge law statement can be used to help formulate the proper relationship: *When a series Wheatstone bridge is null-balanced, the ratio of resistance of any two adjacent arms equals the ratio of resistance of the remaining two arms, taken in the same sense*. In this

<sup>20</sup>Other types of resistance bridges are the *differential series balance bridge*, *shunt balance bridge*, and *differential shunt balance bridge*. These differ in the manner in which the adjustable resistor is incorporated into the circuit.

<sup>21</sup>This gives rise to the alternate names of *zero-indicating bridge* and *null-indicating bridge*.

<sup>22</sup>The unknown resistance can also be determined from the amount of voltage unbalance shown by the meter reading, in which case, the bridge is known as a *deflection bridge* rather than a null-indicating bridge. Deflection bridges are described in Sec. 85.20.

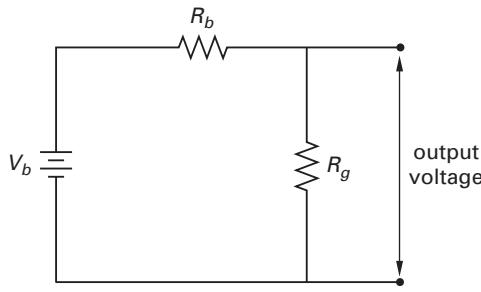

statement, “taken in the same sense” means that both ratios must be formed reading either left to right, right to left, top to bottom, or bottom to top.

## 20. STRAIN GAUGE DETECTION CIRCUITS

The resistance of a strain gauge can be measured by placing the gauge in either a ballast circuit or bridge circuit. A *ballast circuit* consists of a voltage source,  $V_b$ , of less than 10 V (typical); a current-limiting ballast resistance,  $R_b$ ; and the strain gauge of known resistance,  $R_g$ , in series. (See Fig. 85.7.) This is essentially a voltage-divider circuit. The change in voltage,  $\Delta V_g$ , across the strain gauge is measured. The strain,  $\epsilon$ , can be determined from Eq. 85.17.

$$\Delta V_g = \frac{(GF)\epsilon V_b R_b R_g}{(R_b + R_g)^2} \quad 85.17$$

**Figure 85.7** Ballast Circuit

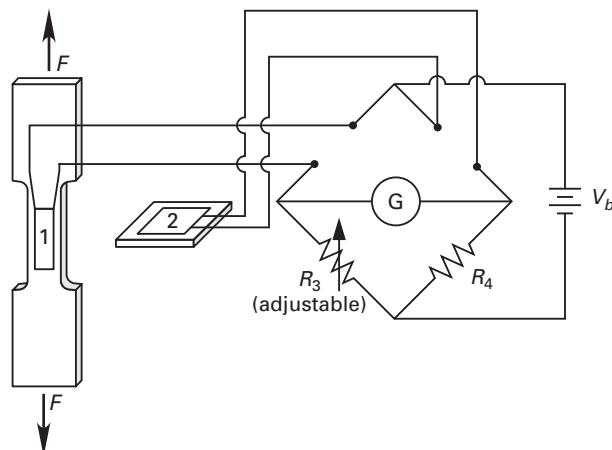

Ballast circuits do not provide temperature compensation, nor is their sensitivity adequate for measuring static strain. Ballast circuits, where used, are often limited to measurement of transient strains. A bridge detection circuit overcomes these limitations.

Figure 85.8 illustrates how a strain gauge can be used with a resistance bridge. Gauge 1 measures the strain, while *dummy gauge* 2 provides temperature compensation.<sup>23</sup> The meter voltage is a function of the input (battery) voltage and the resistors. (As with bridge circuits, the input voltage is typically less than 10 V.) The variable resistance is used for balancing the bridge prior to the strain. When the bridge is balanced,  $V_{\text{meter}}$  is zero.

When the gauge is strained, the bridge becomes unbalanced. Assuming the bridge is initially balanced, the

**Figure 85.8** Strain Gauge in Resistance Bridge

voltage at the meter (known as the *voltage deflection* from the null condition) will be<sup>24</sup>

$$V_{\text{meter}} = V_b \left( \frac{R_1}{R_1 + R_3} - \frac{R_2}{R_2 + R_4} \right) \quad [1/4\text{-bridge}] \quad 85.18$$

For a single strain gauge in a resistance bridge and neglecting lead resistance, the voltage deflection is related to the strain by Eq. 85.19.

$$V_{\text{meter}} = \frac{(GF)\epsilon V_b}{4 + 2(GF)\epsilon} \approx \frac{1}{4}(GF)\epsilon V_b \quad [1/4\text{-bridge}] \quad 85.19$$

## 21. STRAIN GAUGE IN UNBALANCED RESISTANCE BRIDGE

A resistance bridge does not need to be balanced prior to use as long as an accurate digital voltmeter is used in the detection circuit. The voltage ratio difference,  $\Delta VR$ , is defined as the fractional change in the output voltage from the unstrained to the strained condition.

$$\Delta VR = \left( \frac{V_{\text{meter}}}{V_b} \right)_{\text{strained}} - \left( \frac{V_{\text{meter}}}{V_b} \right)_{\text{unstrained}} \quad 85.20$$

If the only resistance change between the strained and unstrained conditions is in the strain gauge and lead resistance is disregarded, the fractional change in gage resistance for a single strain gauge in a resistance bridge is

$$\frac{\Delta R_g}{R_g} = \frac{-4\Delta(VR)}{1 + 2\Delta(VR)} \quad [1/4\text{-bridge}] \quad 85.21$$

<sup>23</sup>This is a “quarter-bridge” or “1/4-bridge” configuration, as described in Sec. 85.23. The strain gauge used for temperature compensation is not active.

<sup>24</sup>Equation 85.18 applies to the unstrained condition as well. However, if the gauge is unstrained and the bridge is balanced, the resistance term in parentheses is zero.

Since the fractional change in gage resistance also occurs in the definition of the gage factor (see Eq. 85.11), the strain is

$$\epsilon = \frac{-4\Delta VR}{(GF)(1 + 2\Delta VR)} \quad [1/4\text{-bridge}] \quad 85.22$$

## 22. BRIDGE CONSTANT

The voltage deflection can be doubled (or quadrupled) by using two (or four) strain gauges in the bridge circuit. The larger voltage deflection is more easily detected, resulting in more accurate measurements.

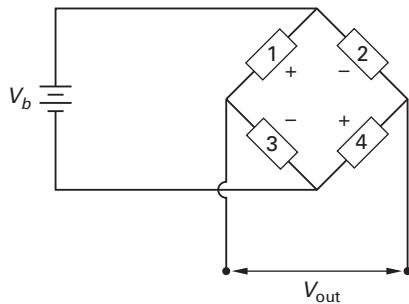

Use of multiple strain gauges is generally limited to configurations where symmetrical strain is available on the member. For example, a beam in bending experiences the same strain on the top and bottom faces. Therefore, if the temperature-compensation strain gauge shown in Fig. 85.8 is bonded to the bottom of the beam, the resistance change would double.

The *bridge constant* (BC) is the ratio of the actual voltage deflection to the voltage deflection from a single gauge. Depending on the number and orientation of the gauges used, bridge constants of 1.0, 1.3, 2.0, 2.6, and 4.0 may be encountered (for materials with a Poisson's ratio of 0.3).

Figure 85.9 illustrates how (up to) four strain gauges can be connected in a Wheatstone bridge circuit. The total strain indicated will be the algebraic sum of the four strains detected. For example, if all four strains are equal in magnitude,  $\epsilon_1$  and  $\epsilon_4$  are tensile (i.e., positive), and  $\epsilon_2$  and  $\epsilon_3$  are compressive (i.e., negative), then the bridge constant would be 4.

$$\epsilon_t = \epsilon_1 - \epsilon_2 - \epsilon_3 + \epsilon_4 \quad 85.23$$

**Figure 85.9** Wheatstone Bridge Strain Gauge Circuit\*

\*The 45° orientations shown are figurative. Actual gauge orientation can be in any direction.

## 23. STRESS MEASUREMENTS IN KNOWN DIRECTIONS

Strain gauges are the most frequently used method of determining the stress in a member. Stress can be

calculated from strain, or the measurement circuitry can be calibrated to give the stress directly.

For stress in only one direction (i.e., the *uniaxial stress* case), such as a simple bar in tension, only one strain gauge is required. The stress can be calculated from *Hooke's law*.

$$\sigma = E\epsilon \quad 85.24$$

When a surface, such as that of a pressure vessel, experiences simultaneous stresses in two directions (the *biaxial stress* case), the strain in one direction affects the strain in the other direction.<sup>25</sup> Therefore, two strain gauges are required, even if the stress in only one direction is needed. The strains actually measured by the gauges are known as the *net strains*.

$$\epsilon_x = \frac{\sigma_x - \nu\sigma_y}{E} \quad 85.25$$

$$\epsilon_y = \frac{\sigma_y - \nu\sigma_x}{E} \quad 85.26$$

The stresses are determined by solving Eq. 85.25 and Eq. 85.26 simultaneously.

$$\sigma_x = \frac{E(\epsilon_x + \nu\epsilon_y)}{1 - \nu^2} \quad 85.27$$

$$\sigma_y = \frac{E(\epsilon_y + \nu\epsilon_x)}{1 - \nu^2} \quad 85.28$$

Figure 85.9 shows how four strain gauges can be interconnected in a bridge circuit. Figure 85.10 shows how (up to) four strain gauges would be physically oriented on a test specimen to measure different types of stress. Not all four gauges are needed in all cases. If four gauges are used, the arrangement is said to be a *full bridge*. If only one or two gauges are used, the terms *quarter-bridge* (1/4-bridge) and *half-bridge* (1/2-bridge), respectively, apply.

In the case of up to four gauges applied to detect bending strain (see Fig. 85.10(a)), the bridge constant (BC) can be 1.0 (one gauge in position 1), 2.0 (two gauges in positions 1 and 2), or 4.0 (all four gauges). The relationships between the stress, strain, and applied force are

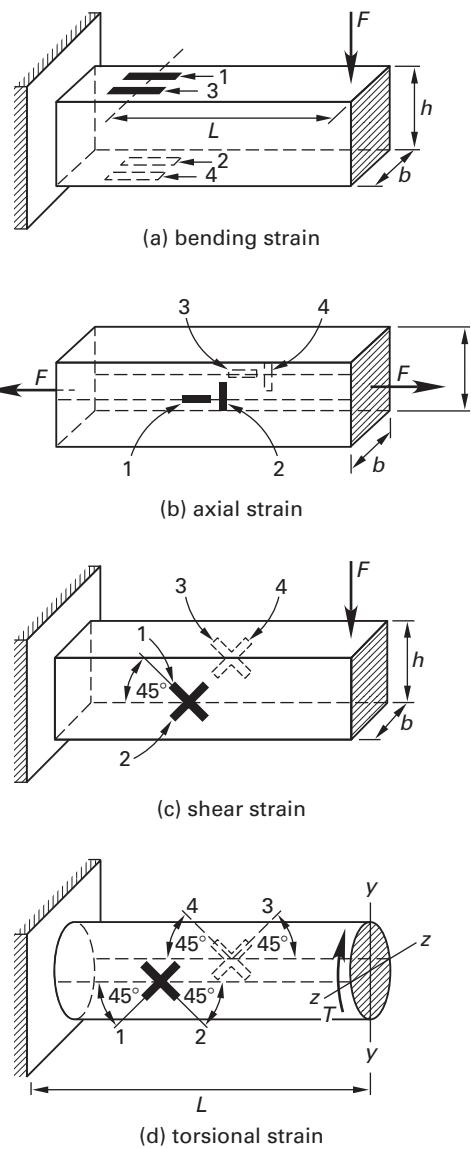

$$\sigma = E\epsilon = \frac{E\epsilon_t}{BC} \quad 85.29$$

$$\sigma = \frac{Mc}{I} = \frac{Mh}{2I} \quad 85.30$$

$$I = \frac{bh^3}{12} \quad [\text{rectangular section}] \quad 85.31$$

For axial strain (see Fig. 85.10(b)) and a material with a Poisson's ratio of 0.3, the bridge constant can be 1.0 (one gauge in position 1), 1.3 (two gauges in positions

<sup>25</sup>Thin-wall pressure vessel theory shows that the circumferential (hoop) stress is twice the longitudinal stress. However, the ratio of circumferential to longitudinal strains is closer to 4:1 than to 2:1.

**Figure 85.10** Orientation of Strain Gauges

1 and 2), 2.0 (two gauges in positions 1 and 3), or 2.6 (all four gauges).

$$\sigma = E\epsilon = \frac{E\epsilon_t}{BC} \quad 85.32$$

$$\sigma = \frac{F}{A} \quad 85.33$$

$$A = bh \quad [\text{rectangular section}] \quad 85.34$$

For shear strain (see Fig. 85.10(c)) and a material with a Poisson's ratio of 0.3, the bridge constant can be 2.0 (two gauges in positions 1 and 2) or 4.0 (all four gauges). The shear strain is twice the axial strain at 45°.

$$\tau = G\gamma = 2G\epsilon = \frac{2G\epsilon_t}{BC} \quad 85.35$$

$$\tau_{\max} = \frac{FQ_{\max}}{bI} \quad 85.36$$

$$\gamma = 2\epsilon \quad [\text{at } 45^\circ] \quad 85.37$$

$$Q_{\max} = \frac{bh^2}{8} \quad [\text{rectangular section}] \quad 85.38$$

$$G = \frac{E}{2(1 + \nu)} \quad 85.39$$

For torsional strain (see Fig. 85.10(d)) and a material with a Poisson's ratio of 0.3, the bridge constant can be 2.0 (two gauges in positions 1 and 2) or 4.0 (all four gauges). The shear strain is twice the axial strain at 45°.

$$\tau = G\gamma = 2G\epsilon = \frac{2G\epsilon_t}{BC} \quad 85.40$$

$$\tau = \frac{Tr}{J} = \frac{Td}{2J} \quad 85.41$$

$$\gamma = 2\epsilon \quad [\text{at } 45^\circ] \quad 85.42$$

$$J = \frac{\pi d^4}{32} \quad [\text{solid circular section}] \quad 85.43$$

$$\phi = \frac{TL}{JG} \quad 85.44$$

$$G = \frac{E}{2(1 + \nu)} \quad 85.45$$

## 24. STRESS MEASUREMENTS IN UNKNOWN DIRECTIONS

In order to calculate the maximum stresses (i.e., the principal stresses) on the surface shown in Fig. 85.10, the gauges would be oriented in the known directions of the principal stresses.

In most cases, however, the directions of the principal stresses are not known. Therefore, rosettes of at least three gauges are used to obtain information in a third direction. Rosettes of three gauges (*rectangular* and *equiangular (delta) rosettes*) are used for this purpose. *T-delta rosettes* include a fourth strain gauge to refine and validate the results of the three primary gauges. Table 85.6 can be used for calculating principal stresses.

## 25. LOAD CELLS

*Load cells* are used to measure forces. A load cell is a transducer that converts a tensile or compressive force into an electrical signal. Though the details of the load cell will vary with the application, the basic elements are (a) a member that is strained by the force and (b) a strain detection system (e.g., strain gauge). The force is calculated from the observed deflection,  $y$ . In Eq. 85.46, the spring constant,  $k$ , is known as the load cell's *deflection constant*.

$$F = ky \quad 85.46$$

Because of their low cost and simple construction, *bending beam load cells* are the most common variety of load cells. Two strain gauges, one on the top and the other

**Table 85.6** Stress-Strain Relationships for Strain Gauge Rosettes<sup>a</sup>

type of rosette			
principal strains, $\epsilon_p, \epsilon_q$	$\frac{1}{2} \left( \frac{\epsilon_a + \epsilon_c}{\pm \sqrt{2(\epsilon_a - \epsilon_b)^2 + 2(\epsilon_b - \epsilon_c)^2}} \right)$	$\frac{1}{3} \left( \frac{\epsilon_a + \epsilon_b + \epsilon_c}{\pm \sqrt{2(\epsilon_a - \epsilon_b)^2 + 2(\epsilon_b - \epsilon_c)^2 + 2(\epsilon_c - \epsilon_a)^2}} \right)$	$\frac{1}{2} \left( \frac{\epsilon_a + \epsilon_d}{\pm \sqrt{(\epsilon_a - \epsilon_d)^2 + \frac{4}{3}(\epsilon_b - \epsilon_c)^2}} \right)$
principal stresses, $\sigma_1, \sigma_2$	$\frac{E}{2} \left( \frac{\epsilon_a + \epsilon_c \pm \frac{1}{1-\nu}}{1-\nu \times \sqrt{2(\epsilon_a - \epsilon_b)^2 + 2(\epsilon_b - \epsilon_c)^2}} \right)$	$\frac{E}{3} \left( \frac{\epsilon_a + \epsilon_b + \epsilon_c \pm \frac{1}{1+\nu}}{1-\nu \times \sqrt{2(\epsilon_a - \epsilon_b)^2 + 2(\epsilon_b - \epsilon_c)^2 + 2(\epsilon_c - \epsilon_a)^2}} \right)$	$\frac{E}{2} \left( \frac{\epsilon_a + \epsilon_d \pm \frac{1}{1+\nu}}{1-\nu \times \sqrt{(\epsilon_a - \epsilon_d)^2 + \frac{4}{3}(\epsilon_b - \epsilon_c)^2}} \right)$
maximum shear, $\tau_{\max}$	$\frac{E}{2(1+\nu)} \times \sqrt{2(\epsilon_a - \epsilon_b)^2 + 2(\epsilon_b - \epsilon_c)^2}$	$\frac{E}{3(1+\nu)} \times \sqrt{2(\epsilon_a - \epsilon_b)^2 + 2(\epsilon_b - \epsilon_c)^2 + 2(\epsilon_c - \epsilon_a)^2}$	$\frac{E}{2(1+\nu)} \times \sqrt{(\epsilon_a - \epsilon_d)^2 + \frac{4}{3}(\epsilon_b - \epsilon_c)^2}$
$\tan 2\theta^b$	$\frac{2\epsilon_b - \epsilon_a - \epsilon_c}{\epsilon_a - \epsilon_c}$	$\frac{\sqrt{3}(\epsilon_c - \epsilon_b)}{2\epsilon_a - \epsilon_b - \epsilon_c}$	$\frac{2}{\sqrt{3}} \left( \frac{\epsilon_c - \epsilon_b}{\epsilon_a - \epsilon_d} \right)$
$0 < \theta < +90^\circ$	$\epsilon_b > \frac{\epsilon_a + \epsilon_c}{2}$	$\epsilon_c > \epsilon_b$	$\epsilon_c > \epsilon_b$

<sup>a</sup> $\theta$  is measured in the counterclockwise direction from the  $a$ -axis of the rosette to the axis of the algebraically larger stress.

<sup>b</sup> $\theta$  is the angle from  $a$ -axis to axis of maximum normal stress.

mounted on the bottom of a cantilever bar, are used. *Shear beam load cells* (which detect force by measuring the shear stress) can be used where the shear does not vary considerably with location, as in the web of an I-beam cross section.<sup>26</sup> The common S-shaped load cell constructed from a machined steel block can be instrumented as either a bending beam or shear beam load cell.

Load cell applications are categorized into grades or accuracy classes, with class III (500 to 10,000 scale divisions) being the most common. Commercial load cells meet standardized limits on errors due to temperature, nonlinearity, and hysteresis. The *temperature effect on output* (TEO) is typically stated in percentage change per 100°F (55.5°C) change in temperature.

Nonlinearity errors are reduced in proportion to the load cell's derating (i.e., using the load cell to measure forces less than its rated force). For example, a 2:1 derating will reduce the nonlinearity errors by 50%. Hysteresis is not normally reduced by derating.

<sup>26</sup>While shear in a rectangular beam varies parabolically with distance from the neutral axis, shear in the web of an I-beam is essentially constant at  $F/A$ . The flanges carry very little of the shear load.

Other advantages of the shear beam load cell include protection from the load and environment, high side load rejection, lower creep, faster RTZ (return to zero) after load removal, and higher tolerance of vibration, dynamic forces, and noise.

The overall error of force measurement can be reduced by a factor of  $1/\sqrt{n}$  (where  $n$  is the number of load cells that share the load equally) by using more than one load cell. Conversely, the applied force can vary by  $\sqrt{n}$  times the known accuracy of a single load cell without decreasing the error.

## 26. DYNAMOMETERS

Torque from large motors and engines is measured by a *dynamometer*. *Absorption dynamometers* (e.g., the simple *friction brake*, *Prony brake*, *water brake*, and *fan brake*) dissipate energy as the torque is measured. Opposing torque in pumps and compressors must be supplied by a *driving dynamometer*, which has its own power input. *Transmission dynamometers* (e.g., *torque meters*, *torsion dynamometers*) use strain gauges to sense torque. They do not absorb or provide energy.

Using a brake dynamometer involves measuring a force, a moment arm, and the angular speed of rotation. The familiar torque-power-speed relationships are used with absorption dynamometers.

$$T = Fr \quad 85.47$$

$$P_{\text{ft-lbf/min}} = 2\pi T_{\text{ft-lbf}} n_{\text{rpm}} \quad 85.48$$

$$P_{\text{kW}} = \frac{T_{\text{N}\cdot\text{m}} n_{\text{rpm}}}{9549} \quad [\text{SI}] \quad 85.49(a)$$

$$P_{\text{hp}} = \frac{2\pi F_{\text{lbf}} r_{\text{ft}} n_{\text{rpm}}}{33,000} \quad [\text{U.S}] \quad 85.49(b)$$

$$= \frac{2\pi T_{\text{ft-lbf}} n_{\text{rpm}}}{33,000}$$

Some brakes and dynamometers are constructed with a “standard” brake arm whose length is 5.252 ft. In that case, the horsepower calculation conveniently reduces to

$$P_{\text{hp}} = \frac{F_{\text{lbf}} n_{\text{rpm}}}{1000} \quad [\text{standard brake arm}] \quad 85.50$$

If an absorption dynamometer uses a DC generator to dissipate energy, the generated voltage ( $V$  in volts) and line current ( $I$  in amps) are used to determine the power. Equation 85.49 and Eq. 85.50 are used to determine the torque.

$$P_{\text{hp}} = \frac{IV}{\eta \left( 1000 \frac{\text{W}}{\text{kW}} \right) \left( 0.7457 \frac{\text{W}}{\text{hp}} \right)} \quad [\text{absorption}] \quad 85.51$$

For a driving dynamometer using a DC motor,

$$P_{\text{hp}} = \frac{IV\eta}{\left( 1000 \frac{\text{W}}{\text{kW}} \right) \left( 0.7457 \frac{\text{W}}{\text{hp}} \right)} \quad [\text{driving}] \quad 85.52$$

Torque can be measured directly by a *torque meter* mounted to the power shaft. Either the angle of twist,  $\phi$ , or the shear strain,  $\tau/G$ , is measured. The torque in a solid shaft of diameter,  $d$ , and length,  $L$ , is

$$T = \frac{JG\phi}{L} = \left( \frac{\pi}{32} \right) d^4 \left( \frac{G\phi}{L} \right)$$

$$= \frac{\pi}{16} d^3 \tau \quad [\text{solid round}] \quad 85.53$$

## 27. INDICATOR DIAGRAMS

*Indicator diagrams* are plots of pressure versus volume and are encountered in the testing of reciprocating engines. In the past, indicator diagrams were actually drawn on an *indicator card* wrapped around a drum through a mechanical linkage of arms and springs. This method is mechanically complex and is not suitable for rotational speeds above 2000 rpm. Modern records of pressure and volume are produced by signals from electronic transducers recorded in real time by computers.

Analysis of indicator diagrams produced by mechanical devices requires knowing the spring constant, also known as the *spring scale*. The *mean effective pressure* (MEP) is calculated by dividing the area of the diagram by the width of the plot and then multiplying by the spring constant.

## 1. PROJECT MANAGEMENT

Project management is the coordination of the entire process of completing a job, from its inception to final move-in and post-occupancy follow-up. In many cases, project management is the responsibility of one person. Large projects can be managed with *partnering*. With this method, the various stakeholders of a project, such as the architect, owner, contractor, engineer, vendors, and others are brought into the decision making process. Partnering can produce much closer communication on a project and shared responsibilities. However, the day-to-day management of a project may be difficult with so many people involved. A clear line of communications and delegation of responsibility should be established and agreed to before the project begins.

Many project managers follow the procedures outlined in *A Guide to the Project Management Body of Knowledge* (PMBOK Guide), published by the Project Management Institute. The PMBOK Guide is an internationally recognized standard (IEEE Std 1490) that defines the fundamentals of project management as they apply to a wide range of projects, including construction, engineering,

software, and many other industries. The PMBOK Guide is process-based, meaning it describes projects as being the outcome of multiple processes. Processes overlap and interact throughout the various phases of a project. Each process occurs within one of five *process groups*, which are related as shown in Fig. 86.1. The five PMBOK process groups are (1) initiating, (2) planning, (3) controlling and monitoring, (4) executing, and (5) closing.

**Figure 86.1** PMBOK Process Groups

The PMBOK Guide identifies nine project management knowledge areas that are typical of nearly all projects. The nine knowledge areas and their respective processes are summarized as follows.

1. *Integration*: develop project charter, project scope statement, and management plan; direct and manage execution; monitor and control work; integrate change control; close project
2. *Scope*: plan, define, create work breakdown structure (WBS), verify, and control scope
3. *Time*: define, sequence, estimate resources, and estimate duration of activities; develop and control schedule
4. *Cost*: estimate, budget, and control costs
5. *Quality*: plan; perform quality assurance and quality control
6. *Human Resources*: plan; acquire, develop, and manage project team
7. *Communications*: plan; distribute information; report on performance; manage stakeholders

8. *Risk:* identify risks; plan risk management and response; perform qualitative and quantitative risk analysis; monitor and control
9. *Procurement:* plan purchases, acquisitions, and contracts; request seller responses; select sellers; administer and close contracts

Each of the processes also falls into one of the five basic process groups, creating a matrix so that every process is related to one knowledge area and one process group. Additionally, processes are described in terms of inputs (documents, plans, designs, etc.), tools and techniques (mechanisms applied to inputs), and outputs (documents, products, etc.).

Establishing a budget (knowledge area 4) and scheduling design and construction (knowledge area 3) are two of the most important parts of project management because they influence many of the design decisions to follow and can determine whether a project is even feasible.

## 2. BUDGETING

Budgets may be established in several ways. For speculative or for-profit projects, the owner or developer works out a pro forma statement listing the expected income of the project and the expected costs to build it. An estimated selling price of the developed project or rent per square foot is calculated and balanced against all the various costs, one of which is the construction price. In order to make the project economically feasible, there will be a limit on the building costs. This becomes the budget within which the work must be completed.

Budgets for municipal and other public projects are often established through public funding or legislation. In these cases, the construction budget is often fixed without the architect's or engineer's involvement, and the project must be designed and built for the fixed amount. Unfortunately, when public officials estimate the cost to build a project, they sometimes neglect to include all aspects of development, such as professional fees, furnishings, and other items.

Budgets may also be based on the proposed project specifics. This is the most realistic and accurate way to establish a preliminary budget because it is based on the actual characteristics of the project. However, this method assumes funding will be available for the project as designed.

There are four basic variables in developing any construction budget: quantity, quality, available funds, and time. There is always a balance among these four variables, and changing one or more affects the others. For instance, if an owner needs a certain area (quantity), needs the project built at a certain time, and has a fixed amount of money to spend, then the quality of construction will have to be adjusted to meet the other constraints. If time, quality, and the total budget are fixed, then the area must be adjusted. For more

information, see the "Time-Cost Trade-Off" section in this chapter. In some cases, *value engineering* can be performed during which individual systems and materials are reviewed to see if the same function can be accomplished in a less expensive way.

### Fee Projections

A *fee projection* is one of the earliest and most important tasks that a project manager must complete. A fee projection takes the total fee the designer will receive for the project and allocates it to the schedule and staff members who will work on the project, after deducting amounts for profit, overhead, and other expenses that will not be used for professional time.

Ideally, fee projections should be developed from a careful projection of the scope of work, its associated costs (direct personnel expenses, indirect expenses, and overhead), consultant fees, reimbursable expenses, and profit desired. These should be determined as a basis for setting the final fee agreement with the client. If this is done correctly, there should be enough money to complete the project within the allotted time.

There are many methods for estimating and allocating fees. Figure 86.2 shows a simple manual form that combines time scheduling with fee projections. In this example, the total working fee, that is, the fee available to pay people to do the job after subtracting for profit, consultants, and other expenses, is listed in the upper right corner of the chart. The various phases or work tasks needed to complete the job are listed in the left-hand column, and the time periods (most commonly in weeks) are listed across the top of the chart.

The project manager estimates the percentage of the total amount of work or fee that he or she thinks each phase will require. This estimate is based on experience and any common rules of thumb the design or construction office may use. The percentages are placed in the third column on the right and multiplied by the total working fee to get the allotted fee for each phase (the figure in the second column on the right). This allotted fee is then divided among the number of time periods in the schedule and placed in the individual columns under each time period.

If phases or tasks overlap (as they do in Fig. 86.2), sum the fees in each period and place this total dollar amount at the bottom of the chart. The total dollar amount can then be divided by an average billing rate for the people working on the project to determine an approximate budgeted number of hours that the office can afford to spend on the project each week and still make a profit. Of course, if the number of weekly hours exceeds about 40, then more than one person will be needed to do the work.

By monitoring time sheets, the project manager can compare the actual hours (or fees) expended against the budgeted time (or fees) and take corrective action if actual time exceeds budgeted time.

Quality planning involves determining with the client what the expectations are concerning design, cost, and other aspects of the project. Quality does not simply mean high-cost finishes, but rather the requirements of the client based on his or her needs. These needs should be clearly defined in the programming phase of a project and written down and approved by the client before design work begins.

## Cost Estimating

Estimators compile and analyze data on all of the factors that can influence costs, such as materials, labor, location, duration of the project, and special machinery requirements. The methods for estimating costs can differ greatly by industry. On a construction project, for example, the estimating process begins with the decision to submit a bid. After reviewing various preliminary drawings and specifications, the estimator visits the site of the proposed project. The estimator needs to gather information on access to the site; the availability of electricity, water, and other services; and surface topography and drainage. The estimator usually records this information in a signed report that is included in the final project estimate.

After the site visit, the estimator determines the quantity of materials and labor the firm will need to furnish. This process, called the quantity survey or “takeoff,” involves

completing standard estimating forms, filling in dimensions, numbers of units, and other information. Table 86.1 is a small part of a larger takeoff report illustrating the degree of detail needed to estimate the project cost. A cost estimator working for a general contractor, for example, uses a construction project’s plans and specifications to estimate the materials dimensions and count the quantities of all items associated with the project.

Though the quantity takeoff process can be done manually using a printout, a red pen, and a clicker, it can also be done with a digitizer that enables the user to take measurements from paper bid documents, or with an integrated *takeoff viewer* program that interprets electronic bid documents. In any case, the objective is to generate a set of takeoff elements (counts, measurements, and other conditions that affect cost) that is used to establish cost estimates. Table 86.1 is an example of a typical quantity take-off report for lumber needed for a construction project.

Although subcontractors estimate their costs as part of their own bidding process, the general contractor’s cost estimator often analyzes bids made by subcontractors. Also during the takeoff process, the estimator must make decisions concerning equipment needs, the sequence of operations, the size of the crew required, and physical constraints at the site. Allowances for wasted materials, inclement weather, shipping delays,

and other factors that may increase costs also must be incorporated in the estimate. After completing the quantity surveys, the estimator prepares a cost summary for the entire project, including the costs of labor, equipment, materials, subcontracts, overhead, taxes, insurance, markup, and any other costs that may affect the project. The chief estimator then prepares the bid proposal for submission to the owner. Construction cost estimators also may be employed by the project's architect or owner to estimate costs or to track actual costs relative to bid specifications as the project develops.

Estimators often specialize in large construction companies employing more than one estimator. For example, one may estimate only electrical work and another may concentrate on excavation, concrete, and forms.

Computers play an integral role in cost estimation because estimating often involves numerous mathematical calculations requiring access to various historical databases. For example, to undertake a parametric analysis (a process used to estimate costs per unit based on square footage or other specific requirements of a

project), cost estimators use a computer database containing information on the costs and conditions of many other similar projects. Although computers cannot be used for the entire estimating process, they can relieve estimators of much of the drudgery associated with routine, repetitive, and time-consuming calculations.

### Cost Influences

There are many variables that affect project cost. Construction cost is only one part of the total project development budget. Other factors include such things as site acquisition, site development, fees, and financing. Table 86.2 lists most of the items commonly found in a project budget and a typical range of values based on construction cost. Not all of these are part of every development, but they illustrate the things that must be considered.

*Building cost* is the money required to construct the building, including structure, exterior cladding, finishes, and electrical and mechanical systems. *Site development*

**Table 86.2** Project Budget Line Items

line item		example
A	site acquisition	\$1,100,000
B	building costs	(assume) \$6,800,000
C	site development	(15%) \$1,020,000
D	total construction cost	\$7,820,000
E	movable equipment	(5%) \$340,000
F	furnishings	\$200,000
G	total construction and furnishings	\$8,360,000
H	professional services	(7%) \$547,400
I	inspection and testing	\$15,000
J	escalation estimate	(10%) \$836,000
K	contingency	(8%) \$668,800
L	financing costs	\$250,000
M	moving expenses	(assume) \$90,000
N	total project budget	\$11,867,200

*costs* are usually a separate item. They include such things as parking, drives, fences, landscaping, exterior lighting, and sprinkler systems. If the development is large and affects the surrounding area, a developer may be required to upgrade roads, extend utility lines, and do other major off-site work as a condition of getting approval from public agencies.

*Movable equipment* and furnishings include furniture, accessories, window coverings, and major equipment necessary to put the facility into operation. These are often listed as separate line items because the funding for them may come out of a separate budget and because they may be supplied under separate contracts.

*Professional services* are architectural and engineering fees as well as costs for such things as topographic surveys, soil tests, special consultants, appraisals and legal fees, and the like. Inspection and testing involve money required for special on-site, full-time inspection (if required), and testing of such things as concrete, steel, window walls, and roofing.

Because construction takes a great deal of time, a factor for inflation should be included. Generally, the present budget estimate is escalated to a time in the future at the expected midpoint of construction. Although it is impossible to predict the future, by using past cost indexes and inflation rates and applying an estimate to the expected condition of the construction, the architect can usually make an educated guess.

A *contingency cost* should also be added to account for unforeseen changes by the client and other conditions that add to the cost. For an early project budget, the percentage of the contingency should be higher than contingencies applied to later budgets, because there are more unknowns. Normally, 5% to 10% should be included.

Financing includes not only the long-term interest paid on permanent financing but also the immediate costs of

loan origination fees, construction loan interest, and other administrative costs. On long-term loans, the cost of financing can easily exceed all of the original building and development costs. In many cases, long-term interest, called *debt service*, is not included in the project budget because it is an ongoing cost to the owner, as are maintenance costs.

Finally, many clients include moving costs in the development budget. For large companies and other types of clients, the money required to physically relocate, including changing stationery, installing telephones, and the like, can be a substantial amount.

### Methods of Budgeting

The costs described in the previous section and shown in Table 86.2 represent a type of budget done during programming or even prior to programming to test the feasibility of a project. The numbers are preliminary, often based on sketchy information. For example, the building cost may simply be an estimated cost per square foot multiplied by the number of gross square feet needed. The square footage cost may be derived from similar buildings in the area, from experience, or from commercially available cost books.

Budgeting, however, is an ongoing activity. At each stage of the design process, there should be a revised budget reflecting the decisions made to that time. As shown in the example, pre-design budgets are usually based only on area, but other units can also be used. For example, many companies have rules of thumb for making estimates based on cost per hospital bed, cost per student, cost per hotel room, or similar functional units.

After the pre-programming budget, the architect usually begins to concentrate on the building and site development costs. At this stage an average cost per square foot may still be used, or the building may be divided into several functional parts and different square footage prices may be assigned to each part. A school, for

example, may be classified into classroom space, laboratory space, shop space, office space, and gymnasium space, each having a different cost per square foot. This type of division can be developed concurrently with the programming of the space requirements.

During schematic design, when more is known about the space requirements and general configuration of the building and site, *system budgeting* is based on major subsystems. Historical cost information on each type of subsystem can be applied to the design. At this point it is easier to see where the money is being used in the building. Design decisions can then be based on studies of alternative systems. A typical subsystem budget is shown in Table 86.3.

**Table 86.3** System Cost Budget of Office Buildings

subsystem	average cost	
	(\$/ft <sup>2</sup> )	(% of total)
foundations	3.96	5.2
floors on grade	3.08	4.0
superstructure	16.51	21.7
roofing	0.18	0.2
exterior walls	9.63	12.6
partitions	5.19	6.8
wall finishes	3.70	4.8
floor finishes	3.78	5.0
ceiling finishes	2.79	3.7
conveying systems	6.45	8.5
specialties	0.70	0.9
fixed equipment	2.74	3.6
HVAC	9.21	12.1
plumbing	3.61	4.6
electrical	4.68	6.1
	76.21	100.0

Values for low-, average-, and high-quality construction for different building types can be obtained from cost databases and published estimating manuals and applied to the structure being budgeted. The dollar amounts included in system cost budgets usually include markup for contractor's overhead and profit and other construction administrative costs.

During the later stages of schematic design and early stages of construction documents, more detailed estimates are made. The procedure most often used is the *parameter method*, which involves an expanded itemization of construction quantities and assignment of unit costs to these quantities. For example, instead of using one number for floor finishes, the cost is broken down into carpeting, vinyl tile, wood strip flooring, unfinished concrete, and so forth. Using an estimated cost per square foot, the cost of each type of flooring can be estimated based on the area. With *parametric budgeting*, it is possible to evaluate the cost implications of each building component and to make decisions concerning both quantity and quality in order to meet the original budget estimate. If floor finishes are over

budget, the architect and the client can review the parameter estimate and decide, for example, that some wood flooring must be replaced with less expensive carpeting. Similar decisions can be made concerning any of the parameters in the budget.

Another way to compare and evaluate alternative construction components is with *matrix costing*. With this technique, a matrix is drawn showing, along one side, the various alternatives and, along the other side, the individual elements that combine to produce the total cost of the alternatives. For example, in evaluating alternatives for workstations, all of the factors that would comprise the final cost could be compared. These factors might include the cost of custom-built versus pre-manufactured workstations, task lighting that could be planned with custom-built units versus higher-wattage ambient lighting, and so on.

Parameter line items are based on commonly used units that relate to the construction element under study. For instance, a gypsum board partition would have an assigned cost per square foot of complete partition of a particular construction type rather than separate costs for metal studs, gypsum board, screws, and finishing. There would be different costs for single-layer gypsum board partitions, 1-hour rated walls, 2-hour rated walls, and other partition types.

### Overhead and Profit

Two additional components of construction cost are the contractor's overhead and profit. Overhead can be further divided into general overhead and project overhead. *General overhead* is the cost to run a contracting business, and involves office rent, secretarial help, heat, and other recurring costs. *Project overhead* is the money it takes to complete a particular job, not including labor, materials, or equipment. Temporary offices, project telephones, sanitary facilities, trash removal, insurance, permits, and temporary utilities are examples of project overhead. The total overhead costs, including both general and project expenses, can range from about 10% to 20% of the total costs for labor, materials, and equipment.

*Profit* is the last item a contractor adds onto an estimate and is listed as a percentage of the total of labor, materials, equipment, and overhead. This is one of the most highly variable parts of a budget. Profit depends on the type of project, its size, the amount of risk involved, how much money the contractor wants to make, the general market conditions, and, of course, whether or not the job is being bid.

During extremely difficult economic conditions, a contractor may cut the profit margin to almost nothing simply to get the job and keep his or her workforce employed. If the contract is being negotiated with only one contractor, the profit percentage will be much higher. In most cases, however, profit will range from 5% to 20% of the total cost of the job. Overall, overhead and profit can total about 15% to 40% of construction cost.

## Cost Information

One of the most difficult aspects of developing project budgets is obtaining current, reliable prices for the kinds of construction units being used. There is no shortage of commercially produced cost books that are published yearly. These books list costs in different ways; some are very detailed, giving the cost for labor and materials for individual construction items, while others list parameter costs and subsystem costs. The detailed price listings are of little use to architects because they are too specific and make comparison of alternate systems difficult.

There are also computerized cost estimating services that only require the architect or engineer to provide general information about the project, location, size, major materials, and so forth. The computer service then applies its current price database to the information and produces a cost budget. Many architects and engineers also work closely with general contractors to develop a realistic budget.

Commercially available cost information, however, is the average of many past construction projects from around the country. Local variations and particular conditions may affect the value of their use on a specific project.

Two conditions that must be accounted for in developing any project budget are geographical location and inflation. These variables can be adjusted by using cost indexes that are published in a variety of sources, including the major architectural and construction trade magazines. Using a base year as index 1000, for example, for selected cities around the country, new indexes are developed each year that reflect the increase in costs (both material and labor) that year.

The indexes can be used to apply costs from one part of the country to another and to escalate past costs to the expected midpoint of construction of the project being budgeted.

### Example 86.1

The cost index in your city is 1257 and the cost index for another city in which you are designing a building is 1308. If the expected construction cost is \$1,250,000 based on prices for your city, what will be the expected cost in the other region?

*Solution*

$$\frac{\text{cost A}}{\text{index A}} = \frac{\text{cost B}}{\text{index B}}$$

$$\text{cost in other region} = \left( \frac{\text{index in other region}}{\text{index in your city}} \right) \left( \frac{\text{your city cost}}{\text{your city index}} \right)$$

$$= (1308) \left( \frac{\$1,250,000}{1257} \right)$$

$$= \$1,300,716$$

## Life-Cycle Cost Analysis

*Life-cycle cost analysis* (LCC) is a method for determining the total cost of a building or building component or system over a specific period of time. It takes into account the initial cost of the element or system under consideration as well as the cost of financing, operation, maintenance, and disposal. Any residual value of the components is subtracted from the other costs. The costs are estimated over a length of time called the *study period*. The duration of the study period varies with the needs of the client and the useful life of the material or system. For example, investors in a building may be interested in comparing various alternate materials over the expected investment time frame, while a city government may be interested in a longer time frame representing the expected life of the building. All future costs are discounted back to a common time, usually the base date, to account for the time value of money. The *discount rate* is used to convert future costs to their equivalent present values.

Using life-cycle cost analysis allows two or more alternatives to be evaluated and their total costs to be compared. This is especially useful when evaluating energy conservation measures where one design alternative may have a higher initial cost than another, but a lower overall cost because of energy savings. Some of the specific costs involved in an LCC of a building element include the following.

- initial costs, which include the cost of acquiring and installing the element
- operational costs for electricity, water, and other utilities
- maintenance costs for the element over the length of the study period, including any repair costs
- replacement costs, if any, during the length of the study period
- finance costs required during the length of the study period
- taxes, if any, for initial costs and operating costs

The *residual value* is the remaining value of the element at the end of the study period based on resale value, salvage value, value in place, or scrap value. All of the costs listed are estimated, discounted to their present value, and added together. Any residual value is discounted to its present value and then subtracted from the total to get the final life-cycle cost of the element.

A life-cycle cost analysis is not the same as a *life-cycle assessment* (LCA). An LCA analyzes the environmental impact of a product or building system over the entire life of the product or system.

### 3. SCHEDULING

There are two primary elements that affect a project's schedule: design sequencing and construction sequencing. The architect has control over design and the production of contract documents, while the contractor has control over construction. The entire project should be scheduled for the best course of action to meet the client's goals. For example, if the client must move by a certain date and normal design and construction sequences make this impossible, the engineer, architect, or contractor may recommend a fast-track schedule or some other approach to meet the deadline.

#### Design Sequencing

Prior to creating a design, the architect needs to gather information about a client's specific goals and objectives, as well as analyzing any additional factors that may influence a project's design. (This gathering of information is known as *programming*.)

Once this preliminary information has been gathered, the design process may begin. The design process normally consists of several clearly defined phases, each of which must be substantially finished and approved by the client before the next phase may begin. These phases are outlined in the "Owner-Architect Agreement," which is published by the American Institute of Architects (AIA), as well as in other AIA documents. The architectural profession commonly refers to the phases as follows.

1. *Schematic Design Phase*: develops the general layout of the project through schematic design drawings, along with any preliminary alternate studies for materials and building systems
2. *Design Development Phase*: refines and further develops any decisions made during the schematic design phase; preliminary or outline specifications are written and a detailed project budget is created
3. *Construction Documents Phase*: final working drawings, as well as the project manual and any bidding or contract documents, are solidified
4. *Bidding or Negotiation Phase*: bids from several contractors are obtained and analyzed; negotiations with a contractor begin and a contractor is selected
5. *Construction Phase*: see the following section, "Construction Sequencing"

The time required for each of these five phases is highly variable and depends on the following factors.

- *Size and complexity of the project*: A 500,000 ft<sup>2</sup> (46 450 m<sup>2</sup>) hospital will take much longer to design than a 30,000 ft<sup>2</sup> (2787 m<sup>2</sup>) office building.
- *Number of people working on the project*: Although adding more people to the job can shorten the schedule, there is a point of diminishing returns. Having too many people only creates a management and

coordination problem, and for some phases only a few people are needed, even for very large jobs.

- *Abilities and design methodology of the project team*: Younger, less-experienced designers will usually need more time to do the same amount of work than would more senior staff members.
- *Type of client, client decision-making, and approval processes of the client*: Large corporations or public agencies are likely to have a multilayered decision-making and approval process. Getting necessary information or approval for one phase from a large client may take weeks or even months, while a small, single-authority client might make the same decision in a matter of days.

The construction schedule may be established by the contractor or construction manager, or it may be estimated by the architect during the programming phase so that the client has some idea of the total time required from project conception to move-in.

Many variables can affect construction time. Most can be controlled in one way or another, but others, like weather, are independent of anyone's control. Beyond the obvious variables of size and complexity, the following is a partial list of some of the more common variables.

- management ability of the contractor to coordinate the work of direct employees with that of any subcontractors
- material delivery times
- quality and completeness of the architect's drawings and specifications
- weather
- labor availability and labor disputes
- new construction or remodeling (remodeling generally takes more time and coordination than for new buildings of equal areas)
- site conditions (construction sites or those with subsurface problems usually take more time to build on)
- characteristics of the architect (some professionals are more diligent than others in performing their duties during construction)
- lender approvals
- agency and governmental approvals

#### Construction Sequencing

*Construction sequencing* involves creating and following a work schedule that balances the timing and sequencing of land disturbance activities (e.g., earthwork) and the installation of *erosion and sedimentation control* (ESC) measures. The objective of construction

sequencing is to reduce on-site erosion and off-site sedimentation that might affect the water quality of nearby water bodies.

The project manager should confirm that the general construction schedule and the construction sequencing schedule are compatible. Key construction activities and associated ESC measures are listed in Table 86.4.

**Table 86.4** Construction Activities and ESC Measures

construction activity	ESC measures
designate site access	Stabilize exposed areas with gravel and/or temporary vegetation. Immediately apply stabilization to areas exposed throughout site development.
protect runoff outlets and conveyance systems	Install principle sediment traps, fences, and basins prior to grading; stabilize stream banks and install storm drains, channels, etc.
land clearing	Mark trees and buffer areas for preservation.
site grading	Install additional ESC measures as needed during grading.
site stabilization	Install temporary and permanent seeding, mulching, sodding, riprap, etc.
building construction and utilities installation	Install additional ESC measures as needed during construction.
landscaping and final site stabilization*	Remove all temporary control measures; install topsoil, trees and shrubs, permanent seeding, mulching, sodding, riprap, etc.; stabilize all open areas, including borrow and spoil areas.

\*This is the last construction phase.

### Time-Cost Trade-Off

A project's completion time and its cost are intricately related. Though some costs are not directly related to the time a project takes, many costs are. This is the essence of the time-cost trade-off: The cost increases as the project time is decreased and vice versa. A project manager's roles include understanding the time-cost relationship, optimizing a project's pace for minimal cost, and predicting the impact of a schedule change on project cost.

The costs associated with a project can be classified as direct costs or indirect costs. The project cost is the sum of the direct and indirect costs.

*Direct costs*, also known as *variable costs*, *operating costs*, *prime costs*, and *on costs*, are costs that vary directly with the level of output (e.g., labor, fuel, power, and the cost of raw material). Generally, direct costs

increase as a project's completion time is decreased, since more resources need to be allocated to increase the pace.

*Indirect costs*, also known as *fixed costs*, are costs that are not directly related to a particular function or product. Indirect costs include taxes, administration, personnel, and security costs. Such costs tend to be relatively steady over the life of the project and decrease as the project duration decreases.

The time required to complete a project is determined by the critical path, so to compress (or "crash") a project schedule (accelerate the project activities in order to complete the project sooner), a project manager must focus on critical path activities.

A procedure for determining the optimal project time, or time-cost-trade-off, is to determine the normal completion time and direct cost for each critical path activity and compare it to its respective "crash time" and direct cost. The *crash time* is the shortest time in which an activity can be completed. If a new critical path emerges, consider this in subsequent time reductions. In this way, one can step through the critical path activities and calculate the total direct project cost versus the project time. (To minimize the cost, those activities that are not on the critical path can be extended without increasing the project completion time.) The indirect, direct, and total project costs can then be calculated for different project durations. The optimal duration is the one with the lowest cost. This model assumes that the normal cost for an activity is lower than the crash cost, the time and cost are linearly related, and the resources needed to shorten an activity are available. If these assumptions are not true, then the model would need to be adapted. Other cost considerations include incentive payments, marketing initiatives, and the like.

### Fast Tracking

Besides efficient scheduling, construction time can be compressed with *fast-track scheduling*. This method overlaps the design and construction phases of a project. Ordering of long-lead materials and equipment can occur, and work on the site and foundations can begin before all the details of the building are completely worked out. With fast-track scheduling, separate contracts are established so that each major system can be bid and awarded by itself to avoid delaying other construction.

Although the fast-track method requires close coordination between the architect, contractor, subcontractors, owner, and others, it makes it possible to construct a high-quality building in 10% to 30% less time than with a conventional construction contract.

### Schedule Management

Several methods are used to schedule and monitor projects. The most common and easiest is the *bar chart* or

*Gantt chart*, such as Fig. 86.3. The various activities of the schedule are listed along the vertical axis. Each activity is given a starting and finishing date, and overlaps are indicated by drawing the bars for each activity so that they overlap. Bar charts are simple to make and understand and are suitable for small to midsize projects. However, they cannot show all the sequences and dependencies of one activity on another.

*Critical path techniques* are used to graphically represent the multiple relationships between stages in a complicated project. The graphical network shows the *precedence relationships* between the various activities. The graphical network can be used to control and monitor the progress, cost, and resources of a project. A critical path technique will also identify the most critical activities in the project.

Critical path techniques use *directed graphs* to represent a project. These graphs are made up of *arcs* (arrows) and *nodes* (junctions). The placement of the arcs and nodes completely specifies the precedences of the project. Durations and precedences are usually given in a *precedence table* (matrix).

#### 4. RESOURCE LEVELING

*Resource leveling* is used to address *overallocation* (i.e., situations that demand more resources than are

available). Usually, people and equipment are the limited resources, although project funding may also be limited if it becomes available in stages. Two common ways are used to level resources: (1) Tasks can be delayed (either by postponing their start dates or extending their completion dates) until resources become available. (2) Tasks can be split so that the parts are completed when planned and the remainders are completed when resources becomes available. The methods used depend on the limitations of the project, including budget, resource availability, finish date, and the amount of flexibility available for scheduling tasks. If resource leveling is used with tasks on a project's critical path, the project's completion date will inevitably be extended.

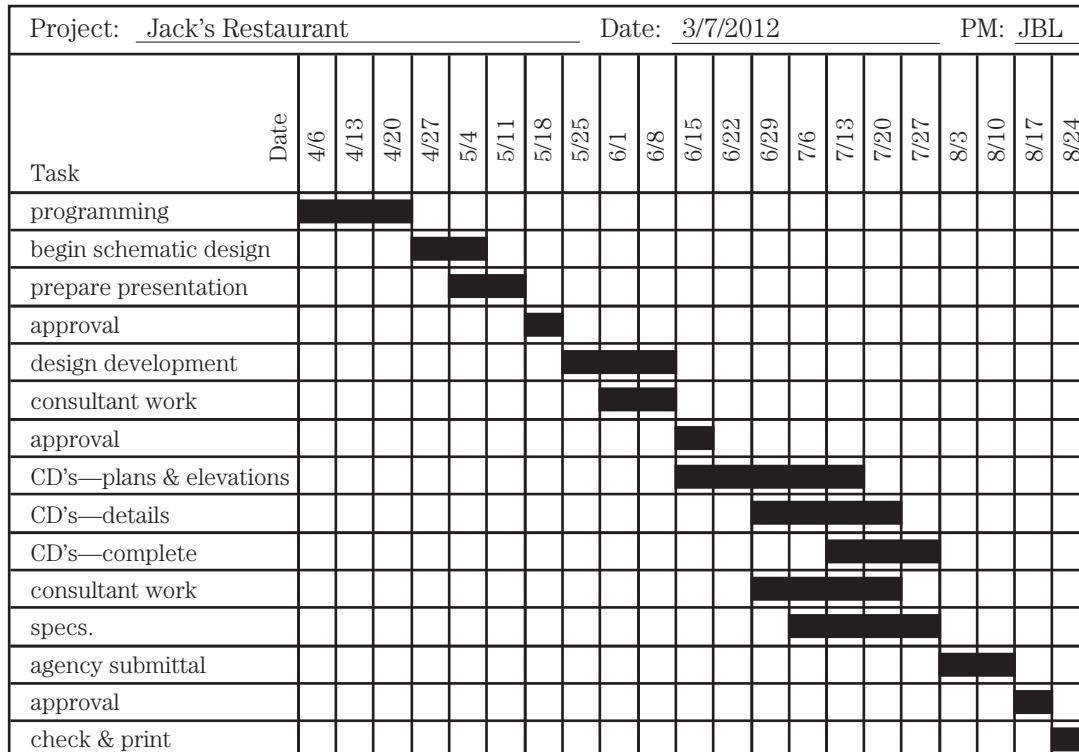

#### Example 86.2

Because of a shortage of reusable forms, a geotechnical contractor decides to build a 250 ft long concrete wall in 25 ft segments. Each segment requires the following crews and times.

- set forms: three carpenters; two days
- pour concrete: three carpenters; one day
- strip forms: four carpenters; one day

The contractor has budgeted for only three carpenters. Compared to the ideal schedule, how many additional days will it take to construct the wall if the number of carpenters is leveled to three?

**Figure 86.3** Gantt Chart

### Solution

Having only three carpenters affects the form stripping operation, but it does not affect the form setting and concrete pouring operations. If the contractor had four carpenters, stripping the forms from each 25 ft segment would take 1 day; stripping forms for the entire 250 ft wall would take (10 segments)(1 day/segment) = 10 days.

With only three carpenters, form stripping productivity is reduced to  $\frac{3}{4}$  of the four-carpenter rate. Each form stripping operation takes  $\frac{4}{3}$  days, and the entire wall takes (10 segments)( $\frac{4}{3}$  days/segment) = 13.3 days. The increase in time is 13.3 days – 10 days = 3.3 days.

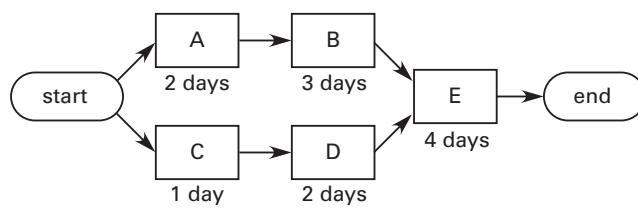

## 5. ACTIVITY-ON-NODE NETWORKS

The *critical path method* (CPM) is one of several critical path techniques that uses a directed graph to describe the precedence of project activities. CPM requires that all activity durations be specified by single values. That is, CPM is a *deterministic method* that does not intrinsically support activity durations that are distributed as random variables.

Another characteristic of CPM is that each activity (task) is traditionally represented by a node (junction), hence the name *activity-on-node network*. Each node is typically drawn on the graph as a square box and labeled with a capital letter, although these are not absolute or universally observed conventions. Each activity can be thought of as a continuum of work, each with its own implicit “start” and “finish” events. For example, the activity “grub building site” starts with the event of a bulldozer arriving at the native site, followed by several days of bulldozing, and ending with the bulldozer leaving the cleaned site. An activity, including its start and finish events, occurs completely within its box (node).

Each activity in a CPM diagram is connected by arcs (connecting arrows, lines, etc.) The arcs merely show precedence and dependencies. Events are not represented on the graph, other than, perhaps, as the heads of tails of the arcs. Nothing happens along the arcs, and the arcs have zero durations. Because of this, arcs are not labeled. (See Fig. 86.4.)

**Figure 86.4** Activity-on-Node Network

For convenience, when a project starts or ends with multiple simultaneous activities, *dummy nodes* with zero durations may be used to specify the start and/or finish of the entire project. Dummy nodes do not add time to the project. They are included for convenience.

Since all CPM arcs have zero durations, the arcs connecting dummy nodes are not different from arcs connecting other activities.

A CPM graph depicts the activities required to complete a project and the sequence in which the activities must be completed. No activity can begin until all of the activities with arcs leading into it have been completed. The duration and various dates are associated with each node, and these dates can be written on the CPM graph for convenience. These dates include the earliest possible start date, ES; the latest start date, LS; the earliest finish date, EF; and, the latest finish date, LF. The ES, EF, LS, and LF dates are calculated from the durations and the activity interdependencies.

After the ES, EF, LS, and LF dates have been determined for each activity, they can be used to identify the critical path. The *critical path* is the sequence of activities (the *critical activities*) that must all be started and finished exactly on time in order to not delay the project. Delaying the starting time of any activity on the critical path, or increasing its duration, will delay the entire project. The critical path is the longest path through the network. If it is desired that the project be completed sooner than expected, then one or more activities in the critical path must be shortened. The critical path is generally identified on the network with heavier (thicker) arcs.

Activities not on the critical path are known as *noncritical activities*. Other paths through the network will require less time than the critical path, and hence, will have inherent delays. The noncritical activities can begin or finish earlier or later (within limits) without affecting the overall schedule. The amount of time that an activity can be delayed without affecting the overall schedule is known as the *float (float time or slack time)*. Float can be calculated in two ways, with identical results. The first way uses Eq. 86.1. The second way is described in the following section, “Solving a CPM Problem.”

$$\text{float} = \text{LS} - \text{ES} = \text{LF} - \text{EF} \quad 86.1$$

Float is zero along the critical path. This fact can be used to identify the activities along the critical path from their respective ES, EF, LS, and LF dates.

It is essential to maintain a distinction between time, date, length, and duration. Like the timeline for engineering economics problems, all projects start at time = 0, but this corresponds to starting on day = 1. That is, work starts on the first day. Work ends on the last day of the project, but this end rarely corresponds to midnight. So, if a project has a critical path length (duration-to-completion) of 15 days and starts on (at the beginning of) May 1, it will finish on (at the end of) May 15, not May 16.

## 6. SOLVING A CPM PROBLEM

As previously described, the solution to a critical path method problem reveals the earliest and latest times

that an activity can be started and finished, and it also identifies the critical path and generates the float for each activity.

As an alternative to using Eq. 86.1, the following procedure may be used to solve a CPM problem. To facilitate the solution, each node should be replaced by a square that has been quartered. The compartments have the meanings indicated by the key.

key	
ES	EF
LS	LF

- ES: Earliest Start
- EF: Earliest Finish
- LS: Latest Start
- LF: Latest Finish

**step 1:** Place the project start time or date in the **ES** and **EF** positions of the start activity. The start time is zero for relative calculations.

**step 2:** Consider any unmarked activity, all of whose predecessors have been marked in the **EF** and **ES** positions. (Go to step 4 if there are none.) Mark in its **ES** position the largest number marked in the **EF** position of those predecessors.

**step 3:** Add the activity time to the **ES** time and write this in the **EF** box. Go to step 2.

**step 4:** Place the value of the latest finish date in the **LS** and **LF** boxes of the finish mode.

**step 5:** Consider unmarked predecessors whose successors have all been marked. Their **LF** is the smallest **LS** of the successors. Go to step 7 if there are no unmarked predecessors.

**step 6:** The **LS** for the new node is **LF** minus its activity time. Go to step 5.

**step 7:** The float for each node is **LS – ES** and **LF – EF**.

**step 8:** The critical path encompasses nodes for which the float equals **LS – ES** from the start node. There may be more than one critical path.

### Example 86.3

Using the precedence table given, construct the precedence matrix and draw an activity-on-node network.

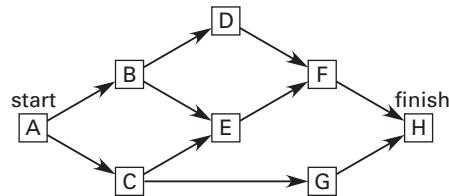

activity	duration (days)	predecessors
A, start	0	—
B	7	A
C	6	A
D	3	B
E	9	B, C
F	1	D, E
G	4	C
H, finish	0	F, G

### Solution

The precedence matrix is

		successor							
		A	B	C	D	E	F	G	H
predecessor	A	■	■						
	B			■	■	■			
C			■	■	■	■		■	
D						■			
E						■			
F							■		
G								■	
H								■	

The activity-on-node network is

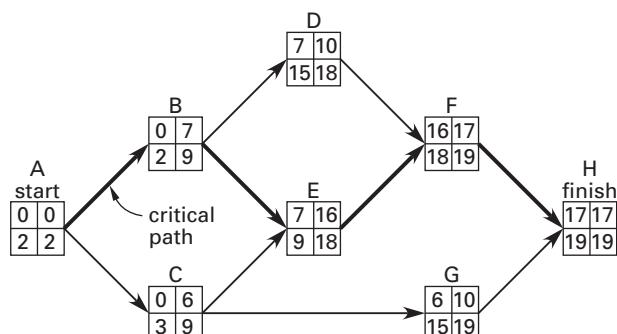

### Example 86.4

Complete the network for the previous example and find the critical path. Assume the desired completion duration is in 19 days.

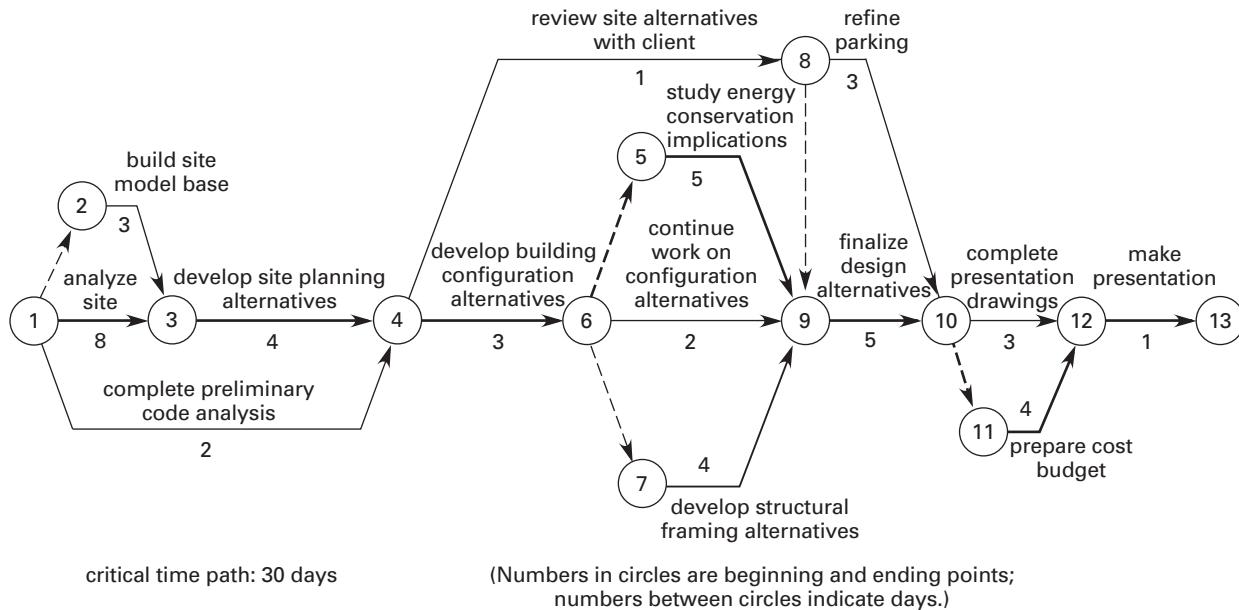

### Solution

The critical path is shown with darker lines.

### 7. ACTIVITY-ON-ARC NETWORKS

Another variety of deterministic critical path techniques represents project activities as arcs. With *activity-on-arc networks* (also known as *activity-on-branch networks*), the continuum of work occupies the arcs, while the nodes represent instantaneous starting and ending events. The arcs have durations, while the nodes do not. Nothing happens on a node, as it represents an instant in time only. As shown in Fig. 86.5, each node is typically drawn on the graph as a circle and labeled with a number, although this format is not universally adhered to. Since the activities are described by the same precedence table as would be used with an activity-on-node graph, the arcs are labeled with the activity capital

**Figure 86.5** Activity-on-Arc Network

letter identifiers or the activity descriptions. The duration of the activity may be written adjacent to its arc. (This is the reason for identifying activities with letters, so that any number appearing with an arc can be interpreted as a duration.)

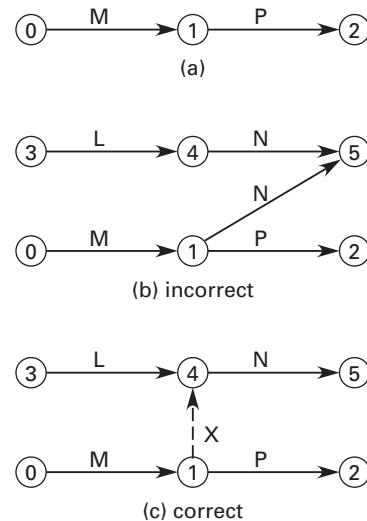

Although the concepts of ES, EF, LS, and LF dates, critical path, and float are equally applicable to activity-on-arc and activity-on-node networks, the two methods cannot be combined within a single project graph. Calculations for activity-on-arc networks may seem less intuitive, and there are other possible complications.

The activity-on-arc method is complicated by the frequent requirement for *dummy activities* and nodes to maintain precedence. Consider the following part of a precedence table.

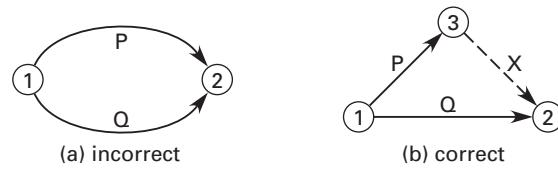

activity	predecessors
L	—
M	—
N	L, M
P	M

Activity P depends on the completion of only M. Figure 86.6(a) is an activity-on-arc representation of this precedence. However, N depends on the completion of both L and M. It would be incorrect to draw the network as Fig. 86.6(b) since the activity N appears twice. To represent the project, the dummy activity X must be used, as shown in Fig. 86.6(c).

If two activities have the same starting and ending events, a *dummy node* is required to give one activity a uniquely identifiable completion event. This is illustrated in Fig. 86.7(b).

**Figure 86.6** Activity-on-Arc Network with Predecessors

The solution method for an activity-on-arc problem is essentially the same as for the activity-on-node problem, requiring forward and reverse passes to determine earliest and latest dates.

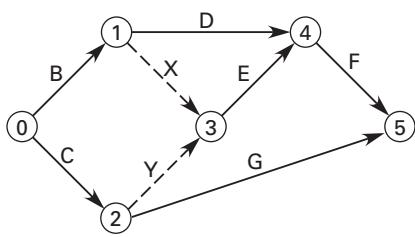

**Figure 86.7** Use of a Dummy Node

**Example 86.5**

Represent the project in Ex. 86.3 as an activity-on-arc network.

*Solution*

event	event description
0	start project
1	finish B, start D
2	finish C, start G
3	finish B and C, start E
4	finish D and E, start F
5	finish F and G

**8. STOCHASTIC CRITICAL PATH MODELS**

*Stochastic models* differ from deterministic models only in the way in which the activity durations are found. Whereas durations are known explicitly for the deterministic model, the time for a stochastic activity is distributed as a random variable.

This stochastic nature complicates the problem greatly since the actual distribution is often unknown. Such problems are solved as a deterministic model using the mean of an assumed duration distribution as the activity duration.

The most common stochastic critical path model is PERT, which stands for *program evaluation and review technique*. PERT diagrams have traditionally been drawn as activity-on-arc networks. In PERT, all duration variables are assumed to come from a *beta distribution*, with mean and standard deviation given by Eq. 86.2 and Eq. 86.3, respectively.

$$\mu = \frac{1}{6}(t_{\min} + 4t_{\text{most likely}} + t_{\max}) \quad 86.2$$

$$\sigma = \frac{1}{6}(t_{\max} - t_{\min}) \quad 86.3$$

The project *completion time* for large projects is assumed to be normally distributed with mean equal to the critical path length and with overall variance equal to the sum of the variances along the critical path.

The probability that a project duration will exceed some length,  $D$ , can be found from Eq. 86.4.  $z$  is the standard normal variable.

$$p\{\text{duration} > D\} = p\{t > z\} \quad 86.4$$

$$z = \frac{D - \mu_{\text{critical path}}}{\sigma_{\text{critical path}}} \quad 86.5$$

**Example 86.6**

The mean times and variances for activities along a PERT critical path are given. What is the probability that the project's completion time will be (a) less than 14 days, (b) more than 14 days, (c) more than 23 days, and (d) between 14 and 23 days?

activity mean time (days)	activity standard deviation (days)
9	1.3
4	0.5
7	2.6

*Solution*

The most likely completion time is the sum of the mean activity times.

$$\begin{aligned} \mu_{\text{critical path}} &= 9 \text{ days} + 4 \text{ days} + 7 \text{ days} \\ &= 20 \text{ days} \end{aligned}$$

The variance of the project's completion times is the sum of the variances along the critical path. Variance,  $\sigma^2$ , is the square of the standard deviation,  $\sigma$ .

$$\begin{aligned} \sigma_{\text{critical path}}^2 &= (1.3 \text{ days})^2 + (0.5 \text{ days})^2 \\ &\quad + (2.6 \text{ days})^2 \\ &= 8.7 \text{ days}^2 \\ \sigma_{\text{critical path}} &= \sqrt{8.7 \text{ days}^2} \\ &= 2.95 \text{ days} \quad [\text{use 3 days}] \end{aligned}$$

The standard normal variable corresponding to 14 days is given by Eq. 86.5.

$$\begin{aligned} z &= \frac{D - \mu_{\text{critical path}}}{\sigma_{\text{critical path}}} = \frac{14 \text{ days} - 20 \text{ days}}{3 \text{ days}} \\ &= -2.0 \end{aligned}$$

From App. 11.A, the area under the standard normal curve is 0.4772 for  $0.0 < z < -2.0$ . Since the normal curve is symmetrical, the negative sign is irrelevant in determining the area.

The standard normal variable corresponding to 23 days is given by Eq. 86.5.

$$\begin{aligned} z &= \frac{D - \mu_{\text{critical path}}}{\sigma_{\text{critical path}}} = \frac{23 \text{ days} - 20 \text{ days}}{3 \text{ days}} \\ &= 1.0 \end{aligned}$$

The area under the standard normal curve is 0.3413 for  $0.0 < z < 1.0$ .

- (a)  $p\{\text{duration} < 14\} = p\{z < -2.0\} = 0.5 - 0.4772 = 0.0228 \quad (2.28\%)$
- (b)  $p\{\text{duration} > 14\} = p\{z > -2.0\} = 0.4772 + 0.5 = 0.9772 \quad (97.72\%)$
- (c)  $p\{\text{duration} > 23\} = p\{z > 1.0\} = 0.5 - 0.3413 = 0.1587 \quad (15.87\%)$
- (d)  $p\{14 < \text{duration} < 23\} = p\{-2.0 < z < 1.0\} = 0.4772 + 0.3413 = 0.8185 \quad (81.85\%)$

## 9. MONITORING

*Monitoring* is keeping track of the progress of the job to see if the planned aspects of time, fee, and quality are being accomplished. The original fee projections can be monitored by comparing weekly time sheets with the original estimate. This can be done manually or with project management software. A manual method is shown in Fig. 86.8, which uses the same example project estimated in Fig. 86.2.

In Fig. 86.8, the budgeted weekly costs are placed in the table under the appropriate time-period column and

phase-of-work row. The actual costs expended are written next to them. At the bottom of the chart, a cumulative graph is plotted that shows the actual money expended against the budgeted fees. The cumulative ratio of percentage completion to cost can also be plotted.

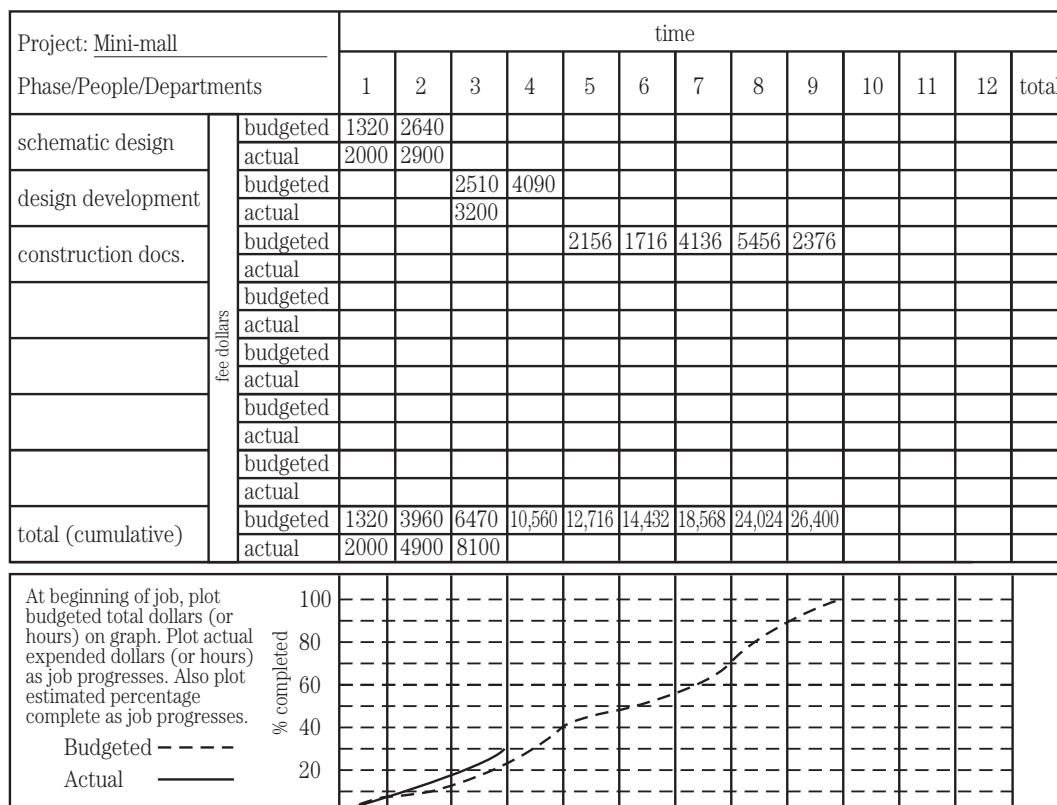

Monitoring quality is more difficult. At regular times during a project, the project manager, designers, and office principals should review the progress of the job to determine if the original project goals are being met and if the job is being produced according to the client's and design firm's expectations. The work in progress can also be reviewed to see whether it is technically correct and if all the contractual obligations are being met.

## 10. COORDINATING

During the project, the project manager must constantly coordinate the various people involved: the architect's staff, the consultants, the client, the building code officials, firm management, and, of course, the construction contractors. This may be done on a weekly, or even daily, basis to make sure the schedule is being maintained and the necessary work is getting done.

The coordination can be done by using checklists, holding weekly project meetings to discuss issues and assign

**Figure 86.8** Project Monitoring Chart

work, and exchanging drawings or project files among the consultants.

## 11. DOCUMENTATION

Everything that is done on a project must be documented in writing. This documentation provides a record in case legal problems develop and serves as a project history to use for future jobs. Documentation is also a vital part of communication. An email or written memo is more accurate, communicates more clearly, and is more difficult to forget than a simple phone call, for example.

Most design firms have standard forms or project management software for documents such as transmittals, job observation reports, time sheets, and the like. Such software makes it easy to record the necessary information. In addition, all meetings should be documented with meeting notes. Phone call logs (listing date, time, participants, and discussion topics), emails, personal daily logs, and formal communications like letters and memos should also be generated and preserved to serve as documentation.

Two types of documents, *change orders* due to unexpected conditions or changes to the plans after bidding, and *as-built construction documents* to record what was actually installed (as opposed to what was shown in the original construction documents) are particularly important.

## 12. EARNED VALUE METHOD

The *earned value method* (EVM), also known as *earned value management*, is a project management technique that correlates actual *project value* (PV) with *earned value* (EV).<sup>1</sup> *Value* is generally defined in dollars, but it may also be defined in hours. Close monitoring of earned value makes it possible to forecast cost and schedule overruns early in a project. In its simplest form, the method monitors the project plan, actual work performed, expenses, and cumulative value to see if the project is on track. Earned value shows how much of the budget and time should have been spent, with regard to the amount of work actually completed. The earned value method differs from typical budget versus expenses models by requiring the cost of work in progress to be quantified. Because of its complexity, the method is best implemented in its entirety in very large projects.

A *work breakdown structure* (WBS) is at the core of the method. A WBS is a hierarchical structure used to organize tasks for reporting schedules and tracking costs. For monitoring, the WBS is subsequently broken

down into manageable *work packages*—small sets of activities at lower and lowest levels of the WBS that collectively constitute the overall project scope. Each work package has a relatively short completion time and can be divided into a series of milestones whose status can be objectively measured. Each work package has start and finish dates and a budget value.

The earned value method uses specific terminology for otherwise common project management and accounting principles. There are three primary measures of project performance: BCWS, ACWP, and BCWP. The *budgeted cost of work scheduled* (BCWS) is a spending plan for the project as a function of schedule and performance. For any specified time period, the *cumulative planned expenditures* is the total amount budgeted for the project up to that point. With EVM, the spending plan serves as a performance baseline for making predictions about cost and schedule variance and estimates of completion.

The *actual cost of work performed* (ACWP) is the actual spending as a function of time or performance. It is the cumulative actual expenditures on the project viewed at regular intervals within the project duration. The *budgeted cost of work performed* (BCWP) is the actual earned value based on the technical accomplishment. BCWP is the cumulative budgeted value of the work actually completed. It may be calculated as the sum of the values budgeted for the work packages actually completed, or it may be calculated by multiplying the fraction of work completed by the planned cost of the project.

The primary measures are used to derive secondary measures that give a different view of the project's current and future health. Figure 86.9 illustrates how some of these measures can be presented graphically.

*Cost variance* (CV) is the difference between the planned and actual costs of the work completed.

$$CV = BCWP - ACWP \quad 86.6$$

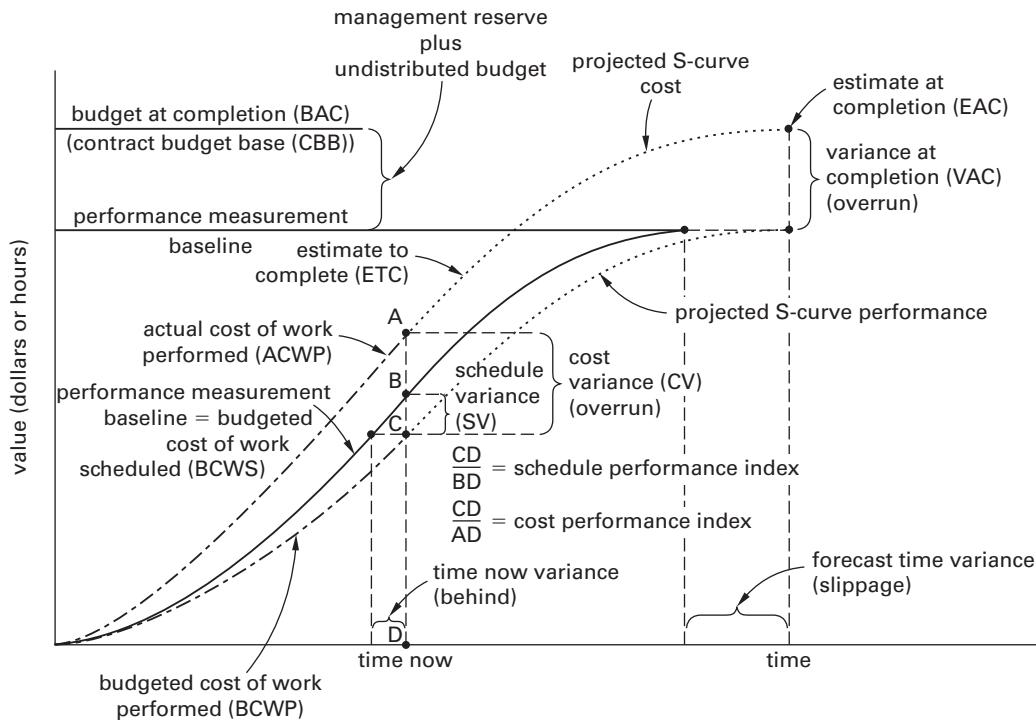

*Schedule variance* (SV) is the difference between the value of work accomplished for a given period and the value of the work planned. It measures how much a project is ahead of or behind schedule. Schedule variance is measured in value (e.g., dollars), not time.

$$SV = BCWP - BCWS \quad 86.7$$

*Cost performance index* (CPI) is a cost efficiency factor representing the relationship between the actual cost expended and the earned value. A CPI  $\geq 1$  suggests efficiency.

$$CPI = \frac{BCWP}{ACWP} \quad 86.8$$

<sup>1</sup>The earned value method may also be referred to as *performance measurement*, *management by objectives*, *budgeted cost of work performed*, and *cost/schedule control systems*.

**Figure 86.9** Earned Value Management Measures

*Schedule performance index (SPI)* is a measure of schedule effectiveness, as determined from the earned value and the initial planned schedule. SPI  $\geq 1$  suggests work is ahead of schedule.

$$\text{SPI} = \frac{\text{BCWP}}{\text{BCWS}} \quad 86.9$$

*Budget at completion (BAC)*, also known as *performance measurement baseline*, is the sum total of the time-phased budget.

*Estimate to complete (ETC)* is a calculated value representing the cost of work required to complete remaining project tasks.

$$\text{ETC} = \text{BAC} - \text{BCWP} \quad 86.10$$

*Estimate at completion (EAC)* is a calculated value that represents the projected total final cost of work when completed.

$$\text{EAC} = \text{ACWP} + \text{ETC} \quad 86.11$$

### Example 86.7

A project was baselined at \$10,000 per week for eight weeks. The project was supposed to be completed at eight weeks but has already taken 11 weeks. One additional week is estimated to complete the project. Determine the (a) budgeted cost of work scheduled; (b) actual cost of work performed; (c) budget at completion;

- (d) percentage of project planned; (e) estimate to complete; (f) estimate at completion; (g) actual percentage of project completed; (h) budgeted cost of work performed; (i) variance at completion; (j) schedule variance; (k) schedule performance index; (l) cost variance; and (m) cost performance index.

#### Solution

- (a) The budgeted cost of work scheduled, BCWS, or the project value (planned value), PV, is

$$\text{BCWS} = \text{PV} = (8 \text{ wk}) \left( 10,000 \frac{\$}{\text{wk}} \right) = \$80,000$$

- (b) The actual cost of work performed, ACWP, or the actual cost, AC, is

$$\text{ACWP} = \text{AC} = (11 \text{ wk}) \left( 10,000 \frac{\$}{\text{wk}} \right) = \$110,000$$

- (c) The budget at completion, BAC, is

$$\text{BAC} = (8 \text{ wk}) \left( 10,000 \frac{\$}{\text{wk}} \right) = \$80,000$$

- (d) The percentage of project planned is 100%, since the project should have been completed by now.

$$\% \text{ completed, planned} = \frac{\text{PV}}{\text{BAC}} = \frac{\$80,000}{\$80,000} = 1 \quad (100\%)$$

(e) The estimate to complete, ETC, is

$$\text{ETC} = (1 \text{ wk}) \left( 10,000 \frac{\$}{\text{wk}} \right) = \$10,000$$

(f) The estimate at completion, EAC, is

$$\text{EAC} = \text{AC} + \text{ETC} = \$110,000 + \$10,000 = \$120,000$$

(g) The actual percentage of project completed is

$$\begin{aligned} \% \text{ completed, actual} &= \frac{\text{AC}}{\text{EAC}} = \frac{\$110,000}{\$120,000} \\ &= 0.917 \quad (91.7\%) \end{aligned}$$

(h) The budgeted cost of work performed, BCWP, or earned value, EV, is

$$\begin{aligned} \text{BCWP} = \text{EV} &= (\text{fraction completed})(\text{BCWS}) \\ &= (0.917)(\$80,000) \\ &= \$73,400 \end{aligned}$$

(i) The variance at completion, VAC, is

$$\begin{aligned} \text{VAC} &= \text{BAC} - \text{EAC} \\ &= \$80,000 - \$120,000 \\ &= -\$40,000 \end{aligned}$$

The VAC is negative, indicating a cost overrun.

(j) The schedule variance, SV, is

$$\text{SV} = \text{EV} - \text{PV} = \$73,400 - \$80,000 = -\$6600$$

(k) The schedule performance index, SPI, is

$$\text{SPI} = \frac{\text{BCWP}}{\text{BCWS}} = \frac{\$73,400}{\$80,000} = 0.917$$

(l) The cost variance, CV, is

$$\text{CV} = \text{EV} - \text{AC} = \$73,400 - \$110,000 = -\$36,600$$

The CV is negative, indicating a cost overrun.

(m) The cost performance index, CPI, is

$$\text{CPI} = \frac{\text{BCWP}}{\text{ACWP}} = \frac{\$73,400}{\$110,000} = 0.667$$

The CPI is less than 1.0, which indicates that the project is over budget.

## Nomenclature

A	annual amount	\$
B	present worth of all benefits	\$
BV <sub>j</sub>	book value at end of the $j$ th year	\$
C	cost or present worth of all costs	\$
d	declining balance depreciation rate	decimal
D	demand	various
D	depreciation	\$
DR	present worth of after-tax depreciation recovery	\$
e	constant inflation rate	decimal
$\mathcal{E}$	expected value	various
E <sub>0</sub>	initial amount of an exponentially growing cash flow	\$
EAA	equivalent annual amount	\$
EUAC	equivalent uniform annual cost	\$
f	federal income tax rate	decimal
F	forecasted quantity	various
F	future worth	\$
g	exponential growth rate	decimal
G	uniform gradient amount	\$
i	effective interest rate	decimal
i%	effective interest rate	%
i'	effective interest rate corrected for inflation	decimal
j	number of years	-

<i>k</i>	number of compounding periods per year	—
<i>m</i>	an integer	—
<i>n</i>	number of compounding periods or years in life of asset	—
<i>p</i>	probability	decimal
<i>P</i>	present worth	\$
<i>r</i>	nominal rate per year (rate per annum)	decimal per unit time
ROI	return on investment	\$
ROR	rate of return	decimal per unit time
<i>s</i>	state income tax rate	decimal
<i>S<sub>n</sub></i>	expected salvage value in year <i>n</i>	\$
<i>t</i>	composite tax rate	decimal
<i>t</i>	time	years (typical)
<i>T</i>	a quantity equal to $\frac{1}{2}n(n + 1)$	—
TC	tax credit	\$
<i>z</i>	a quantity equal to $\frac{1+i}{1-d}$	decimal

**Symbols**

$\alpha$	smoothing coefficient for forecasts	—
$\phi$	effective rate per period	decimal

**Subscripts**

<i>0</i>	initial
<i>j</i>	at time <i>j</i>
<i>n</i>	at time <i>n</i>
<i>t</i>	at time <i>t</i>

**1. INTRODUCTION**

In its simplest form, an *engineering economic analysis* is a study of the desirability of making an investment.<sup>1</sup> The decision-making principles in this chapter can be applied by individuals as well as by companies. The nature of the spending opportunity or industry is not important. Farming equipment, personal investments, and multimillion dollar factory improvements can all be evaluated using the same principles.

Similarly, the applicable principles are insensitive to the monetary units. Although *dollars* are used in this chapter, it is equally convenient to use pounds, yen, or euros.

Finally, this chapter may give the impression that investment alternatives must be evaluated on a year-by-year basis. Actually, the *effective period* can be defined as a day, month, century, or any other convenient period of time.

**2. MULTIPLICITY OF SOLUTION METHODS**

Most economic conclusions can be reached in more than one manner. There are usually several different

analyses that will eventually result in identical answers.<sup>2</sup> Other than the pursuit of elegant solutions in a timely manner, there is no reason to favor one procedural method over another.<sup>3</sup>

**3. PRECISION AND SIGNIFICANT DIGITS**

The full potential of electronic calculators will never be realized in engineering economic analyses. Considering that calculations are based on estimates of far-future cash flows and that unrealistic assumptions (no inflation, identical cost structures of replacement assets, etc.) are routinely made, it makes little sense to carry cents along in calculations.

The calculations in this chapter have been designed to illustrate and review the principles presented. Because of this, greater precision than is normally necessary in everyday problems may be used. Though used, such precision is not warranted.

Unless there is some compelling reason to strive for greater precision, the following rules are presented for use in reporting final answers to engineering economic analysis problems.

- Omit fractional parts of the dollar (i.e., cents).
- Report and record a number to a maximum of four significant digits unless the first digit of that number is 1, in which case, a maximum of five significant digits should be written. For example,

\$49	not	\$49.43
\$93,450	not	\$93,453
\$1,289,700	not	\$1,289,673

**4. NONQUANTIFIABLE FACTORS**

An engineering economic analysis is a quantitative analysis. Some factors cannot be introduced as numbers into the calculations. Such factors are known as *non-quantitative factors*, *judgment factors*, and *irreducible factors*. Typical nonquantifiable factors are

- preferences
- political ramifications
- urgency
- goodwill
- prestige
- utility
- corporate strategy
- environmental effects

<sup>2</sup>Because of round-off errors, particularly when factors are taken from tables, these different calculations will produce slightly different numerical results (e.g., \$49.49 versus \$49.50). However, this type of divergence is well known and accepted in engineering economic analysis.

<sup>3</sup>This does not imply that approximate methods, simplifications, and rules of thumb are acceptable.

<sup>1</sup>This subject is also known as *engineering economics* and *engineering economy*. There is very little, if any, true economics in this subject.

- health and safety rules
- reliability
- political risks

Since these factors are not included in the calculations, the policy is to disregard the issues entirely. Of course, the factors should be discussed in a final report. The factors are particularly useful in breaking ties between competing alternatives that are economically equivalent.

## 5. YEAR-END AND OTHER CONVENTIONS

Except in short-term transactions, it is simpler to assume that all receipts and disbursements (cash flows) take place at the end of the year in which they occur.<sup>4</sup> This is known as the *year-end convention*. The exceptions to the year-end convention are initial project cost (purchase cost), trade-in allowance, and other cash flows that are associated with the inception of the project at  $t = 0$ .

On the surface, such a convention appears grossly inappropriate since repair expenses, interest payments, corporate taxes, and so on seldom coincide with the end of a year. However, the convention greatly simplifies engineering economic analysis problems, and it is justifiable on the basis that the increased precision associated with a more rigorous analysis is not warranted (due to the numerous other simplifying assumptions and estimates initially made in the problem).

There are various established procedures, known as *rules* or *conventions*, imposed by the Internal Revenue Service on U.S. taxpayers. An example is the *half-year rule*, which permits only half of the first-year depreciation to be taken in the first year of an asset's life when certain methods of depreciation are used. These rules are subject to constantly changing legislation and are not covered in this book. The implementation of such rules is outside the scope of engineering practice and is best left to accounting professionals.

## 6. CASH FLOW DIAGRAMS

Although they are not always necessary in simple problems (and they are often unwieldy in very complex problems), *cash flow diagrams* can be drawn to help visualize and simplify problems having diverse receipts and disbursements.

The following conventions are used to standardize cash flow diagrams.

- The horizontal (time) axis is marked off in equal increments, one per period, up to the duration (or *horizon*) of the project.

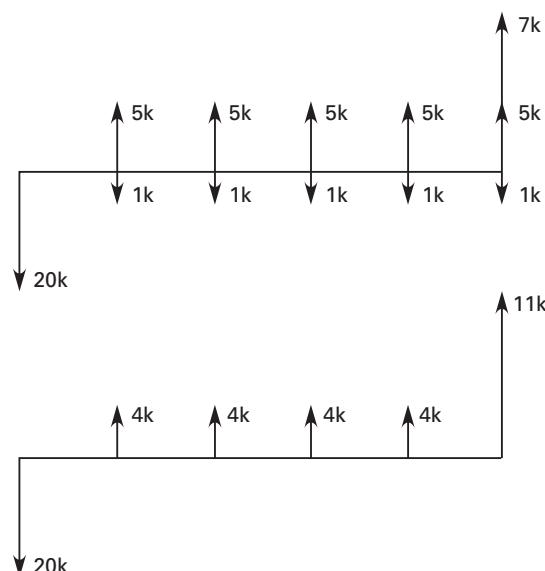

<sup>4</sup>A *short-term transaction* typically has a lifetime of five years or less and has payments or compounding that are more frequent than once per year.

- Two or more transfers in the same period are placed end to end, and these may be combined.
- Expenses incurred before  $t = 0$  are called *sunk costs*. Sunk costs are not relevant to the problem unless they have tax consequences in an after-tax analysis.
- *Receipts* are represented by arrows directed upward. *Disbursements* are represented by arrows directed downward. The arrow length is proportional to the magnitude of the cash flow.

### Example 87.1

A mechanical device will cost \$20,000 when purchased. Maintenance will cost \$1000 each year. The device will generate revenues of \$5000 each year for five years, after which the salvage value is expected to be \$7000. Draw and simplify the cash flow diagram.

*Solution*

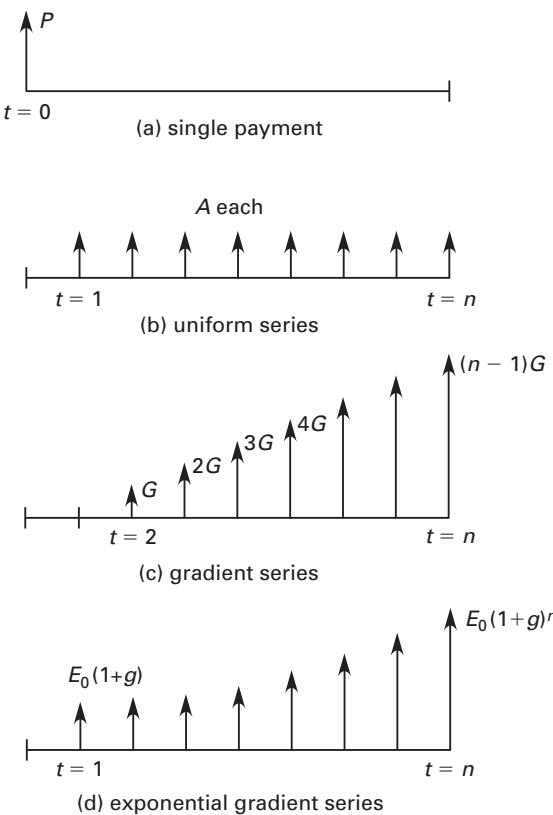

## 7. TYPES OF CASH FLOWS

To evaluate a real-world project, it is necessary to present the project's cash flows in terms of standard cash flows that can be handled by engineering economic analysis techniques. The standard cash flows are single payment cash flow, uniform series cash flow, gradient series cash flow, and the infrequently encountered exponential gradient series cash flow. (See Fig. 87.1.)

A *single payment cash flow* can occur at the beginning of the time line (designated as  $t = 0$ ), at the end of the time line (designated as  $t = n$ ), or at any time in between.

The *uniform series cash flow* consists of a series of equal transactions starting at  $t = 1$  and ending at  $t = n$ .

**Figure 87.1** Standard Cash Flows

The symbol  $A$  is typically given to the magnitude of each individual cash flow.<sup>5</sup>

The *gradient series cash flow* starts with a cash flow (typically given the symbol  $G$ ) at  $t = 2$  and increases by  $G$  each year until  $t = n$ , at which time the final cash flow is  $(n-1)G$ .

An *exponential gradient series cash flow* is based on a phantom value (typically given the symbol  $E_0$ ) at  $t = 0$  and grows or decays exponentially according to the following relationship.<sup>6</sup>

$$\text{amount at time } t = E_t = E_0(1+g)^t \quad [t=1, 2, 3, \dots, n] \quad 87.1$$

In Eq. 87.1,  $g$  is the *exponential growth rate*, which can be either positive or negative. Exponential gradient cash

<sup>5</sup>The cash flows do not begin at  $t = 0$ . This is an important concept with all of the series cash flows. This convention has been established to accommodate the timing of annual maintenance (and similar) cash flows for which the year-end convention is applicable.

<sup>6</sup>By convention, for an exponential cash flow series: The first cash flow,  $E_0$ , is at  $t = 1$ , as in the uniform annual series. However, the first cash flow is  $E_0(1+g)$ . The cash flow of  $E_0$  at  $t = 0$  is absent (i.e., is a *phantom cash flow*).

flows are rarely seen in economic justification projects assigned to engineers.<sup>7</sup>

## 8. TYPICAL PROBLEM TYPES

There is a wide variety of problem types that, collectively, are considered to be engineering economic analysis problems.

By far, the majority of engineering economic analysis problems are *alternative comparisons*. In these problems, two or more mutually exclusive investments compete for limited funds. A variation of this is a *replacement/retirement analysis*, which is repeated each year to determine if an existing asset should be replaced. Finding the percentage return on an investment is a *rate of return problem*, one of the alternative comparison solution methods.

Investigating interest and principal amounts in loan payments is a *loan repayment problem*. An *economic life analysis* will determine when an asset should be retired. In addition, there are miscellaneous problems involving economic order quantity, learning curves, break-even points, product costs, and so on.

## 9. IMPLICIT ASSUMPTIONS

Several assumptions are implicitly made when solving engineering economic analysis problems. Some of these assumptions are made with the knowledge that they are or will be poor approximations of what really will happen. The assumptions are made, regardless, for the benefit of obtaining a solution.

The most common assumptions are the following.

- The year-end convention is applicable.
- There is no inflation now, nor will there be any during the lifetime of the project.
- Unless otherwise specifically called for, a before-tax analysis is needed.
- The effective interest rate used in the problem will be constant during the lifetime of the project.
- Nonquantifiable factors can be disregarded.
- Funds invested in a project are available and are not urgently needed elsewhere.
- Excess funds continue to earn interest at the effective rate used in the analysis.

This last assumption, like most of the assumptions listed, is almost never specifically mentioned in the body of a solution. However, it is a key assumption when comparing two alternatives that have different initial costs.

<sup>7</sup>For one of the few discussions on exponential cash flow, see *Capital Budgeting*, Robert V. Oakford, The Ronald Press Company, New York, 1970.

For example, suppose two investments, one costing \$10,000 and the other costing \$8000, are to be compared at 10%. It is obvious that \$10,000 in funds is available, otherwise the costlier investment would not be under consideration. If the smaller investment is chosen, what is done with the remaining \$2000? The last assumption yields the answer: The \$2000 is “put to work” in some investment earning (in this case) 10%.

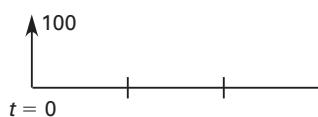

## 10. EQUIVALENCE

Industrial decision makers using engineering economic analysis are concerned with the magnitude and timing of a project’s cash flow as well as with the total profitability of that project. In this situation, a method is required to compare projects involving receipts and disbursements occurring at different times.

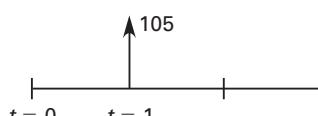

By way of illustration, consider \$100 placed in a bank account that pays 5% effective annual interest at the end of each year. After the first year, the account will have grown to \$105. After the second year, the account will have grown to \$110.25.

Assume that you will have no need for money during the next two years, and any money received will immediately go into your 5% bank account. Then, which of the following options would be more desirable?

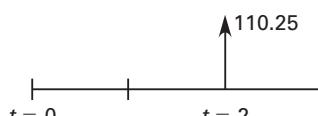

**option A: \$100 now**

**option B: \$105 to be delivered in one year**

**option C: \$110.25 to be delivered in two years**

As illustrated, none of the options is superior under the assumptions given. If the first option is chosen, you will immediately place \$100 into a 5% account, and in two years the account will have grown to \$110.25. In fact, the account will contain \$110.25 at the end of two years regardless of the option chosen. Therefore, these alternatives are said to be *equivalent*.

Equivalence may or may not be the case, depending on the interest rate, so an alternative that is acceptable to one decision maker may be unacceptable to another.

The interest rate that is used in actual calculations is known as the *effective interest rate*.<sup>8</sup> If compounding is once a year, it is known as the *effective annual interest rate*. However, effective quarterly, monthly, daily, and so on, interest rates are also used.

The fact that \$100 today grows to \$105 in one year (at 5% annual interest) is an example of what is known as the *time value of money* principle. This principle simply articulates what is obvious: Funds placed in a secure investment will increase to an equivalent future amount. The procedure for determining the present investment from the equivalent future amount is known as *discounting*.

## 11. SINGLE-PAYMENT EQUIVALENCE

The equivalence of any present amount,  $P$ , at  $t = 0$ , to any future amount,  $F$ , at  $t = n$ , is called the *future worth* and can be calculated from Eq. 87.2.

$$F = P(1 + i)^n \quad 87.2$$

The factor  $(1 + i)^n$  is known as the single payment *compound amount factor* and has been tabulated in App. 87.B for various combinations of  $i$  and  $n$ .

Similarly, the equivalence of any future amount to any present amount is called the *present worth* and can be calculated from Eq. 87.3.

$$P = F(1 + i)^{-n} = \frac{F}{(1 + i)^n} \quad 87.3$$

The factor  $(1 + i)^{-n}$  is known as the *single payment present worth factor*.<sup>9</sup>

The interest rate used in Eq. 87.2 and Eq. 87.3 must be the effective rate per period. Also, the basis of the rate (annually, monthly, etc.) must agree with the type of period used to count  $n$ . Therefore, it would be incorrect to use an effective annual interest rate if  $n$  was the number of compounding periods in months.

### Example 87.2

How much should you put into a 10% (effective annual rate) savings account in order to have \$10,000 in five years?

<sup>8</sup>The adjective *effective* distinguishes this interest rate from other interest rates (e.g., nominal interest rates) that are not meant to be used directly in calculating equivalent amounts.

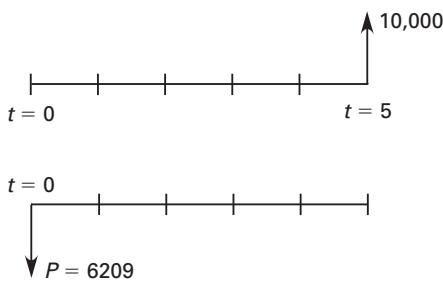

<sup>9</sup>The *present worth* is also called the *present value* and *net present value*. These terms are used interchangeably and no significance should be attached to the terms *value*, *worth*, and *net*.

**Solution**

This problem could also be stated: What is the equivalent present worth of \$10,000 five years from now if money is worth 10% per year?

$$\begin{aligned} P &= F(1 + i)^{-n} = (\$10,000)(1 + 0.10)^{-5} \\ &= \$6209 \end{aligned}$$

The factor 0.6209 would usually be obtained from the tables.

## 12. STANDARD CASH FLOW FACTORS AND SYMBOLS

Equation 87.2 and Eq. 87.3 may give the impression that solving engineering economic analysis problems involves a lot of calculator use, and, in particular, a lot of exponentiation. Such calculations may be necessary from time to time, but most problems are simplified by the use of tabulated values of the factors.

Rather than actually writing the formula for the compound amount factor (which converts a present amount to a future amount), it is common convention to substitute the standard functional notation of  $(F/P, i\%, n)$ . Therefore, the future value in  $n$  periods of a present amount would be written symbolically as

$$F = P(F/P, i\%, n) \quad 87.4$$

Similarly, the present worth factor has a functional notation of  $(P/F, i\%, n)$ . Therefore, the present worth of a future amount  $n$  periods in the future would be symbolically written as

$$P = F(P/F, i\%, n) \quad 87.5$$

Values of these *cash flow (discounting) factors* are tabulated in App. 87.B. There is often initial confusion about whether the  $(F/P)$  or  $(P/F)$  column should be used in a particular problem. There are several ways of remembering what the functional notations mean.

One method of remembering which factor should be used is to think of the factors as conditional probabilities. The conditional probability of event **A** given that event **B** has occurred is written as  $p\{\mathbf{A}|\mathbf{B}\}$ , where the given event comes after the vertical bar. In the standard notational form of discounting factors, the given amount is similarly placed after the slash. What you

want comes before the slash.  $(F/P)$  would be a factor to find  $F$  given  $P$ .

Another method of remembering the notation is to interpret the factors algebraically. The  $(F/P)$  factor could be thought of as the fraction  $F/P$ . Algebraically, Eq. 87.4 would be

$$F = P\left(\frac{F}{P}\right) \quad 87.6$$

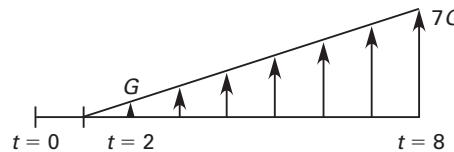

This algebraic approach is actually more than an interpretation. The numerical values of the discounting factors are consistent with this algebraic manipulation. The  $(F/A)$  factor could be calculated as  $(F/P) \times (P/A)$ . This consistent relationship can be used to calculate other factors that might be occasionally needed, such as  $(F/G)$  or  $(G/P)$ . For instance, the annual cash flow that would be equivalent to a uniform gradient may be found from

$$A = G(P/G, i\%, n)(A/P, i\%, n) \quad 87.7$$

Formulas for the compounding and discounting factors are contained in Table 87.1. Normally, it will not be necessary to calculate factors from the formulas. For solving most problems, App. 87.B is adequate.

### Example 87.3

What factor will convert a gradient cash flow ending at  $t = 8$  to a future value at  $t = 8$ ? (That is, what is the  $(F/G, i\%, n)$  factor?) The effective annual interest rate is 10%.

### Solution

#### method 1:

From Table 87.1, the  $(F/G, i\%, n)$  factor is

$$\begin{aligned} (F/G, 10\%, 8) &= \frac{(1 + i)^n - 1}{i^2} - \frac{n}{i} \\ &= \frac{(1 + 0.10)^8 - 1}{(0.10)^2} - \frac{8}{0.10} \\ &= 34.3589 \end{aligned}$$

#### method 2:

The tabulated values of  $(P/G)$  and  $(F/P)$  in App. 87.B can be used to calculate the factor.

$$\begin{aligned} (F/G, 10\%, 8) &= (P/G, 10\%, 8)(F/P, 10\%, 8) \\ &= (16.0287)(2.1436) \\ &= 34.3591 \end{aligned}$$

**Table 87.1** Discount Factors for Discrete Compounding

factor name	converts	symbol	formula
single payment compound amount	P to F	(F/P, $i\%$ , n)	$(1 + i)^n$
single payment present worth	F to P	(P/F, $i\%$ , n)	$(1 + i)^{-n}$
uniform series sinking fund	F to A	(A/F, $i\%$ , n)	$\frac{i}{(1 + i)^n - 1}$
capital recovery	P to A	(A/P, $i\%$ , n)	$\frac{i(1 + i)^n}{(1 + i)^n - 1}$
uniform series compound amount	A to F	(F/A, $i\%$ , n)	$\frac{(1 + i)^n - 1}{i}$
uniform series present worth	A to P	(P/A, $i\%$ , n)	$\frac{(1 + i)^n - 1}{i(1 + i)^n}$
uniform gradient present worth	G to P	(P/G, $i\%$ , n)	$\frac{(1 + i)^n - 1}{i^2(1 + i)^n} - \frac{n}{i(1 + i)^n}$
uniform gradient future worth	G to F	(F/G, $i\%$ , n)	$\frac{(1 + i)^n - 1}{i^2} - \frac{n}{i}$
uniform gradient uniform series	G to A	(A/G, $i\%$ , n)	$\frac{1}{i} - \frac{n}{(1 + i)^n - 1}$

The  $(F/G)$  factor could also have been calculated as the product of the  $(A/G)$  and  $(F/A)$  factors.

$t = n$  in the future. Since the annual deposit is calculated as  $A = F(A/F, i\%, n)$ , the  $(A/F)$  factor is known as the *sinking fund factor*. An *annuity* is a series of equal payments,  $A$ , made over a period of time.<sup>10</sup> Usually, it is necessary to “buy into” an investment (a bond, an insurance policy, etc.) in order to ensure the annuity. In the simplest case of an annuity that starts at the end of the first year and continues for  $n$  years, the purchase price,  $P$ , is

$$P = A(P/A, i\%, n) \quad 87.9$$

The present worth of an *infinite (perpetual)* series of annual amounts is known as a *capitalized cost*. There is no  $(P/A, i\%, \infty)$  factor in the tables, but the capitalized cost can be calculated simply as

$$P = \frac{A}{i} \quad [i \text{ in decimal form}] \quad 87.10$$

Alternatives with different lives will generally be compared by way of *equivalent uniform annual cost* (EUAC). An EUAC is the annual amount that is equivalent to all of the cash flows in the alternative. The EUAC differs in sign from all of the other cash flows. Costs and expenses expressed as EUACs, which

<sup>10</sup>An annuity may also consist of a lump sum payment made at some future time. However, this interpretation is not considered in this chapter.

$$F = A(F/A, i\%, n) \quad 87.8$$

A *sinking fund* is a fund or account into which annual deposits of  $A$  are made in order to accumulate  $F$  at

would normally be considered negative, are actually positive. The term *cost* in the designation EUAC serves to make clear the meaning of a positive number.

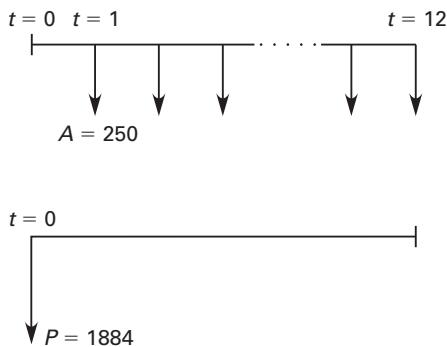

#### Example 87.4

Maintenance costs for a machine are \$250 each year. What is the present worth of these maintenance costs over a 12-year period if the interest rate is 8%?

*Solution*

Using Eq. 87.9,

$$\begin{aligned} P &= A(P/A, 8\%, 12) = (-\$250)(7.5361) \\ &= -\$1884 \end{aligned}$$

#### 14. FINDING PAST VALUES

From time to time, it will be necessary to determine an amount in the past equivalent to some current (or future) amount. For example, you might have to calculate the original investment made 15 years ago given a current annuity payment.

Such problems are solved by placing the  $t = 0$  point at the time of the original investment, and then calculating the past amount as a  $P$  value. For example, the original investment,  $P$ , can be extracted from the annuity,  $A$ , by using the standard cash flow factors.

$$P = A(P/A, i\%, n) \quad 87.11$$

The choice of  $t = 0$  is flexible. As a general rule, the  $t = 0$  point should be selected for convenience in solving a problem.

#### Example 87.5

You currently pay \$250 per month to lease your office phone equipment. You have three years (36 months) left on the five-year (60-month) lease. What would have been an equivalent purchase price two years ago? The effective interest rate per month is 1%.

*Solution*

The solution of this example is not affected by the fact that investigation is being performed in the middle of the horizon. This is a simple calculation of present worth.

$$\begin{aligned} P &= A(P/A, 1\%, 60) \\ &= (-\$250)(44.9550) \\ &= -\$11,239 \end{aligned}$$

#### 15. TIMES TO DOUBLE AND TRIPLE AN INVESTMENT

If an investment doubles in value (in  $n$  compounding periods and with  $i\%$  effective interest), the ratio of current value to past investment will be 2.

$$F/P = (1 + i)^n = 2 \quad 87.12$$

Similarly, the ratio of current value to past investment will be 3 if an investment triples in value. This can be written as

$$F/P = (1 + i)^n = 3 \quad 87.13$$

It is a simple matter to extract the number of periods,  $n$ , from Eq. 87.12 and Eq. 87.13 to determine the *doubling time* and *tripling time*, respectively. For example, the doubling time is

$$n = \frac{\log 2}{\log(1 + i)} \quad 87.14$$

When a quick estimate of the doubling time is needed, the *rule of 72* can be used. The doubling time is approximately  $72/i$ .

The tripling time is

$$n = \frac{\log 3}{\log(1 + i)} \quad 87.15$$

Equation 87.14 and Eq. 87.15 form the basis of Table 87.2.

#### 16. VARIED AND NONSTANDARD CASH FLOWS

##### Gradient Cash Flow

A common situation involves a uniformly increasing cash flow. If the cash flow has the proper form, its present worth can be determined by using the *uniform gradient factor*,  $(P/G, i\%, n)$ . The uniform gradient factor finds the present worth of a uniformly increasing cash flow that starts in year two (not in year one).

There are three common difficulties associated with the form of the uniform gradient. The first difficulty is that the initial cash flow occurs at  $t = 2$ . This convention recognizes that annual costs, if they increase uniformly, begin with some value at  $t = 1$  (due to the year-end convention) but do not begin to increase until  $t = 2$ .

**Table 87.2** Doubling and Tripling Times for Various Interest Rates

interest rate (%)	doubling time (periods)	tripling time (periods)
1	69.7	110.4
2	35.0	55.5
3	23.4	37.2
4	17.7	28.0
5	14.2	22.5
6	11.9	18.9
7	10.2	16.2
8	9.01	14.3
9	8.04	12.7
10	7.27	11.5
11	6.64	10.5
12	6.12	9.69
13	5.67	8.99
14	5.29	8.38
15	4.96	7.86
16	4.67	7.40
17	4.41	7.00
18	4.19	6.64
19	3.98	6.32
20	3.80	6.03

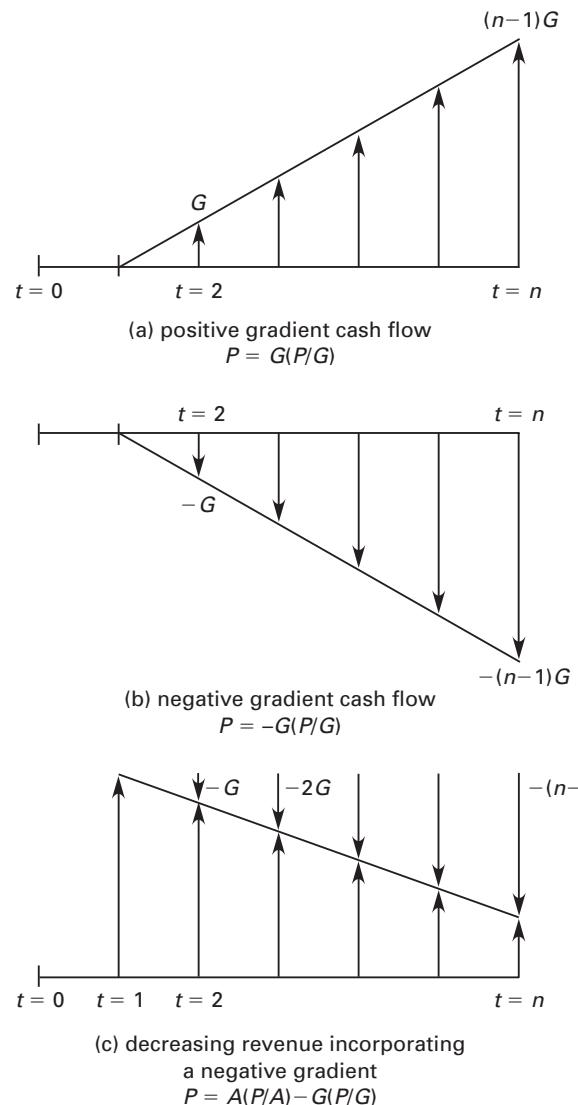

The tabulated values of  $(P/G)$  have been calculated to find the present worth of only the increasing part of the annual expense. The present worth of the base expense incurred at  $t = 1$  must be found separately with the  $(P/A)$  factor.

The second difficulty is that, even though the factor  $(P/G, i\%, n)$  is used, there are only  $n - 1$  actual cash flows. It is clear that  $n$  must be interpreted as the *period number* in which the last gradient cash flow occurs, not the number of gradient cash flows.

The sign convention used with gradient cash flows may seem confusing. If an expense increases each year (as in Ex. 87.6), the gradient will be negative, since it is an expense. If a revenue increases each year, the gradient will be positive. In most cases, the sign of the gradient depends on whether the cash flow is an expense or a revenue.<sup>11</sup> Figure 87.2 illustrates positive and negative gradient cash flows.

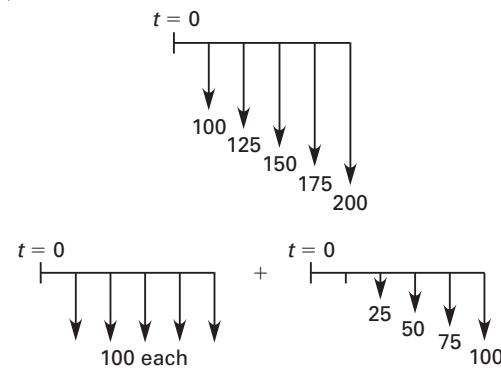

### Example 87.6

Maintenance on an old machine is \$100 this year but is expected to increase by \$25 each year thereafter. What is the present worth of five years of the costs of maintenance? Use an interest rate of 10%.

**Figure 87.2** Positive and Negative Gradient Cash Flows

### Solution

In this problem, the cash flow must be broken down into parts. (The five-year gradient factor is used even though there are only four nonzero gradient cash flows.)

<sup>11</sup>This is not a universal rule. It is possible to have a uniformly decreasing revenue as in Fig. 87.2(c). In this case, the gradient would be negative.

Therefore, the present worth is

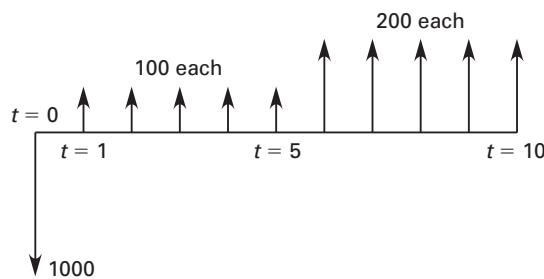

$$\begin{aligned} P &= A(P/A, 10\%, 5) + G(P/G, 10\%, 5) \\ &= (-\$100)(3.7908) - (\$25)(6.8618) \\ &= -\$551 \end{aligned}$$

### Stepped Cash Flows

*Stepped cash flows* are easily handled by the technique of *superposition of cash flows*. This technique is used in Ex. 87.7.

#### Example 87.7

An investment costing \$1000 returns \$100 for the first five years and \$200 for the following five years. How would the present worth of this investment be calculated?

#### Solution

Using the principle of superposition, the revenue cash flow can be thought of as \$200 each year from  $t = 1$  to  $t = 10$ , with a negative revenue of \$100 from  $t = 1$  to  $t = 5$ . Superimposed, these two cash flows make up the actual performance cash flow.

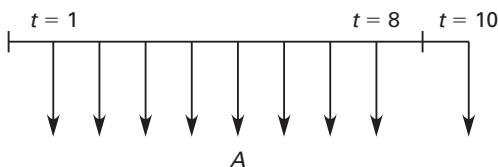

$$P = -\$1000 + (\$200)(P/A, i\%, 10) - (\$100)(P/A, i\%, 5)$$

### Missing and Extra Parts of Standard Cash Flows

A missing or extra part of a standard cash flow can also be handled by superposition. For example, suppose an annual expense is incurred each year for 10 years, except in the ninth year, as is illustrated in Fig. 87.3. The present worth could be calculated as a subtractive process.

$$P = A(P/A, i\%, 10) - A(P/F, i\%, 9) \quad 87.16$$

Figure 87.3 Cash Flow with a Missing Part

Alternatively, the present worth could be calculated as an additive process.

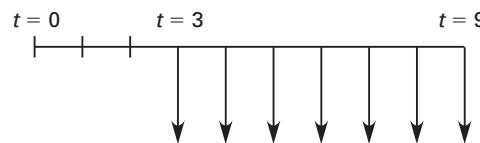

$$P = A(P/A, i\%, 8) + A(P/F, i\%, 10) \quad 87.17$$

### Delayed and Premature Cash Flows

There are cases when a cash flow matches a standard cash flow exactly, except that the cash flow is delayed or starts sooner than it should. Often, such cash flows can be handled with superposition. At other times, it may be more convenient to shift the time axis. This shift is known as the *projection method*. Example 87.8 demonstrates the projection method.

#### Example 87.8

An expense of \$75 is incurred starting at  $t = 3$  and continues until  $t = 9$ . There are no expenses or receipts until  $t = 3$ . Use the projection method to determine the present worth of this stream of expenses.

#### Solution

Determine a cash flow at  $t = 2$  that is equivalent to the entire expense stream. If  $t = 0$  was where  $t = 2$  actually is, the present worth of the expense stream would be

$$P' = (-\$75)(P/A, i\%, 7)$$

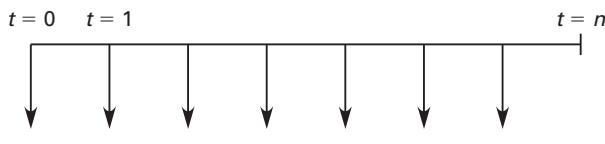

$P'$  is a cash flow at  $t = 2$ . It is now simple to find the present worth (at  $t = 0$ ) of this future amount.

$$P = P'(P/F, i\%, 2) = (-\$75)(P/A, i\%, 7)(P/F, i\%, 2)$$

### Cash Flows at Beginnings of Years: The Christmas Club Problem

This type of problem is characterized by a stream of equal payments (or expenses) starting at  $t = 0$  and ending at  $t = n - 1$ , as shown in Fig. 87.4. It differs from the standard annual cash flow in the existence of a cash flow at  $t = 0$  and the absence of a cash flow at  $t = n$ . This problem gets its name from the service provided by some savings institutions whereby money is automatically deposited each week or month (starting immediately, when the savings plan is opened) in order to accumulate money to purchase Christmas presents at the end of the year.

It may seem that the present worth of the savings stream can be determined by directly applying the  $(P/A)$  factor. However, this is not the case, since the

**Figure 87.4** Cash Flows at Beginnings of Years

Christmas Club cash flow and the standard annual cash flow differ. The Christmas Club problem is easily handled by superposition, as demonstrated by Ex. 87.9.

### Example 87.9

How much can you expect to accumulate by  $t = 10$  for a child's college education if you deposit \$300 at the beginning of each year for a total of 10 payments?

*Solution*

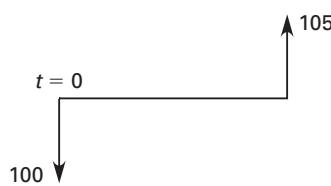

The first payment is made at  $t=0$ , and there is no payment at  $t=10$ . The future worth of the first payment is calculated with the  $(F/P)$  factor. The absence of the payment at  $t=10$  is handled by superposition. This "correction" is not multiplied by a factor.

$$\begin{aligned} F &= (\$300)(F/P, i\%, 10) + (\$300)(F/A, i\%, 10) - \$300 \\ &= (\$300)(F/A, i\%, 11) - \$300 \end{aligned}$$

## 17. THE MEANING OF PRESENT WORTH AND $i$

If \$100 is invested in a 5% bank account (using annual compounding), you can remove \$105 one year from now; if this investment is made, you will receive a *return on investment* (ROI) of \$5. The cash flow diagram, as shown in Fig. 87.5, and the present worth of the two transactions are as follows.

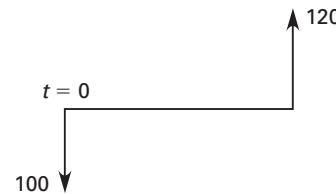

$$\begin{aligned} P &= -\$100 + (\$105)(P/F, 5\%, 1) \\ &= -\$100 + (\$105)(0.9524) \\ &= 0 \end{aligned}$$

**Figure 87.5** Cash Flow Diagram

The present worth is zero even though you will receive a \$5 return on your investment.

However, if you are offered \$120 for the use of \$100 over a one-year period, the cash flow diagram, as shown in Fig. 87.6, and present worth (at 5%) would be

$$\begin{aligned} P &= -\$100 + (\$120)(P/F, 5\%, 1) \\ &= -\$100 + (\$120)(0.9524) \\ &= \$14.29 \end{aligned}$$

**Figure 87.6** Cash Flow Diagram

Therefore, the present worth of an alternative is seen to be equal to the equivalent value at  $t = 0$  of the increase in return above that which you would be able to earn in an investment offering  $i\%$  per period. In the previous case, \$14.29 is the present worth of  $(\$20 - \$5)$ , the difference in the two ROIs.

The present worth is also the amount that you would have to be given to dissuade you from making an investment, since placing the initial investment amount along with the present worth into a bank account earning  $i\%$  will yield the same eventual return on investment. Relating this to the previous paragraphs, you could be dissuaded from investing \$100 in an alternative that would return \$120 in one year by a  $t = 0$  payment of \$14.29. Clearly,  $(\$100 + \$14.29)$  invested at  $t = 0$  will also yield \$120 in one year at 5%.

Income-producing alternatives with negative present worths are undesirable, and alternatives with positive present worths are desirable because they increase the average earning power of invested capital. (In some cases, such as municipal and public works projects, the present worths of all alternatives are negative, in which case, the least negative alternative is best.)

The selection of the interest rate is difficult in engineering economics problems. Usually, it is taken as the average rate of return that an individual or business organization has realized in past investments. Alternatively, the interest rate may be associated with a particular level of risk. Usually,  $i$  for individuals is the interest rate that can be earned in relatively *risk-free investments*.

## 18. SIMPLE AND COMPOUND INTEREST

If \$100 is invested at 5%, it will grow to \$105 in one year. During the second year, 5% interest continues to be accrued, but on \$105, not on \$100. This is the

principle of *compound interest*: The interest accrues interest.<sup>12</sup>

If only the original principal accrues interest, the interest is said to be *simple interest*. Simple interest is rarely encountered in long-term engineering economic analyses, but the concept may be incorporated into short-term transactions.

## 19. EXTRACTING THE INTEREST RATE: RATE OF RETURN

An intuitive definition of the *rate of return* (ROR) is the effective annual interest rate at which an investment accrues income. That is, the rate of return of a project is the interest rate that would yield identical profits if all money were invested at that rate. Although this definition is correct, it does not provide a method of determining the rate of return.

It was previously seen that the present worth of a \$100 investment invested at 5% is zero when  $i = 5\%$  is used to determine equivalence. Therefore, a working definition of rate of return would be the effective annual interest rate that makes the present worth of the investment zero. Alternatively, rate of return could be defined as the effective annual interest rate that will discount all cash flows to a total present worth equal to the required initial investment.

It is tempting, but impractical, to determine a rate of return analytically. It is simply too difficult to extract the interest rate from the equivalence equation. For example, consider a \$100 investment that pays back \$75 at the end of each of the first two years. The present worth equivalence equation (set equal to zero in order to determine the rate of return) is

$$P = 0 = -\$100 + (\$75)(1 + i)^{-1} + (\$75)(1 + i)^{-2} \quad 87.18$$

Solving Eq. 87.18 requires finding the roots of a quadratic equation. In general, for an investment or project spanning  $n$  years, the roots of an  $n$ th-order polynomial would have to be found. It should be obvious that an analytical solution would be essentially impossible for more complex cash flows. (The rate of return in this example is 31.87%.)

If the rate of return is needed, it can be found from a trial-and-error solution. To find the rate of return of an investment, proceed as follows.

*step 1:* Set up the problem as if to calculate the present worth.

*step 2:* Arbitrarily select a reasonable value for  $i$ . Calculate the present worth.

<sup>12</sup>This assumes, of course, that the interest remains in the account. If the interest is removed and spent, only the remaining funds accumulate interest.

*step 3:* Choose another value of  $i$  (not too close to the original value), and again solve for the present worth.

*step 4:* Interpolate or extrapolate the value of  $i$  that gives a zero present worth.

*step 5:* For increased accuracy, repeat steps 2 and 3 with two more values that straddle the value found in step 4.

A common, although incorrect, method of calculating the rate of return involves dividing the annual receipts or returns by the initial investment. (See Sec. 87.56.) However, this technique ignores such items as salvage, depreciation, taxes, and the time value of money. This technique also is inadequate when the annual returns vary.

It is possible that more than one interest rate will satisfy the zero present worth criteria. This confusing situation occurs whenever there is more than one change in sign in the investment's cash flow.<sup>13</sup> Table 87.3 indicates the numbers of possible interest rates as a function of the number of sign reversals in the investment's cash flow.

**Table 87.3** Multiplicity of Rates of Return

number of sign reversals	number of distinct rates of return
0	0
1	0 or 1
2	0, 1, or 2
3	0, 1, 2, or 3
4	0, 1, 2, 3, or 4
$m$	0, 1, 2, 3, ..., $m - 1, m$

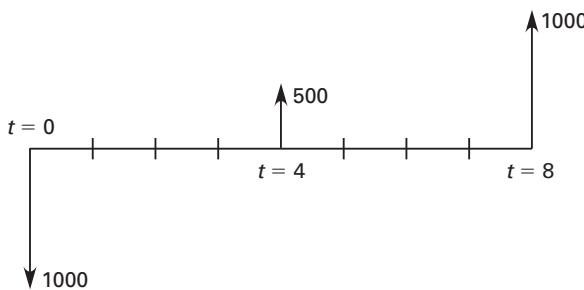

Difficulties associated with interpreting the meaning of multiple rates of return can be handled with the concepts of external investment and external rate of return. An *external investment* is an investment that is distinct from the investment being evaluated (which becomes known as the *internal investment*). The *external rate of return*, which is the rate of return earned by the external investment, does not need to be the same as the rate earned by the internal investment.

Generally, the multiple rates of return indicate that the analysis must proceed as though money will be invested outside of the project. The mechanics of how this is done are not covered here.

<sup>13</sup>There will always be at least one change of sign in the cash flow of a legitimate investment. (This excludes municipal and other tax-supported functions.) At  $t = 0$ , an investment is made (a negative cash flow). Hopefully, the investment will begin to return money (a positive cash flow) at  $t = 1$  or shortly thereafter. Although it is possible to conceive of an investment in which all of the cash flows were negative, such an investment would probably be classified as a *hobby*.

**Example 87.10**

What is the rate of return on invested capital if \$1000 is invested now with \$500 being returned in year 4 and \$1000 being returned in year 8?

**Solution**

First, set up the problem as a present worth calculation.

Try  $i = 5\%$ .

$$\begin{aligned} P &= -\$1000 + (\$500)(P/F, 5\%, 4) \\ &\quad + (\$1000)(P/F, 5\%, 8) \\ &= -\$1000 + (\$500)(0.8227) + (\$1000)(0.6768) \\ &= \$88 \end{aligned}$$

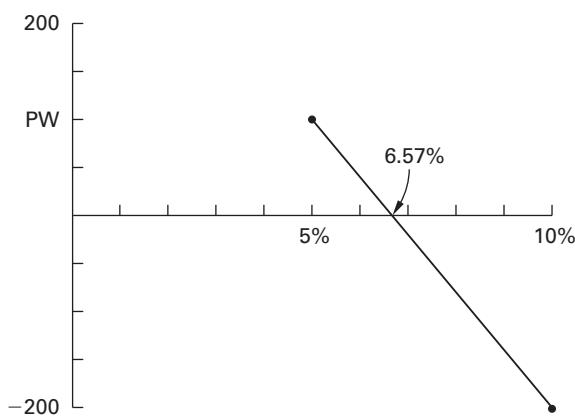

Next, try a larger value of  $i$  to reduce the present worth. If  $i = 10\%$ ,

$$\begin{aligned} P &= -\$1000 + (\$500)(P/F, 10\%, 4) \\ &\quad + (\$1000)(P/F, 10\%, 8) \\ &= -\$1000 + (\$500)(0.6830) + (\$1000)(0.4665) \\ &= -\$192 \end{aligned}$$

Using simple interpolation, the rate of return is

$$\begin{aligned} \text{ROR} &= 5\% + \left( \frac{\$88}{\$88 + \$192} \right) (10\% - 5\%) \\ &= 6.57\% \end{aligned}$$

A second iteration between 6% and 7% yields 6.39%.

**Example 87.11**

A biomedical company is developing a new drug. A venture capital firm gives the company \$25 million initially and \$55 million more at the end of the first year. The drug patent will be sold at the end of year 5 to the highest bidder, and the biomedical company will receive \$80 million. (The venture capital firm will receive everything in excess of \$80 million.) The firm invests unused money in short-term commercial paper earning 10% effective interest per year through its bank. In the meantime, the biomedical company incurs development expenses of \$50 million annually for the first three years. The drug is to be evaluated by a government agency and there will be neither expenses nor revenues during the fourth year. What is the biomedical company's rate of return on this investment?

**Solution**

Normally, the rate of return is determined by setting up a present worth problem and varying the interest rate until the present worth is zero. Writing the cash flows, though, shows that there are two reversals of sign: one at  $t = 2$  (positive to negative) and the other at  $t = 5$  (negative to positive). Therefore, there could be two interest rates that produce a zero present worth. (In fact, there actually are two interest rates: 10.7% and 41.4%).

time	cash flow (millions)
0	+25
1	+55 - 50 = +5
2	-50
3	-50
4	0
5	+80

However, this problem can be reduced to one with only one sign reversal in the cash flow series. The initial \$25 million is invested in commercial paper (an *external investment* having nothing to do with the drug development process) during the first year at 10%. The accumulation of interest and principal after one year is

$$(25)(1 + 0.10) = 27.5$$

This 27.5 is combined with the 5 (the money remaining after all expenses are paid at  $t = 1$ ) and invested externally, again at 10%. The accumulation of interest and principal after one year (i.e., at  $t = 2$ ) is

$$(27.5 + 5)(1 + 0.10) = 35.75$$

This 35.75 is combined with the development cost paid at  $t = 2$ .

The cash flow for the development project (the internal investment) is

time	cash flow (millions)
0	0
1	0
2	$35.75 - 50 = -14.25$
3	-50
4	0
5	+80

There is only one sign reversal in the cash flow series. The *internal rate of return* on this development project is found by the traditional method to be 10.3%. This is different from the rate the company can earn from investing externally in commercial paper.

## 20. RATE OF RETURN VERSUS RETURN ON INVESTMENT

*Rate of return* (ROR) is an effective annual interest rate, typically stated in percent per year. *Return on investment* (ROI) is a dollar amount. *Rate of return* and *return on investment* are not synonymous.

Return on investment can be calculated in two different ways. The accounting method is to subtract the total of all investment costs from the total of all net profits (i.e., revenues less expenses). The time value of money is not considered.

In engineering economic analysis, the return on investment is calculated from equivalent values. Specifically, the present worth (at  $t = 0$ ) of all investment costs is subtracted from the future worth (at  $t = n$ ) of all net profits.

When there are only two cash flows, a single investment amount and a single payback, the two definitions of return on investment yield the same numerical value. When there are more than two cash flows, the returns on investment will be different depending on which definition is used.

## 21. MINIMUM ATTRACTIVE RATE OF RETURN

A company may not know what effective interest rate,  $i$ , to use in engineering economic analysis. In such a case, the company can establish a minimum level of economic performance that it would like to realize on all investments. This criterion is known as the *minimum attractive rate of return* (MARR). Unlike the effective interest rate,  $i$ , the minimum attractive rate of return is not used in numerical calculations.<sup>14</sup> It is used only in comparisons with the rate of return.

Once a rate of return for an investment is known, it can be compared to the minimum attractive rate of return. To be a viable alternative, the rate of return must be greater than the minimum attractive rate of return.

<sup>14</sup>Not everyone adheres to this rule. Some people use “minimum attractive rate of return” and “effective interest rate” interchangeably.

The advantage of using comparisons to the minimum attractive rate of return is that an effective interest rate,  $i$ , never needs to be known. The minimum attractive rate of return becomes the correct interest rate for use in present worth and equivalent uniform annual cost calculations.

## 22. TYPICAL ALTERNATIVE-COMPARISON PROBLEM FORMATS

With the exception of some investment and rate of return problems, the typical problem involving engineering economics will have the following characteristics.

- An interest rate will be given.
- Two or more alternatives will be competing for funding.
- Each alternative will have its own cash flows.
- It will be necessary to select the best alternative.

## 23. DURATIONS OF INVESTMENTS

Because they are handled differently, short-term investments and short-lived assets need to be distinguished from investments and assets that constitute an infinitely lived project. Short-term investments are easily identified: a drill press that is needed for three years or a temporary factory building that is being constructed to last five years.

Investments with perpetual cash flows are also (usually) easily identified: maintenance on a large flood control dam and revenues from a long-span toll bridge. Furthermore, some items with finite lives can expect renewal on a repeated basis.<sup>15</sup> For example, a major freeway with a pavement life of 20 years is unlikely to be abandoned; it will be resurfaced or replaced every 20 years.

Actually, if an investment’s finite lifespan is long enough, it can be considered an infinite investment because money 50 or more years from now has little impact on current decisions. The  $(P/F, 10\%, 50)$  factor, for example, is 0.0085. Therefore, one dollar at  $t = 50$  has an equivalent present worth of less than one penny. Since these far-future cash flows are eclipsed by present cash flows, long-term investments can be considered finite or infinite without significant impact on the calculations.

## 24. CHOICE OF ALTERNATIVES: COMPARING ONE ALTERNATIVE WITH ANOTHER ALTERNATIVE

Several methods exist for selecting a superior alternative from among a group of proposals. Each method has its own merits and applications.

<sup>15</sup>The term *renewal* can be interpreted to mean replacement or repair.

## Present Worth Method

When two or more alternatives are capable of performing the same functions, the superior alternative will have the largest present worth. The *present worth method* is restricted to evaluating alternatives that are mutually exclusive and that have the same lives. This method is suitable for ranking the desirability of alternatives.

### Example 87.12

Investment A costs \$10,000 today and pays back \$11,500 two years from now. Investment B costs \$8000 today and pays back \$4500 each year for two years. If an interest rate of 5% is used, which alternative is superior?

*Solution*

$$\begin{aligned} P(A) &= -\$10,000 + (\$11,500)(P/F, 5\%, 2) \\ &= -\$10,000 + (\$11,500)(0.9070) \\ &= \$431 \end{aligned}$$

$$\begin{aligned} P(B) &= -\$8000 + (\$4500)(P/A, 5\%, 2) \\ &= -\$8000 + (\$4500)(1.8594) \\ &= \$367 \end{aligned}$$

Alternative A is superior and should be chosen.

## Capitalized Cost Method

The present worth of a project with an infinite life is known as the *capitalized cost* or *life-cycle cost*. Capitalized cost is the amount of money at  $t = 0$  needed to perpetually support the project on the earned interest only. Capitalized cost is a positive number when expenses exceed income.

In comparing two alternatives, each of which is infinitely lived, the superior alternative will have the lowest capitalized cost.

Normally, it would be difficult to work with an infinite stream of cash flows since most economics tables do not list factors for periods in excess of 100 years. However, the  $(A/P)$  discounting factor approaches the interest rate as  $n$  becomes large. Since the  $(P/A)$  and  $(A/P)$  factors are reciprocals of each other, it is possible to divide an infinite series of equal cash flows by the interest rate in order to calculate the present worth of the infinite series. This is the basis of Eq. 87.19.

$$\text{capitalized cost} = \text{initial cost} + \frac{\text{annual costs}}{i} \quad 87.19$$

Equation 87.19 can be used when the annual costs are equal in every year. If the operating and maintenance costs occur irregularly instead of annually, or if the costs vary from year to year, it will be necessary to somehow

determine a cash flow of equal annual amounts (EAA) that is equivalent to the stream of original costs.

The equal annual amount may be calculated in the usual manner by first finding the present worth of all the actual costs and then multiplying the present worth by the interest rate (the  $(A/P)$  factor for an infinite series). However, it is not even necessary to convert the present worth to an equal annual amount since Eq. 87.20 will convert the equal amount back to the present worth.

$$\begin{aligned} \text{capitalized cost} &= \text{initial cost} + \frac{\text{EAA}}{i} \\ &= \text{initial cost} + \frac{\text{present worth}}{\text{of all expenses}} \end{aligned} \quad 87.20$$

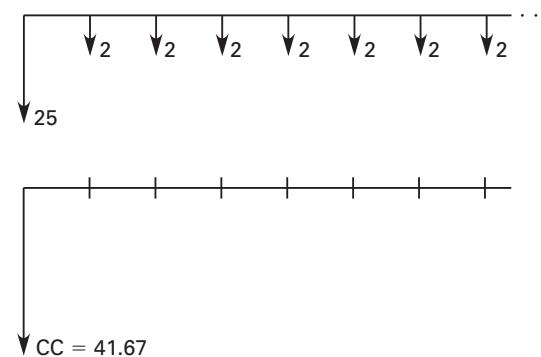

### Example 87.13

What is the capitalized cost of a public works project that will cost \$25,000,000 now and will require \$2,000,000 in maintenance annually? The effective annual interest rate is 12%.

*Solution*

Worked in millions of dollars, from Eq. 87.19, the capitalized cost is

$$\begin{aligned} \text{capitalized cost} &= 25 + (2)(P/A, 12\%, \infty) \\ &= 25 + \frac{2}{0.12} \\ &= 41.67 \end{aligned}$$

## Annual Cost Method

Alternatives that accomplish the same purpose but that have unequal lives must be compared by the *annual cost method*.<sup>16</sup> The annual cost method assumes that each alternative will be replaced by an identical twin at the end of its useful life (infinite renewal). This method, which may also be used to rank alternatives according

<sup>16</sup>Of course, the annual cost method can be used to determine the superiority of assets with identical lives as well.

to their desirability, is also called the *annual return method* or *capital recovery method*.

Restrictions are that the alternatives must be mutually exclusive and repeatedly renewed up to the duration of the longest-lived alternative. The calculated annual cost is known as the *equivalent uniform annual cost* (EUAC) or just *equivalent annual cost*. Cost is a positive number when expenses exceed income.

#### Example 87.14

Which of the following alternatives is superior over a 30-year period if the interest rate is 7%?

	alternative A	alternative B
type	brick	wood
life	30 years	10 years
initial cost	\$1800	\$450
maintenance	\$5/year	\$20/year

*Solution*

$$\begin{aligned} \text{EUAC(A)} &= (\$1800)(A/P, 7\%, 30) + \$5 \\ &= (\$1800)(0.0806) + \$5 \\ &= \$150 \end{aligned}$$

$$\begin{aligned} \text{EUAC(B)} &= (\$450)(A/P, 7\%, 10) + \$20 \\ &= (\$450)(0.1424) + \$20 \\ &= \$84 \end{aligned}$$

Alternative B is superior since its annual cost of operation is the lowest. It is assumed that three wood facilities, each with a life of 10 years and a cost of \$450, will be built to span the 30-year period.

### 25. CHOICE OF ALTERNATIVES: COMPARING AN ALTERNATIVE WITH A STANDARD

With specific economic performance criteria, it is possible to qualify an investment as acceptable or unacceptable without having to compare it with another investment. Two such performance criteria are the benefit-cost ratio and the minimum attractive rate of return.

#### Benefit-Cost Ratio Method

The *benefit-cost ratio method* is often used in municipal project evaluations where benefits and costs accrue to different segments of the community. With this method, the present worth of all benefits (irrespective of the beneficiaries) is divided by the present worth of all costs. The project is considered acceptable if the ratio equals or exceeds 1.0, that is, if  $B/C \geq 1.0$ .

When the benefit-cost ratio method is used, disbursements by the initiators or sponsors are *costs*. Disbursements by the users of the project are known as

*disbenefits*. It is often difficult to determine whether a cash flow is a cost or a disbenefit (whether to place it in the numerator or denominator of the benefit-cost ratio calculation).

Regardless of where the cash flow is placed, an acceptable project will always have a benefit-cost ratio greater than or equal to 1.0, although the actual numerical result will depend on the placement. For this reason, the benefit-cost ratio method should not be used to rank competing projects.

The benefit-cost ratio method of comparing alternatives is used extensively in transportation engineering where the ratio is often (but not necessarily) written in terms of annual benefits and annual costs instead of present worths. Another characteristic of highway benefit-cost ratios is that the route (road, highway, etc.) is usually already in place and that various alternative upgrades are being considered. There will be existing benefits and costs associated with the current route. Therefore, the *change* (usually an increase) in benefits and costs is used to calculate the benefit-cost ratio.<sup>17</sup>

$$B/C = \frac{\Delta_{\text{user}}^{\text{benefits}}}{\Delta_{\text{investment}}^{\text{cost}} + \Delta_{\text{maintenance}} - \Delta_{\text{residual}}^{\text{value}}} \quad 87.21$$

The change in *residual value (terminal value)* appears in the denominator as a negative item. An increase in the residual value would decrease the denominator.

#### Example 87.15

By building a bridge over a ravine, a state department of transportation can shorten the time it takes to drive through a mountainous area. Estimates of costs and benefits (due to decreased travel time, fewer accidents, reduced gas usage, etc.) have been prepared. Should the bridge be built? Use the benefit-cost ratio method of comparison.

	millions
initial cost	40
capitalized cost of perpetual annual maintenance	12
capitalized value of annual user benefits	49
residual value	0

<sup>17</sup>This discussion of highway benefit-cost ratios is not meant to imply that everyone agrees with Eq. 87.21. In *Economic Analysis for Highways* (International Textbook Company, Scranton, PA, 1969), author Robley Winfrey took a strong stand on one aspect of the benefits versus disbenefits issue: highway maintenance. According to Winfrey, regular highway maintenance costs should be placed in the numerator as a subtraction from the user benefits. Some have called this mandate the *Winfrey method*.

**Solution**

If Eq. 87.21 is used, the benefit-cost ratio is

$$B/C = \frac{49}{40 + 12 - 0} = 0.942$$

Since the benefit-cost ratio is less than 1.00, the bridge should not be built.

If the maintenance costs are placed in the numerator (per Ftn. 17), the benefit-cost ratio value will be different, but the conclusion will not change.

$$B/C_{\text{alternate method}} = \frac{49 - 12}{40} = 0.925$$

**Rate of Return Method**

The minimum attractive rate of return (MARR) has already been introduced as a standard of performance against which an investment's actual *rate of return* (ROR) is compared. If the rate of return is equal to or exceeds the minimum attractive rate of return, the investment is qualified. This is the basis for the *rate of return method* of alternative selection.

Finding the rate of return can be a long, iterative process. Usually, the actual numerical value of rate of return is not needed; it is sufficient to know whether or not the rate of return exceeds the minimum attractive rate of return. This *comparative analysis* can be accomplished without calculating the rate of return simply by finding the present worth of the investment using the minimum attractive rate of return as the effective interest rate (i.e.,  $i = \text{MARR}$ ). If the present worth is zero or positive, the investment is qualified. If the present worth is negative, the rate of return is less than the minimum attractive rate of return.

**26. RANKING MUTUALLY EXCLUSIVE MULTIPLE PROJECTS**

Ranking of multiple investment alternatives is required when there is sufficient funding for more than one investment. Since the best investments should be selected first, it is necessary to place all investments into an ordered list.

Ranking is relatively easy if the present worths, future worths, capitalized costs, or equivalent uniform annual costs have been calculated for all the investments. The highest ranked investment will be the one with the largest present or future worth, or the smallest capitalized or annual cost. Present worth, future worth, capitalized cost, and equivalent uniform annual cost can all be used to rank multiple investment alternatives.

However, neither rates of return nor benefit-cost ratios should be used to rank multiple investment alternatives. Specifically, if two alternatives both have rates of return exceeding the minimum acceptable rate of return, it is

not sufficient to select the alternative with the highest rate of return.

An *incremental analysis*, also known as a *rate of return on added investment study*, should be performed if rate of return is used to select between investments. An incremental analysis starts by ranking the alternatives in order of increasing initial investment. Then, the cash flows for the investment with the lower initial cost are subtracted from the cash flows for the higher-priced alternative on a year-by-year basis. This produces, in effect, a third alternative representing the costs and benefits of the added investment. The added expense of the higher-priced investment is not warranted unless the rate of return of this third alternative exceeds the minimum attractive rate of return as well. The choice criterion is to select the alternative with the higher initial investment if the incremental rate of return exceeds the minimum attractive rate of return.

An incremental analysis is also required if ranking is to be done by the benefit-cost ratio method. The incremental analysis is accomplished by calculating the ratio of differences in benefits to differences in costs for each possible pair of alternatives. If the ratio exceeds 1.0, alternative 2 is superior to alternative 1. Otherwise, alternative 1 is superior.<sup>18</sup>

$$\frac{B_2 - B_1}{C_2 - C_1} \geq 1 \quad [\text{alternative 2 superior}] \quad 87.22$$

**27. ALTERNATIVES WITH DIFFERENT LIVES**

Comparison of two alternatives is relatively simple when both alternatives have the same life. For example, a problem might be stated: "Which would you rather have: car A with a life of three years, or car B with a life of five years?"

However, care must be taken to understand what is going on when the two alternatives have different lives. If car A has a life of three years and car B has a life of five years, what happens at  $t = 3$  if the five-year car is chosen? If a car is needed for five years, what happens at  $t = 3$  if the three-year car is chosen?

In this type of situation, it is necessary to distinguish between the length of the need (the *analysis horizon*) and the lives of the alternatives or assets intended to meet that need. The lives do not have to be the same as the horizon.

**Finite Horizon with Incomplete Asset Lives**

If an asset with a five-year life is chosen for a three-year need, the disposition of the asset at  $t = 3$  must be known in order to evaluate the alternative. If the asset is sold at  $t = 3$ , the salvage value is entered into the analysis (at  $t = 3$ ) and the alternative is evaluated as a three-year investment. The fact that the asset is sold

<sup>18</sup>It goes without saying that the benefit-cost ratios for all investment alternatives by themselves must also be equal to or greater than 1.0.

when it has some useful life remaining does not affect the analysis horizon.

Similarly, if a three-year asset is chosen for a five-year need, something about how the need is satisfied during the last two years must be known. Perhaps a rental asset will be used. Or, perhaps the function will be "farmed out" to an outside firm. In any case, the costs of satisfying the need during the last two years enter the analysis, and the alternative is evaluated as a five-year investment.

If both alternatives are "converted" to the same life, any of the alternative selection criteria (present worth method, annual cost method, etc.) can be used to determine which alternative is superior.

### **Finite Horizon with Integer Multiple Asset Lives**

It is common to have a long-term horizon (need) that must be met with short-lived assets. In special instances, the horizon will be an integer number of asset lives. For example, a company may be making a 12-year transportation plan and may be evaluating two cars: one with a three-year life, and another with a four-year life.

In this example, four of the first car or three of the second car are needed to reach the end of the 12-year horizon.

If the horizon is an integer number of asset lives, any of the alternative selection criteria can be used to determine which is superior. If the present worth method is used, all alternatives must be evaluated over the entire horizon. (In this example, the present worth of 12 years of car purchases and use must be determined for both alternatives.)

If the equivalent uniform annual cost method is used, it may be possible to base the calculation of annual cost on one lifespan of each alternative only. It may not be necessary to incorporate all of the cash flows into the analysis. (In the running example, the annual cost over three years would be determined for the first car; the annual cost over four years would be determined for the second car.) This simplification is justified if the subsequent asset replacements (renewals) have the same cost and cash flow structure as the original asset. This assumption is typically made implicitly when the annual cost method of comparison is used.

### **Infinite Horizon**

If the need horizon is infinite, it is not necessary to impose the restriction that asset lives of alternatives be integer multiples of the horizon. The superior alternative will be replaced (renewed) whenever it is necessary to do so, forever.

Infinite horizon problems are almost always solved with either the annual cost or capitalized cost method. It is common to (implicitly) assume that the cost and cash flow structure of the asset replacements (renewals) are the same as the original asset.

### **28. OPPORTUNITY COSTS**

An *opportunity cost* is an imaginary cost representing what will not be received if a particular strategy is rejected. It is what you will lose if you do or do not do something. As an example, consider a growing company with an existing operational computer system. If the company trades in its existing computer as part of an upgrade plan, it will receive a *trade-in allowance*. (In other problems, a *salvage value* may be involved.)

If one of the alternatives being evaluated is not to upgrade the computer system at all, the trade-in allowance (or, salvage value in other problems) will not be realized. The amount of the trade-in allowance is an opportunity cost that must be included in the problem analysis.

Similarly, if one of the alternatives being evaluated is to wait one year before upgrading the computer, the *difference in trade-in allowances* is an opportunity cost that must be included in the problem analysis.

### **29. REPLACEMENT STUDIES**

An investigation into the retirement of an existing process or piece of equipment is known as a *replacement study*. Replacement studies are similar in most respects to other alternative comparison problems: An interest rate is given, two alternatives exist, and one of the previously mentioned methods of comparing alternatives is used to choose the superior alternative. Usually, the annual cost method is used on a year-by-year basis.

In replacement studies, the existing process or piece of equipment is known as the *defender*. The new process or piece of equipment being considered for purchase is known as the *challenger*.

### **30. TREATMENT OF SALVAGE VALUE IN REPLACEMENT STUDIES**

Since most defenders still have some market value when they are retired, the problem of what to do with the salvage arises. It seems logical to use the salvage value of the defender to reduce the initial purchase cost of the challenger. This is consistent with what would actually happen if the defender were to be retired.

By convention, however, the defender's salvage value is subtracted from the defender's present value. This does not seem logical, but it is done to keep all costs and benefits related to the defender with the defender. In this case, the salvage value is treated as an opportunity cost that would be incurred if the defender is not retired.

If the defender and the challenger have the same lives and a present worth study is used to choose the superior alternative, the placement of the salvage value will have no effect on the net difference between present worths for the challenger and defender. Although the values of the two present worths will be different depending on the placement, the difference in present worths will be the same.

If the defender and the challenger have different lives, an annual cost comparison must be made. Since the salvage value would be “spread over” a different number of years depending on its placement, it is important to abide by the conventions listed in this section.

There are a number of ways to handle salvage value in retirement studies. The best way is to calculate the cost of keeping the defender one more year. In addition to the usual operating and maintenance costs, that cost includes an opportunity interest cost incurred by not selling the defender, and also a drop in the salvage value if the defender is kept for one additional year. Specifically,

$$\begin{aligned} \text{EUAC (defender)} = & \text{next year's maintenance costs} \\ & + i(\text{current salvage value}) \\ & + \text{current salvage} \\ & - \text{next year's salvage} \end{aligned} \quad 87.23$$

It is important in retirement studies not to double count the salvage value. That is, it would be incorrect to add the salvage value to the defender and at the same time subtract it from the challenger.

Equation 87.23 contains the difference in salvage value between two consecutive years. This calculation shows that the defender/challenger decision must be made on a year-by-year basis. One application of Eq. 87.23 will not usually answer the question of whether the defender should remain in service indefinitely. The calculation must be repeatedly made as long as there is a drop in salvage value from one year to the next.

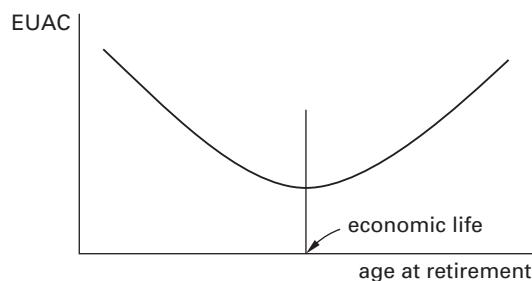

### 31. ECONOMIC LIFE: RETIREMENT AT MINIMUM COST

As an asset grows older, its operating and maintenance costs typically increase. Eventually, the cost to keep the asset in operation becomes prohibitive, and the asset is retired or replaced. However, it is not always obvious when an asset should be retired or replaced.

As the asset’s maintenance cost is increasing each year, the amortized cost of its initial purchase is decreasing. It is the sum of these two costs that should be evaluated to determine the point at which the asset should be retired or replaced. Since an asset’s initial purchase price is likely to be high, the amortized cost will be the controlling factor in those years when the maintenance costs are low. Therefore, the EUAC of the asset will decrease in the initial part of its life.

However, as the asset grows older, the change in its amortized cost decreases while maintenance cost increases. Eventually, the sum of the two costs reaches a minimum and then starts to increase. The age of the asset at the minimum cost point is known as the *economic life* of the asset. The economic life generally is less than the length of need and the technological lifetime of the asset, as shown in Fig. 87.7.

**Figure 87.7 EUAC Versus Age at Retirement**

The determination of an asset’s economic life is demonstrated by Ex. 87.16.

#### Example 87.16

Buses in a municipal transit system have the characteristics listed. In order to minimize its annual operating expenses, when should the city replace its buses if money can be borrowed at 8%?

year	initial cost of bus: \$120,000		
	maintenance cost	salvage value	
1	35,000	60,000	
2	38,000	55,000	
3	43,000	45,000	
4	50,000	25,000	
5	65,000	15,000	

#### Solution

The annual maintenance is different each year. Each maintenance cost must be spread over the life of the bus. This is done by first finding the present worth and then amortizing the maintenance costs. If a bus is kept for one year and then sold, the annual cost will be

$$\begin{aligned} \text{EUAC}(1) = & (\$120,000)(A/P, 8\%, 1) \\ & + (\$35,000)(A/F, 8\%, 1) \\ & - (\$60,000)(A/F, 8\%, 1) \\ = & (\$120,000)(1.0800) + (\$35,000)(1.000) \\ & - (\$60,000)(1.000) \\ = & \$104,600 \end{aligned}$$

If a bus is kept for two years and then sold, the annual cost will be

$$\begin{aligned} \text{EUAC}(2) = & (\$120,000 + (\$35,000)(P/F, 8\%, 1)) \\ & \times (A/P, 8\%, 2) \\ & + (\$38,000 - \$55,000)(A/F, 8\%, 2) \\ = & (\$120,000 + (\$35,000)(0.9259))(0.5608) \\ & + (\$38,000 - \$55,000)(0.4808) \\ = & \$77,296 \end{aligned}$$

If a bus is kept for three years and then sold, the annual cost will be

$$\begin{aligned} \text{EUAC}(3) &= (\$120,000 + (\$35,000)(P/F, 8\%, 1) \\ &\quad + (\$38,000)(P/F, 8\%, 2))(A/P, 8\%, 3) \\ &\quad + (\$43,000 - \$45,000)(A/F, 8\%, 3) \\ &= (\$120,000 + (\$35,000)(0.9259) \\ &\quad + (\$38,000)(0.8573))(0.3880) \\ &\quad - (\$2000)(0.3080) \\ &= \$71,158 \end{aligned}$$

This process is continued until the annual cost begins to increase. In this example, EUAC(4) is \$71,700. Therefore, the buses should be retired after three years.

## 32. LIFE-CYCLE COST

The *life-cycle cost* of an alternative is the equivalent value (at  $t = 0$ ) of the alternative's cash flow over the alternative's lifespan. Since the present worth is evaluated using an effective interest rate of  $i$  (which would be the interest rate used for all engineering economic analyses), the life-cycle cost is the same as the alternative's present worth. If the alternative has an infinite horizon, the life-cycle cost and capitalized cost will be identical.

## 33. CAPITALIZED ASSETS VERSUS EXPENSES

High expenses reduce profit, which in turn reduces income tax. It seems logical to label each and every expenditure, even an asset purchase, as an expense. As an alternative to this *expensing the asset*, it may be decided to capitalize the asset. *Capitalizing the asset* means that the cost of the asset is divided into equal or unequal parts, and only one of these parts is taken as an expense each year. Expensing is clearly the more desirable alternative, since the after-tax profit is increased early in the asset's life.

There are long-standing accounting conventions as to what can be expensed and what must be capitalized.<sup>19</sup> Some companies capitalize everything—regardless of cost—with expected lifetimes greater than one year. Most companies, however, expense items whose purchase costs are below a cutoff value. A cutoff value in the range of \$250–500, depending on the size of the company, is chosen as the maximum purchase cost of an expensed asset. Assets costing more than this are capitalized.

It is not necessary for a large corporation to keep track of every lamp, desk, and chair for which the purchase price is greater than the cutoff value. Such assets, all of which

<sup>19</sup>For example, purchased vehicles must be capitalized; payments for leased vehicles can be expensed. Repainting a building with paint that will last five years is an expense, but the replacement cost of a leaking roof must be capitalized.

have the same lives and have been purchased in the same year, can be placed into groups or *asset classes*. A group cost, equal to the sum total of the purchase costs of all items in the group, is capitalized as though the group was an identifiable and distinct asset itself.

## 34. PURPOSE OF DEPRECIATION

Depreciation is an *artificial expense* that spreads the purchase price of an asset or other property over a number of years.<sup>20</sup> Depreciating an asset is an example of capitalization, as previously defined. The inclusion of depreciation in engineering economic analysis problems will increase the after-tax present worth (profitability) of an asset. The larger the depreciation, the greater will be the profitability. Therefore, individuals and companies eligible to utilize depreciation want to maximize and accelerate the depreciation available to them.

Although the entire property purchase price is eventually recognized as an expense, the net recovery from the expense stream never equals the original cost of the asset. That is, depreciation cannot realistically be thought of as a fund (an annuity or sinking fund) that accumulates capital to purchase a replacement at the end of the asset's life. The primary reason for this is that the depreciation expense is reduced significantly by the impact of income taxes, as will be seen in later sections.

## 35. DEPRECIATION BASIS OF AN ASSET

The *depreciation basis* of an asset is the part of the asset's purchase price that is spread over the *depreciation period*, also known as the *service life*.<sup>21</sup> Usually, the depreciation basis and the purchase price are not the same.

A common depreciation basis is the difference between the purchase price and the expected salvage value at the end of the depreciation period. That is,

$$\text{depreciation basis} = C - S_n \quad 87.24$$

There are several methods of calculating the year-by-year depreciation of an asset. Equation 87.24 is not

<sup>20</sup>In the United States, the tax regulations of Internal Revenue Service (IRS) allow depreciation on almost all forms of *business property* except land. The following types of property are distinguished: *real* (e.g., buildings used for business), *residential* (e.g., buildings used as rental property), and *personal* (e.g., equipment used for business). Personal property does *not* include items for personal use (such as a personal residence), despite its name. *Tangible personal property* is distinguished from *intangible property* (goodwill, copyrights, patents, trademarks, franchises, agreements not to compete, etc.).

<sup>21</sup>The *depreciation period* is selected to be as short as possible within recognized limits. This depreciation will not normally coincide with the *economic life* or *useful life* of an asset. For example, a car may be capitalized over a depreciation period of three years. It may become uneconomical to maintain and use at the end of an economic life of nine years. However, the car may be capable of operation over a useful life of 25 years.

universally compatible with all depreciation methods. Some methods do not consider the salvage value. This is known as an *unadjusted basis*. When the depreciation method is known, the depreciation basis can be rigorously defined.<sup>22</sup>

## 36. DEPRECIATION METHODS

Generally, tax regulations do not allow the cost of an asset to be treated as a deductible expense in the year of purchase. Rather, portions of the depreciation basis must be allocated to each of the  $n$  years of the asset's depreciation period. The amount that is allocated each year is called the *depreciation*.

Various methods exist for calculating an asset's depreciation each year.<sup>23</sup> Although the depreciation calculations may be considered independently (for the purpose of determining book value or as an academic exercise), it is important to recognize that depreciation has no effect on engineering economic analyses unless income taxes are also considered.

### Straight-Line Method

With the *straight-line* (SL) method, depreciation is the same each year. The depreciation basis ( $C - S_n$ ) is allocated uniformly to all of the  $n$  years in the depreciation period. Each year, the depreciation will be

$$D = \frac{C - S_n}{n} \quad 87.25$$

### Constant Percentage Method

The *constant percentage method*<sup>24</sup> is similar to the straight line method in that the depreciation is the same each year. If the fraction of the basis used as depreciation is  $1/n$ , there is no difference between the constant percentage and straight line methods. The two methods differ only in what information is available. (With the straight line method, the life is known. With the constant percentage method, the depreciation fraction is known.)

<sup>22</sup>For example, with the Accelerated Cost Recovery System (ACRS) the *depreciation basis* is the total purchase cost, regardless of the expected salvage value. With declining balance methods, the depreciation basis is the purchase cost less any previously taken depreciation.

<sup>23</sup>This discussion gives the impression that any form of depreciation may be chosen regardless of the nature and circumstances of the purchase. In reality, the IRS tax regulations place restrictions on the higher-rate (accelerated) methods, such as declining balance and sum-of-the-years' digits methods. Furthermore, the *Economic Recovery Act of 1981* and the *Tax Reform Act of 1986* substantially changed the laws relating to personal and corporate income taxes.

<sup>24</sup>The *constant percentage method* should not be confused with the declining balance method, which used to be known as the *fixed percentage on diminishing balance method*.

Each year, the depreciation will be

$$\begin{aligned} D &= (\text{depreciation fraction})(\text{depreciation basis}) \\ &= (\text{depreciation fraction})(C - S_n) \end{aligned} \quad 87.26$$

### Sum-of-the-Years' Digits Method

In *sum-of-the-years' digits* (SOYD) depreciation, the digits from 1 to  $n$  inclusive are summed. The total,  $T$ , can also be calculated from

$$T = \frac{1}{2}n(n + 1) \quad 87.27$$

The depreciation in year  $j$  can be found from Eq. 87.28. Notice that the depreciation in year  $j$ ,  $D_j$ , decreases by a constant amount each year.

$$D_j = \frac{(C - S_n)(n - j + 1)}{T} \quad 87.28$$

### Double Declining Balance Method<sup>25</sup>

*Double declining balance*<sup>26</sup> (DDB) depreciation is independent of salvage value. Furthermore, the book value never stops decreasing, although the depreciation decreases in magnitude. Usually, any book value in excess of the salvage value is written off in the last year of the asset's depreciation period. Unlike any of the other depreciation methods, double declining balance depends on accumulated depreciation.

$$D_{\text{first year}} = \frac{2C}{n} \quad 87.29$$

$$D_j = \frac{2 \left( C - \sum_{m=1}^{j-1} D_m \right)}{n} \quad 87.30$$

Calculating the depreciation in the middle of an asset's life appears particularly difficult with double declining balance, since all previous years' depreciation amounts seem to be required. It appears that the depreciation in the sixth year, for example, cannot be calculated unless the values of depreciation for the first five years are calculated. However, this is not true.

<sup>25</sup>In the past, the *declining balance method* has also been known as the *fixed percentage of book value* and *fixed percentage on diminishing balance method*.

<sup>26</sup>Double declining balance depreciation is a particular form of *declining balance depreciation*, as defined by the IRS tax regulations. Declining balance depreciation includes 125% declining balance and 150% declining balance depreciations that can be calculated by substituting 1.25 and 1.50, respectively, for the 2 in Eq. 87.29.

Depreciation in the middle of an asset's life can be found from the following equations. ( $d$  is known as the *depreciation rate*.)

$$d = \frac{2}{n} \left[ \begin{array}{c} \text{double declining} \\ \text{balance} \end{array} \right] \quad 87.31$$

$$D_j = dC(1 - d)^{j-1} \quad 87.32$$

### Statutory Depreciation Systems

In the United States, property placed into service in 1981 and thereafter must use the *Accelerated Cost Recovery System* (ACRS), and after 1986, the *Modified Accelerated Cost Recovery System* (MACRS) or other statutory method. Other methods (straight line, declining balance, etc.) cannot be used except in special cases.

Property placed into service in 1980 or before must continue to be depreciated according to the method originally chosen (e.g., straight line, declining balance, or sum-of-the-years' digits). ACRS and MACRS cannot be used.

Under ACRS and MACRS, the cost recovery amount in the  $j$ th year of an asset's cost recovery period is calculated by multiplying the initial cost by a factor.

$$D_j = C \times \text{factor} \quad 87.33$$

The initial cost used is not reduced by the asset's salvage value for ACRS and MACRS calculations. The factor used depends on the asset's cost recovery period. (See Table 87.4.) Such factors are subject to continuing legislation changes. Current tax publications should be consulted before using this method.

**Table 87.4** Representative MACRS Depreciation Factors\*

year, $j$	depreciation rate for recovery period, $n$			
	3 years	5 years	7 years	10 years
1	33.33%	20.00%	14.29%	10.00%
2	44.45%	32.00%	24.49%	18.00%
3	14.81%	19.20%	17.49%	14.40%
4	7.41%	11.52%	12.49%	11.52%
5		11.52%	8.93%	9.22%
6		5.76%	8.92%	7.37%
7			8.93%	6.55%
8			4.46%	6.55%
9				6.56%
10				6.55%
11				3.28%

\*Values are for the "half-year" convention. This table gives typical values only. Since these factors are subject to continuing revision, they should not be used without consulting an accounting professional.

### Production or Service Output Method

If an asset has been purchased for a specific task and that task is associated with a specific lifetime amount of

output or production, the depreciation may be calculated by the fraction of total production produced during the year. Under the *units of production* method, the depreciation is not expected to be the same each year.

$$D_j = (C - S_n) \left( \frac{\text{actual output in year } j}{\text{estimated lifetime output}} \right) \quad 87.34$$

### Sinking Fund Method

The *sinking fund method* is seldom used in industry because the initial depreciation is low. The formula for sinking fund depreciation (which increases each year) is

$$D_j = (C - S_n)(A/F, i\%, n)(F/P, i\%, j-1) \quad 87.35$$

### Example 87.17

An asset is purchased for \$9000. Its estimated economic life is 10 years, after which it will be sold for \$200. Find the depreciation in the first three years using straight-line, double declining balance, and sum-of-the-years' digits depreciation methods.

*Solution*

$$\text{SL: } D = \frac{\$9000 - \$200}{10} = \$880 \text{ each year}$$

$$\text{DDB: } D_1 = \frac{(2)(\$9000)}{10} = \$1800 \text{ in year 1}$$

$$D_2 = \frac{(2)(\$9000 - \$1800)}{10} = \$1440 \text{ in year 2}$$

$$D_3 = \frac{(2)(\$9000 - \$3240)}{10} = \$1152 \text{ in year 3}$$

$$\text{SOYD: } T = \left(\frac{1}{2}\right)(10)(11) = 55$$

$$D_1 = \left(\frac{19}{55}\right)(\$9000 - \$200) = \$1600 \text{ in year 1}$$

$$D_2 = \left(\frac{9}{55}\right)(\$8800) = \$1440 \text{ in year 2}$$

$$D_3 = \left(\frac{8}{55}\right)(\$8800) = \$1280 \text{ in year 3}$$

### 37. ACCELERATED DEPRECIATION METHODS

An *accelerated depreciation method* is one that calculates a depreciation amount greater than a straight line amount. Double declining balance and sum-of-the-years' digits methods are accelerated methods. The ACRS and MACRS methods are explicitly accelerated methods. Straight line and sinking fund methods are not accelerated methods.

Use of an accelerated depreciation method may result in unexpected tax consequences when the depreciated asset or property is disposed of. Professional tax advice should be obtained in this area.

### 38. BONUS DEPRECIATION

*Bonus depreciation* is a special, one-time, depreciation authorized by legislation for specific types of equipment, to be taken in the first year, in addition to the standard depreciation normally available for the equipment. Bonus depreciation is usually enacted in order to stimulate investment in or economic recovery of specific industries (e.g., aircraft manufacturing).

### 39. BOOK VALUE

The difference between original purchase price and accumulated depreciation is known as *book value*.<sup>27</sup> At the end of each year, the book value (which is initially equal to the purchase price) is reduced by the depreciation in that year.

It is important to properly synchronize depreciation calculations. It is difficult to answer the question, "What is the book value in the fifth year?" unless the timing of the book value change is mutually agreed upon. It is better to be specific about an inquiry by identifying when the book value change occurs. For example, the following question is unambiguous: "What is the book value at the end of year 5, after subtracting depreciation in the fifth year?" or "What is the book value after five years?"

Unfortunately, this type of care is seldom taken in book value inquiries, and it is up to the respondent to exercise reasonable care in distinguishing between beginning-of-year book value and end-of-year book value. To be consistent, the book value equations in this chapter have been written in such a way that the year subscript,  $j$ , has the same meaning in book value and depreciation calculations. That is,  $BV_5$  means the book value at the end of the fifth year, after five years of depreciation, including  $D_5$ , have been subtracted from the original purchase price.

There can be a great difference between the book value of an asset and the *market value* of that asset. There is no legal requirement for the two values to coincide, and no intent for book value to be a reasonable measure of market value.<sup>28</sup> Therefore, it is apparent that book value is merely an accounting convention with little practical use. Even when a depreciated asset is disposed of, the book value is used to determine the consequences of disposal, not the price the asset should bring at sale.

<sup>27</sup>The balance sheet of a corporation usually has two asset accounts: the *equipment account* and the *accumulated depreciation account*. There is no book value account on this financial statement, other than the implicit value obtained from subtracting the accumulated depreciation account from the equipment account. The book values of various assets, as well as their original purchase cost, date of purchase, salvage value, and so on, and accumulated depreciation appear on detail sheets or other peripheral records for each asset.

<sup>28</sup>Common examples of assets with great divergences of book and market values are buildings (rental houses, apartment complexes, factories, etc.) and company luxury automobiles (Porsches, Mercedes, etc.) during periods of inflation. Book values decrease, but actual values increase.

The calculation of book value is relatively easy, even for the case of the declining balance depreciation method.

For the straight line depreciation method, the book value at the end of the  $j$ th year, after the  $j$ th depreciation deduction has been made, is

$$BV_j = C - \frac{j(C - S_n)}{n} = C - jD \quad 87.36$$

For the sum-of-the-years' digits method, the book value is

$$BV_j = (C - S_n) \left( 1 - \frac{j(2n+1-j)}{n(n+1)} \right) + S_n \quad 87.37$$

As discussed in Ftn. 26, for the declining balance method, including double declining balance, the book value is

$$BV_j = C(1 - d)^j \quad 87.38$$

For the sinking fund method, the book value is calculated directly as

$$BV_j = C - (C - S_n)(A/F, i\%, n)(F/P, i\%, j) \quad 87.39$$

Of course, the book value at the end of year  $j$  can always be calculated for any method by successive subtractions (i.e., subtraction of the accumulated depreciation), as Eq. 87.40 illustrates.

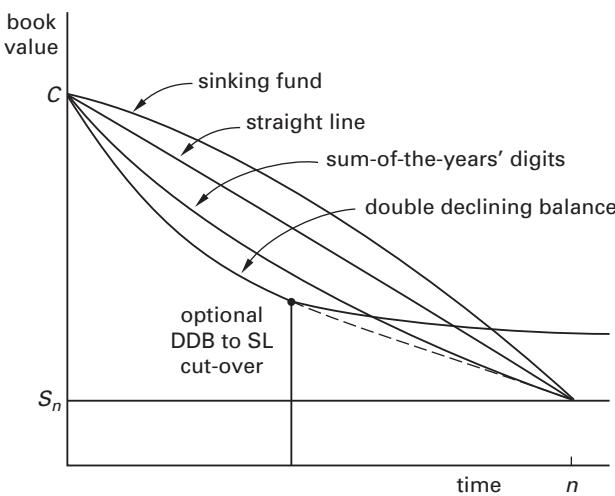

$$BV_j = C - \sum_{m=1}^j D_m \quad 87.40$$

Figure 87.8 illustrates the book value of a hypothetical asset depreciated using several depreciation methods. Notice that the double declining balance method initially produces the fastest write-off, while the sinking fund method produces the slowest write-off. Also, the book value does not automatically equal the salvage value at the end of an asset's depreciation period with the double declining balance method.<sup>29</sup>

#### Example 87.18

For the asset described in Ex. 87.17, calculate the book value at the end of the first three years if sum-of-the-years' digits depreciation is used. The book value at the beginning of year 1 is \$9000.

<sup>29</sup>This means that the straight line method of depreciation may result in a lower book value at some point in the depreciation period than if double declining balance is used. A *cut-over* from double declining balance to straight line may be permitted in certain cases. Finding the *cut-over point*, however, is usually done by comparing book values determined by both methods. The analytical method is complicated.

**Figure 87.8** Book Value with Different Depreciation Methods

*Solution*

From Eq. 87.40,

$$BV_1 = \$9000 - \$1600 = \$7400$$

$$BV_2 = \$7400 - \$1440 = \$5960$$

$$BV_3 = \$5960 - \$1280 = \$4680$$

## 40. AMORTIZATION

Amortization and depreciation are similar in that they both divide up the cost basis or value of an asset. In fact, in certain cases, the term "amortization" may be used in place of the term "depreciation." However, depreciation is a specific form of amortization.

Amortization spreads the cost basis or value of an asset over some base. The base can be time, units of production, number of customers, and so on. The asset can be tangible (e.g., a delivery truck or building) or intangible (e.g., goodwill or a patent).

If the asset is tangible, if the base is time, and if the length of time is consistent with accounting standards and taxation guidelines, then the term "depreciation" is appropriate. However, if the asset is intangible, if the base is some other variable, or if some length of time other than the customary period is used, then the term "amortization" is more appropriate.<sup>30</sup>

### Example 87.19

A company purchases complete and exclusive patent rights to an invention for \$1,200,000. It is estimated that once commercially produced, the invention will have a

<sup>30</sup>From time to time, the U.S. Congress has allowed certain types of facilities (e.g., emergency, grain storage, and pollution control) to be written off more rapidly than would otherwise be permitted in order to encourage investment in such facilities. The term "amortization" has been used with such write-off periods.

specific but limited market of 1200 units. For the purpose of allocating the patent right cost to production cost, what is the amortization rate in dollars per unit?

*Solution*

The patent should be amortized at the rate of

$$\frac{\$1,200,000}{1200 \text{ units}} = \$1000 \text{ per unit}$$

## 41. DEPLETION

*Depletion* is another artificial deductible operating expense, designed to compensate mining organizations for decreasing mineral reserves. Since original and remaining quantities of minerals are seldom known accurately, the *depletion allowance* is calculated as a fixed percentage of the organization's gross income. These percentages are usually in the 10–20% range and apply to such mineral deposits as oil, natural gas, coal, uranium, and most metal ores.

## 42. BASIC INCOME TAX CONSIDERATIONS

The issue of income taxes is often overlooked in academic engineering economic analysis exercises. Such a position is justifiable when an organization (e.g., a non-profit school, a church, or the government) pays no income taxes. However, if an individual or organization is subject to income taxes, the income taxes must be included in an economic analysis of investment alternatives.

Assume that an organization pays a fraction,  $f$ , of its profits to the federal government as income taxes. If the organization also pays a fraction  $s$  of its profits as state income taxes and if state taxes paid are recognized by the federal government as tax-deductible expenses, then the composite tax rate is

$$t = s + f - sf \quad 87.41$$

The basic principles used to incorporate taxation into engineering economic analyses are the following.

- Initial purchase expenditures are unaffected by income taxes.
- Salvage revenues are unaffected by income taxes.
- Deductible expenses, such as operating costs, maintenance costs, and interest payments, are reduced by the fraction  $t$  (i.e., multiplied by the quantity  $(1 - t)$ ).
- Revenues are reduced by the fraction  $t$  (i.e., multiplied by the quantity  $(1 - t)$ ).

- Since tax regulations allow the depreciation in any year to be handled as if it were an actual operating expense, and since operating expenses are deductible from the income base prior to taxation, the after-tax profits will be increased. If  $D$  is the depreciation, the net result to the after-tax cash flow will be the addition of  $tD$ . Depreciation is multiplied by  $t$  and added to the appropriate year's cash flow, increasing that year's present worth.

For simplicity, most engineering economics practice problems involving income taxes specify a single income tax rate. In practice, however, federal and most state tax rates depend on the income level. Each range of incomes and its associated tax rate are known as *income bracket* and *tax bracket*, respectively. For example, the state income tax rate might be 4% for incomes up to and including \$30,000, and 5% for incomes above \$30,000. The income tax for a taxpaying entity with an income of \$50,000 would have to be calculated in two parts.

$$\begin{aligned} \text{tax} &= (0.04)(\$30,000) + (0.05)(\$50,000 - \$30,000) \\ &= \$2200 \end{aligned}$$

Income taxes and depreciation have no bearing on municipal or governmental projects since municipalities, states, and the U.S. government pay no taxes.

### Example 87.20

A corporation that pays 53% of its profit in income taxes invests \$10,000 in an asset that will produce a \$3000 annual revenue for eight years. If the annual expenses are \$700, salvage after eight years is \$500, and 9% interest is used, what is the after-tax present worth? Disregard depreciation.

*Solution*

$$\begin{aligned} P &= -\$10,000 + (\$3000)(P/A, 9\%, 8)(1 - 0.53) \\ &\quad - (\$700)(P/A, 9\%, 8)(1 - 0.53) \\ &\quad + (\$500)(P/F, 9\%, 8) \\ &= -\$10,000 + (\$3000)(5.5348)(0.47) \\ &\quad - (\$700)(5.5348)(0.47) + (\$500)(0.5019) \\ &= -\$3766 \end{aligned}$$

### 43. TAXATION AT THE TIMES OF ASSET PURCHASE AND SALE

There are numerous rules and conventions that governmental tax codes and the accounting profession impose on organizations. Engineers are not normally expected to be aware of most of the rules and conventions, but

occasionally it may be necessary to incorporate their effects into an engineering economic analysis.

### Tax Credit

A *tax credit* (also known as an *investment tax credit* or *investment credit*) is a one-time credit against income taxes.<sup>31</sup> Therefore, it is added to the after-tax present worth as a last step in an engineering economic analysis. Such tax credits may be allowed by the government from time to time for equipment purchases, employment of various classes of workers, rehabilitation of historic landmarks, and so on.

A tax credit is usually calculated as a fraction of the initial purchase price or cost of an asset or activity.

$$\text{TC} = \text{fraction} \times \text{initial cost} \quad 87.42$$

When the tax credit is applicable, the fraction used is subject to legislation. A professional tax expert or accountant should be consulted prior to applying the tax credit concept to engineering economic analysis problems.

Since the investment tax credit reduces the buyer's tax liability, a tax credit should be included only in after-tax engineering economic analyses. The credit is assumed to be received at the end of the year.

### Gain or Loss on the Sale of a Depreciated Asset

If an asset that has been depreciated over a number of prior years is sold for more than its current book value, the difference between the book value and selling price is taxable income in the year of the sale. Alternatively, if the asset is sold for less than its current book value, the difference between the selling price and book value is an expense in the year of the sale.

### Example 87.21

One year, a company makes a \$5000 investment in a historic building. The investment is not depreciable, but it does qualify for a one-time 20% tax credit. In that same year, revenue is \$45,000 and expenses (exclusive of the \$5000 investment) are \$25,000. The company pays a total of 53% in income taxes. What is the after-tax present worth of this year's activities if the company's interest rate for investment is 10%?

*Solution*

The tax credit is

$$\text{TC} = (0.20)(\$5000) = \$1000$$

<sup>31</sup>Strictly, *tax credit* is the more general term, and applies to a credit for doing anything creditable. An *investment tax credit* requires an investment in something (usually real property or equipment).

This tax credit is assumed to be received at the end of the year. The after-tax present worth is

$$\begin{aligned} P &= -\$5000 + (\$45,000 - \$25,000)(1 - 0.53) \\ &\quad \times (P/F, 10\%, 1) + (\$1000)(P/F, 10\%, 1) \\ &= -\$5000 + (\$20,000)(0.47)(0.9091) \\ &\quad + (\$1000)(0.9091) \\ &= \$4455 \end{aligned}$$

#### 44. DEPRECIATION RECOVERY

The economic effect of depreciation is to reduce the income tax in year  $j$  by  $tD_j$ . The present worth of the asset is also affected: The present worth is increased by  $tD_j(P/F, i\%, j)$ . The after-tax present worth of all depreciation effects over the depreciation period of the asset is called the *depreciation recovery* (DR).<sup>32</sup>

$$DR = t \sum_{j=1}^n D_j(P/F, i\%, j) \quad 87.43$$

There are multiple ways depreciation can be calculated, as summarized in Table 87.5. *Straight-line* (SL) *depreciation recovery* from an asset is easily calculated, since the depreciation is the same each year. Assuming the asset has a constant depreciation of  $D$  and depreciation period of  $n$  years, the depreciation recovery is

$$DR = tD(P/A, i\%, n) \quad 87.44$$

$$D = \frac{C - S_n}{n} \quad 87.45$$

*Sum-of-the-years' digits depreciation recovery* is also relatively easily calculated, since the depreciation decreases uniformly each year.

$$DR = \left( \frac{t(C - S_n)}{T} \right) (n(P/A, i\%, n) - (P/G, i\%, n)) \quad 87.46$$

Finding *double declining balance* (DDB) *depreciation recovery* is more involved. There are three difficulties. The first (the apparent need to calculate all previous depreciations in order to determine the subsequent depreciation) has already been addressed by Eq. 87.32.

The second difficulty is that there is no way to ensure (that is, to force) the book value to be  $S_n$  at  $t = n$ . Therefore, it is common to write off the remaining book value (down to  $S_n$ ) at  $t = n$  in one lump sum. This assumes  $BV_n \geq S_n$ .

The third difficulty is that of finding the present worth of an *exponentially decreasing cash flow*. Although the

proof is omitted here, such exponential cash flows can be handled with the *exponential gradient factor*,  $(P/EG)$ .<sup>33</sup>

$$(P/EG, z - 1, n) = \frac{z^n - 1}{z^n(z - 1)} \quad 87.47$$

$$z = \frac{1+i}{1-d} \quad 87.48$$

Then, as long as  $BV_n > S_n$ , the declining balance depreciation recovery is

$$DR = tC \left( \frac{d}{1-d} \right) (P/EG, z - 1, n) \quad 87.49$$

#### Example 87.22

For the asset described in Ex. 87.17, calculate the after-tax depreciation recovery with straight line and sum-of-the-years' digits depreciation methods. Use 6% interest with 48% income taxes.

*Solution*

Using SL, the depreciation recovery is

$$\begin{aligned} DR &= (0.48)(\$880)(P/A, 6\%, 10) \\ &= (0.48)(\$880)(7.3601) \\ &= \$3109 \end{aligned}$$

Using SOYD, the depreciation series can be thought of as a constant \$1600 term with a negative \$160 gradient.

$$\begin{aligned} DR &= (0.48)(\$1600)(P/A, 6\%, 10) \\ &\quad - (0.48)(\$160)(P/G, 6\%, 10) \\ &= (0.48)(\$1600)(7.3601) \\ &\quad - (0.48)(\$160)(29.6023) \\ &= \$3379 \end{aligned}$$

The 10-year ( $P/G$ ) factor is used even though there are only nine years in which the gradient reduces the initial \$1600 amount.

#### Example 87.23

What is the after-tax present worth of the asset described in Ex. 87.20 if straight-line, sum-of-the-years' digits, and double declining balance depreciation methods are used?

*Solution*

Using SL, the depreciation recovery is

$$\begin{aligned} DR &= (0.53) \left( \frac{\$10,000 - \$500}{8} \right) (P/A, 9\%, 8) \\ &= (0.53) \left( \frac{\$9500}{8} \right) (5.5348) \\ &= \$3483 \end{aligned}$$

<sup>32</sup>Since the depreciation benefit is reduced by taxation, depreciation cannot be thought of as an annuity to fund a replacement asset.

<sup>33</sup>The ( $P/A$ ) columns in App. 87.B can be used for ( $P/EG$ ) as long as the interest rate is assumed to be  $z - 1$ .

**Table 87.5** Depreciation Calculation Summary

method	depreciation basis	depreciation in year $j$ , $D_j$	book value after $j$ th depreciation, $BV_j$	present worth of after-tax depreciation recovery, DR	supplementary formulas
straight line (SL)	$C - S_n$	$\frac{C - S_n}{n}$ (constant)	$C - jD$	$tD(P/A, i\%, n)$	
constant percentage	$C - S_n$	fraction $\times (C - S_n)$ (constant)	$C - jD$	$tD(P/A, i\%, n)$	
sum-of-the-years' digits (SOYD)	$C - S_n$	$\frac{(C - S_n)}{T} \times \left(1 - \frac{j(2n+1-j)}{n(n+1)}\right) + S_n$	$(C - S_n)$ $\times \left(1 - \frac{j(2n+1-j)}{n(n+1)}\right) + S_n$	$\frac{t(C - S_n)}{T} \times (n(P/A, i\%, n) - (P/G, i\%, n))$	$T = \frac{1}{2}n(n+1)$
double declining balance (DDB)	$C$	$dC(1-d)^{j-1}$	$C(1-d)^j$	$tC\left(\frac{d}{1-d}\right) \times (P/EG, z-1, n)$	$d = \frac{2}{n}; z = \frac{1+i}{1-d}$ $(P/EG, z-1, n) = \frac{z^n - 1}{z^n(z-1)}$
sinking fund (SF)	$C - S_n$	$\frac{(C - S_n)}{\times (A/F, i\%, n) \times (F/P, i\%, j-1)}$	$C - (C - S_n)$ $\times (A/F, i\%, n) \times (F/A, i\%, j)$	$\frac{t(C - S_n)(A/F, i\%, n)}{1+i}$	
accelerated cost recovery system (ACRS/MACRS)	$C$	$C \times \text{factor}$	$C - \sum_{m=1}^j D_m$	$t \sum_{j=1}^n D_j (P/F, i\%, j)$	
units of production or service output	$C - S_n$	$\frac{(C - S_n)}{\times \left( \frac{\text{actual output in year } j}{\text{lifetime output}} \right)}$	$C - \sum_{m=1}^j D_m$	$t \sum_{j=1}^n D_j (P/F, i\%, j)$	

Using SOYD, the depreciation recovery is calculated as follows.

$$T = \left(\frac{1}{2}\right)(8)(9) = 36$$

depreciation base = \$10,000 - \$500 = \$9500

$$D_1 = \left(\frac{8}{36}\right)(\$9500) = \$2111$$

$$G = \left(\frac{1}{36}\right)(\$9500) = \$264$$

$$\begin{aligned} DR &= (0.53) \left( (\$2111)(P/A, 9\%, 8) \right. \\ &\quad \left. - (\$264)(P/G, 9\%, 8) \right) \end{aligned}$$

$$\begin{aligned} &= (0.53) \left( (\$2111)(5.5348) \right. \\ &\quad \left. - (\$264)(16.8877) \right) \end{aligned}$$

$$= \$3830$$

Using DDB, the depreciation recovery is calculated as follows.<sup>34</sup>

$$d = \frac{2}{8} = 0.25$$

$$z = \frac{1+0.09}{1-0.25} = 1.4533$$

$$(P/EG, z-1, n) = \frac{(1.4533)^8 - 1}{(1.4533)^8(0.4533)} = 2.095$$

<sup>34</sup>This method should start by checking that the book value at the end of the depreciation period is greater than the salvage value. In this example, such is the case. However, the step is not shown.

From Eq. 87.49,

$$\begin{aligned} DR &= (0.53) \left( \frac{(0.25)(\$10,000)}{0.75} \right) (2.095) \\ &= \$3701 \end{aligned}$$

The after-tax present worth, neglecting depreciation, was previously found to be  $-\$3766$ .

The after-tax present worths, including depreciation recovery, are

$$SL: P = -\$3766 + \$3483 = -\$283$$

$$SOYD: P = -\$3766 + \$3830 = \$64$$

$$DDB: P = -\$3766 + \$3701 = -\$65$$

## 45. OTHER INTEREST RATES

The *effective interest rate per period*,  $i$  (also called *yield* by banks), is the only interest rate that should be used in equivalence equations. The interest rates at the top of the factor tables in App. 87.B are implicitly all effective interest rates. Usually, the period will be one year, hence the name *effective annual interest rate*. However, there are other interest rates in use as well.

The term *nominal interest rate*,  $r$  (*rate per annum*), is encountered when compounding is more than once per year. The nominal rate does not include the effect of compounding and is not the same as the effective rate. And, since the effective interest rate can be calculated from the nominal rate only if the number of compounding periods per year is known, nominal rates cannot be compared unless the method of compounding is specified. The only practical use for a nominal rate per year is for calculating the effective rate per period.

## 46. RATE AND PERIOD CHANGES

If there are  $k$  compounding periods during the year (two for semiannual compounding, four for quarterly compounding, twelve for monthly compounding, etc.) and the nominal rate is  $r$ , the *effective rate per compounding period* is

$$\phi = \frac{r}{k} \quad 87.50$$

The effective annual rate,  $i$ , can be calculated from the effective rate per period,  $\phi$ , by using Eq. 87.51.

$$\begin{aligned} i &= (1 + \phi)^k - 1 \\ &= \left(1 + \frac{r}{k}\right)^k - 1 \quad 87.51 \end{aligned}$$

Sometimes, only the effective rate per period (e.g., per month) is known. However, that will be a simple

problem since compounding for  $n$  periods at an effective rate per period is not affected by the definition or length of the period.

The following rules may be used to determine which interest rate is given.

- Unless specifically qualified, the interest rate given is an annual rate.
- If the compounding is annual, the rate given is the effective rate. If compounding is other than annual, the rate given is the nominal rate.

The effective annual interest rate determined on a *daily compounding basis* will not be significantly different than if *continuous compounding* is assumed.<sup>35</sup> In the case of continuous (or daily) compounding, the discounting factors can be calculated directly from the nominal interest rate and number of years, without having to find the effective interest rate per period. Table 87.6 can be used to determine the discount factors for continuous compounding.

**Table 87.6** Discount Factors for Continuous Compounding  
( $n$  is the number of years)

symbol	formula
$(F/P, r\%, n)$	$e^{rn}$
$(P/F, r\%, n)$	$e^{-rn}$
$(A/F, r\%, n)$	$\frac{e^r - 1}{e^{rn} - 1}$
$(F/A, r\%, n)$	$\frac{e^{rn} - 1}{e^r - 1}$
$(A/P, r\%, n)$	$\frac{e^r - 1}{1 - e^{-rn}}$
$(P/A, r\%, n)$	$\frac{1 - e^{-rn}}{e^r - 1}$

### Example 87.24

A savings and loan offers a nominal rate of 5.25% compounded daily over 365 days in a year. What is the effective annual rate?

*Solution*

*method 1:* Use Eq. 87.51.

$$r = 0.0525, k = 365$$

$$i = \left(1 + \frac{r}{k}\right)^k - 1 = \left(1 + \frac{0.0525}{365}\right)^{365} - 1 = 0.0539$$

<sup>35</sup>The number of *banking days in a year* (250, 360, etc.) must be specifically known.

*method 2:* Assume daily compounding is the same as continuous compounding.

$$\begin{aligned} i &= (F/P, r\%, 1) - 1 \\ &= e^{0.0525} - 1 \\ &= 0.0539 \end{aligned}$$

### Example 87.25

A real estate investment trust pays \$7,000,000 for an apartment complex with 100 units. The trust expects to sell the complex in 10 years for \$15,000,000. In the meantime, it expects to receive an average rent of \$900 per month from each apartment. Operating expenses are expected to be \$200 per month per occupied apartment. A 95% occupancy rate is predicted. In similar investments, the trust has realized a 15% effective annual return on its investment. Compare to those past investments the expected present worth of this investment when calculated assuming (a) annual compounding (i.e., the year-end convention), and (b) monthly compounding. Disregard taxes, depreciation, and all other factors.

*Solution*

(a) The net annual income will be

$$\begin{aligned} (0.95)(100 \text{ units}) \left( \frac{\$900}{\text{unit-mo}} - \frac{\$200}{\text{unit-mo}} \right) \left( 12 \frac{\text{mo}}{\text{yr}} \right) \\ = \$798,000/\text{yr} \end{aligned}$$

The present worth of 10 years of operation is

$$\begin{aligned} P &= -\$7,000,000 + (\$798,000)(P/A, 15\%, 10) \\ &\quad + (\$15,000,000)(P/F, 15\%, 10) \\ &= -\$7,000,000 + (\$798,000)(5.0188) \\ &\quad + (\$15,000,000)(0.2472) \\ &= \$713,000 \end{aligned}$$

(b) The net monthly income is

$$\begin{aligned} (0.95)(100 \text{ units}) \left( \frac{\$900}{\text{unit-mo}} - \frac{\$200}{\text{unit-mo}} \right) \\ = \$66,500/\text{mo} \end{aligned}$$

Equation 87.51 is used to calculate the effective monthly rate,  $\phi$ , from the effective annual rate,  $i = 15\%$ , and the number of compounding periods per year,  $k = 12$ .

$$\begin{aligned} \phi &= (1 + i)^{1/k} - 1 \\ &= (1 + 0.15)^{1/12} - 1 \\ &= 0.011715 \quad (1.1715\%) \end{aligned}$$

The number of compounding periods in 10 years is

$$n = (10 \text{ yr}) \left( 12 \frac{\text{mo}}{\text{yr}} \right) = 120 \text{ mo}$$

The present worth of 120 months of operation is

$$\begin{aligned} P &= -\$7,000,000 + (\$66,500)(P/A, 1.1715\%, 120) \\ &\quad + (\$15,000,000)(P/F, 1.1715\%, 120) \end{aligned}$$

Since table values for 1.1715% discounting factors are not available, the factors are calculated from Table 87.1.

$$\begin{aligned} (P/A, 1.1715\%, 120) &= \frac{(1 + i)^n - 1}{i(1 + i)^n} \\ &= \frac{(1 + 0.011715)^{120} - 1}{(0.011715)(1 + 0.011715)^{120}} \\ &= 64.261 \end{aligned}$$

$$\begin{aligned} (P/F, 1.1715\%, 120) &= (1 + i)^{-n} = (1 + 0.011715)^{-120} \\ &= 0.2472 \end{aligned}$$

The present worth over 120 monthly compounding periods is

$$\begin{aligned} P &= -\$7,000,000 + (\$66,500)(64.261) \\ &\quad + (\$15,000,000)(0.2472) \\ &= \$981,357 \end{aligned}$$

## 47. BONDS

A *bond* is a method of long-term financing commonly used by governments, states, municipalities, and very large corporations.<sup>36</sup> The bond represents a contract to pay the bondholder specific amounts of money at specific times. The holder purchases the bond in exchange for specific payments of interest and principal. Typical municipal bonds call for quarterly or semiannual interest payments and a payment of the *face value of the bond* on the *date of maturity* (end of the bond period).<sup>37</sup> Due to the practice of discounting in the bond market, a bond's face value and its purchase price generally will not coincide.

In the past, a bondholder had to submit a coupon or ticket in order to receive an interim interest payment. This has given rise to the term *coupon rate*, which is the nominal annual interest rate on which the interest payments are made. Coupon books are seldom used with modern bonds, but the term survives. The coupon rate determines the magnitude of the semiannual (or otherwise) interest payments during the life of the bond.

<sup>36</sup>In the past, 30-year bonds were typical. Shorter term 10-year, 15-year, 20-year, and 25-year bonds are also commonly issued.

<sup>37</sup>A *fully amortized bond* pays back interest and principal throughout the life of the bond. There is no balloon payment.

The bondholder's own effective interest rate should be used for economic decisions about the bond.

Actual *bond yield* is the bondholder's actual rate of return of the bond, considering the purchase price, interest payments, and face value payment (or, value realized if the bond is sold before it matures). By convention, bond yield is calculated as a nominal rate (rate per annum), not an effective rate per year. The bond yield should be determined by finding the effective rate of return per payment period (e.g., per semiannual interest payment) as a conventional rate of return problem. Then, the nominal rate can be found by multiplying the effective rate per period by the number of payments per year, as in Eq. 87.51.

### Example 87.26

What is the maximum amount an investor should pay for a 25-year bond with a \$20,000 face value and 8% coupon rate (interest only paid semiannually)? The bond will be kept to maturity. The investor's effective annual interest rate for economic decisions is 10%.

*Solution*

For this problem, take the compounding period to be six months. Then, there are 50 compounding periods. Since 8% is a nominal rate, the effective bond rate per period is calculated from Eq. 87.50 as

$$\phi_{\text{bond}} = \frac{r}{k} = \frac{8\%}{2} = 4\%$$

The bond payment received semiannually is

$$(0.04)(\$20,000) = \$800$$

10% is the investor's effective rate per year, so Eq. 87.51 is again used to calculate the effective analysis rate per period.

$$\begin{aligned} 0.10 &= (1 + \phi)^2 - 1 \\ \phi &= 0.04881 \quad (4.88\%) \end{aligned}$$

The maximum amount that the investor should be willing to pay is the present worth of the investment.

$$\begin{aligned} P &= (\$800)(P/A, 4.88\%, 50) \\ &\quad + (\$20,000)(P/F, 4.88\%, 50) \end{aligned}$$

Table 87.1 can be used to calculate the following factors.

$$\begin{aligned} (P/A, 4.88\%, 50) &= \frac{(1 + i)^n - 1}{i(1 + i)^n} \\ &= \frac{(1 + 0.0488)^{50} - 1}{(0.0488)(1.0488)^{50}} \\ &= 18.600 \end{aligned}$$

$$\begin{aligned} (P/F, 4.88\%, 50) &= \frac{1}{(1 + i)^n} \\ &= \frac{1}{(1 + 0.0488)^{50}} \\ &= 0.09233 \end{aligned}$$

Then, the present worth is

$$\begin{aligned} P &= (\$800)(18.600) + (\$20,000)(0.09233) \\ &= \$16,727 \end{aligned}$$

### 48. PROBABILISTIC PROBLEMS

If an alternative's cash flows are specified by an implicit or explicit probability distribution rather than being known exactly, the problem is *probabilistic*.

Probabilistic problems typically possess the following characteristics.

- There is a chance of loss that must be minimized (or, rarely, a chance of gain that must be maximized) by selection of one of the alternatives.
- There are multiple alternatives. Each alternative offers a different degree of protection from the loss. Usually, the alternatives with the greatest protection will be the most expensive.
- The magnitude of loss or gain is independent of the alternative selected.

Probabilistic problems are typically solved using annual costs and expected values. An *expected value* is similar to an *average value* since it is calculated as the mean of the given probability distribution. If cost 1 has a probability of occurrence,  $p_1$ , cost 2 has a probability of occurrence,  $p_2$ , and so on, the expected value is

$$\mathcal{E}\{\text{cost}\} = p_1(\text{cost } 1) + p_2(\text{cost } 2) + \dots \quad 87.52$$

### Example 87.27

Flood damage in any year is given according to the following table. What is the present worth of flood damage for a 10-year period? Use 6% as the effective annual interest rate.

damage	probability
0	0.75
\$10,000	0.20
\$20,000	0.04
\$30,000	0.01

*Solution*

The expected value of flood damage in any given year is

$$\begin{aligned} \mathcal{E}\{\text{damage}\} &= (0)(0.75) + (\$10,000)(0.20) \\ &\quad + (\$20,000)(0.04) + (\$30,000)(0.01) \\ &= \$3100 \end{aligned}$$

The present worth of 10 years of expected flood damage is

$$\begin{aligned}\text{present worth} &= (\$3100)(P/A, 6\%, 10) \\ &= (\$3100)(7.3601) \\ &= \$22,816\end{aligned}$$

### Example 87.28

A dam is being considered on a river that periodically overflows and causes \$600,000 damage. The damage is essentially the same each time the river causes flooding. The project horizon is 40 years. A 10% interest rate is being used.

Three different designs are available, each with different costs and storage capacities.

design alternative	cost	maximum capacity
A	\$500,000	1 unit
B	\$625,000	1.5 units
C	\$900,000	2.0 units

The National Weather Service has provided a statistical analysis of annual rainfall runoff from the watershed draining into the river.

annual rainfall	probability
0	0.10
0.1–0.5	0.60
0.6–1.0	0.15
1.1–1.5	0.10
1.6–2.0	0.04
2.1 or more	0.01

Which design alternative would you choose assuming the dam is essentially empty at the start of each rainfall season?

### Solution

The sum of the construction cost and the expected damage should be minimized. If alternative A is chosen, it will have a capacity of 1 unit. Its capacity will be exceeded (causing \$600,000 damage) when the annual rainfall exceeds 1 unit. Therefore, the expected value of the annual cost of alternative A is

$$\begin{aligned}\mathcal{E}\{\text{EUAC(A)}\} &= (\$500,000)(A/P, 10\%, 40) \\ &\quad + (\$600,000)(0.10 + 0.04 + 0.01) \\ &= (\$500,000)(0.1023) + (\$600,000)(0.15) \\ &= \$141,150\end{aligned}$$

Similarly,

$$\begin{aligned}\mathcal{E}\{\text{EUAC(B)}\} &= (\$625,000)(A/P, 10\%, 40) \\ &\quad + (\$600,000)(0.04 + 0.01) \\ &= (\$625,000)(0.1023) + (\$600,000)(0.05) \\ &= \$93,938\end{aligned}$$

$$\begin{aligned}\mathcal{E}\{\text{EUAC(C)}\} &= (\$900,000)(A/P, 10\%, 40) \\ &\quad + (\$600,000)(0.01) \\ &= (\$900,000)(0.1023) + (\$600,000)(0.01) \\ &= \$98,070\end{aligned}$$

Alternative B should be chosen.

### 49. WEIGHTED COSTS

The reliability of preliminary cost estimates can be increased by considering as much historical data as possible. For example, the cost of finishing a concrete slab when the contractor has not yet been selected should be estimated from actual recent costs from as many local jobs as is practical. Most jobs are not directly comparable, however, because they differ in size or in some other characteristic. A *weighted cost* (*weighted average cost*) is a cost that has been averaged over some rational basis. The weighted cost is calculated by weighting the individual cost elements,  $C_i$ , by their respective weights,  $w_i$ . Respective weights are usually *relative fractions* (*relative importance*) based on other characteristics, such as length, area, number of units, frequency of occurrence, points, etc.

$$C_{\text{weighted}} = w_1 C_1 + w_2 C_2 + \cdots + w_N C_N \quad 87.53$$

$$w_j = \frac{A_j}{\sum_{i=1}^N A_i} \quad [\text{weighting by area}] \quad 87.54$$

It is implicit in calculating weighted average costs that the costs with the largest weights are more important to the calculation. For example, costs from a job of 10,000 ft<sup>2</sup> are considered to be twice as reliable (important, relevant, etc.) as costs from a 5000 ft<sup>2</sup> job. This assumption must be carefully considered.

Determining a weighted average from Eq. 87.53 disregards the fixed and variable natures of costs. In effect, fixed costs are allocated over entire jobs, increasing the apparent variable costs. For that reason, it is important to include in the calculation only costs of similar cases. This requires common sense segregation of the initial cost data. For example, it is probably not appropriate to include very large (e.g., supermarket and mall) concrete finishing job costs in the calculation of a weighted average cost used to estimate residential slab finishing costs.

### Example 87.29

Calculate a weighted average cost per unit length of concrete wall to be used for estimating future job costs. Data from three similar walls are available.

- wall 1: length, 50 ft; actual cost, \$9000
- wall 2: length, 90 ft; actual cost, \$15,000
- wall 3: length, 65 ft; actual cost, \$11,000

**Solution**

Consider wall 1. The cost per foot of wall is \$9000/50 ft. According to Eq. 87.54, accuracy of cost data is proportional to wall length (i.e., cost per foot from a wall of length  $2X$  is twice as reliable as cost per foot from a wall of length  $X$ ). This cost per foot value is given a weight of  $50 \text{ ft}/(50 \text{ ft} + 90 \text{ ft} + 65 \text{ ft})$ . So, the weighted cost per foot for wall 1 is

$$w_1 C_{\text{ft},1} = \frac{(50 \text{ ft}) \left( \frac{\$9000}{50 \text{ ft}} \right)}{50 \text{ ft} + 90 \text{ ft} + 65 \text{ ft}} = \frac{\$9000}{50 \text{ ft} + 90 \text{ ft} + 65 \text{ ft}}$$

Similarly, the weighted cost per foot for wall 2 is  $w_2 C_{\text{ft},2} = \$15,000/(50 \text{ ft} + 90 \text{ ft} + 65 \text{ ft})$ , and the weighted cost per foot for wall 3 is  $w_3 C_{\text{ft},3} = \$11,000/(50 \text{ ft} + 90 \text{ ft} + 65 \text{ ft})$ .

From Eq. 87.53, the total weighted cost per foot is

$$\begin{aligned} C_{\text{ft}} &= w_1 C_{\text{ft},1} + w_2 C_{\text{ft},2} + w_3 C_{\text{ft},3} \\ &= \frac{\$9000 + \$15,000 + \$11,000}{50 \text{ ft} + 90 \text{ ft} + 65 \text{ ft}} \\ &= \$170.73 \text{ per foot} \end{aligned}$$

## 50. FIXED AND VARIABLE COSTS

The distinction between fixed and variable costs depends on how these costs vary when an independent variable changes. For example, factory or machine production is frequently the independent variable. However, it could just as easily be vehicle miles driven, hours of operation, or quantity (mass, volume, etc.). Examples of fixed and variable costs are given in Table 87.7.

If a cost is a function of the independent variable, the cost is said to be a *variable cost*. The change in cost per unit variable change (i.e., what is usually called the *slope*) is known as the *incremental cost*. Material and labor costs are examples of variable costs. They increase in proportion to the number of product units manufactured.

If a cost is not a function of the independent variable, the cost is said to be a *fixed cost*. Rent and lease payments are typical fixed costs. These costs will be incurred regardless of production levels.

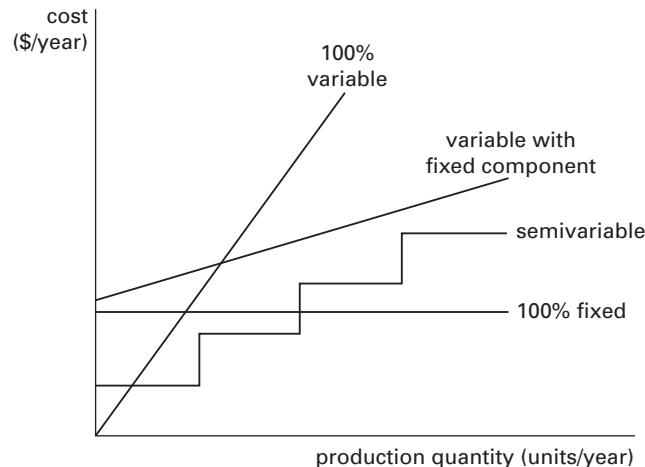

Some costs have both fixed and variable components, as Fig. 87.9 illustrates. The fixed portion can be determined by calculating the cost at zero production.

An additional category of cost is the *semivariable cost*. This type of cost increases stepwise. Semivariable cost structures are typical of situations where *excess capacity* exists. For example, supervisory cost is a stepwise function of the number of production shifts. Also, labor cost for truck drivers is a stepwise function of weight

**Table 87.7** Summary of Fixed and Variable Costs

<i>fixed costs</i>
rent
property taxes
interest on loans
insurance
janitorial service expense
tooling expense
setup, cleanup, and tear-down expenses
depreciation expense
marketing and selling costs
cost of utilities
general burden and overhead expense
<i>variable costs</i>
direct material costs
direct labor costs
cost of miscellaneous supplies
payroll benefit costs
income taxes
supervision costs

**Figure 87.9** Fixed and Variable Costs

(volume) transported. As long as a truck has room left (i.e., excess capacity), no additional driver is needed. As soon as the truck is filled, labor cost will increase.

## 51. ACCOUNTING COSTS AND EXPENSE TERMS

The accounting profession has developed special terms for certain groups of costs. When annual costs are incurred due to the functioning of a piece of equipment, they are known as *operating and maintenance* (O&M) *costs*. The annual costs associated with operating a business (other than the costs directly attributable to production) are known as *general, selling, and administrative* (GS&A) *expenses*.

*Direct labor costs* are costs incurred in the factory, such as assembly, machining, and painting labor costs. *Direct material costs* are the costs of all materials that go into

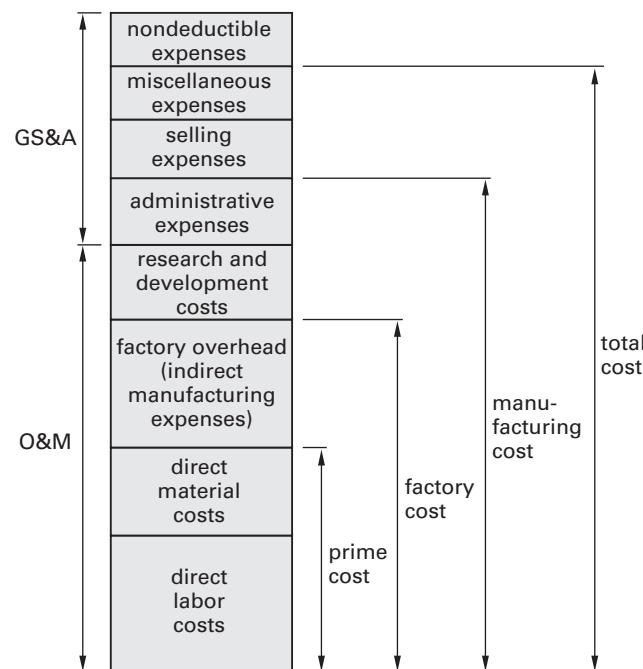

production.<sup>38</sup> Typically, both direct labor and direct material costs are given on a per-unit or per-item basis. The sum of the direct labor and direct material costs is known as the *prime cost*.

There are certain additional expenses incurred in the factory, such as the costs of factory supervision, stock-picking, quality control, factory utilities, and miscellaneous supplies (cleaning fluids, assembly lubricants, routing tags, etc.) that are not incorporated into the final product. Such costs are known as *indirect manufacturing expenses* (IME) or *indirect material and labor costs*.<sup>39</sup> The sum of the per-unit indirect manufacturing expense and prime cost is known as the *factory cost*.

*Research and development (R&D) costs* and *administrative expenses* are added to the factory cost to give the *manufacturing cost* of the product.

Additional costs are incurred in marketing the product. Such costs are known as *selling expenses* or *marketing expenses*. The sum of the selling expenses and manufacturing cost is the *total cost* of the product. Figure 87.10 illustrates these terms.<sup>40</sup>

**Figure 87.10** Costs and Expenses Combined

The distinctions among the various forms of cost (particularly with overhead costs) are not standardized. Each company must develop a classification system to deal with the various cost factors in a consistent manner. There are also other terms in use (e.g., *raw*

<sup>38</sup>There may be problems with pricing the material when it is purchased from an outside vendor and the stock on hand derives from several shipments purchased at different prices.

<sup>39</sup>The *indirect material and labor costs* usually exclude costs incurred in the office area.

<sup>40</sup>Total cost does not include income taxes.

*materials, operating supplies, general plant overhead*), but these terms must be interpreted within the framework of each company's classification system. Table 87.8 is typical of such classification systems.

## 52. ACCOUNTING PRINCIPLES

### Basic Bookkeeping

An accounting or *bookkeeping system* is used to record historical financial transactions. The resultant records are used for product costing, satisfaction of statutory requirements, reporting of profit for income tax purposes, and general company management.

Bookkeeping consists of two main steps: recording the transactions, followed by categorization of the transactions.<sup>41</sup> The transactions (receipts and disbursements) are recorded in a *journal (book of original entry)* to complete the first step. Such a journal is organized in a simple chronological and sequential manner. The transactions are then categorized (into interest income, advertising expense, etc.) and posted (i.e., entered or written) into the appropriate *ledger account*.<sup>42</sup>

The ledger accounts together constitute the *general ledger* or *ledger*. All ledger accounts can be classified into one of three types: *asset accounts*, *liability accounts*, and *owners' equity accounts*. Strictly speaking, income and expense accounts, kept in a separate journal, are included within the classification of owners' equity accounts.

Together, the journal and ledger are known simply as "the books" of the company, regardless of whether bound volumes of pages are actually involved.

### Balancing the Books

In a business environment, *balancing the books* means more than reconciling the checkbook and bank statements. All accounting entries must be posted in such a way as to maintain the equality of the *basic accounting equation*,

$$\text{assets} = \text{liability} + \text{owner's equity} \quad 87.55$$

In a *double-entry bookkeeping system*, the equality is maintained within the ledger system by entering each transaction into two balancing ledger accounts. For example, paying a utility bill would decrease the cash account (an asset account) and decrease the utility expense account (a liability account) by the same amount.

<sup>41</sup>These two steps are not to be confused with the *double-entry bookkeeping method*.

<sup>42</sup>The two-step process is more typical of a *manual bookkeeping system* than a computerized *general ledger system*. However, even most computerized systems produce reports in journal entry order, as well as account summaries.

Transactions are either *debits* or *credits*, depending on their sign. Increases in asset accounts are debits; decreases are credits. For liability and equity accounts, the opposite is true: Increases are credits, and decreases are debits.<sup>43</sup>

### Cash and Accrual Systems<sup>44</sup>

The simplest form of bookkeeping is based on the *cash system*. The only transactions that are entered into the journal are those that represent cash receipts and disbursements. In effect, a checkbook register or bank deposit book could serve as the journal.

During a given period (e.g., month or quarter), expense liabilities may be incurred even though the payments for those expenses have not been made. For example, an invoice (bill) may have been received but not paid. Under the *accrual system*, the obligation is posted into the appropriate expense account before it is paid.<sup>45</sup> Analogous to expenses, under the accrual system, income will be claimed before payment is received. Specifically, a sales transaction can be recorded as income when the customer's order is received, when the outgoing invoice is generated, or when the merchandise is shipped.

### Financial Statements

Each period, two types of corporate financial statements are typically generated: the *balance sheet* and *profit and loss (P&L) statement*.<sup>46</sup> The profit and loss statement, also known as a *statement of income and retained earnings*, is a summary of sources of *income* or *revenue* (interest, sales, fees charged, etc.) and *expenses* (utilities, advertising, repairs, etc.) for the period. The expenses are subtracted from the revenues to give a *net income* (generally, before taxes).<sup>47</sup> Figure 87.11 illustrates a simplified profit and loss statement.

The *balance sheet* presents the *basic accounting equation* in tabular form. The balance sheet lists the major

<sup>43</sup>There is a difference in sign between asset and liability accounts. An increase in an expense account is actually a decrease. The accounting profession, apparently, is comfortable with the common confusion that exists between debits and credits.

<sup>44</sup>There is also a distinction made between cash flows that are known and those that are expected. It is a *standard accounting principle* to record losses in full, at the time they are recognized, even before their occurrence. In the construction industry, for example, losses are recognized in full and projected to the end of a project as soon as they are foreseeable. Profits, on the other hand, are recognized only as they are realized (typically, as a percentage of project completion). The difference between cash and accrual systems is a matter of *bookkeeping*. The difference between loss and profit recognition is a matter of *accounting convention*. Engineers seldom need to be concerned with the accounting tradition.

<sup>45</sup>The expense for an item or service might be accrued even *before* the invoice is received. It might be recorded when the purchase order for the item or service is generated, or when the item or service is received.

<sup>46</sup>Other types of financial statements (*statements of changes in financial position*, *cost of sales statements*, inventory and asset reports, etc.) also will be generated, depending on the needs of the company.

<sup>47</sup>Financial statements also can be prepared with percentages (of total assets and net revenue) instead of dollars, in which case they are known as *common size financial statements*.

**Table 87.8** Typical Classification of Expenses

<i>direct labor expenses</i>
machining and forming
assembly
finishing
inspection
testing
<i>direct material expenses</i>
items purchased from other vendors
manufactured assemblies
<i>factory overhead expenses (indirect manufacturing expenses)</i>
supervision
benefits
pension
medical insurance
vacations
wages overhead
unemployment compensation taxes
social security taxes
disability taxes
stock-picking
quality control and inspection
expediting
rework
maintenance
miscellaneous supplies
routing tags
assembly lubricants
cleaning fluids
wiping cloths
janitorial supplies
packaging (materials and labor)
factory utilities
laboratory
depreciation on factory equipment
<i>research and development expenses</i>
engineering (labor)
patents
testing
prototypes (material and labor)
drafting
O&M of R&D facility
<i>administrative expenses</i>
corporate officers
accounting
secretarial/clerical/reception
security (protection)
medical (nurse)
employment (personnel)
reproduction
data processing
production control
depreciation on nonfactory equipment
office supplies
office utilities
O&M of offices
<i>selling expenses</i>
marketing (labor)
advertising
transportation (if not paid by customer)
outside sales force (labor and expenses)
demonstration units
commissions
technical service and support
order processing
branch office expenses
<i>miscellaneous expenses</i>
insurance
property taxes
interest on loans
<i>nondeductible expenses</i>
federal income taxes
fines and penalties

categories of assets and outstanding liabilities. The difference between asset values and liabilities is the *equity*, as defined in Eq. 87.55. This equity represents what would be left over after satisfying all debts by liquidating the company.

Figure 87.12 is a simplified balance sheet.

**Figure 87.11** Simplified Profit and Loss Statement

<i>revenue</i>	
interest	2000
sales	237,000
returns	(23,000)
<b>net revenue</b>	<b>216,000</b>
<i>expenses</i>	
salaries	149,000
utilities	6000
advertising	28,000
insurance	4000
supplies	1000
<b>net expenses</b>	<b>188,000</b>
<i>period net income</i>	<b>28,000</b>
<i>beginning retained earnings</i>	<b>63,000</b>

**Figure 87.12** Simplified Balance Sheet

<b>ASSETS</b>	
<i>current assets</i>	
cash	14,000
accounts receivable	36,000
notes receivable	20,000
inventory	89,000
prepaid expenses	3000
<b>total current assets</b>	<b>162,000</b>
<i>plant, property, and equipment</i>	
land and buildings	217,000
motor vehicles	31,000
equipment	94,000
accumulated depreciation	(52,000)
<b>total fixed assets</b>	<b>290,000</b>
<b>total assets</b>	<b>452,000</b>
<b>LIABILITIES AND OWNERS' EQUITY</b>	
<i>current liabilities</i>	
accounts payable	66,000
accrued income taxes	17,000
accrued expenses	8000
<b>total current liabilities</b>	<b>91,000</b>
<i>long-term debt</i>	
notes payable	117,000
mortgage	23,000
<b>total long-term debt</b>	<b>140,000</b>
<i>owners' and stockholders' equity</i>	
stock	130,000
retained earnings	91,000
<b>total owners' equity</b>	<b>221,000</b>
<b>total liabilities and owners' equity</b>	<b>452,000</b>

There are several terms that appear regularly on balance sheets.

- *current assets*: cash and other assets that can be converted quickly into cash, such as accounts receivable, notes receivable, and merchandise (inventory). Also known as *liquid assets*.
- *fixed assets*: relatively permanent assets used in the operation of the business and relatively difficult to convert into cash. Examples are land, buildings, and equipment. Also known as *nonliquid assets*.
- *current liabilities*: liabilities due within a short period of time (e.g., within one year) and typically paid out of current assets. Examples are accounts payable, notes payable, and other accrued liabilities.
- *long-term liabilities*: obligations that are not totally payable within a short period of time (e.g., within one year).

### Analysis of Financial Statements

Financial statements are evaluated by management, lenders, stockholders, potential investors, and many other groups for the purpose of determining the *health of the company*. The health can be measured in terms of *liquidity* (ability to convert assets to cash quickly), *solvency* (ability to meet debts as they become due), and *relative risk* (of which one measure is *leverage*—the portion of total capital contributed by owners).

The analysis of financial statements involves several common ratios, usually expressed as percentages. The following are some frequently encountered ratios.

- *current ratio*: an index of short-term paying ability.

$$\text{current ratio} = \frac{\text{current assets}}{\text{current liabilities}} \quad 87.56$$

- *quick (or acid-test) ratio*: a more stringent measure of short-term debt-paying ability. The *quick assets* are defined to be current assets minus inventories and prepaid expenses.

$$\text{quick ratio} = \frac{\text{quick assets}}{\text{current liabilities}} \quad 87.57$$

- *receivable turnover*: a measure of the average speed with which accounts receivable are collected.

$$\text{receivable turnover} = \frac{\text{net credit sales}}{\text{average net receivables}} \quad 87.58$$

- *average age of receivables*: number of days, on the average, in which receivables are collected.

$$\text{average age of receivables} = \frac{365}{\text{receivable turnover}} \quad 87.59$$

- *inventory turnover*: a measure of the speed with which inventory is sold, on the average.

$$\text{inventory turnover} = \frac{\text{cost of goods sold}}{\text{average cost of inventory on hand}} \quad 87.60$$

- *days supply of inventory on hand*: number of days, on the average, that the current inventory would last.

$$\text{days supply of inventory on hand} = \frac{365}{\text{inventory turnover}} \quad 87.61$$

- *book value per share of common stock*: number of dollars represented by the balance sheet owners' equity for each share of common stock outstanding.

$$\begin{aligned} &\text{book value per share of common stock} \\ &= \frac{\text{common shareholders' equity}}{\text{number of outstanding shares}} \quad 87.62 \end{aligned}$$

- *gross margin*: gross profit as a percentage of sales. (Gross profit is sales less cost of goods sold.)

$$\text{gross margin} = \frac{\text{gross profit}}{\text{net sales}} \quad 87.63$$

- *profit margin ratio*: percentage of each dollar of sales that is net income.

$$\text{profit margin} = \frac{\text{net income before taxes}}{\text{net sales}} \quad 87.64$$

- *return on investment ratio*: shows the percent return on owners' investment.

$$\text{return on investment} = \frac{\text{net income}}{\text{owners' equity}} \quad 87.65$$

- *price-earnings ratio*: indication of relationship between earnings and market price per share of common stock, useful in comparisons between alternative investments.

$$\text{price-earnings} = \frac{\text{market price per share}}{\text{earnings per share}} \quad 87.66$$

## 53. COST ACCOUNTING

*Cost accounting* is the system that determines the cost of manufactured products. Cost accounting is called *job cost accounting* if costs are accumulated by part number or contract. It is called *process cost accounting* if costs are accumulated by departments or manufacturing processes.

Cost accounting is dependent on historical and recorded data. The unit product cost is determined from actual expenses and numbers of units produced. Allowances (i.e., budgets) for future costs are based on these historical figures. Any deviation from historical figures is called a *variance*. Where adequate records are available,

variances can be divided into *labor variance* and *material variance*.

When determining a unit product cost, the direct material and direct labor costs are generally clear-cut and easily determined. Furthermore, these costs are 100% variable costs. However, the indirect cost per unit of product is not as easily determined. Indirect costs (*burden, overhead, etc.*) can be fixed or semivariable costs. The amount of indirect cost allocated to a unit will depend on the unknown future overhead expense as well as the unknown future production (*vehicle size*).

A typical method of allocating indirect costs to a product is as follows.

*step 1:* Estimate the total expected indirect (and overhead) costs for the upcoming year.

*step 2:* Determine the most appropriate vehicle (basis) for allocating the overhead to production. Usually, this vehicle is either the number of units expected to be produced or the number of direct hours expected to be worked in the upcoming year.

*step 3:* Estimate the quantity or size of the overhead vehicle.

*step 4:* Divide expected overhead costs by the expected overhead vehicle to obtain the unit overhead.

*step 5:* Regardless of the true size of the overhead vehicle during the upcoming year, one unit of overhead cost is allocated per unit of overhead vehicle.

Once the prime cost has been determined and the indirect cost calculated based on projections, the two are combined into a *standard factory cost* or *standard cost*, which remains in effect until the next budgeting period (usually a year).

During the subsequent manufacturing year, the standard cost of a product is not generally changed merely because it is found that an error in projected indirect costs or production quantity (vehicle size) has been made. The allocation of indirect costs to a product is assumed to be independent of errors in forecasts. Rather, the difference between the expected and actual expenses, known as the *burden (overhead) variance*, experienced during the year is posted to one or more *variance accounts*.

Burden (overhead) variance is caused by errors in forecasting both the actual indirect expense for the upcoming year and the overhead vehicle size. In the former case, the variance is called *burden budget variance*; in the latter, it is called *burden capacity variance*.

### Example 87.30

A company expects to produce 8000 items in the coming year. The current material cost is \$4.54 each. Sixteen minutes of direct labor are required per unit. Workers are paid \$7.50 per hour. 2133 direct labor hours are

forecasted for the product. Miscellaneous overhead costs are estimated at \$45,000.

Find the per-unit (a) expected direct material cost, (b) direct labor cost, (c) prime cost, (d) burden as a function of production and direct labor, and (e) total cost.

#### *Solution*

(a) The direct material cost was given as \$4.54.

(b) The direct labor cost is

$$\left( \frac{16 \text{ min}}{60 \frac{\text{min}}{\text{hr}}} \right) \left( \$7.50 \frac{\text{hr}}{\text{min}} \right) = \$2.00$$

(c) The prime cost is

$$\$4.54 + \$2.00 = \$6.54$$

(d) If the burden vehicle is production, the burden rate is  $\$45,000/8000 = \$5.63$  per item.

If the burden vehicle is direct labor hours, the burden rate is  $\$45,000/2133 = \$21.10$  per hour.

(e) If the burden vehicle is production, the total cost is

$$\$4.54 + \$2.00 + \$5.63 = \$12.17$$

If the burden vehicle is direct labor hours, the total cost is

$$\$4.54 + \$2.00 + \left( \frac{16 \text{ min}}{60 \frac{\text{min}}{\text{hr}}} \right) \left( \$21.10 \frac{\text{hr}}{\text{min}} \right) = \$12.17$$

#### **Example 87.31**

The actual performance of the company in Ex. 87.30 is given by the following figures.

actual production: 7560

actual overhead costs: \$47,000

What are the burden budget variance and the burden capacity variance?

#### *Solution*

The burden capacity variance is

$$\$45,000 - (7560)(\$5.63) = \$2437$$

The burden budget variance is

$$\$47,000 - \$45,000 = \$2000$$

The overall burden variance is

$$\$47,000 - (7560)(\$5.63) = \$4437$$

The sum of the burden capacity and burden budget variances should equal the overall burden variance.

$$\$2437 + \$2000 = \$4437$$

#### **54. COST OF GOODS SOLD**

*Cost of goods sold* (COGS) is an accounting term that represents an inventory account adjustment.<sup>48</sup> Cost of goods sold is the difference between the starting and ending inventory valuations. That is,

$$\begin{aligned} \text{COGS} &= \text{starting inventory valuation} \\ &\quad - \text{ending inventory valuation} \end{aligned} \quad 87.67$$

Cost of goods sold is subtracted from *gross profit* to determine the *net profit* of a company. Despite the fact that cost of goods sold can be a significant element in the profit equation, the inventory adjustment may not be made each accounting period (e.g., each month) due to the difficulty in obtaining an accurate inventory valuation.

With a *perpetual inventory system*, a company automatically maintains up-to-date inventory records, either through an efficient stocking and stock-releasing system or through a *point of sale (POS) system* integrated with the inventory records. If a company only counts its inventory (i.e., takes a *physical inventory*) at regular intervals (e.g., once a year), it is said to be operating on a *periodic inventory system*.

Inventory accounting is a source of many difficulties. The inventory value is calculated by multiplying the quantity on hand by the standard cost. In the case of completed items actually assembled or manufactured at the company, this standard cost usually is the manufacturing cost, although factory cost also can be used. In the case of purchased items, the standard cost will be the cost per item charged by the supplying vendor. In some cases, delivery and transportation costs will be included in this standard cost.

It is not unusual for the elements in an item's inventory to come from more than one vendor, or from one vendor in more than one order. Inventory valuation is more difficult if the price paid is different for these different purchases. There are four methods of determining the cost of elements in inventory. Any of these methods can be used (if applicable), but the method must be used consistently from year to year. The four methods are as follows.

- *specific identification method:* Each element can be uniquely associated with a cost. Inventory elements with serial numbers fit into this costing scheme. Stock, production, and sales records must include the serial number.

<sup>48</sup>The cost of goods sold inventory adjustment is posted to the COGS expense account.

- *average cost method:* The standard cost of an item is the average of (recent or all) purchase costs for that item.
- *first-in, first-out (FIFO) method:* This method keeps track of how many of each item were purchased each time and the number remaining out of each purchase, as well as the price paid at each purchase. The inventory system assumes that the oldest elements are issued first.<sup>49</sup> Inventory value is a weighted average dependent on the number of elements from each purchase remaining. Items issued no longer contribute to the inventory value.
- *last-in, first-out (LIFO) method:* This method keeps track of how many of each item were purchased each time and the number remaining out of each purchase, as well as the price paid at each purchase.<sup>50</sup> The inventory value is a weighted average dependent on the number of elements from each purchase remaining. Items issued no longer contribute to the inventory value.

## 55. BREAK-EVEN ANALYSIS

### Special Nomenclature

<i>a</i>	incremental cost to produce one additional item (also called <i>marginal cost</i> or <i>differential cost</i> )
<i>C</i>	total cost
<i>f</i>	fixed cost that does not vary with production
<i>p</i>	incremental value (price)
<i>Q</i>	quantity sold
<i>Q*</i>	quantity at break-even point
<i>R</i>	total revenue

*Break-even analysis* is a method of determining when the value of one alternative becomes equal to the value of another. A common application is that of determining when costs exactly equal revenue. If the manufactured quantity is less than the break-even quantity, a loss is incurred. If the manufactured quantity is greater than the break-even quantity, a profit is made. (See Fig. 87.13.)

Assuming no change in the inventory, the *break-even point* can be found by setting costs equal to revenue ( $C = R$ ).

$$C = f + aQ \quad 87.68$$

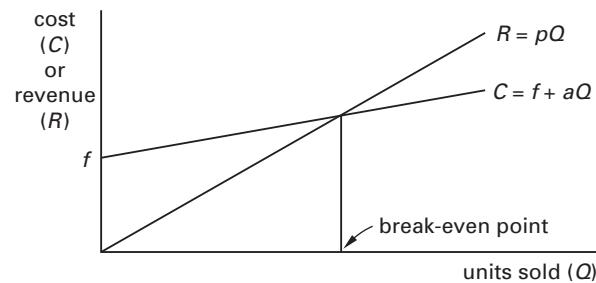

$$R = pQ \quad 87.69$$

$$Q^* = \frac{f}{p - a} \quad 87.70$$

<sup>49</sup>If all elements in an item's inventory are identical, and if all shipments of that item are agglomerated, there will be no way to guarantee that the oldest element in inventory is issued first. But, unless *spoilage* is a problem, it really does not matter.

<sup>50</sup>See previous footnote.

Figure 87.13 Break-Even Quality

An alternative form of the break-even problem is to find the number of units per period for which two alternatives have the same total costs. Fixed costs are to be spread over a period longer than one year using the equivalent uniform annual cost (EUAC) concept. One of the alternatives will have a lower cost if production is less than the break-even point. The other will have a lower cost for production greater than the break-even point.

### Example 87.32

Two plans are available for a company to obtain automobiles for its sales representatives. How many miles must the cars be driven each year for the two plans to have the same costs? Use an interest rate of 10%. (Use the year-end convention for all costs.)

*plan 1:* Lease the cars and pay \$0.15 per mile.

*plan 2:* Purchase the cars for \$5000. Each car has an economic life of three years, after which it can be sold for \$1200. Gas and oil cost \$0.04 per mile. Insurance is \$500 per year.

### Solution

Let  $x$  be the number of miles driven per year. Then, the EUAC for both alternatives is

$$\text{EUAC(A)} = 0.15x$$

$$\begin{aligned}\text{EUAC(B)} &= 0.04x + \$500 + (\$5000)(A/P, 10\%, 3) \\ &\quad - (\$1200)(A/F, 10\%, 3) \\ &= 0.04x + \$500 + (\$5000)(0.4021) \\ &\quad - (\$1200)(0.3021) \\ &= 0.04x + 2148\end{aligned}$$

Setting EUAC(A) and EUAC(B) equal and solving for  $x$  yields 19,527 miles per year as the break-even point.

## 56. PAY-BACK PERIOD

The *pay-back period* is defined as the length of time, usually in years, for the cumulative net annual profit to equal the initial investment. It is tempting to introduce

equivalence into pay-back period calculations, but by convention, this is generally not done.<sup>51</sup>

$$\text{pay-back period} = \frac{\text{initial investment}}{\text{net annual profit}} \quad 87.71$$

### Example 87.33

A ski resort installs two new ski lifts at a total cost of \$1,800,000. The resort expects the annual gross revenue to increase by \$500,000 while it incurs an annual expense of \$50,000 for lift operation and maintenance. What is the pay-back period?

*Solution*

From Eq. 87.71,

$$\text{pay-back period} = \frac{\$1,800,000}{\frac{\$500,000}{\text{yr}} - \frac{\$50,000}{\text{yr}}} = 4 \text{ yr}$$

## 57. MANAGEMENT GOALS

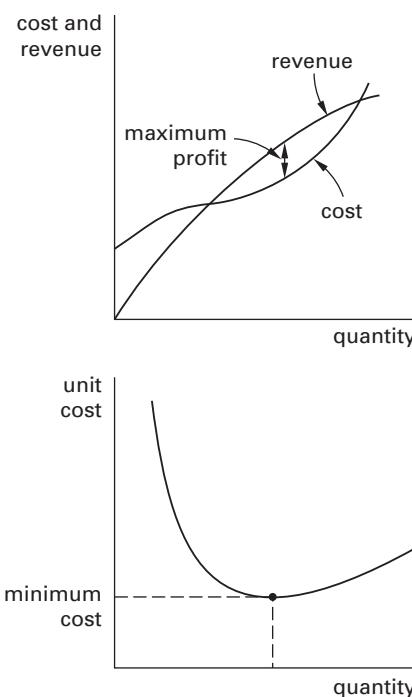

Depending on many factors (market position, age of the company, age of the industry, perceived marketing and sales windows, etc.), a company may select one of many production and marketing strategic goals. Three such strategic goals are

- maximization of product demand
- minimization of cost
- maximization of profit

Such goals require knowledge of how the dependent variable (e.g., demand quantity or quantity sold) varies as a function of the independent variable (e.g., price). Unfortunately, these three goals are not usually satisfied simultaneously. For example, minimization of product cost may require a large production run to realize economies of scale, while the actual demand is too small to take advantage of such economies of scale.

If sufficient data are available to plot the independent and dependent variables, it may be possible to optimize the dependent variable graphically. (See Fig. 87.14.) Of course, if the relationship between independent and dependent variables is known algebraically, the dependent variable can be optimized by taking derivatives or by use of other numerical methods.

**Figure 87.14** Graphs of Management Goal Functions

## 58. INFLATION

It is important to perform economic studies in terms of *constant value dollars*. One method of converting all cash flows to constant value dollars is to divide the flows by some annual *economic indicator* or price index.

If indicators are not available, cash flows can be adjusted by assuming that inflation is constant at a decimal rate,  $e$ , per year. Then, all cash flows can be converted to  $t = 0$  dollars by dividing by  $(1 + e)^n$ , where  $n$  is the year of the cash flow.

An alternative is to replace the effective annual interest rate,  $i$ , with a value corrected for inflation. This corrected value,  $i'$ , is

$$i' = i + e + ie \quad 87.72$$

This method has the advantage of simplifying the calculations. However, precalculated factors are not available for the non-integer values of  $i'$ . Therefore, Table 87.1 must be used to calculate the factors.

### Example 87.34

What is the uninflated present worth of a \$2000 future value in two years if the average inflation rate is 6% and  $i$  is 10%?

<sup>51</sup>Equivalence (i.e., interest and compounding) generally is not considered when calculating the “pay-back period.” However, if it is desirable to include equivalence, then the term *pay-back period* should not be used. Other terms, such as *cost recovery period* or *life of an equivalent investment*, should be used. Unfortunately, this convention is not always followed in practice.

*Solution*

$$\begin{aligned} P &= \frac{F}{(1+i)^n(1+e)^n} \\ &= \frac{\$2000}{(1+0.10)^2(1+0.06)^2} \\ &= \$1471 \end{aligned}$$

### Example 87.35

Repeat Ex. 87.34 using Eq. 87.72.

*Solution*

$$\begin{aligned} i' &= i + e + ie = 0.10 + 0.06 + (0.10)(0.06) \\ &= 0.166 \\ P &= \frac{F}{(1+i')^2} = \frac{\$2000}{(1+0.166)^2} = \$1471 \end{aligned}$$

## 59. CONSUMER LOANS

*Special Nomenclature*

$BAL_j$	balance after the $j$ th payment
$j$	payment or period number
LV	principal total value loaned (cost minus down payment)
$N$	total number of payments to pay off the loan
$PI_j$	$j$ th interest payment
$PP_j$	$j$ th principal payment
$PT_j$	$j$ th total payment
$\phi$	effective rate per period ( $r/k$ )

Many different arrangements can be made between a borrower and a lender. With the advent of creative financing concepts, it often seems that there are as many variations of loans as there are loans made. Nevertheless, there are several traditional types of transactions. Real estate or investment texts, or a financial consultant, should be consulted for more complex problems.

### Simple Interest

Interest due does not compound with a *simple interest loan*. The interest due is merely proportional to the length of time that the principal is outstanding. Because of this, simple interest loans are seldom made for long periods (e.g., more than one year). (For loans less than one year, it is commonly assumed that a year consists of 12 months of 30 days each.)

### Example 87.36

A \$12,000 simple interest loan is taken out at 16% per annum interest rate. The loan matures in two years with no intermediate payments. How much will be due at the end of the second year?

*Solution*

The interest each year is

$$PI = (0.16)(\$12,000) = \$1920$$

The total amount due in two years is

$$PT = \$12,000 + (2)(\$1920) = \$15,840$$

### Example 87.37

\$4000 is borrowed for 75 days at 16% per annum simple interest. There are 360 banking days per year. How much will be due at the end of 75 days?

*Solution*

$$\begin{aligned} \text{amount due} &= \$4000 + (0.16) \left( \frac{75 \text{ days}}{360 \frac{\text{days}}{\text{bank yr}}} \right) (\$4000) \\ &= \$4133 \end{aligned}$$

### Loans with Constant Amount Paid Toward Principal

With this loan type, the payment is not the same each period. The amount paid toward the principal is constant, but the interest varies from period to period. (See Fig. 87.15.) The equations that govern this type of loan are

$$BAL_j = LV - j(PP) \quad 87.73$$

$$PI_j = \phi(BAL)_{j-1} \quad 87.74$$

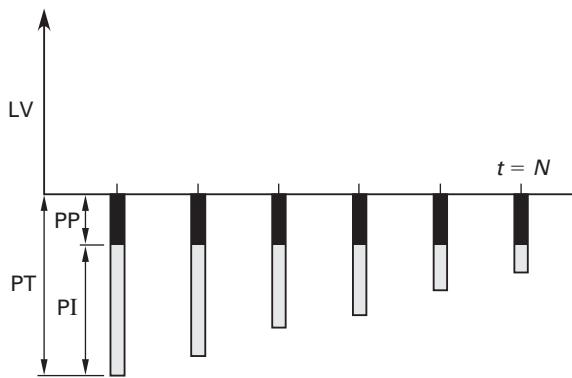

$$PT_j = PP + PI_j \quad 87.75$$

$$PP = \frac{LV}{N} \quad 87.76$$

$$N = \frac{LV}{PP} \quad 87.77$$

$$\begin{aligned} LV &= (PP + PI_1)(P/A, \phi, N) \\ &\quad - PI_N(P/G, \phi, N) \end{aligned} \quad 87.78$$

$$\begin{aligned} 1 &= \left( \frac{1}{N} + \phi \right) (P/A, \phi, N) \\ &\quad - \left( \frac{\phi}{N} \right) (P/G, \phi, N) \end{aligned} \quad 87.79$$

**Figure 87.15** Loan with Constant Amount Paid Toward Principal**Example 87.38**

A \$12,000 six-year loan is taken from a bank that charges 15% effective annual interest. Payments toward the principal are uniform, and repayments are made at the end of each year. Tabulate the interest, total payments, and the balance remaining after each payment is made.

*Solution*

The amount of each principal payment is

$$PP = \frac{LV}{N} = \frac{\$12,000}{6} = \$2000$$

At the end of the first year (before the first payment is made), the principal balance is \$12,000 (i.e.,  $BAL_0 = \$12,000$ ). From Eq. 87.74, the interest payment is

$$PI_1 = \phi(BAL)_0 = (0.15)(\$12,000) = \$1800$$

The total first payment is

$$\begin{aligned} PT_1 &= PP + PI = \$2000 + \$1800 \\ &= \$3800 \end{aligned}$$

The following table is similarly constructed.

$j$	$BAL_j$	$PP_j$	$PI_j$	$PT_j$
(in dollars)				
0	12,000	—	—	—
1	10,000	2000	1800	3800
2	8000	2000	1500	3500
3	6000	2000	1200	3200
4	4000	2000	900	2900
5	2000	2000	600	2600
6	0	2000	300	2300

**Direct Reduction Loans**

This is the typical “interest paid on unpaid balance” loan. The amount of the periodic payment is constant, but the amounts paid toward the principal and interest both vary. (See Fig. 87.16.)

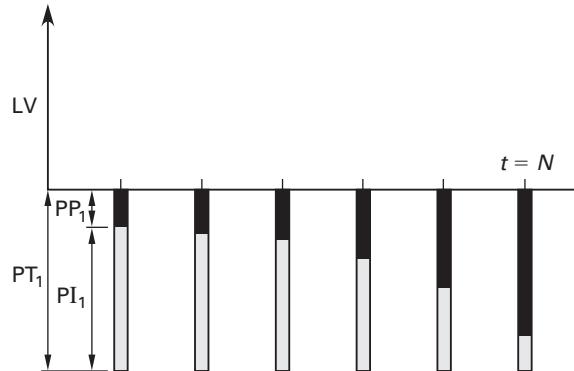

$$BAL_{j-1} = PT \left( \frac{1 - (1 + \phi)^{j-1-N}}{\phi} \right) \quad 87.80$$

$$PI_j = \phi(BAL)_{j-1} \quad 87.81$$

$$PP_j = PT - PI_j \quad 87.82$$

$$BAL_j = BAL_{j-1} - PP_j \quad 87.83$$

$$N = \frac{-\ln \left( 1 - \frac{\phi(LV)}{PT} \right)}{\ln(1 + \phi)} \quad 87.84$$

**Figure 87.16** Direct Reduction Loan

Equation 87.84 calculates the number of payments necessary to pay off a loan. This equation can be solved with effort for the total periodic payment ( $PT$ ) or the initial value of the loan ( $LV$ ). It is easier, however, to use the  $(A/P, I\%, n)$  factor to find the payment and loan value.

$$PT = LV(A/P, \phi\%, N) \quad 87.85$$

If the loan is repaid in yearly installments, then  $i$  is the effective annual rate. If the loan is paid off monthly, then  $i$  should be replaced by the effective rate per month ( $\phi$  from Eq. 87.51). For monthly payments,  $N$  is the number of months in the loan period.

**Example 87.39**

A \$45,000 loan is financed at 9.25% per annum. The monthly payment is \$385. What are the amounts paid toward interest and principal in the 14th period? What is the remaining principal balance after the 14th payment has been made?

**Solution**

The effective rate per month is

$$\begin{aligned}\phi &= \frac{r}{k} = \frac{0.0925}{12} \\ &= 0.0077083 \dots \quad [\text{use } 0.007708]\end{aligned}$$

From Eq. 87.84,

$$\begin{aligned}N &= \frac{-\ln\left(1 - \frac{\phi(LV)}{PT}\right)}{\ln(1 + \phi)} \\ &= \frac{-\ln\left(1 - \frac{(0.007708)(45,000)}{385}\right)}{\ln(1 + 0.007708)} \\ &= 301\end{aligned}$$

From Eq. 87.80,

$$\begin{aligned}\text{BAL}_{14-1} &= PT \left( \frac{1 - (1 + \phi)^{14-1-N}}{\phi} \right) \\ &= (\$385) \left( \frac{1 - (1 + 0.007708)^{14-1-301}}{0.007708} \right) \\ &= \$44,476.39\end{aligned}$$

From Eq. 87.81,

$$\begin{aligned}\text{PI}_{14} &= \phi(\text{BAL})_{14-1} \\ &= (0.007708)(\$44,476.39) \\ &= \$342.82\end{aligned}$$

From Eq. 87.82,

$$\text{PP}_{14} = PT - \text{PI}_{14} = \$385 - \$342.82 = \$42.18$$

Therefore, using Eq. 87.83, the remaining principal balance is

$$\begin{aligned}\text{BAL}_{14} &= \text{BAL}_{14-1} - \text{PP}_{14} \\ &= \$44,476.39 - \$42.18 \\ &= \$44,434.21\end{aligned}$$

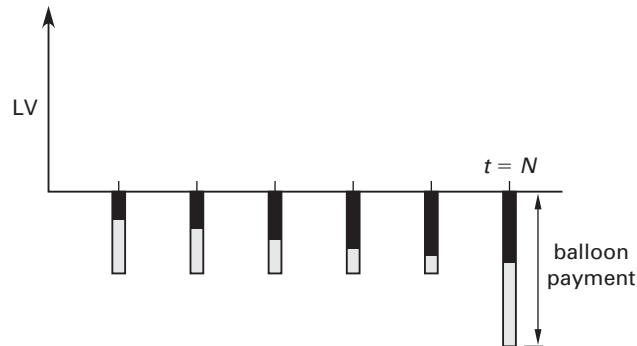

### Direct Reduction Loans with Balloon Payments

This type of loan has a constant periodic payment, but the duration of the loan is insufficient to completely pay back the principal (i.e., the loan is not fully amortized). Therefore, all remaining unpaid principal must be paid back in a lump sum when the loan matures. This large

payment is known as a *balloon payment*.<sup>52</sup> (See Fig. 87.17.)

Equation 87.80 through Eq. 87.84 also can be used with this type of loan. The remaining balance after the last payment is the balloon payment. This balloon payment must be repaid along with the last regular payment calculated.

**Figure 87.17** Direct Reduction Loan with Balloon Payment

## 60. FORECASTING

There are many types of forecasting models, although most are variations of the basic types.<sup>53</sup> All models produce a *forecast*,  $F_{t+1}$ , of some quantity (*demand* is used in this section) in the next period based on actual measurements,  $D_j$ , in current and prior periods. All of the models also try to provide *smoothing* (or *damping*) of extreme data points.

### Forecasts by Moving Averages

The method of *moving average forecasting* weights all previous demand data points equally and provides some smoothing of extreme data points. The amount of smoothing increases as the number of data points,  $n$ , increases.

$$F_{t+1} = \frac{1}{n} \sum_{m=t+1-n}^t D_m \quad 87.86$$

### Forecasts by Exponentially Weighted Averages

With *exponentially weighted forecasts*, the more current (most recent) data points receive more weight. This method uses a *weighting factor*,  $\alpha$ , also known as a *smoothing coefficient*, which typically varies between 0.01 and 0.30. An initial forecast is needed to start the method. Forecasts immediately following are sensitive

<sup>52</sup>The term *balloon payment* may include the final interest payment as well. Generally, the problem statement will indicate whether the balloon payment is inclusive or exclusive of the regular payment made at the end of the loan period.

<sup>53</sup>For example, forecasting models that take into consideration steady (linear), cyclical, annual, and seasonal trends are typically variations of the exponentially weighted model. A truly different forecasting tool, however, is *Monte Carlo simulation*.

to the accuracy of this first forecast. It is common to choose  $F_0 = D_1$  to get started.

$$F_{t+1} = \alpha D_t + (1 - \alpha) F_t \quad 87.87$$

## 61. LEARNING CURVES

### Special Nomenclature

$b$	learning curve constant
$n$	total number of items produced
$R$	decimal learning curve rate ( $2^{-b}$ )
$T_1$	time or cost for the first item
$T_n$	time or cost for the $n$ th item

The more products that are made, the more efficient the operation becomes due to experience gained. Therefore, direct labor costs decrease.<sup>54</sup> Usually, a *learning curve* is specified by the decrease in cost each time the cumulative quantity produced doubles. If there is a 20% decrease per doubling, the curve is said to be an 80% learning curve (i.e., the *learning curve rate*,  $R$ , is 80%).

Then, the time to produce the  $n$ th item is

$$T_n = T_1 n^{-b} \quad 87.88$$

The total time to produce units from quantity  $n_1$  to  $n_2$  inclusive is approximately given by Eq. 87.89.  $T_1$  is a constant, the time for item 1, and does not correspond to  $n$  unless  $n_1 = 1$ .

$$\int_{n_1}^{n_2} T_n dn \approx \left( \frac{T_1}{1-b} \right) \left( \left( n_2 + \frac{1}{2} \right)^{1-b} - \left( n_1 - \frac{1}{2} \right)^{1-b} \right) \quad 87.89$$

The *average time per unit* over the production from  $n_1$  to  $n_2$  is the above total time from Eq. 87.89 divided by the quantity produced,  $(n_2 - n_1 + 1)$ .

$$T_{\text{ave}} = \frac{\int_{n_1}^{n_2} T_n dn}{n_2 - n_1 + 1} \quad 87.90$$

Table 87.9 lists representative values of the *learning curve constant*,  $b$ . For learning curve rates not listed in the table, Eq. 87.91 can be used to find  $b$ .

$$b = \frac{-\log_{10} R}{\log_{10}(2)} = \frac{-\log_{10} R}{0.301} \quad 87.91$$

**Table 87.9** Learning Curve Constants

learning curve rate, $R$	$b$
0.70 (70%)	0.515
0.75 (75%)	0.415
0.80 (80%)	0.322
0.85 (85%)	0.234
0.90 (90%)	0.152
0.95 (95%)	0.074

### Example 87.40

A 70% learning curve is used with an item whose first production time is 1.47 hr. (a) How long will it take to produce the 11th item? (b) How long will it take to produce the 11th through 27th items?

#### Solution

(a) From Eq. 87.88,

$$T_{11} = T_1 n^{-b} = (1.47 \text{ hr})(11)^{-0.515} \\ = 0.428 \text{ hr}$$

(b) The time to produce the 11th item through 27th item is given by Eq. 87.89.

$$T \approx \left( \frac{T_{11}}{1-b} \right) \left( \left( n_{27} + \frac{1}{2} \right)^{1-b} - \left( n_{11} - \frac{1}{2} \right)^{1-b} \right) \\ T \approx \left( \frac{1.47 \text{ hr}}{1-0.515} \right) \left( (27.5)^{1-0.515} - (10.5)^{1-0.515} \right) \\ = 5.643 \text{ hr}$$

## 62. ECONOMIC ORDER QUANTITY

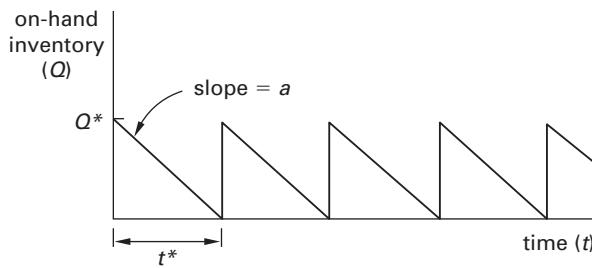

### Special Nomenclature

$a$	constant depletion rate (items/unit time)
$h$	inventory storage cost (\$/item-unit time)
$H$	total inventory storage cost between orders (\$)
$K$	fixed cost of placing an order (\$)
$Q$	order quantity (original quantity on hand)
$t^*$	time at depletion

The *economic order quantity* (EOQ) is the order quantity that minimizes the inventory costs per unit time. Although there are many different EOQ models, the simplest is based on the following assumptions.

- Reordering is instantaneous. The time between order placement and receipt is zero, as shown in Fig. 87.18.
- Shortages are not allowed.
- Demand for the inventory item is deterministic (i.e., is not a random variable).
- Demand is constant with respect to time.
- An order is placed when the inventory is zero.

<sup>54</sup>Learning curve reductions apply only to direct labor costs. They are not applied to indirect labor or direct material costs.

**Figure 87.18** Inventory with Instantaneous Reorder

If the original quantity on hand is  $Q$ , the stock will be depleted at

$$t^* = \frac{Q}{a} \quad 87.92$$

The total inventory storage cost between  $t_0$  and  $t^*$  is

$$H = \frac{1}{2}Qht^* = \frac{Q^2h}{2a} \quad 87.93$$

The total inventory and ordering cost per unit time is

$$C_t = \frac{aK}{Q} + \frac{hQ}{2} \quad 87.94$$

$C_t$  can be minimized with respect to  $Q$ . The economic order quantity and time between orders are

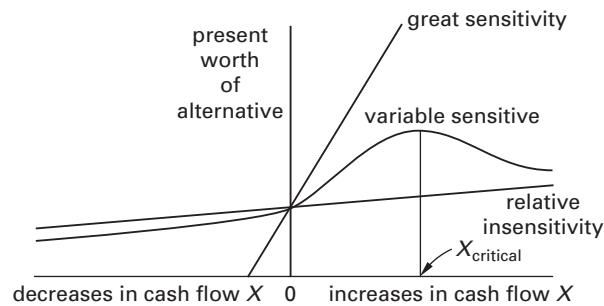

$$Q^* = \sqrt{\frac{2aK}{h}} \quad 87.95$$

$$t^* = \frac{Q^*}{a} \quad 87.96$$

### 63. SENSITIVITY ANALYSIS

Data analysis and forecasts in economic studies require estimates of costs that will occur in the future. There are always uncertainties about these costs. However, these uncertainties are insufficient reason not to make the best possible estimates of the costs. Nevertheless, a decision between alternatives often can be made more confidently if it is known whether or not the conclusion is sensitive to moderate changes in data forecasts. Sensitivity analysis provides this extra dimension to an economic analysis.

The sensitivity of a decision is determined by inserting a range of estimates for critical cash flows and other parameters. If radical changes can be made to a cash flow without changing the decision, the decision is said to be *insensitive* to uncertainties regarding that cash flow. However, if a small change in the estimate of a cash flow will alter the decision, that decision is said to be very *sensitive* to changes in the estimate. If the decision is sensitive only for a limited range of cash flow values, the term *variable sensitivity* is used. Figure 87.19 illustrates these terms.

**Figure 87.19** Types of Sensitivity

An established semantic tradition distinguishes between risk analysis and uncertainty analysis. *Risk analysis* addresses variables that have a known or estimated probability distribution. In this regard, statistics and probability theory can be used to determine the probability of a cash flow varying between given limits. On the other hand, *uncertainty analysis* is concerned with situations in which there is not enough information to determine the probability or frequency distribution for the variables involved.

As a first step, sensitivity analysis should be applied one at a time to the dominant factors. Dominant cost factors are those that have the most significant impact on the present value of the alternative.<sup>55</sup> If warranted, additional investigation can be used to determine the sensitivity to several cash flows varying simultaneously. Significant judgment is needed, however, to successfully determine the proper combinations of cash flows to vary. It is common to plot the dependency of the present value on the cash flow being varied in a two-dimensional graph. Simple linear interpolation is used (within reason) to determine the critical value of the cash flow being varied.

### 64. VALUE ENGINEERING

The *value* of an investment is defined as the ratio of its return (performance or utility) to its cost (effort or investment). The basic object of *value engineering* (VE, also referred to as *value analysis*) is to obtain the maximum per-unit value.<sup>56</sup>

Value engineering concepts often are used to reduce the cost of mass-produced manufactured products. This is done by eliminating unnecessary, redundant, or superfluous features, by redesigning the product for a less expensive manufacturing method, and by including features for easier assembly without sacrificing utility and

<sup>55</sup>In particular, engineering economic analysis problems are sensitive to the choice of effective interest rate,  $i$ , and to accuracy in cash flows at or near the beginning of the horizon. The problems will be less sensitive to accuracy in far-future cash flows, such as salvage value and subsequent generation replacement costs.

<sup>56</sup>Value analysis, the methodology that has become today's value engineering, was developed in the early 1950s by Lawrence D. Miles, an analyst at General Electric.

function.<sup>57</sup> However, the concepts are equally applicable to one-time investments, such as buildings, chemical processing plants, and space vehicles. In particular, value engineering has become an important element in all federally funded work.<sup>58</sup>

Typical examples of large-scale value engineering work are using stock-sized bearings and motors (instead of custom manufactured units), replacing rectangular concrete columns with round columns (which are easier to form), and substituting custom buildings with prefabricated structures.

Value engineering is usually a team effort. And, while the original designers may be on the team, usually outside consultants are utilized. The cost of value engineering is usually returned many times over through reduced construction and life-cycle costs.

<sup>57</sup>Some people say that value engineering is the act of going over the plans and taking out everything that is interesting.

<sup>58</sup>U.S. Government Office of Management and Budget Circular A-131 outlines value engineering for federally funded construction projects.

## 1. FORMS OF COMPANY OWNERSHIP

There are three basic forms of company ownership in the United States: (a) sole proprietorship, (b) partnership, and (c) corporation.<sup>2</sup> Each of these forms of ownership has advantages and disadvantages.

## 2. SOLE PROPRIETORSHIPS

A *sole proprietorship* (*single proprietorship*) is the easiest form of ownership to establish. Other than the necessary licenses, filings, and notices (which apply to all forms of ownership), no legal formalities are required to start business operations. A sole proprietor (the owner) has virtually total control of the business and makes all supervisory and management decisions.

<sup>1</sup>This chapter is not intended to be a substitute for professional advice. Law is not always black and white. For every rule there are exceptions. For every legal principle, there are variations. For every type of injury, there are numerous legal precedents. This chapter covers the superficial basics of a small subset of U.S. law affecting engineers.

<sup>2</sup>The discussion of forms of company ownership in Sec. 88.2, Sec. 88.3, and Sec. 88.4 applies equally to service-oriented companies (e.g., consulting engineering firms) and product-oriented companies.

Legally, there is no distinction between the sole proprietor and the sole proprietorship (the business). This is the greatest disadvantage of this form of business. The owner is solely responsible for the operation of the business, even if the owner hires others for assistance. The owner assumes personal, legal, and financial liability for all acts and debts of the company. If the company debts remain unpaid, or in the event there is a legal judgment against the company, the owner's personal assets (home, car, savings, etc.) can be seized or attached.

Another disadvantage of the sole proprietorship is the lack of significant organizational structure. In times of business crisis or trouble, there may be no one to share the responsibility or to help make decisions. When the owner is sick or dies, there may be no way to continue the business.

There is also no distinction between the incomes of the business and the owner. Therefore, the business income is taxed at the owner's income tax rate. Depending on the owner's financial position, the success of the business, and the tax structure, this can be an advantage or a disadvantage.<sup>3</sup>

## 3. PARTNERSHIPS

A *partnership* (also known as a *general partnership*) is ownership by two or more persons known as *general partners*. Legally, this form is very similar to a sole proprietorship, and the two forms of business have many of the same advantages and disadvantages. For example, with the exception of an optional *partnership agreement*, there are a minimum of formalities to setting up business. The partners make all business and management decisions themselves according to an agreed-upon process. The business income is split among the partners and taxed at the partners' individual tax rates.<sup>4</sup> Continuity of the business is still a problem since most partnerships are automatically dissolved upon the withdrawal or death of one of the partners.<sup>5</sup>

One advantage of a partnership over a sole proprietorship is the increase in available funding. Not only do

<sup>3</sup>To use a simplistic example, if the corporate tax rates are higher than the individual tax rates, it would be *financially* better to be a sole proprietor because the company income would be taxed at a lower rate.

<sup>4</sup>The percentage split is specified in the partnership agreement.

<sup>5</sup>Some or all of the remaining partners may want to form a new partnership, but this is not always possible.

more partners bring in more start-up capital, but the resource pool may make business credit easier to obtain. Also, the partners bring a diversity of skills and talents.

Unless the partnership agreement states otherwise, each partner can individually obligate (i.e., *bind*) the partnership without the consent of the other partners. Similarly, each partner has personal responsibility and liability for the acts and debts of the partnership company, just as sole proprietors do. In fact, each partner assumes the *sole* responsibility, not just a proportionate share. If one or more partners are unable to pay, the remaining partners shoulder the entire debt. The possibility of one partner having to pay for the actions of another partner must be considered when choosing this form of business ownership.

A *limited partnership* differs from a general partnership in that one (or more) of the partners is silent. The *limited partners* make a financial contribution to the business and receive a share of the profit but do not participate in the management and cannot bind the partnership. While *general partners* have unlimited personal liabilities, limited partners are generally liable only to the extent of their investment.<sup>6</sup> A written partnership agreement is required, and the agreement must be filed with the proper authorities.

#### 4. CORPORATIONS

A corporation is a legal entity (i.e., a legal person) distinct from the founders and owners. The separation of ownership and management makes the corporation a fundamentally different business form than a sole proprietorship or partnership, with very different advantages and disadvantages.

A corporation becomes legally distinct from its founders upon formation and proper registration. Ownership of the corporation is through shares of stock, distributed to the founders and investors according to some agreed-upon investment and distribution rule. The founders and investors become the stockholders (i.e., owners) of the corporation. A *closely held (private) corporation* is one in which all stock is owned by a family or small group of co-investors. A *public corporation* is one whose stock is available for the public-at-large to purchase.

There is no mandatory connection between ownership and management functions. The decision-making power is vested in the executive officers and a *board of directors* that governs by majority vote. The stockholders elect the board of directors which, in turn, hires the executive officers, management, and other employees. Employees of the corporation may or may not be stockholders.

Disadvantages (at least for a person or persons who could form a partnership or sole proprietorship) include

<sup>6</sup>That is, if the partnership fails or is liquidated to pay debts, the limited partners lose no more than their initial investments.

the higher corporate tax rate, difficulty and complexity of formation (some states require a minimum number of persons on the board of directors), and additional legal and accounting paperwork.

However, since a corporation is distinctly separate from its founders and investors, those individuals are not liable for the acts and debts of the corporation. Debts are paid from the corporate assets. Income to the corporation is not taxable income to the owners. (Only the salaries, if any, paid to the employees by the corporation are taxable to the employees.) Even if the corporation were to go bankrupt, the assets of the owners would not ordinarily be subject to seizure or attachment.

A corporation offers the best guarantee of continuity of operation in the event of the death, incapacitation, or retirement of the founders since, as a legal entity, it is distinct from the founders and owners.

#### 5. LIMITED LIABILITY ENTITIES

A variety of other legal entities have been established that blur the lines between the three traditional forms of business (i.e., proprietorship, partnership, and corporation). The *limited liability partnership*, LLP, extends a measure of corporate-like protection to professionals while permitting partnership-like personal participation in management decisions. Since LLPs are formed and operated under state laws, actual details vary from state to state. However, most LLPs allow the members to participate in management decisions, while not being responsible for the misdeeds of other partners. As in a corporation, the debts of the LLP do not become debts of the members.<sup>7</sup> The *double taxation* characteristic of traditional corporations is avoided, as profits to the LLP flow through to the members.

For engineers and architects (as well as doctors, lawyers, and accountants), the *professional corporation*, PC, offers protection from the actions (e.g., malpractice) of other professionals within a shared environment, such as a design firm. While a PC does not shield the individual from responsibility for personal negligence or malpractice, it does permit the professional to be associated with a larger entity, such as a partnership of other PCs, without accepting responsibility for the actions of the other members. In that sense, the protection is similar to that of an LLP. Unlike a traditional corporation, a PC may have a board of directors consisting of only a single individual, the professional.

The *limited liability company*,<sup>8</sup> LLC, also combines advantages from partnerships and corporations. In an LLC, the members are shielded from debts of the LLC

<sup>7</sup>Depending on the state, the shield may be complete or limited. It is common that the protection only applies to negligence-related claims, as opposed to intentional tort claims, contract-related obligations, and day-to-day operating expenses such as rent, utilities, and employees.

<sup>8</sup>LLC does not mean *limited liability corporation*. LLCs are not corporations.

while enjoying the pass-through of all profits.<sup>9</sup> Like a partnership or shareholder, a member's obligation is limited to the *membership interest* in (i.e., contribution to) the LLC. LLCs are directed and controlled by one or more managers who may also be members. A variation of the LLC specifically for design, medical, and other professionals is the *professional limited liability company*, PLLC.

The traditional corporation, as described in Sec. 88.4, is referred to as a *Subchapter C corporation* or "*C corp*".<sup>10</sup> A variant is the *S corporation* ("*S corp*") which combines characteristics of the C corporation with pass-through for taxation. S corporations can be limited or treated differently than C corporations by state and federal law.

## 6. PIERCING THE CORPORATE VEIL

An individual operating as a corporation, LLP, LLC, or PC entity may lose all protection if his or her actions are fraudulent, or if the court decides the business is an "alter ego" of the individual. Basically, this requires the business to be run as a business. Business and personal assets cannot be intermingled, and business decisions must be made and documented in a business-like manner. If operated fraudulently or loosely, a court may assign liability directly to an individual, an action known as *piercing the corporate veil*.

## 7. AGENCY

In some contracts, decision-making authority and right of action are transferred from one party (the owner, or *principal*) who would normally have that authority to another person (the *agent*). For example, in construction contracts, the engineer may be the agent of the owner for certain transactions. Agents are limited in what they can do by the scope of the agency agreement. Within that scope, however, an agent acts on behalf of the principal, and the principal is liable for the acts of the agent and is bound by contracts made in the principal's name by the agent.

Agents are required to execute their work with care, skill, and diligence. Specifically, agents have *fiduciary responsibility* toward their principal, meaning that agent must be honest and loyal. Agents are liable for damages resulting from a lack of diligence, loyalty, and/or honesty. If the agents misrepresented their skills when obtaining the agency, they can be liable for breach of contract or fraud.

<sup>9</sup>LLCs enjoy *check the box taxation*, which means they can elect to be taxed as sole proprietorships, partnerships, or corporations.

<sup>10</sup>The reference is to subchapter C of the Internal Revenue Code.

## 8. GENERAL CONTRACTS

A *contract* is a legally binding agreement or promise to exchange goods or services.<sup>11</sup> A written contract is merely a documentation of the agreement. Some agreements must be in writing, but most agreements for engineering services can be verbal, particularly if the parties to the agreement know each other well.<sup>12</sup> Written contract documents do not need to contain intimidating legal language, but all agreements must satisfy three basic requirements to be enforceable (binding).

- There must be a clear, specific, and definite *offer* with no room for ambiguity or misunderstanding.
- There must be some form of conditional future *consideration* (i.e., payment).<sup>13</sup>
- There must be an *acceptance* of the offer.

There are other conditions that the agreement must meet to be enforceable. These conditions are not normally part of the explicit agreement but represent the conditions under which the agreement was made.

- The agreement must be *voluntary* for all parties.
- All parties must have *legal capacity* (i.e., be mentally competent, of legal age, not under coercion, and uninfluenced by drugs).
- The purpose of the agreement must be *legal*.

For small projects, a simple *letter of agreement* on one party's stationery may suffice. For larger, complex projects, a more formal document may be required. Some clients prefer to use a *purchase order*, which can function as a contract if all basic requirements are met.

Regardless of the format of the written document—letter of agreement, purchase order, or standard form—a contract should include the following features.<sup>14</sup>

- introduction, preamble, or preface indicating the purpose of the contract
- name, address, and business forms of both contracting parties
- signature date of the agreement

<sup>11</sup>Not all agreements are legally binding (i.e., enforceable). Two parties may agree on something, but unless the agreement meets all of the requirements and conditions of a contract, the parties cannot hold each other to the agreement.

<sup>12</sup>All states have a *statute of frauds* that, among other things, specifies what types of contracts must be in writing to be enforceable. These include contracts for the sale of land, contracts requiring more than one year for performance, contracts for the sale of goods over \$500 in value, contracts to satisfy the debts of another, and marriage contracts. Contracts to provide engineering services do not fall under the statute of frauds.

<sup>13</sup>Actions taken or payments made prior to the agreement are irrelevant. Also, it does not matter to the courts whether the exchange is based on equal value or not.

<sup>14</sup>*Construction contracts* are unique unto themselves. Items that might also be included as part of the *contract documents* are the agreement form, the general conditions, drawings, specifications, and addenda.

- effective date of the agreement (if different from the signature date)
- duties and obligations of both parties
- deadlines and required service dates
- fee amount
- fee schedule and payment terms
- agreement expiration date
- standard boilerplate clauses
- signatures of parties or their agents
- declaration of authority of the signatories to bind the contracting parties
- supporting documents

## 9. STANDARD BOILERPLATE CLAUSES

It is common for full-length contract documents to include important *boilerplate clauses*. These clauses have specific wordings that should not normally be changed, hence the name “boilerplate.” Some of the most common boilerplate clauses are paraphrased here.

- Delays and inadequate performance due to war, strikes, and acts of God and nature are forgiven (*force majeure*).
- The contract document is the complete agreement, superseding all prior verbal and written agreements.
- The contract can be modified or canceled only in writing.
- Parts of the contract that are determined to be void or unenforceable will not affect the enforceability of the remainder of the contract (*severability*). Alternatively, parts of the contract that are determined to be void or unenforceable will be rewritten to accomplish their intended purpose without affecting the remainder of the contract.
- None (or one, or both) of the parties can (or cannot) assign its (or their) rights and responsibilities under the contract (*assignment*).
- All notices provided for in the agreement must be in writing and sent to the address in the agreement.
- Time is of the essence.<sup>15</sup>
- The subject headings of the agreement paragraphs are for convenience only and do not control the meaning of the paragraphs.
- The laws of the state in which the contract is signed must be used to interpret and govern the contract.
- Disagreements shall be arbitrated according to the rules of the American Arbitration Association.

<sup>15</sup>Without this clause in writing, damages for delay cannot be claimed.

- Any lawsuits related to the contract must be filed in the county and state in which the contract is signed.
- Obligations under the agreement are unique, and in the event of a breach, the defaulting party waives the defense that the loss can be adequately compensated by monetary damages (*specific performance*).
- In the event of a lawsuit, the prevailing party is entitled to an award of reasonable attorneys' and court fees.<sup>16</sup>
- Consequential damages are not recoverable in a lawsuit.

## 10. SUBCONTRACTS

When a party to a contract engages a third party to perform the work in the original contract, the contract with the third party is known as a *subcontract*. Whether or not responsibilities can be subcontracted under the original contract depends on the content of the *assignment clause* in the original contract.

## 11. PARTIES TO A CONSTRUCTION CONTRACT

A specific set of terms has developed for referring to parties in consulting and construction contracts. The *owner* of a construction project is the person, partnership, or corporation that actually owns the land, assumes the financial risk, and ends up with the completed project. The *developer* contracts with the architect and/or engineer for the design and with the contractors for the construction of the project. In some cases, the owner and developer are the same, in which case the term *owner-developer* can be used.

The *architect* designs the project according to established codes and guidelines but leaves most stress and capacity calculations to the *engineer*.<sup>17</sup> Depending on the construction contract, the engineer may work for the architect, or vice versa, or both may work for the developer.

Once there are approved plans, the developer hires *contractors* to do the construction. Usually, the entire construction project is awarded to a *general contractor*. Due to the nature of the construction industry, separate *subcontracts* are used for different tasks (electrical, plumbing, mechanical, framing, fire sprinkler installation, finishing, etc.). The general contractor who hires all of these different *subcontractors* is known as the *prime contractor* (or *prime*). (The subcontractors can also work directly for the owner-developer, although this is less

<sup>16</sup>Without this clause in writing, attorneys' fees and court costs are rarely recoverable.

<sup>17</sup>On simple small projects, such as wood-framed residential units, the design may be developed by a *building designer*. The legal capacities of building designers vary from state to state.

common.) The prime contractor is responsible for all acts of the subcontractors and is liable for any damage suffered by the owner-developer due to those acts.

Construction is managed by an agent of the owner-developer known as the *construction manager*, who may be the engineer, the architect, or someone else.

## 12. STANDARD CONTRACTS FOR DESIGN PROFESSIONALS

Several professional organizations have produced standard agreement forms and other standard documents for design professionals.<sup>18</sup> Among other standard forms, notices, and agreements, the following standard contracts are available.<sup>19</sup>

- standard contract between engineer and client
- standard contract between engineer and architect
- standard contract between engineer and contractor
- standard contract between owner and construction manager

Besides completeness, the major advantage of a standard contract is that the meanings of the clauses are well established, not only among the design professionals and their clients but also in the courts. The clauses in these contracts have already been litigated many times. Where a clause has been found to be unclear or ambiguous, it has been rewritten to accomplish its intended purpose.

## 13. CONSULTING FEE STRUCTURE

Compensation for consulting engineering services can incorporate one or more of the following concepts.

<sup>18</sup>There are two main sources of standardized construction and design agreements: EJCDC and AIA. Consensus documents, known as *ConsensusDOCS*, for every conceivable situation have been developed by the *Engineers Joint Contracts Documents Committee*, EJCDC. EJCDC includes the American Society of Civil Engineers (ASCE), the American Council of Engineering Companies (ACEC), National Society of Professional Engineers' (NSPE's) Professional Engineers in Private Practice Division, Associated General Contractors of America (AGC), and more than fifteen other participating professional engineering design, construction, owner, legal, and risk management organizations, including the Associated Builders and Contractors; American Subcontractors Association; Construction Users Roundtable; National Roofing Contractors Association; Mechanical Contractors Association of America; and National Plumbing, Heating-Cooling Contractors Association. The American Institute of Architects, AIA, has developed its own standardized agreements in a less collaborative manner. Though popular with architects, AIA provisions are considered less favorable to engineers, contractors, and subcontractors who believe the AIA documents assign too much authority to architects, too much risk and liability to contractors, and too little flexibility in how construction disputes are addressed and resolved.

<sup>19</sup>The Construction Specifications Institute (CSI) has produced standard specifications for materials. The standards have been organized according to a UNIFORMAT structure consistent with ASTM Standard E1557.

- *lump-sum fee*: This is a predetermined fee agreed upon by client and engineer. This payment can be used for small projects where the scope of work is clearly defined.

- *cost plus fixed fee*: All costs (labor, material, travel, etc.) incurred by the engineer are paid by the client. The client also pays a predetermined fee as profit. This method has an advantage when the scope of services cannot be determined accurately in advance. Detailed records must be kept by the engineer in order to allocate costs among different clients.
- *per diem fee*: The engineer is paid a specific sum for each day spent on the job. Usually, certain direct expenses (e.g., travel and reproduction) are billed in addition to the per diem rate.
- *salary plus*: The client pays for the employees on an engineer's payroll (the salary) plus an additional percentage to cover indirect overhead and profit plus certain direct expenses.
- *retainer*: This is a minimum amount paid by the client, usually in total and in advance, for a normal amount of work expected during an agreed-upon period. None of the retainer is returned, regardless of how little work the engineer performs. The engineer can be paid for additional work beyond what is normal, however. Some direct costs, such as travel and reproduction expenses, may be billed directly to the client.
- *percentage of construction cost*: This method, which is widely used in construction design contracts, pays the architect and/or the engineer a percentage of the final total cost of the project. Costs of land, financing, and legal fees are generally not included in the construction cost, and other costs (plan revisions, project management labor, value engineering, etc.) are billed separately.

## 14. MECHANIC'S LIENS

For various reasons, providers and material, labor, and design services to construction sites may not be promptly paid or even paid at all. Such providers have, of course, the right to file a lawsuit demanding payment, but due to the nature of the construction industry, such relief may be insufficient or untimely. Therefore, such providers have the right to file a *mechanic's lien* (also known as a *construction lien*, *materialman's lien*, *supplier's lien*, or *laborer's lien*) against the property. Although there are strict requirements for deadlines, filing, and notices, the procedure for obtaining (and removing) such a lien is simple. The lien establishes the supplier's security interest in the property. Although the details depend on the state, essentially the property owner is prevented from transferring title (i.e., selling) the property until the lien has been removed by the supplier. The act of filing a lawsuit to obtain payment is known as "perfected the lien." Liens are perfected by

forcing a judicial foreclosure sale. The court orders the property sold, and the proceeds are used to pay off any lien-holders.

## 15. DISCHARGE OF A CONTRACT

A contract is normally discharged when all parties have satisfied their obligations. However, a contract can also be terminated for the following reasons:

- mutual agreement of all parties to the contract
- impossibility of performance (e.g., death of a party to the contract)
- illegality of the contract
- material breach by one or more parties to the contract
- fraud on the part of one or more parties
- failure (i.e., loss or destruction) of consideration (e.g., the burning of a building one party expected to own or occupy upon satisfaction of the obligations)

Some contracts may be dissolved by actions of the court (e.g., bankruptcy), passage of new laws and public acts, or a declaration of war.

*Extreme difficulty* (including economic hardship) in satisfying the contract does not discharge it, even if it becomes more costly or less profitable than originally anticipated.

## 16. BREACH OF CONTRACT, NEGLIGENCE, MISREPRESENTATION, AND FRAUD

A *breach of contract* occurs when one of the parties fails to satisfy all of its obligations under a contract. The breach can be *willful* (as in a contractor walking off a construction job) or *unintentional* (as in providing less than adequate quality work or materials). A *material breach* is defined as nonperformance that results in the injured party receiving something substantially less than or different from what the contract intended.

Normally, the only redress that an *injured party* has through the courts in the event of a breach of contract is to force the breaching party to provide *specific performance*—that is, to satisfy all remaining contract provisions and to pay for any damage caused. Normally, *punitive damages* (to punish the breaching party) are unavailable.

*Negligence* is an action, willful or unwillful, taken without proper care or consideration for safety, resulting in damages to property or injury to persons. “Proper care” is a subjective term, but in general it is the diligence that would be exercised by a reasonably prudent

person.<sup>20</sup> Damages sustained by a negligent act are recoverable in a tort action. (See Sec. 88.17.) If the plaintiff is partially at fault (as in the case of *comparative negligence*), the defendant will be liable only for the portion of the damage caused by the defendant.

Punitive damages are available, however, if the breaching party was fraudulent in obtaining the contract. In addition, the injured party has the right to void (nullify) the contract entirely. A *fraudulent act* is basically a special case of *misrepresentation* (i.e., an intentionally false statement known to be false at the time it is made). Misrepresentation that does not result in a contract is a tort. When a contract is involved, misrepresentation can be a breach of that contract (i.e., *fraud*).

Unfortunately, it is extremely difficult to prove *compensatory fraud* (i.e., fraud for which damages are available). Proving fraud requires showing *beyond a reasonable doubt* (a) a reckless or intentional misstatement of a material fact, (b) an intention to deceive, (c) it resulted in misleading the innocent party to contract, and (d) it was to the innocent party’s detriment.

For example, if an engineer claims to have experience in designing steel buildings but actually has none, the court might consider the misrepresentation a fraudulent action. If, however, the engineer has some experience, but an insufficient amount to do an adequate job, the engineer probably will not be considered to have acted fraudulently.

## 17. TORTS

A *tort* is a civil wrong committed by one person causing damage to another person or person’s property, emotional well-being, or reputation.<sup>21</sup> It is a breach of the rights of an individual to be secure in person or property. In order to correct the wrong, a civil lawsuit (*tort action* or *civil complaint*) is brought by the alleged injured party (the *plaintiff*) against the *defendant*. To be a valid *tort action* (i.e., lawsuit), there must have been injury (i.e., damage). Generally, there will be no contract between the two parties, so the tort action cannot claim a breach of contract.<sup>22</sup>

Tort law is concerned with compensation for the injury, not punishment. Therefore, tort awards usually consist

<sup>20</sup>Negligence of a design professional (e.g., an engineer or architect) is the absence of a *standard of care* (i.e., customary and normal care and attention) that would have been provided by other engineers. It is highly subjective.

<sup>21</sup>The difference between a *civil tort* (*lawsuit*) and a *criminal lawsuit* is the alleged injured party. A *crime* is a wrong against society. A criminal lawsuit is brought by the state against a defendant.

<sup>22</sup>It is possible for an injury to be both a breach of contract and a tort. Suppose an owner has an agreement with a contractor to construct a building, and the contract requires the contractor to comply with all state and federal safety regulations. If the owner is subsequently injured on a stairway because there was no guardrail, the injury could be recoverable both as a tort and as a breach of contract. If a third party unrelated to the contract was injured, however, that party could recover only through a tort action.

of general, compensatory, and special damages and rarely include punitive and exemplary damages. (See Sec. 88.20 for definitions of these damages.)

## 18. STRICT LIABILITY IN TORT

*Strict liability in tort* means that the injured party wins if the injury can be proven. It is not necessary to prove negligence, breach of explicit or implicit warranty, or the existence of a contract (*privity of contract*). Strict liability in tort is most commonly encountered in product liability cases. A defect in a product, regardless of how the defect got there, is sufficient to create strict liability in tort.

Case law surrounding defective products has developed and refined the following requirements for winning a strict liability in tort case. The following points must be proved.

- The product was defective in manufacture, design, labeling, and so on.
- The product was defective when used.
- The defect rendered the product unreasonably dangerous.
- The defect caused the injury.
- The specific use of the product that caused the damage was reasonably foreseeable.

## 19. MANUFACTURING AND DESIGN LIABILITY

Case law makes a distinction between *design professionals* (architects, structural engineers, building designers, etc.) and manufacturers of consumer products. Design professionals are generally consultants whose primary product is a design service sold to sophisticated clients. Consumer product manufacturers produce specific product lines sold through wholesalers and retailers to the unsophisticated public.

The law treats design professionals favorably. Such professionals are expected to meet a *standard of care* and skill that can be measured by comparison with the conduct of other professionals. However, professionals are not expected to be infallible. In the absence of a contract provision to the contrary, design professionals are not held to be guarantors of their work in the strict sense of legal liability. Damages incurred due to design errors are recoverable through tort actions, but proving a breach of contract requires showing negligence (i.e., not meeting the standard of care).

On the other hand, the law is much stricter with consumer product manufacturers, and perfection is (essentially) expected of them. They are held to the standard of strict liability in tort without regard to negligence.

A manufacturer is held liable for all phases of the design and manufacturing of a product being marketed to the public.<sup>23</sup>

Prior to 1916, the court's position toward product defects was exemplified by the expression *caveat emptor* ("let the buyer beware").<sup>24</sup> Subsequent court rulings have clarified that "... a manufacturer is strictly liable in tort when an article [it] places on the market, knowing that it will be used without inspection, proves to have a defect that causes injury to a human being."<sup>25</sup>

Although all defectively designed products can be traced back to a design engineer or team, only the manufacturing company is usually held liable for injury caused by the product. This is more a matter of economics than justice. The company has liability insurance; the product design engineer (who is merely an employee of the company) probably does not. Unless the product design or manufacturing process is intentionally defective, or unless the defect is known in advance and covered up, the product design engineer will rarely be punished by the courts.<sup>26</sup>

## 20. DAMAGES

An injured party can sue for *damages* as well as for specific performance. Damages are the award made by the court for losses incurred by the injured party.

- *General or compensatory damages* are awarded to make up for the injury that was sustained.
- *Special damages* are awarded for the direct financial loss due to the breach of contract.
- *Nominal damages* are awarded when responsibility has been established but the injury is so slight as to be inconsequential.
- *Liquidated damages* are amounts that are specified in the contract document itself for nonperformance.
- *Punitive or exemplary damages* are awarded, usually in tort and fraud cases, to punish and make an

<sup>23</sup>The reason for this is that the public is not considered to be as sophisticated as a client who contracts with a design professional for building plans.

<sup>24</sup>1916, *MacPherson v. Buick*. MacPherson bought a Buick from a car dealer. The car had a defective wheel, and there was evidence that reasonable inspection would have uncovered the defect. MacPherson was injured when the wheel broke and the car collapsed, and he sued Buick. Buick defended itself under the ancient *prerequisite of privity* (i.e., the requirement of a face-to-face contractual relationship in order for liability to exist), since the dealer, not Buick, had sold the car to MacPherson, and no contract between Buick and MacPherson existed. The judge disagreed, thus establishing the concept of *third party liability* (i.e., manufacturers are responsible to consumers even though consumers do not buy directly from manufacturers).

<sup>25</sup>1963, *Greenman v. Yuba Power Products*. Greenman purchased and was injured by an electric power tool.

<sup>26</sup>The engineer can expect to be discharged from the company. However, for strategic reasons, this discharge probably will not occur until after the company loses the case.

example of the defendant (i.e., to deter others from doing the same thing).

- *Consequential damages* provide compensation for indirect losses incurred by the injured party but not directly related to the contract.

## 21. INSURANCE

---

Most design firms and many independent design professionals carry *errors and omissions insurance* to protect them from claims due to their mistakes. Such policies are costly, and for that reason, some professionals choose to “go bare.”<sup>27</sup> Policies protect against inadvertent mistakes only, not against willful, knowing, or conscious efforts to defraud or deceive.

---

<sup>27</sup>Going bare appears foolish at first glance, but there is a perverted logic behind the strategy. One-person consulting firms (and perhaps, firms that are not profitable) are “judgment-proof.” Without insurance or other assets, these firms would be unable to pay any large judgments against them. When damage victims (and their lawyers) find this out in advance, they know that judgments will be uncollectable. So, often the lawsuit never makes its way to trial.

## 1. CREEDS, CODES, CANONS, STATUTES, AND RULES

It is generally conceded that an individual acting on his or her own cannot be counted on to always act in a proper and moral manner. Creeds, statutes, rules, and codes all attempt to complete the guidance needed for an engineer to do "...the correct thing."

A *creed* is a statement or oath, often religious in nature, taken or assented to by an individual in ceremonies. For example, the *Engineers' Creed* adopted by the National Society of Professional Engineers (NSPE) in 1954 is<sup>1</sup>

As a professional engineer, I dedicate my professional knowledge and skill to the advancement and betterment of human welfare.

I pledge...

...to give the utmost of performance;

...to participate in none but honest enterprise;

...to live and work according to the laws of man and the highest standards of professional conduct;

...to place service before profit, the honor and standing of the profession before personal advantage, and the public welfare above all other considerations.

In humility and with need for Divine Guidance, I make this pledge.

A *code* is a system of nonstatutory, nonmandatory canons of personal conduct. A *canon* is a fundamental belief that usually encompasses several rules. For

<sup>1</sup>The *Faith of an Engineer* adopted by the Accreditation Board for Engineering and Technology (ABET), formerly the Engineer's Council for Professional Development (ECPD), is a similar but more detailed creed.

example, the code of ethics of the American Society of Civil Engineers (ASCE) contains seven canons.

1. Engineers shall hold paramount the safety, health, and welfare of the public and shall strive to comply with the principles of sustainable development in the performance of their professional duties.
2. Engineers shall perform services only in areas of their competence.
3. Engineers shall issue public statements only in an objective and truthful manner.
4. Engineers shall act in professional matters for each employer or client as faithful agents or trustees and shall avoid conflicts of interest.
5. Engineers shall build their professional reputation on the merit of their service and shall not compete unfairly with others.
6. Engineers shall act in such a manner as to uphold and enhance the honor, integrity, and dignity of the engineering profession, and shall act with zero tolerance for bribery, fraud, and corruption.
7. Engineers shall continue their professional development throughout their careers and shall provide opportunities for the professional development of those engineers under their supervision.

A *rule* is a guide (principle, standard, or norm) for conduct and action in a certain situation. A *statutory rule* is enacted by the legislative branch of a state or federal government and carries the weight of law. Some U.S. engineering registration boards have statutory *rules of professional conduct*.

## 2. PURPOSE OF A CODE OF ETHICS

Many different sets of *codes of ethics* (*canons of ethics*, *rules of professional conduct*, etc.) have been produced by various engineering societies, registration boards, and other organizations.<sup>2</sup> The purpose of these ethical

<sup>2</sup>All of the major engineering technical and professional societies in the United States (ASCE, IEEE, ASME, AIChE, NSPE, etc.) and throughout the world have adopted codes of ethics. Most U.S. societies have endorsed the *Code of Ethics of Engineers* developed by the Accreditation Board for Engineering and Technology (ABET). The National Council of Examiners for Engineering and Surveying (NCEES) has developed its *Model Rules of Professional Conduct* as a guide for state registration boards in developing guidelines for the professional engineers in those states.

guidelines is to guide the conduct and decision making of engineers. Most codes are primarily educational. Nevertheless, from time to time they have been used by the societies and regulatory agencies as the basis for disciplinary actions.

Fundamental to ethical codes is the requirement that engineers render faithful, honest, professional service. In providing such service, engineers must represent the interests of their employers or clients and, at the same time, protect public health, safety, and welfare.

There is an important distinction between what is legal and what is ethical. Many actions that are legal can be violations of codes of ethical or professional behavior.<sup>3</sup> For example, an engineer's contract with a client may give the engineer the right to assign the engineer's responsibilities, but doing so without informing the client would be unethical.

Ethical guidelines can be categorized on the basis of who is affected by the engineer's actions—the client, vendors and suppliers, other engineers, or the public at large.<sup>4</sup>

### 3. ETHICAL PRIORITIES

There are frequently conflicting demands on engineers. While it is impossible to use a single decision-making process to solve every ethical dilemma, it is clear that ethical considerations will force engineers to subjugate their own self-interests. Specifically, the ethics of engineers dealing with others need to be considered in the following order, from highest to lowest priority.

- society and the public
- the law
- the engineering profession
- the engineer's client
- the engineer's firm
- other involved engineers
- the engineer personally

<sup>3</sup>Whether the guidelines emphasize ethical behavior or professional conduct is a matter of wording. The intention is the same: to provide guidelines that transcend the requirements of the law.

<sup>4</sup>Some authorities also include ethical guidelines for dealing with the employees of an engineer. However, these guidelines are no different for an engineering employer than they are for a supermarket, automobile assembly line, or airline employer. Ethics is not a unique issue when it comes to employees.

### 4. DEALING WITH CLIENTS AND EMPLOYERS

The most common ethical guidelines affecting engineers' interactions with their employer (the *client*) can be summarized as follows.<sup>5</sup>

- An engineer should not accept assignments for which he/she does not have the skill, knowledge, or time.
- An engineer must recognize his/her own limitations, and use associates and other experts when the design requirements exceed his/her ability.
- The client's interests must be protected. The extent of this protection exceeds normal business relationships and transcends the legal requirements of the engineer-client contract.
- An engineer must not be bound by what the client wants in instances where such desires would be unsuccessful, dishonest, unethical, unhealthy, or unsafe.
- Confidential client information remains the property of the client and must be kept confidential.
- An engineer must avoid conflicts of interest and should inform the client of any business connections or interests that might influence his/her judgment. An engineer should also avoid the *appearance* of a conflict of interest when such an appearance would be detrimental to the profession, the client, or the engineer.
- The engineer's sole source of income for a particular project should be the fee paid by the client. An engineer should not accept compensation in any form from more than one party for the same services.
- If the client rejects the engineer's recommendations, the engineer should fully explain the consequences to the client.
- An engineer must freely and openly admit to the client any errors made.

All courts of law have required an engineer to perform in a manner consistent with normal professional standards. This is not the same as saying an engineer's work must be error-free. If an engineer completes a design, has the design and calculations checked by another competent engineer, and an error is subsequently shown to have been made, the engineer may be held responsible, but the engineer will probably not be considered negligent.

<sup>5</sup>These general guidelines contain references to contractors, plans, specifications, and contract documents. This language is common, though not unique, to the situation of an engineer supplying design services to an owner-developer or architect. However, most of the ethical guidelines are general enough to apply to engineers in industry as well.

## 5. DEALING WITH SUPPLIERS

Engineers routinely deal with manufacturers, contractors, and vendors (*suppliers*). In this regard, engineers have great responsibility and influence. Such a relationship requires that engineers deal justly with both clients and suppliers.

An engineer will often have an interest in maintaining good relationships with suppliers since this often leads to future work. Nevertheless, relationships with suppliers must remain highly ethical. Suppliers should not be encouraged to feel that they have any special favors coming to them because of a long-standing relationship with the engineer.

The ethical responsibilities relating to suppliers are listed as follows.

- An engineer must not accept or solicit gifts or other valuable considerations from a supplier during, prior to, or after any job. An engineer should not accept discounts, allowances, commissions, or any other indirect compensation from suppliers, contractors, or other engineers in connection with any work or recommendations.
- An engineer must enforce the plans and specifications (i.e., the *contract documents*), but must also interpret the contract documents fairly.
- Plans and specifications developed by an engineer on behalf of the client must be complete, definite, and specific.
- Suppliers should not be required to spend time or furnish materials that are not called for in the plans and contract documents.
- An engineer should not unduly delay the performance of suppliers.

## 6. DEALING WITH OTHER ENGINEERS

Engineers should try to protect the engineering profession as a whole, to strengthen it, and to enhance its public stature. The following ethical guidelines apply.

- An engineer should not attempt to maliciously injure the professional reputation, business practice, or employment position of another engineer. However, if there is proof that another engineer has acted unethically or illegally, the engineer should advise the proper authority.
- An engineer should not review someone else's work while the other engineer is still employed unless the other engineer is made aware of the review.
- An engineer should not try to replace another engineer once the other engineer has received employment.

- An engineer should not use the advantages of a salaried position to compete unfairly (i.e., moonlight) with other engineers who have to charge more for the same consulting services.
- Subject to legal and proprietary restraints, an engineer should freely report, publish, and distribute information that would be useful to other engineers.

## 7. DEALING WITH (AND AFFECTING) THE PUBLIC

In regard to the social consequences of engineering, the relationship between an engineer and the public is essentially straightforward. Responsibilities to the public demand that the engineer place service to humankind above personal gain. Furthermore, proper ethical behavior requires that an engineer avoid association with projects that are contrary to public health and welfare or that are of questionable legal character.

- An engineer must consider the safety, health, and welfare of the public in all work performed.
- An engineer must uphold the honor and dignity of his/her profession by refraining from self-laudatory advertising, by explaining (when required) his/her work to the public, and by expressing opinions only in areas of knowledge.
- When an engineer issues a public statement, he/she must clearly indicate if the statement is being made on anyone's behalf (i.e., if anyone is benefitting from his/her position).
- An engineer must keep his/her skills at a state-of-the-art level.
- An engineer should develop public knowledge and appreciation of the engineering profession and its achievements.
- An engineer must notify the proper authorities when decisions adversely affecting public safety and welfare are made.<sup>6</sup>

## 8. COMPETITIVE BIDDING

The ethical guidelines for dealing with other engineers presented here and in more detailed codes of ethics no longer include a prohibition on *competitive bidding*. Until 1971, most codes of ethics for engineers considered competitive bidding detrimental to public welfare, since cost-cutting normally results in a lower quality design.

However, in a 1971 case against NSPE that went all the way to the U.S. Supreme Court, the prohibition against competitive bidding was determined to be a violation of the Sherman Antitrust Act (i.e., it was an unreasonable restraint of trade).

<sup>6</sup>This practice has come to be known as *whistle-blowing*.

The opinion of the Supreme Court does not *require* competitive bidding—it merely forbids a prohibition against competitive bidding in NSPE's code of ethics. The following points must be considered.

- Engineers and design firms may individually continue to refuse to bid competitively on engineering services.
- Clients are not required to seek competitive bids for design services.
- Federal, state, and local statutes governing the procedures for procuring engineering design services, even those statutes that prohibit competitive bidding, are not affected.
- Any prohibitions against competitive bidding in individual state engineering registration laws remain unaffected.
- Engineers and their societies may actively and aggressively lobby for legislation that would prohibit competitive bidding for design services by public agencies.

## 9. MODERN ETHICAL ISSUES

---

With few exceptions, ethical concepts have changed little for engineers since they were first developed by the fledgling engineering societies. Ethical rules covering such issues as service-before-self, conflicts of interest, bribery and kickbacks, moonlighting and unfair competition, respectable dealings with engineering competitors, and respect for the profession and its image may have seen wording changes, but their basic concepts have not changed. Even protection for whistle-blowers can be traced back to the early 1900s, although environmental whistle-blowing came into its own in the 1970s.

Modern engineers, however, have to deal with newer concepts such as environmental protection, sustainable (green) design, offshoring, energy efficiency and dependency, cultural diversity and tolerance, nutrition and safety of foodstuffs and drugs, national sufficiency, and issues affecting national security and personal privacy and security. Most engineers have little experience or training in these concepts, and for some issues, neither regulations nor technology exist to help engineers arrive at definitive decisions.

*Environmental protection*, from an ethical standpoint, places burdens on engineers that go far beyond adhering to EPA and U.S. Army Corps of Engineers regulations. Issues include waste, pollution, loss of biodiversity, introduction of invasive species, release of genetically modified organisms, genetically modified foodstuffs, and release of toxic substances.

In 2006, the American Society of Civil Engineers amended its first canon to include mention of *sustainable development*, which is subsequently defined as follows: “Sustainable development is the process of applying natural, human, and economic resources to enhance the safety, welfare, and quality of life for all of society while maintaining the availability of the remaining natural resources.”

*Offshoring* broadly means the replacement of a service originally performed within an organization by a service located in a foreign country. Offshoring applies to designing facilities and processes sited in foreign countries, as well as the more common issue of sending jobs to foreign countries. Closer to home, the engineering professional itself has struggled with respecting and accepting offshore engineering services. The very cost-cutting moves that engineers have pursued in service to their employers have hurt engineers and their profession and has given rise to a form of nationalism founded on resentment.

10. PE Examination Format .....	90-3

## 1. ABOUT LICENSING

*Engineering licensing* (also known as *engineering registration*) in the United States is an examination process by which a state's *board of engineering licensing* (typically referred to as the "engineers' board" or "board of registration") determines and certifies that an engineer has achieved a minimum level of competence.<sup>1</sup> This process is intended to protect the public by preventing unqualified individuals from offering engineering services.

Most engineers in the United States do not need to be licensed.<sup>2</sup> In particular, most engineers who work for companies that design and manufacture products are exempt from the licensing requirement. This is known as the *industrial exemption*, something that is built into the laws of most states.<sup>3</sup>

Nevertheless, there are many good reasons to become a licensed engineer. For example, an engineer cannot offer consulting engineering services in any state unless he or she is licensed in that state. Even within a product-oriented corporation, an engineer may find that employment, advancement, and managerial positions are limited to licensed engineers.

Once an engineer has met the licensing requirements, he or she will be allowed to use the titles *Professional*

<sup>1</sup>Licensing of engineers is not unique to the United States. However, the practice of requiring a degreed engineer to take an examination is not common in other countries. Licensing in many countries requires a degree and may also require experience, references, and demonstrated knowledge of ethics and law, but no technical examination.

<sup>2</sup>Less than one-third of the degreed engineers in the United States are licensed.

<sup>3</sup>Only one or two states have abolished the industrial exemption. There has always been a lot of "talk" among engineers about abolishing it, but there has been little success in actually trying to do so. One of the reasons is that manufacturers' lobbies are very strong.

*Engineer (PE), Registered Engineer (RE), and Consulting Engineer (CE)* as permitted by the state.

Although the licensing process is similar in each of the 50 states, each has its own licensing law. Unless an engineer offers consulting engineering services in more than one state, however, there is no need to be licensed in the other states.

## 2. THE U.S. LICENSING PROCEDURE

The licensing procedure is similar in all states. A candidate will take two written examinations. The full process requires the candidate to complete two applications, one for each of the two examinations. The first examination is the *Fundamentals of Engineering (FE) examination*, formerly known (and still commonly referred to) as the *Engineer-In-Training (EIT) examination*.<sup>4</sup> This examination covers basic subjects from all of the engineering courses required by an undergraduate program.

The second examination is the *Professional Engineering (PE) examination*, also known as the *Principles and Practice (P&P) of Engineering examination*. This examination covers only the subjects specific to an engineering discipline (e.g., civil, mechanical, electrical, and others).

The actual details of licensing qualifications, experience requirements, minimum education levels, fees, and examination schedules vary from state to state. Each state's licensing board has more information. Contact information (websites, telephone numbers, email addresses, etc.) for all U.S. state and territorial boards of registration is provided at [ppi2pass.com/stateboards](http://ppi2pass.com/stateboards).

## 3. NATIONAL COUNCIL OF EXAMINERS FOR ENGINEERING AND SURVEYING

The *National Council of Examiners for Engineering and Surveying* (NCEES) in Clemson, South Carolina, writes, distributes, and scores the national FE and PE examinations.<sup>5</sup> The individual states purchase the examinations from NCEES and administer them in a uniform, controlled environment dictated by NCEES.

<sup>4</sup>The terms *engineering intern (EI)* and *intern engineer (IE)* have also been used in the past to designate the status of an engineer who has passed the first exam. These uses are rarer but may still be encountered in some states.

<sup>5</sup>National Council of Examiners for Engineering and Surveying, P.O. Box 1686, Clemson, SC 29633, (800) 250-3196, [ncees.org](http://ncees.org).

## 4. UNIFORM EXAMINATIONS

Although each state has its own licensing law and is, theoretically, free to administer its own exams, none does so for the major disciplines. All states have chosen to use the NCEES exams. The exams from all the states are sent to NCEES to be graded. Each state adopts the cut-off passing scores recommended by NCEES. These practices have led to the term *uniform examination*.

## 5. RECIPROCITY AMONG STATES

With minor exceptions, having a license from one state will not permit an engineer to practice in another state. A professional engineering license from each state is required to work in that state. Most engineers do not work across state lines or in multiple states, but some do. Luckily, it is not too difficult to get a license from every state worked in once a license from one of them is obtained.

All states use the NCEES examinations. If an engineer takes and passes the FE or PE examination in one state, the certificate or license will be honored by all of the other states. Upon proper application, payment of fees, and proof of engineering license, a license by the new state will be issued. Although there may be other special requirements imposed by a state, it will not be necessary to retake the FE or PE examinations.<sup>6</sup> The issuance of an engineering license based on another state's licensing is known as *reciprocity* or *comity*.

## 6. APPLYING FOR THE FE EXAMINATION

The FE exam is administered at approved Pearson VUE testing centers. Registration is open year-round and can be completed online through an NCEES account.<sup>7</sup> Registration fees may be paid online. Once a candidate receives notification of eligibility from NCEES, the exam can be scheduled through an NCEES account. A letter from Pearson VUE confirming the exam location and date will be sent via email.

Whether or not applying for and taking the exam is the same as applying for a state's FE certificate depends on the state. In most cases, a candidate might take the exam without a state board ever knowing about it. In fact, as part of the NCEES online exam application process, candidates have to agree to the following statement:

Passage of the FE exam alone does not ensure certification as an engineer intern or engineer-in-training in any U.S. state or territory. To obtain certification, you must file an application with an engineering licensing board and meet that board's requirements.

<sup>6</sup>For example, California requires all civil engineering applicants to pass special examinations in seismic design and surveying in addition to their regular eight-hour PE exams. Licensed engineers from other states only have to pass these two special exams. They do not need to retake the PE exam.

<sup>7</sup>PPI is not associated with NCEES.

After a state's education requirements have been met and a candidate is ready to obtain an FE (EIT, IE, etc.) certificate, he or she must apply and pay an additional fee to that state. In some cases, passing an additional nontechnical exam related to professional practice in that state may be required. Actual procedures will vary from state to state.

Approximately 7–10 days after the exam, a candidate will receive an email notification that the exam results are ready for viewing through the NCEES account. This notification may include information about additional state-specific steps in the process.

All states make special accommodations for candidates who are physically challenged or who have religious or other special needs. Needs must be communicated to Pearson VUE well in advance of the examination day.

## 7. APPLYING FOR THE PE EXAMINATION

As with the FE exam, applying for the PE exam includes the steps of registering with NCEES, registering with a state, paying fees to that state, paying fees to NCEES, sending documentation to that state, and notifying that state and NCEES of what has been done. The sequence of these steps varies from state to state.<sup>8</sup>

In some states, the first thing a candidate does is reserve a seat for the upcoming exam through an NCEES account. In other states, the first thing a candidate does is to register with his or her state. In some states, registering with NCEES is the very last thing done, and a candidate may not even be able to notify NCEES until the entire application has been approved by his or her state. Some states use a third-party testing organization with whom a candidate must register. In some states, all fees are paid directly to the state. In other states, all fees are paid to NCEES. In some states, fees are paid to both. In some states, NCEES forms are included with the state application; in other states, state forms are included with the NCEES application. Both the states and NCEES have their own application deadlines, and a state's deadlines will not necessarily coincide with NCEES deadlines.

If a candidate has special physical needs or requirements, these must be coordinated directly with the state. The method and deadline for requesting special accommodations depends on the state. A candidate should keep copies of all forms and correspondence with NCEES and the state.

All states require an application containing a detailed work history. The application form may be available online to print out, or the state may have it mailed. All states require submitted evidence of qualifying engineering experience in the form of written corroborative statements (typically referred to as "professional references") provided and signed by supervising engineers,

<sup>8</sup>Each state board of registration (licensure board) is the most definitive source of information about the application process. A summary of each state's application process is also listed on the NCEES website, ncees.org.

usually other professional engineers. The nature and format of these applications and corroborative statements depend on the state. An application is not complete until all professional references have been received by the state. The state will notify a candidate if one or more references have not been received in a timely manner.

Approximately 2–3 weeks before the exam, NCEES will email the candidate a link to the Exam Authorization Admittance notice, which should be printed out. This document must be presented along with a valid, government-issued photo ID in order to enter the exam site.

The examination results will be released by NCEES to each state 8–10 weeks after the exam. Soon thereafter, states will notify candidates via mail, email, or web access, or alternatively, NCEES may notify candidates via email that results are accessible from an NCEES account. If a state-specific examination was taken, but was not written or graded by NCEES, the state will notify a candidate separately of those results.

## 8. EXAMINATION DATES

The FE examination is administered eight months out of the year: January, February, April, May, July, August, October, and November. There are multiple testing dates within each of those months. No exams are administered in March, June, September, or December.

The PE examination is administered twice a year (usually in mid-April and late October), on the same weekends in all states. For a current exam schedule, check [ppi2pass.com/CE](http://ppi2pass.com/CE). Click on the Exam FAQs link.

## 9. FE EXAMINATION FORMAT

The FE exam is a computer-based test that contains 110 multiple-choice questions given over two consecutive sessions (sections, parts, etc.). Each session contains approximately 55 multiple-choice questions that are grouped together by knowledge area (subject, topic, etc.). The subjects are not explicitly labeled, and the beginning and ending of the subjects are not noted. No subject spans the two exam sessions. That is, if a subject

appears in the first session of the exam, it will not appear in the second.

The exam is six hours long and includes an 8-minute tutorial, a 25-minute break, and a brief survey at the conclusion of the exam. Questions from all undergraduate technical courses appear in the examination, including mathematics, physics, and engineering.

The FE exam is essentially entirely in SI units. There may be a few non-SI problems and some opportunities to choose between identical SI and non-SI problems.

The FE exam is a limited-reference exam. NCEES provides its own reference handbook for use in the examination. Personal books or notes may not be used, though candidates may bring an approved calculator. A reusable, erasable notepad and compatible writing instrument to use for scratchwork are provided during the exam.

## 10. PE EXAMINATION FORMAT

The NCEES PE examination consists of two four-hour sessions, separated by a one-hour lunch period. It covers only subjects in your major field of study (e.g., civil engineering). There are several variations in PE exam format, but the most common type has 40 questions in each session.

All questions are *objectively scored*. This means that each question is machine graded. There is no penalty for guessing or wrong answers, but there is also no partial credit for correct methods and assumptions.

Unlike the FE exam where SI units are used extensively, virtually all of the questions on the PE exam are in customary U.S. units. There are a few exceptions (e.g., environmental topics), but most problems use pounds, feet, seconds, gallons, and British thermal units.

The PE examination is open book. While some states have a few restrictions, generally a candidate may bring in an unlimited number of personal references. Pencils and erasers are provided, and calculators must be selected from a list of calculators approved by NCEES for exam use.

## APPENDIX 7.A

### Mensuration of Two-Dimensional Areas

**Nomenclature**

$A$	total surface area
$b$	base
$c$	chord length
$d$	distance
$h$	height
$L$	length
$p$	perimeter
$r$	radius
$s$	side (edge) length, arc length
$\theta$	vertex angle, in radians
$\phi$	central angle, in radians

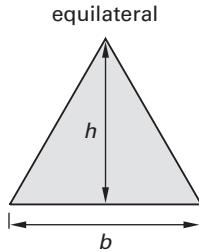

**Circular Sector**

$$A = \frac{1}{2}\phi r^2 = \frac{1}{2}sr$$

$$\phi = \frac{s}{r}$$

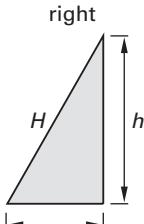

$$s = r\phi$$

$$c = 2r \sin\left(\frac{\phi}{2}\right)$$

**Triangle**

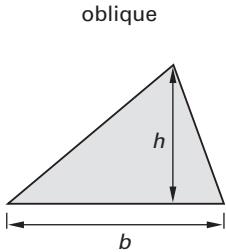

$$A = \frac{1}{2}bh = \frac{\sqrt{3}}{4}b^2$$

$$h = \frac{\sqrt{3}}{2}b$$

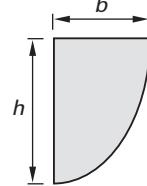

$$A = \frac{1}{2}bh$$

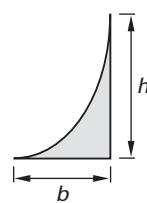

$$H^2 = b^2 + h^2$$

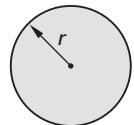

$$A = \frac{1}{2}bh$$

**Parabola**

$$A = \frac{2}{3}bh$$

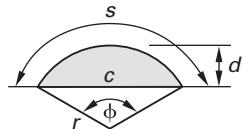

$$A = \frac{1}{3}bh$$

**Circle**

$$p = 2\pi r$$

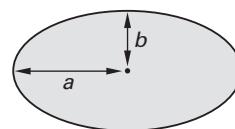

$$A = \pi r^2 = \frac{p^2}{4\pi}$$

**Circular Segment**

$$A = \frac{1}{2}r^2(\phi - \sin \phi)$$

$$\phi = \frac{s}{r} = 2\left(\arccos \frac{r-d}{r}\right)$$

$$c = 2r \sin\left(\frac{\phi}{2}\right)$$

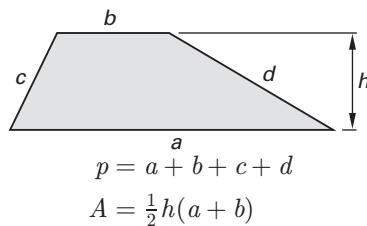

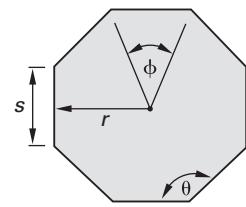

**Ellipse**

$$A = \pi ab$$

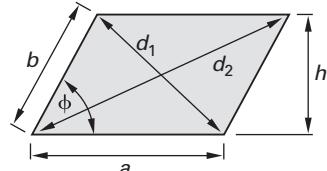

$$p \approx 2\pi \sqrt{\frac{1}{2}(a^2 + b^2)} \quad \begin{bmatrix} \text{Euler's} \\ \text{upper bound} \end{bmatrix}$$

*(continued)*

**APPENDIX 7.A (continued)**  
 Mensuration of Two-Dimensional Areas

**Trapezoid**

**Regular Polygon ( $n$  equal sides)**

If  $c = d$ , the trapezoid is isosceles.

**Parallelogram**

$$\begin{aligned} p &= 2(a + b) \\ d_1 &= \sqrt{a^2 + b^2 - 2ab \cos \phi} \\ d_2 &= \sqrt{a^2 + b^2 + 2ab \cos \phi} \\ d_1^2 + d_2^2 &= 2(a^2 + b^2) \\ A &= ah = ab \sin \phi \end{aligned}$$

If  $a = b$ , the parallelogram is a rhombus.

$$\phi = \frac{2\pi}{n}$$

$$\theta = \frac{\pi(n-2)}{n} = \pi - \phi$$

$$p = ns$$

$$s = 2r \tan \frac{\theta}{2}$$

$$A = \frac{1}{2}nsr$$

## APPENDIX 7.B

### Mensuration of Three-Dimensional Volumes

**Nomenclature**

$A$	surface area
$b$	base
$h$	height
$r$	radius
$R$	radius
$s$	side (edge) length
$V$	internal volume

**Sphere**

$$V = \frac{4}{3}\pi r^3 = \frac{4}{3}\pi \left(\frac{d}{2}\right)^3 = \frac{1}{6}\pi d^3$$

$$A = 4\pi r^2$$

**Right Circular Cone (excluding base area)**

$$V = \frac{1}{3}\pi r^2 h = \frac{1}{3}\pi \left(\frac{d}{2}\right)^2 h = \frac{1}{12}\pi d^2 h$$

$$A = \pi r \sqrt{r^2 + h^2}$$

**Right Circular Cylinder (excluding end areas)**

$$V = \pi r^2 h$$

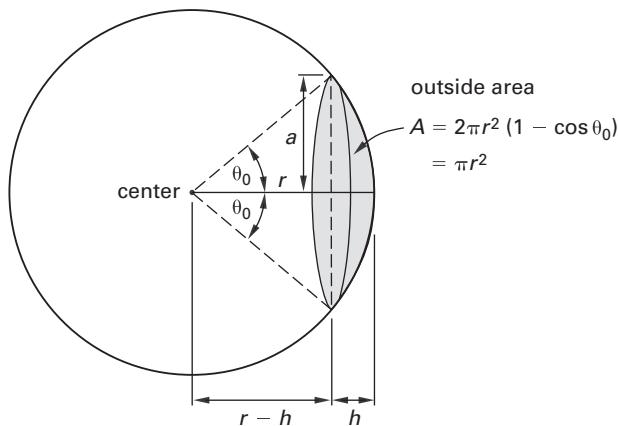

$$A = 2\pi r h$$

**Spherical Segment (spherical cap)**

Surface area of a spherical segment of radius  $r$  cut out by an angle  $\theta_0$  rotated from the center about a radius,  $r$ , is

$$A = 2\pi r^2 (1 - \cos \theta_0)$$

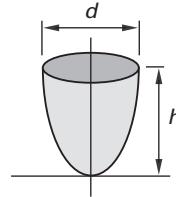

$$\omega = \frac{A}{r^2} = 2\pi(1 - \cos \theta_0)$$

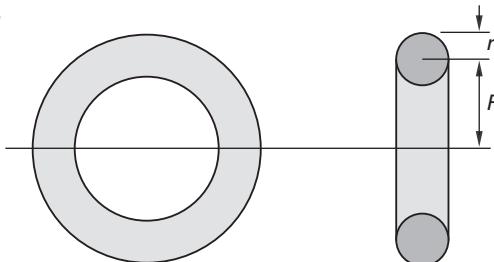

$$V_{cap} = \frac{1}{6}\pi h(3a^2 + h^2)$$

$$= \frac{1}{3}\pi h^2(3r - h)$$

$$a = \sqrt{h(2r - h)}$$

**Paraboloid of Revolution**

$$V = \frac{1}{8}\pi d^2 h$$

**Torus**

$$A = 4\pi^2 Rr$$

$$V = 2\pi^2 Rr^2$$

**Regular Polyhedra (identical faces)**

name	number of faces	form of faces	total surface area	volume
tetrahedron	4	equilateral triangle	$1.7321 s^2$	$0.1179 s^3$
cube	6	square	$6.0000 s^2$	$1.0000 s^3$
octahedron	8	equilateral triangle	$3.4641 s^2$	$0.4714 s^3$
dodecahedron	12	regular pentagon	$20.6457 s^2$	$7.6631 s^3$
icosahedron	20	equilateral triangle	$8.6603 s^2$	$2.1817 s^3$

The radius of a sphere inscribed within a regular polyhedron is

$$r = \frac{3V_{polyhedron}}{A_{polyhedron}}$$

**APPENDIX 9.A**

Abbreviated Table of Indefinite Integrals

(In each case, add a constant of integration. All angles are measured in radians.)

**General Formulas**

1.  $\int dx = x$
2.  $\int c dx = c \int dx$
3.  $\int (dx + dy) = \int dx + \int dy$
4.  $\int u dv = uv - \int v du$  [integration by parts;  $u$  and  $v$  are functions of the same variable]

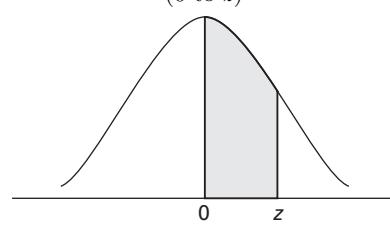

**Algebraic Forms**

5.  $\int x^n dx = \frac{x^{n+1}}{n+1}$  [ $n \neq -1$ ]
6.  $\int x^{-1} dx = \int \frac{dx}{x} = \ln|x|$
7.  $\int (ax + b)^n dx = \frac{(ax + b)^{n+1}}{a(n+1)}$  [ $n \neq -1$ ]
8.  $\int \frac{dx}{ax + b} = \frac{1}{a} \ln(ax + b)$
9.  $\int \frac{x dx}{ax + b} = \frac{1}{a^2} \left( ax + b - b \ln(ax + b) \right)$
10.  $\int \frac{x dx}{(ax + b)^2} = \frac{1}{a^2} \left( \frac{b}{ax + b} + \ln(ax + b) \right)$
11.  $\int \frac{dx}{x(ax + b)} = \frac{1}{b} \ln\left(\frac{x}{ax + b}\right)$
12.  $\int \frac{dx}{x(ax + b)^2} = \frac{1}{b(ax + b)} + \frac{1}{b^2} \ln\left(\frac{x}{ax + b}\right)$
13.  $\int \frac{dx}{x^2 + a^2} = \frac{1}{a} \arctan\left(\frac{x}{a}\right)$
14.  $\int \frac{dx}{a^2 - x^2} = \frac{1}{a} \operatorname{arctanh}\left(\frac{x}{a}\right)$
15.  $\int \frac{x dx}{ax^2 + b} = \frac{1}{2a} \ln(ax^2 + b)$
16.  $\int \frac{dx}{x(ax^n + b)} = \frac{1}{bn} \ln\left(\frac{x^n}{ax^n + b}\right)$
17.  $\int \frac{dx}{ax^2 + bx + c} = \frac{1}{\sqrt{b^2 - 4ac}} \ln\left(\frac{2ax + b - \sqrt{b^2 - 4ac}}{2ax + b + \sqrt{b^2 - 4ac}}\right)$  [ $b^2 > 4ac$ ]
18.  $\int \frac{dx}{ax^2 + bx + c} = \frac{2}{\sqrt{4ac - b^2}} \arctan\left(\frac{2ax + b}{\sqrt{4ac - b^2}}\right)$  [ $b^2 < 4ac$ ]
19.  $\int \sqrt{a^2 - x^2} dx = \frac{x}{2} \sqrt{a^2 - x^2} + \frac{a^2}{2} \arcsin\left(\frac{x}{a}\right)$
20.  $\int x \sqrt{a^2 - x^2} dx = -\frac{1}{3}(a^2 - x^2)^{3/2}$
21.  $\int \frac{dx}{\sqrt{a^2 - x^2}} = \arcsin\left(\frac{x}{a}\right)$
22.  $\int \frac{x dx}{\sqrt{a^2 - x^2}} = -\sqrt{a^2 - x^2}$

**APPENDIX 10.A**  
Laplace Transforms

$f(t)$	$\mathcal{L}(f(t))$	$f(t)$	$\mathcal{L}(f(t))$
$\delta(t)$ [unit impulse at $t=0$ ]	1	$1 - \cos at$	$\frac{a^2}{s(s^2 + a^2)}$

200	60.12	$6.370 \times 10^{-6}$	$0.341 \times 10^{-5}$	$0.412 \times 10^{-2}$	27.61	$308 \times 10^3$
212	59.83	$5.930 \times 10^{-6}$	$0.319 \times 10^{-5}$	$0.404 \times 10^{-2}$	35.38	$300 \times 10^3$

<sup>a</sup>based on actual densities, not on standard “cold, clear water”<sup>b</sup>can also be calculated from steam tables as  $(p_{\text{saturation}})(12 \text{ in}/\text{ft})^2(v_f)(g_c/g)$ <sup>c</sup>Multiply the vapor pressure head by the specific weight and divide by  $(12 \text{ in}/\text{ft})^2$  to obtain lbf/in<sup>2</sup>.

3400	2940	0.0117	$12.52 \times 10^{-7}$	$345.3 \times 10^{-5}$

<sup>a</sup>Temperatures are rounded to the nearest whole degree, but all significant digits were used in calculations.

<sup>b</sup>Density is calculated from the ideal gas law using  $p = 14.696 \text{ lbf/in}^2$  and  $R_{\text{air}} = 53.35 \text{ ft-lbf/lbm} \cdot \text{R}$ .

<sup>c</sup>Absolute viscosity is calculated from Sutherland's formula using  $C_{\text{Sutherland}} = 109.1^\circ\text{C}$  and  $\mu_0 = 0.14592 \text{ kg/m} \cdot \text{s}$ , and is subsequently converted to customary U.S. units. Error is  $\sim 0$  at  $530^\circ\text{R}$ . Error is expected to be less than 0.7% at  $300^\circ\text{R}$  and 0.2% at  $3400^\circ\text{R}$ .

<sup>d</sup>Kinematic viscosity is calculated as  $\nu = \mu g_c / \rho$ , with  $g_c = 32.1742 \text{ lbm-ft/lbf-sec}^2$ .

<sup>a</sup>Temperatures are rounded to the nearest whole degree, but all significant digits were used in calculations.

<sup>b</sup>Density is calculated from the ideal gas law using  $p = 101.325$  kPa; and  $R_{\text{air}} = 287.058$  J/kg·K.

<sup>c</sup>Absolute viscosity is calculated from Sutherland's formula using  $C_{\text{Sutherland}} = 109.1^\circ\text{C}$  and  $\mu_0 = 0.14592$  kg/m·s. Error is ~0 at 293K. Error is expected to be less than 0.7% at 175K and 0.2% at 1900K.

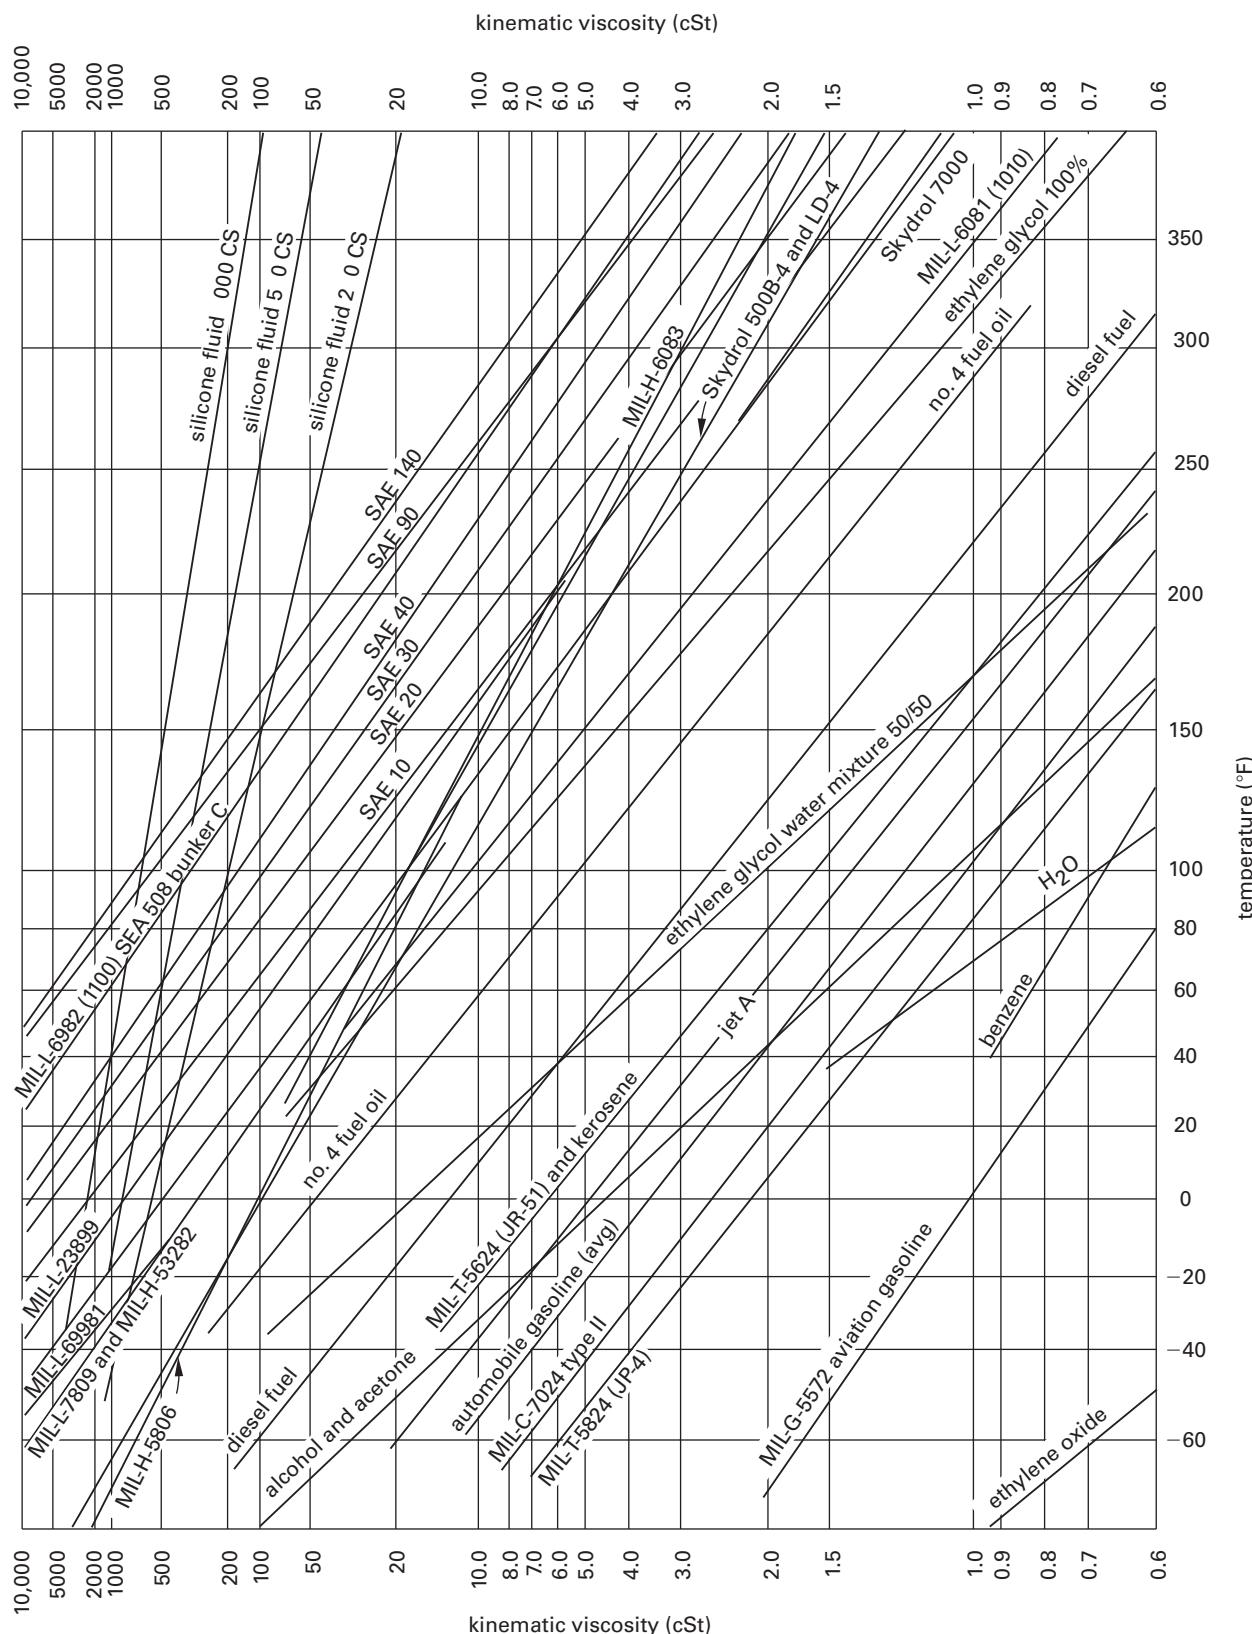

<sup>d</sup>Kinematic viscosity is calculated as  $\nu = \mu/\rho$ .

 Viscosities Versus Temperature of  
 Hydrocarbons, Lubricants, Fuels, and Heat Transfer Fluids

## APPENDIX 14.H

### Properties of Uncommon Fluids

Typical fluid viscosities are listed in the following table. The values given for thixotropic fluids are effective viscosities at normal pumping shear rates. Effective viscosity can vary greatly with changes in solids content, concentration, and so on.

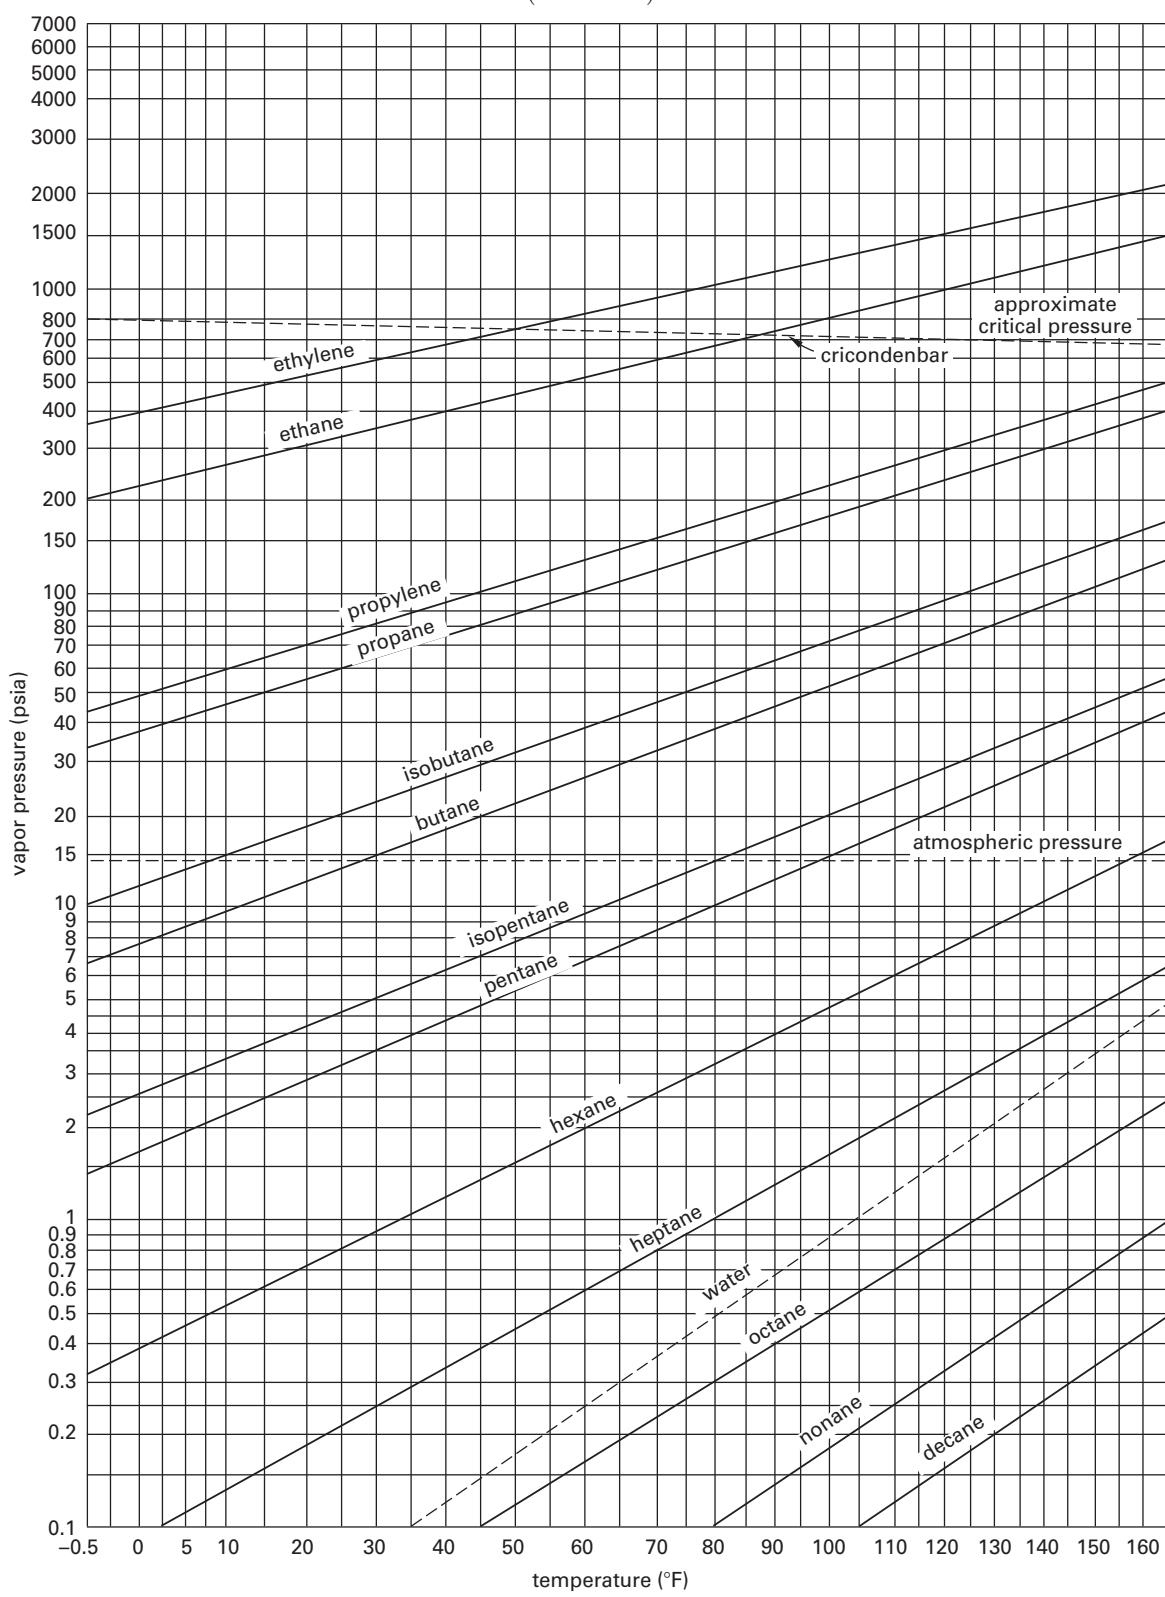

**Viscous Behavior Type:** N—Newtonian T—Thixotropic

fluid	specific gravity	viscosity CPS	viscous behavior type	fluid	specific gravity	viscosity CPS	viscous behavior type
reference—water	1.0	1.0	N	meat products			
adhesives				animal fat, melted	0.9	43 at 100°F	N
“box” adhesives	1±	3000	T	ground beef fat	0.9	11,000 at 60°F	T
PVA	1.3	100	T	meat emulsion	1.0	22,000 at 40°F	T
rubber and solvents	1.0	15,000	N	pet food	1.0	11,000 at 40°F	T
bakery				pork fat slurry	1.0	650 at 40°F	T
batter	1	2200	T	paint			
butter, melted	0.98	18 at 140°F	N	auto paint, metallic		200	T
egg, whole	0.5	60 at 50°F	N	solvents	0.8–0.9	0.5–10	N
emulsifier		20	T	titanium dioxide slurry		10,000	T
frosting	1	10,000	T	varnish	1.06	140 at 100°F	
lecithin		3250 at 125°F	T	turpentine	0.86	2 at 60°F	
77% sweetened condensed milk	1.3	10,000 at 77°F	N	paper and textile			
yeast slurry, 15%	1	180	T	black liquor	1.3	1100 at 122°F	
beer, wine				black liquor soap		7000 at 122°F	
beer	1.0	1.1 at 40°F	N	black liquor tar		2000 at 300°F	
brewers concentrated yeast, 80% solids		16,000 at 40°F	T	paper coating, 35%		400	
wine	1.0			sulfide, 6%		1600	
chemicals, miscellaneous glycols	1.1	35 at range		petroleum and petroleum products			
confectionary				asphalt, unblended	1.3	500–2500	
caramel	1.2	400 at 140°F		gasoline	0.7	0.8 at 60°F	N
chocolate	1.1	17,000 at 120°F	T	kerosene	0.8	3 at 68°F	N
fudge, hot	1.1	36,000	T	fuel oil no. 6	0.9	660 at 122°F	N
toffee	1.2	87,000	T	auto lube oil SAE 40	0.9	200 at 100°F	N
cosmetics, soaps				auto trans oil SAE 90	0.9	320 at 100°F	N
face cream		10,000	T	propane	0.46	0.2 at 100°F	N
gel, hair	1.4	5000	T	tars	1.2	wide range	
shampoo		5000	T	pharmaceuticals			
toothpaste		20,000	T	castor oil	0.96	350	N
hand cleaner		2000	T	cough syrup	1.0	190	N
dairy				“stomach” remedy slurries		1500	T
cottage cheese	1.08	225	T	pill pastes		5000±	T
cream	1.02	20 at 40°F	N	plastics*, resins			
milk	1.03	1.2 at 60°F	N	butadiene	0.94	0.17 at 40°F	
cheese, processed		30,000 at 160°F	T	polyester resin (typ)	1.4	3000	
yogurt		1100	T	PVA resin (typ)	1.3	65,000	T
detergents		10	N	starches, gums			
detergent concentrate				cornstarch sol 22°F	1.18	32	T
dyes and inks				cornstarch sol 25°F	1.21	300	T
ink, printers	1–1.38	10,000	T	sugar, syrups, molasses			
dye	1.1	10	N	corn syrup 41°Be	1.39	15,000 at 60°F	N
gum		5000	T	corn syrup 45°Be	1.45	12,000 at 130°F	N
fats and oils				glucose	1.42	10,000 at 100°F	
corn oils	0.92	30	N	molasses			
lard	0.96	60 at 100°F	N	A	1.4–1.47	280–5000 at 100°F	
linseed oil	0.93	30 at 100°F	N	B			
peanut oil	0.92	42 at 100°F	N	C	1.46–1.49	2600–5000 at 100°F	
soybean oil	0.95	36 at 100°F	N				
vegetable oil	0.92	3 at 300°F	N				
foods, miscellaneous							
black bean paste		10,000	T				
cream style corn		130 at 190°F	T				
catsup	1.11	560 at 145°F	T				
pablum		4500	T				
pear pulp		4000 at 160°F	T				
potato, mashed	1.0	20,000	T				
potato skins and caustic		20,000 at 100°F	T				
prune juice	1.0	60 at 120°F	T				
orange juice concentrate	1.1	5000 at 38°F	T				
tapioca pudding	0.7	1000 at 235°F	T				
mayonnaise	1.0	5000 at 75°F	T				
tomato paste, 33%	1.14	7000	T				
honey	1.5	1500 at 100°F	T				

\*A wide variety of plastics can be pumped; viscosity varies greatly.

(Multiply in by 25.4 to obtain mm.)

(Multiply in<sup>2</sup> by 645 to obtain mm<sup>2</sup>.)

<sup>a</sup>Designations are per ANSI B36.10.

<sup>b</sup>The "S" wall thickness was formerly designated as "standard weight." Standard weight and schedule-40 are the same for all diameters through 10 in. For diameters between 12 in and 24 in, standard weight pipe has a wall thickness of 0.375 in. The "X" (or "XS") wall thickness was formerly designated as "extra strong." Extra strong weight and schedule-80 are the same for all diameters through 8 in. For diameters between 10 in and 24 in, extra strong weight pipe has a wall thickness of 0.50 in. The "XX" (or "XXS") wall thickness was formerly designated as "double extra strong." Double extra strong weight pipe does not have a corresponding schedule number.

<sup>c</sup>Pipe sizes and weights in most common usage are listed. Other weights and sizes exist.

abbreviations

CL – pressure class (same as PC)

DR – dimensional ratio (constant ratio of outside diameter/wall thickness)

DWCP – double wall corrugated pipe

HW – heavy weight

PC – pressure class (same as CL)

PS – pipe stiffness (resistance to vertical diametral deflection due to compression from burial soil and surface loading, in lbf/in<sup>2</sup>; calculated uncorrected as vertical load in lbf per inch of pipe length divided by deflection in inches)

SDR – standard dimension ratio (constant ratio of outside diameter/wall thickness)

(Multiply in by 25.4 to obtain mm.)

(Multiply lbf/in<sup>2</sup> by 6.895 to obtain kPa.)

168	4200	14.0
174	4350	14.5
180	4500	15.0

(Multiply in by 25.4 to obtain mm.)

\*wall A thickness in inches = diameter in feet

**ASTM C361 – RCPP: Reinforced Concrete Low Head Pressure Pipe**

“Low head” means 125 ft (54 psi; 375 kPa) or less. Standard pipe with 12 in (300 mm) to 108 in (2700 mm) diameters are available. ASTM C361 limits tensile stress (and, therefore, strain) and flexural deformation. Any reinforcement design that meets these limitations is permitted. Internal and external dimensions typically correspond to C76 (wall B) pipe, but wall C may also be used.

**ASTM C655 – Reinforced Concrete D-Load Culvert, Storm Drain, and Sewer Pipe**

Pipes smaller than 72 in (1800 mm) are often specified by D-load. Pipe manufactured to satisfy ASTM C655 will support a specified concentrated vertical load (applied in three-point loading) in pounds per ft of length per ft of diameter. Some standard C76 pipe meets this standard. In order to use C76 (and other) pipes, D-loads are mapped onto C76 pipe classes. In some cases, special pipe designs are required. Pipe selection by D-load is accomplished by first determining the size of pipe required to carry the flow, then choosing the appropriate class of pipe according to the required D-load.

D <sub>0.01</sub> -load range	C76 pipe class
1–800	class 1 (I)
801–1000	class 2 (II)
1001–1350	class 3 (III)
1351–2000	class 4 (IV)
2000–3000	class 5 (V)
>3000	no equivalent class pipe

(Multiply in by 25.4 to obtain mm.)

(Multiply lbf/ft<sup>2</sup> by 0.04788 to obtain kN/m<sup>2</sup> (kPa).)

**APPENDIX 16.G**  
 Dimensions of Cast-Iron and Ductile Iron Pipe  
 Standard Pressure Classes  
 (customary U.S. units)

**ANSI/AWWA C106 Gray Cast-Iron Pipe**

The ANSI/AWWA C106 standard is obsolete. The outside diameters of 4–48 in (100–1200 mm) diameter gray cast-iron pipes are the same as for C150 pipes. Ductile iron pipe is interchangeable with respect to joining diameters, accessories, and fittings. However, inside diameters of cast-iron pipe are substantially greater than C150 pipe. Outside diameters and thicknesses of AWWA 1908 standard cast-iron pipe are substantially different from C150 values.

**ANSI/AWWA C150/A21.50 and ANSI/AWWA C151/A21.51**

64	65.67	0.56	0.64	0.72	0.80	0.87	0.09			

(Multiply in by 25.4 to obtain mm.)

(Multiply lbf/in<sup>2</sup> by 6.895 to obtain kPa.)

<sup>a</sup>Per ANSI/AWWA C150/A21.50, the tabulated minimum wall thicknesses include a 0.08 in (2 mm) service allowance and the appropriate casting tolerance. Listed thicknesses are adequate for the rated water working pressure plus a surge allowance of 100 lbf/in<sup>2</sup> (690 kPa). Values are based on a yield strength of 42,000 lbf/in<sup>2</sup> (290 MPa), the sum of the working pressure and 100 lbf/in<sup>2</sup> (690 kPa) surge allowance, and a safety factor of 2.0.

<sup>b</sup>Pressure class is defined as the rated gage water pressure of the pipe in lbf/in<sup>2</sup>.

<sup>c</sup>Limited by manufacturing. Calculated required thickness is less.

**APPENDIX 16.H**

(Multiply in by 25.4 to obtain mm.)

(Multiply lbf/in<sup>2</sup> by 6.895 to obtain kPa.)

“Formerly designated “standard thickness classes.” These special pressure classes are as shown in AWWA C150 and C151. Special classes are most appropriate for some threaded, grooved, or ball and socket pipes, or for extraordinary design conditions. They are generally less available than standard pressure class pipe.

<sup>b</sup>60 in (1500 mm) and 64 in (1600 mm) pipe sizes are not available in special pressure classes.

**ASTM A746 Cement-Lined Gravity Sewer Pipe**

The thicknesses for cement-lined pipe are the same as those in AWWA C150 and C151.

**ASTM A746 Flexible Lining Gravity Sewer Pipe**

The thicknesses for flexible lining pipe are the same as those in AWWA C150 and C151.

(Multiply in by 25.4 to obtain mm.)

(Multiply in<sup>2</sup> by 645 to obtain mm<sup>2</sup>.)

<sup>a</sup>Abstracted from information provided by the United States Steel Corporation.

<sup>b</sup>Values in this table are not to be used for tubes in condensers and heat-exchangers unless those tubes are specified by BWG.

<sup>c</sup>Birmingham wire gauge, commonly used for ferrous tubing, is identical to Stubs iron-wire gauge.

(Multiply ft by 0.3048 to obtain m.)

<sup>a</sup> $C$  values for sludge pipes are 20% to 40% less than the corresponding water pipe values.

<sup>b</sup>The following guidelines are provided for selecting Hazen-Williams coefficients for cast-iron pipes of different ages. Values for welded steel pipe are similar to those of cast-iron pipe five years older. New pipe, all sizes:  $C = 130$ . 5 yr old pipe:  $C = 120$  ( $d < 24$  in);  $C = 115$  ( $d \geq 24$  in). 10 yr old pipe:  $C = 105$  ( $d = 4$  in);  $C = 110$  ( $d = 12$  in);  $C = 85$  ( $d \geq 30$  in). 40 yr old pipe:  $C = 65$  ( $d = 4$  in);  $C = 80$  ( $d = 16$  in).

**APPENDIX 17.E**  
Hazen-Williams Nomograph ( $C = 100$ )

Quantity (i.e., flow rate) and velocity are proportional to the  $C$ -value. For values of  $C$  other than 100, the quantity and velocity must be converted according to  $\dot{V}_{\text{actual}} = \dot{V}_{\text{chart}} C_{\text{actual}} / 100$ . When quantity is the unknown, use the chart with known values of diameter, slope, or velocity to find  $\dot{V}_{\text{chart}}$ , and then convert to  $\dot{V}_{\text{actual}}$ . When velocity is the unknown, use the chart with the known values of diameter, slope, or quantity to find  $\dot{V}_{\text{chart}}$ , then convert to  $\dot{V}_{\text{actual}}$ . If  $\dot{V}_{\text{actual}}$  is known, it must be converted to  $\dot{V}_{\text{chart}}$  before this nomograph can be used. In that case, the diameter, loss, and quantity are as read from this chart.

(Multiply gal/min by 0.0631 to obtain L/s.)  
 (Multiply ft<sup>3</sup>/sec by 28.3 to obtain L/s.)  
 (Multiply in by 25.4 to obtain mm.)  
 (Multiply ft/1000 ft by 0.1 to obtain m/100 m.)  
 (Multiply ft/sec by 0.3048 to obtain m/s.)

**APPENDIX 17.F**  
Corrugated Metal Pipe

*Corrugated metal pipe* (CMP, also known as *corrugated steel pipe*) is frequently used for culverts. Pipe is made from corrugated sheets of galvanized steel that are rolled and riveted together along a longitudinal seam. Aluminized steel may also be used in certain ranges of soil pH. Standard round pipe diameters range from 8 in to 96 in (200 mm to 2450 mm). Metric dimensions of standard diameters are usually rounded to the nearest 25 mm or 50 mm (e.g., a 42 in culvert would be specified as a 1050 mm culvert, not 1067 mm).

Larger and noncircular culverts can be created out of curved steel plate. Standard section lengths are 10 ft to 20 ft (3 m to 6 m). Though most corrugations are transverse (i.e., annular), helical corrugations are also used. Metal gages of 8, 10, 12, 14, and 16 are commonly used, depending on the depth of burial.

The most common corrugated steel pipe has transverse corrugations that are  $\frac{1}{2}$  in (13 mm) deep and  $2\frac{2}{3}$  in (68 mm) from crest to crest. These are referred to as "2 $\frac{1}{2}$  inch" or "68 × 13" corrugations. For larger culverts, corrugations with a 2 in (25 mm) depth and 3, 5, and 6 in (76, 125, or 152 mm) pitches are used. Plate-based products using 6 in by 2 in (152 mm by 51 mm) corrugations are known as *structural plate corrugated steel pipe* (SPCSP) and *multiplate* after the trade-named product "Multi-Plate™".

The flow area for circular culverts is based on the nominal culvert diameter, regardless of the gage of the plate metal used to construct the pipe. Flow area is calculated to (at most) three significant digits.

A Hazen-Williams coefficient,  $C$ , of 60 is typically used with all sizes of corrugated pipe. Values of  $C$  and Manning's constant,  $n$ , for corrugated pipe are generally not affected by age. *Design Charts for Open Channel Flow* (U.S. Department of Transportation, 1979) recommends a Manning constant of  $n = 0.024$  for all cases. The U.S. Department of the Interior recommends the following values. For standard ( $2\frac{2}{3}$  in by  $\frac{1}{2}$  in or 68 mm by 13 mm) corrugated pipe with the diameters given: 12 in (457 mm), 0.027; 24 in (610 mm), 0.025; 36 in to 48 in (914 mm to 1219 mm), 0.024; 60 in to 84 in (1524 mm to 2134 mm), 0.023; 96 in (2438 mm), 0.022. For (6 in by 2 in or 152 mm by 51 mm) multiplate construction with the diameters given: 5 ft to 6 ft (1.5 m to 1.8 m), 0.034; 7 ft to 8 ft (2.1 m to 2.4 m), 0.033; 9 ft to 11 ft (2.7 m to 3.3 m), 0.032; 12 ft to 13 ft (3.6 m to 3.9 m), 0.031; 14 ft to 15 ft (4.2 m to 4.5 m), 0.030; 16 ft to 18 ft (4.8 m to 5.4 m), 0.029; 19 ft to 20 ft (5.8 m to 6.0 m), 0.028; 21 ft to 22 ft (6.3 m to 6.6 m), 0.027.

If the inside of the corrugated pipe has been asphalted completely smooth  $360^\circ$  circumferentially, Manning's  $n$  ranges from 0.009 to 0.011. For culverts with 40% asphalted invert,  $n = 0.019$ . For other percentages of paved invert, the resulting value is proportional to the percentage and the values normally corresponding to that diameter pipe. For field-bolted corrugated metal pipe arches,  $n = 0.025$ .

It is also possible to calculate the Darcy friction loss if the corrugation depth, 0.5 in (13 mm) for standard corrugations and 2.0 in (51 mm) for multiplate, is taken as the specific roughness.

Values in this table were calculated from *NIST Standard Reference Database 10*, “NIST/ASME Steam Properties,” Ver. 2.11, National Institute of Standards and Technology, U.S. Department of Commerce, Gaithersburg, MD, 1997, which has been licensed to PPI.

## APPENDIX 19.A

Manning's Roughness Coefficient<sup>a,b</sup>  
(design use)

channel material	<i>n</i>
plastic (PVC and ABS)	0.009
clean, uncoated cast iron	0.013–0.015
clean, coated cast iron	0.012–0.014
dirty, tuberculated cast iron	0.015–0.035
riveted steel	0.015–0.017
lock-bar and welded steel pipe	0.012–0.013
galvanized iron	0.015–0.017
brass and glass	0.009–0.013
wood stave	
small diameter	0.011–0.012
large diameter	0.012–0.013
concrete	
average value used	0.013
typical commercial, ball and spigot	
rubber gasketed end connections	
– full (pressurized and wet)	0.010
– partially full	0.0085
with rough joints	0.016–0.017
dry mix, rough forms	0.015–0.016
wet mix, steel forms	0.012–0.014
very smooth, finished	0.011–0.012
vitrified sewer	0.013–0.015
common-clay drainage tile	0.012–0.014
asbestos	0.011
planed timber (flume)	0.012 (0.010–0.014)
canvas	0.012
unplaned timber (flume)	0.013 (0.011–0.015)
brick	0.016
rubble masonry	0.017
smooth earth	0.018
firm gravel	0.023
corrugated metal pipe (CMP)	0.022–0.033
natural channels, good condition	0.025
rip rap	0.035
natural channels with stones and weeds	0.035
very poor natural channels	0.060

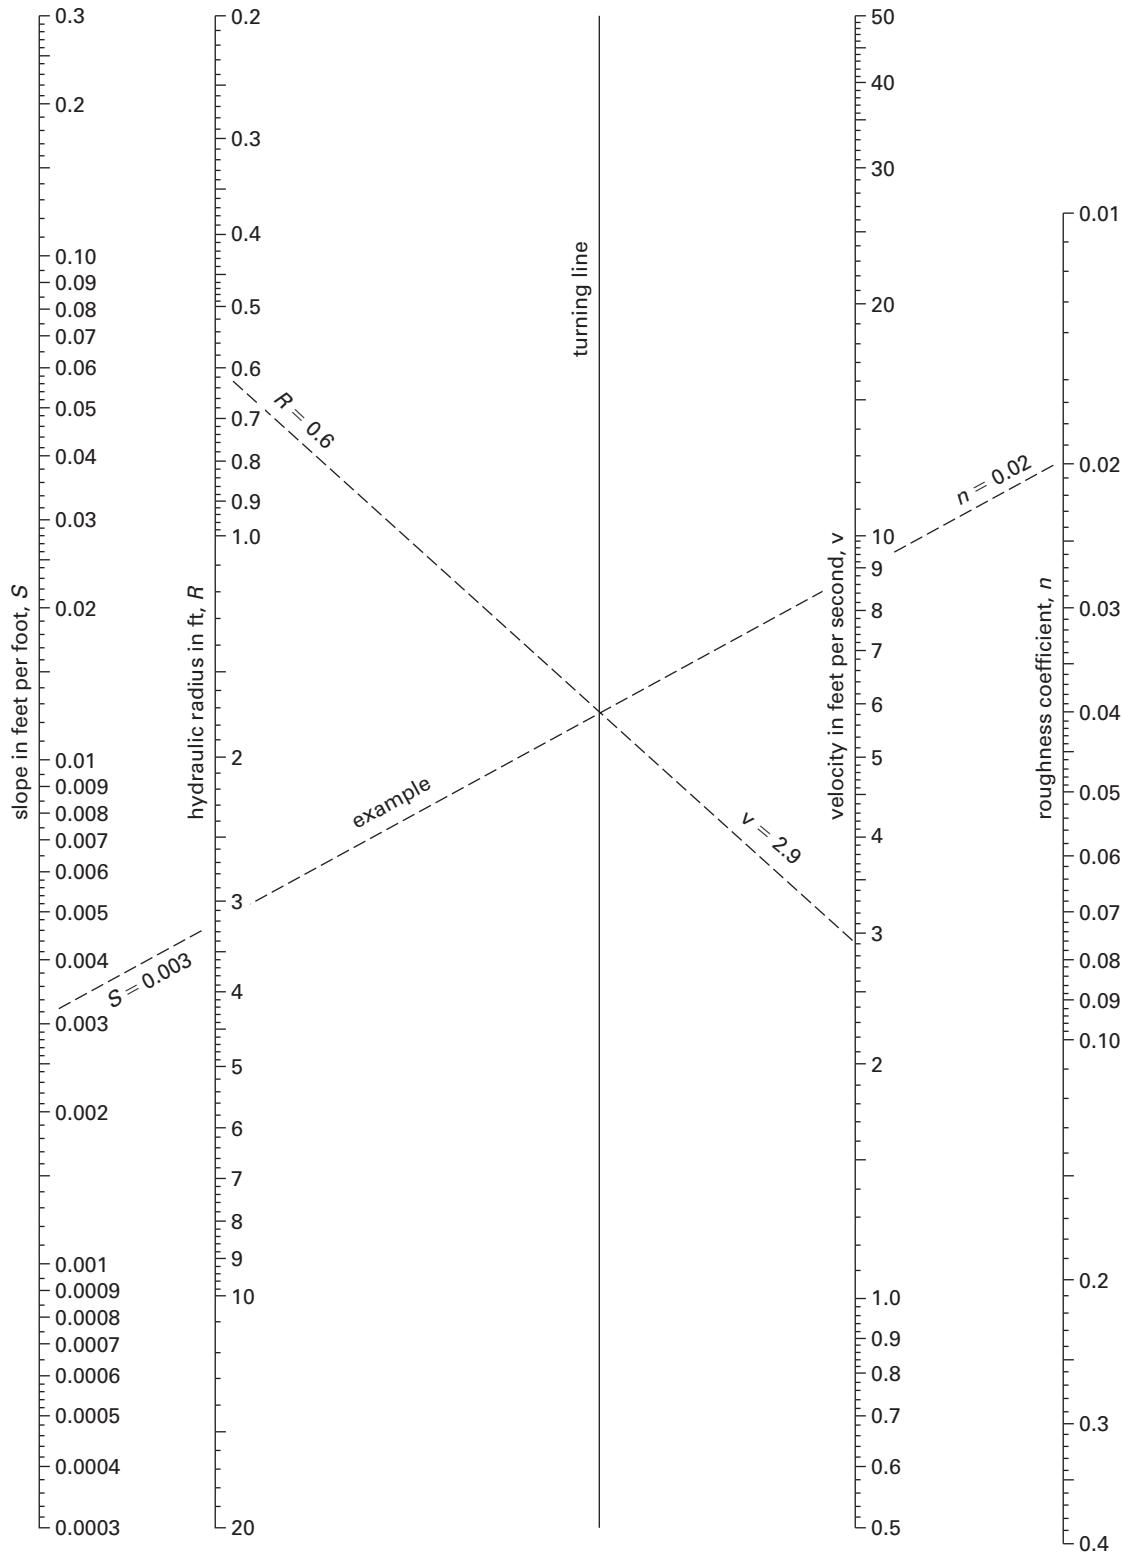

<sup>a</sup>compiled from various sources

<sup>b</sup>Values outside these ranges have been observed, but these values are typical.

## APPENDIX 19.B

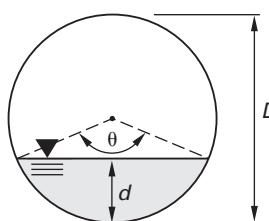

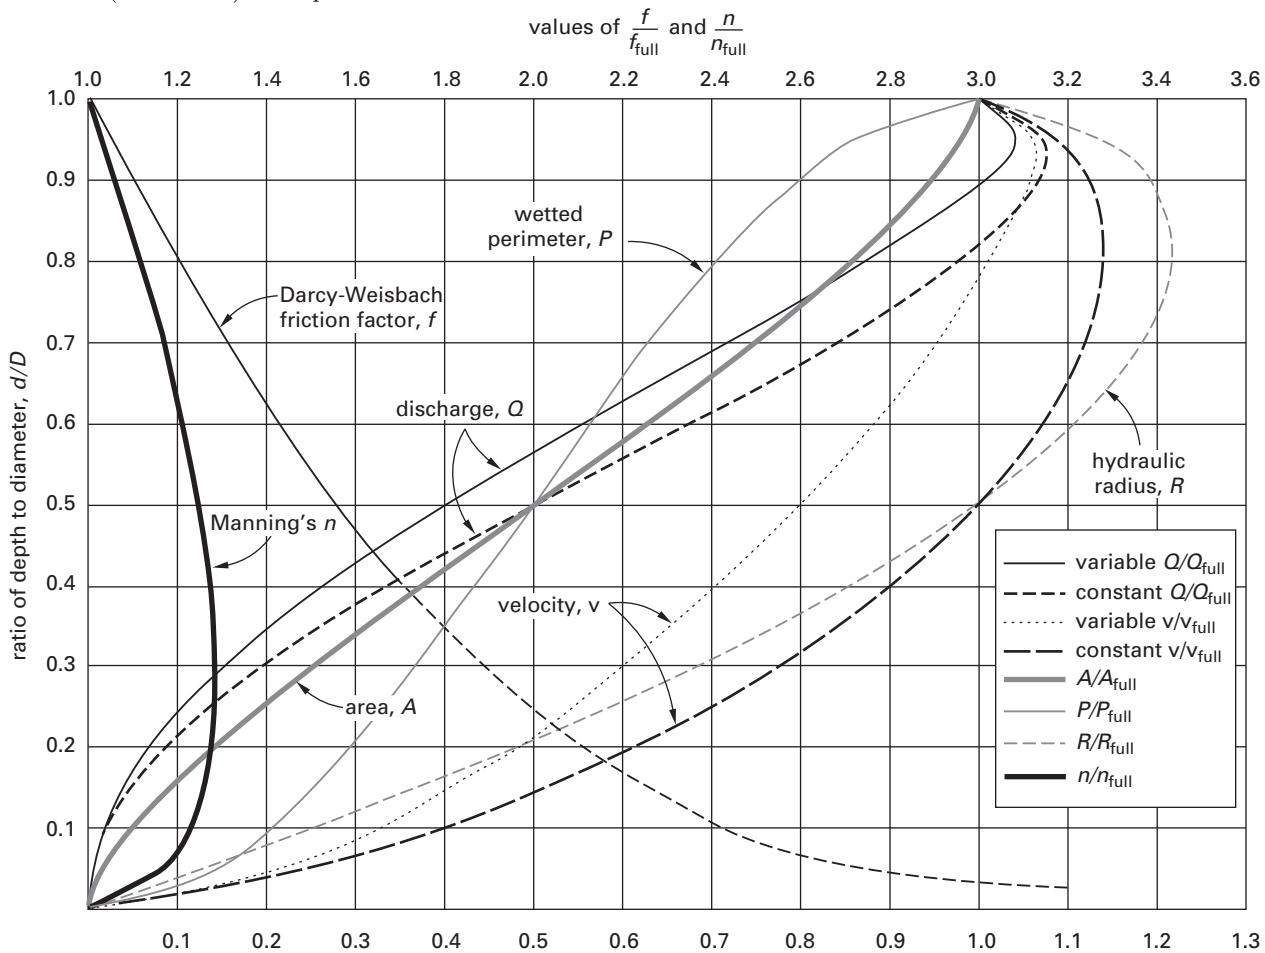

Manning Equation Nomograph

$$\left( \text{solves } v = \frac{1.486}{n} R^{2/3} \sqrt{S} \right)$$

**APPENDIX 19.C**  
 Circular Channel Ratios \*

Experiments have shown that  $n$  varies slightly with depth. This figure gives velocity and flow rate ratios for varying  $n$  (solid line) and constant  $n$  (broken line) assumptions.

$$\theta_{\text{deg}} = 2 \arccos \left( \frac{\frac{D}{2} - d}{\frac{D}{2}} \right)$$

$$A = \left( \frac{D}{2} \right)^2 \frac{\theta_{\text{rad}} - \sin \theta_{\text{deg}}}{2}$$

$$P = \frac{D \theta_{\text{rad}}}{2}$$

$$R = \frac{A}{P}$$

**Governing equations**

$$v = \left( \frac{1.486}{n} \right) R^{\frac{2}{3}} \sqrt{S}$$

$$Q = Av$$

Slope is constant.

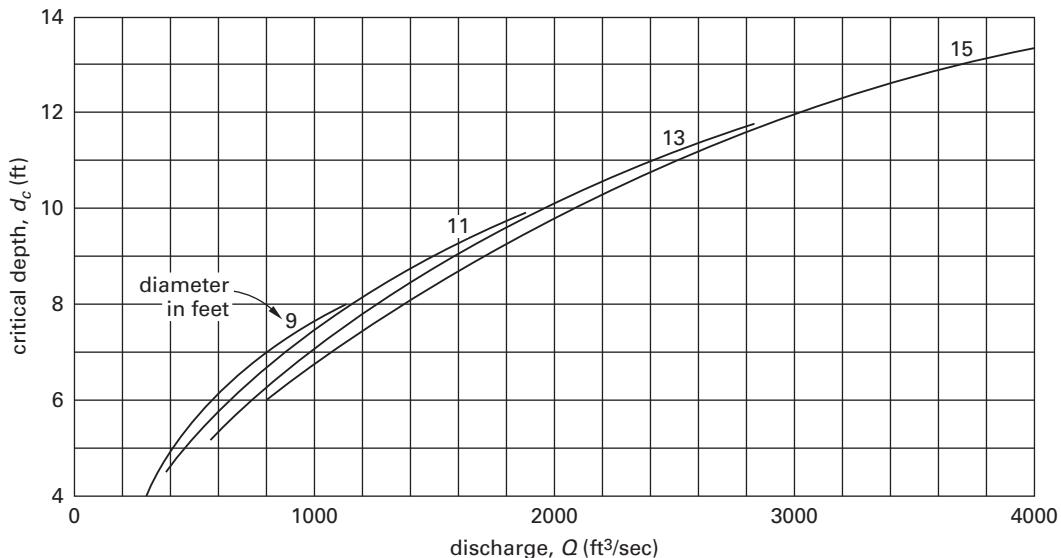

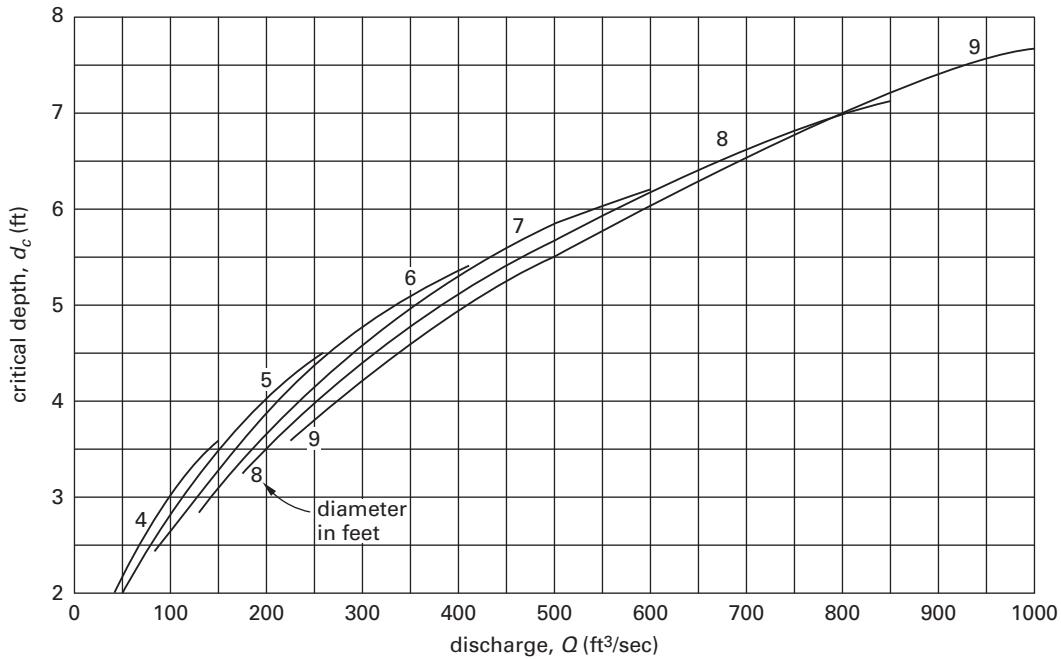

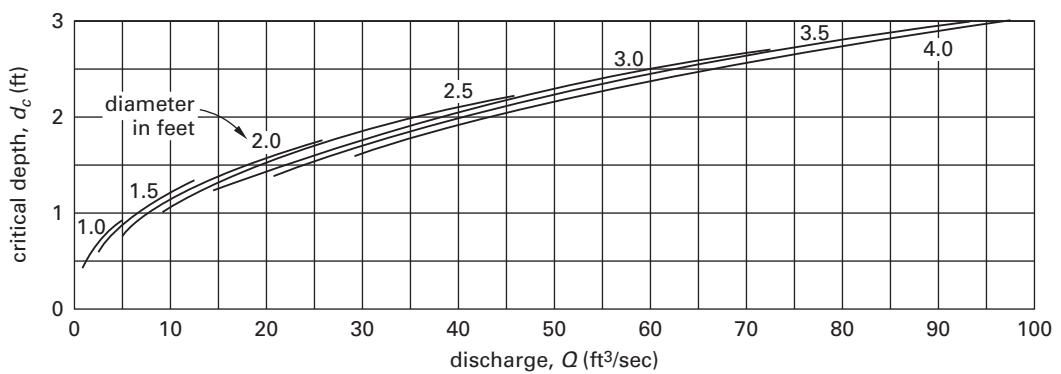

$$n = 0.013$$

$$\frac{n}{n_{\text{full}}} = 1 + \left( \frac{d}{D} \right)^{0.540} - \left( \frac{d}{D} \right)^{1.200}$$

\*For  $n = 0.013$ .

Adapted from *Design and Construction of Sanitary and Storm Sewers*, p. 87, ASCE, 1969, as originally presented in "Design of Sewers to Facilitate Flow", Camp, T. R., *Sewage Works Journal*, 18, 3 (1946).

## The Periodic Table of Elements (Long Form)

The number of electrons in filled shells is shown in the column at the extreme left; the remaining electrons for each element are shown immediately below the symbol for each element. Atomic numbers are enclosed in brackets. Atomic weights (rounded, based on carbon-12) are shown above the symbols. Atomic weight values in parentheses are those of the isotopes of longest half-life for certain radioactive elements whose atomic weights cannot be precisely quoted without knowledge of origin of the element.

<sup>a</sup>For saturation at barometric pressures other than 760 mm Hg (29.92 in Hg),  $C'_s$  is related to the corresponding tabulated value,  $C_s$ , by the following equation.

$$C'_s = C_s \left( \frac{P - p}{760 - p} \right)$$

$C'_s$  = solubility at barometric pressure  $P$  and given temperature, mg/L

$C_s$  = saturation solubility at given temperature from appendix, mg/L

$P$  = barometric pressure, mm Hg

$p$  = pressure of saturated water vapor at temperature of the water selected from appendix, mm Hg

<sup>b</sup>Zero-chloride values from *Volunteer Stream Monitoring: A Methods Manual* (EPA 841-B-97-003), Environmental Protection Agency, Office of Water, Sec. 5.2 "Dissolved Oxygen and Biochemical Oxygen Demand," 1997.

**APPENDIX 22.E**  
Names and Formulas of Important Chemicals

common name	chemical name	chemical formula
acetone	acetone	(CH <sub>3</sub> ) <sub>2</sub> CO
acetylene	acetylene	C <sub>2</sub> H <sub>2</sub>
ammonia	ammonia	NH <sub>3</sub>
ammonium	ammonium hydroxide	NH <sub>4</sub> OH
aniline	aniline	C <sub>6</sub> H <sub>5</sub> NH <sub>2</sub>
bauxite	hydrated aluminum oxide	Al <sub>2</sub> O <sub>3</sub> ·2H <sub>2</sub> O
bleach	calcium hypochlorite	Ca(ClO) <sub>2</sub>
borax	sodium tetraborate	Na <sub>2</sub> B <sub>4</sub> O <sub>7</sub> ·10H <sub>2</sub> O
carbide	calcium carbide	CaC <sub>2</sub>
carbolic acid	phenol	C <sub>6</sub> H <sub>5</sub> OH
carbon dioxide	carbon dioxide	CO <sub>2</sub>
carborundum	silicon carbide	SiC
caustic potash	potassium hydroxide	KOH
caustic soda/lye	sodium hydroxide	NaOH
chalk	calcium carbonate	CaCO <sub>3</sub>
cinnabar	mercuric sulfide	HgS
ether	diethyl ether	(C <sub>2</sub> H <sub>5</sub> ) <sub>2</sub> O
formic acid	methanoic acid	HCOOH
Glauber's salt	decahydrated sodium sulfate	Na <sub>2</sub> SO <sub>4</sub> ·10H <sub>2</sub> O
glycerine	glycerine	C <sub>3</sub> H <sub>5</sub> (OH) <sub>3</sub>
grain alcohol	ethanol	C <sub>2</sub> H <sub>5</sub> OH
graphite	crystalline carbon	C
gypsum	calcium sulfate	CaSO <sub>4</sub> ·2H <sub>2</sub> O
halite	sodium chloride	NaCl
iron chloride	ferrous chloride	FeCl <sub>2</sub> ·4H <sub>2</sub> O
laughing gas	nitrous oxide	N <sub>2</sub> O
limestone	calcium carbonate	CaCO <sub>3</sub>
magnesia	magnesium oxide	MgO
marsh gas	methane	CH <sub>4</sub>
muriate of potash	potassium chloride	KCl
muriatic acid	hydrochloric acid	HCl
niter	sodium nitrate	NaNO <sub>3</sub>
niter cake	sodium bisulfate	NaHSO <sub>4</sub>
oleum	fuming sulfuric acid	SO <sub>3</sub> in H <sub>2</sub> SO <sub>4</sub>
potash	potassium carbonate	K <sub>2</sub> CO <sub>3</sub>
prussic acid	hydrogen cyanide	HCN
pyrites	ferrous sulfide	FeS
pyrolusite	manganese dioxide	MnO <sub>2</sub>
quicklime	calcium oxide	CaO
sal soda	decahydrated sodium carbonate	NaCO <sub>3</sub> ·10H <sub>2</sub> O
salammoniac	ammonium chloride	NH <sub>4</sub> Cl
sand or silica	silicon dioxide	SiO <sub>2</sub>
salt cake	sodium sulfate (crude)	Na <sub>2</sub> SO <sub>4</sub>
slaked lime	calcium hydroxide	Ca(OH) <sub>2</sub>
soda ash	sodium carbonate	Na <sub>2</sub> CO <sub>3</sub>
soot	amorphous carbon	C
stannous chloride	stannous chloride	SnCl <sub>2</sub> ·2H <sub>2</sub> O
superphosphate	monohydrated primary calcium phosphate	Ca(H <sub>2</sub> PO <sub>4</sub> ) <sub>2</sub> ·H <sub>2</sub> O
table salt	sodium chloride	NaCl
table sugar	sucrose	C <sub>12</sub> H <sub>22</sub> O <sub>11</sub>
trilene	trichloroethylene	C <sub>2</sub> HCl <sub>3</sub>
urea	urea	CO(NH <sub>2</sub> ) <sub>2</sub>
vinegar (acetic acid)	ethanoic acid	CH <sub>3</sub> COOH
washing soda	decahydrated sodium carbonate	Na <sub>2</sub> CO <sub>3</sub> ·10H <sub>2</sub> O
wood alcohol	methanol	CH <sub>3</sub> OH
zinc blende	zinc sulfide	ZnS

\*Values for steam and Freon are approximate and should be used only for low pressures and high temperatures.

**APPENDIX 25.A**  
 National Primary Drinking Water Regulations  
 Code of Federal Regulations (CFR), Title 40, Ch. I, Part 141, Subpart G

microorganisms	MCLG <sup>a</sup> (mg/L) <sup>b</sup>	MCL or TT <sup>a</sup> (mg/L) <sup>b</sup>	potential health effects from ingestion of water	sources of contaminant in drinking water
<i>Cryptosporidium</i>	0	TT <sup>c</sup>	gastrointestinal illness (e.g., diarrhea, vomiting, cramps)	human and animal fecal waste
<i>Giardia lamblia</i>	0	TT <sup>c</sup>	gastrointestinal illness (e.g., diarrhea, vomiting, cramps)	human and animal fecal waste
heterotrophic plate count	n/a	TT <sup>c</sup>	HPC has no health effects; it is an analytic method used to measure the variety of bacteria that are common in water. The lower the concentration of bacteria in drinking water, the better maintained the water is.	HPC measures a range of bacteria that are naturally present in the environment.
<i>Legionella</i>	0	TT <sup>c</sup>	Legionnaire's disease, a type of pneumonia	found naturally in water; multiplies in heating systems
total coliforms (including fecal coliform and <i>E. coli</i> )	0	5.0% <sup>d</sup>	Not a health threat in itself; it is used to indicate whether other potentially harmful bacteria may be present. <sup>e</sup>	Coliforms are naturally present in the environment as well as in feces; fecal coliforms and <i>E. coli</i> only come from human and animal fecal waste.
turbidity	n/a	TT <sup>c</sup>	Turbidity is a measure of the cloudiness of water. It is used to indicate water quality and filtration effectiveness (e.g., whether disease causing organisms are present). Higher turbidity levels are often associated with higher levels of disease causing microorganisms such as viruses, parasites, and some bacteria. These organisms can cause symptoms such as nausea, cramps, diarrhea, and associated headaches.	soil runoff
viruses (enteric)	0	TT <sup>c</sup>	gastrointestinal illness (e.g., diarrhea, vomiting, cramps)	human and animal fecal waste
disinfection products	MCLG <sup>a</sup> (mg/L) <sup>b</sup>	MCL or TT <sup>a</sup> (mg/L) <sup>b</sup>	potential health effects from ingestion of water	sources of contaminant in drinking water
bromate	0	0.010	increased risk of cancer	by-product of drinking-water disinfection
chlorite	0.8	1.0	anemia in infants and young children; nervous system effects	by-product of drinking-water disinfection
haloacetic acids (HAA5)	n/a <sup>f</sup>	0.060	increased risk of cancer	by-product of drinking-water disinfection
total trihalomethanes (TTHMs)	n/a <sup>f</sup>	0.080	liver, kidney, or central nervous system problems; increased risk of cancer	by-product of drinking-water disinfection

(continued)

uranium	0	30 µg/L as of December 8, 2003	increased risk of cancer; kidney toxicity	erosion of natural deposits

<sup>a</sup>Definitions:

*Maximum Contaminant Level (MCL):* The highest level of a contaminant that is allowed in drinking water. MCLs are set as close to MCLGs as feasible using the best available treatment technology and taking cost into consideration. MCLs are enforceable standards.

*Maximum Contaminant Level Goal (MCLG):* The level of a contaminant in drinking water below which there is no known or expected risk to health. MCLGs allow for a margin of safety and are non-enforceable public health goals.

*Maximum Residual Disinfectant Level (MRDL):* The highest level of a disinfectant allowed in drinking water. There is convincing evidence that addition of a disinfectant is necessary for control of microbial contaminants.

*Maximum Residual Disinfectant Level Goal (MRDLG):* The level of a drinking water disinfectant below which there is no known or expected risk to health. MRDLGs do not reflect the benefits of the use of disinfectants to control microbial contaminants.

*Treatment Technique:* A required process intended to reduce the level of a contaminant in drinking water.

<sup>b</sup>Units are in milligrams per liter (mg/L) unless otherwise noted. Milligrams per liter are equivalent to parts per million.

National Primary Drinking Water Regulations  
Code of Federal Regulations (CFR), Title 40, Ch. I, Part 141, Subpart G

<sup>c</sup>The EPA's surface water treatment rules require systems using surface water or ground water under the direct influence of surface water to (1) disinfect their water, and (2) filter their water or meet criteria for avoiding filtration so that the following contaminants are controlled at the following levels.

- Cryptosporidium (as of January 1, 2002, for systems serving >10,000 and January 14, 2005, for systems serving < 10,000): 99% removal
- *Giardia lamblia*: 99.9% removal/inactivation
- *Legionella*: No limit, but the EPA believes that if *Giardia* and viruses are removed/inactivated, *Legionella* will also be controlled.
- Turbidity: At no time can turbidity (cloudiness of water) go above 5 nephelometric turbidity units (NTU); systems that filter must ensure that the turbidity go no higher than 1 NTU (0.5 NTU for conventional or direct filtration) in at least 95% of the daily samples in any month. As of January 1, 2002, turbidity may never exceed 1 NTU, and must not exceed 0.3 NTU in 95% of daily samples in any month.
- Heterotrophic plate count (HPC): No more than 500 bacterial colonies per milliliter.
- Long Term 1 Enhanced Surface Water Treatment (as of January 14, 2005): Surface water systems or ground water under direct influence (GWUDI) systems serving fewer than 10,000 people must comply with the applicable Long Term 1 Enhanced Surface Water Treatment Rule provisions (e.g., turbidity standards, individual filter monitoring, cryptosporidium removal requirements, updated watershed control requirements for unfiltered systems).
- Filter Backwash Recycling: The Filter Backwash Recycling Rule requires systems that recycle to return specific recycle flows through all processes of the systems' existing conventional or direct filtration system or at an alternate location approved by the state.

<sup>d</sup>More than 5.0% of samples are total coliform-positive in a month. (For water systems that collect fewer than 40 routine samples per month, no more than one sample can be total coliform-positive per month.) Every sample that has total coliform must be analyzed for either fecal coliforms or *E. coli*. If two consecutive samples are TC-positive, and one is also positive for *E. coli* or fecal coliforms, the system has an acute MCL violation.

<sup>e</sup>Fecal coliform and *E. coli* are bacteria whose presence indicates that the water may be contaminated with human or animal wastes. Disease-causing microbes (pathogens) in these wastes can cause diarrhea, cramps, nausea, headaches, or other symptoms. These pathogens may pose a special health risk for infants, young children, and people with severely compromised immune systems.

<sup>f</sup>Although there is no collective MCLG for this contaminant group, there are individual MCLGs for some of the individual contaminants.

- Haloacetic acids: dichloroacetic acid (0); trichloroacetic acid (0.3 mg/L). Monochloroacetic acid, bromoacetic acid, and dibromoacetic acid are regulated with this group but have no MCLGs.
- Trihalomethanes: bromodichloromethane (0); bromoform (0); dibromochloromethane (0.06 mg/L). Chloroform is regulated with this group but has no MCLG.

<sup>g</sup>MCLGs were not established before the 1986 Amendments to the Safe Drinking Water Act. Therefore, there is no MCLG for this contaminant.

<sup>h</sup>Lead and copper are regulated by a treatment technique that requires systems to control the corrosiveness of their water. If more than 10% of tap water samples exceed the action level, water systems must take additional steps. For copper, the action level is 1.3 mg/L, and for lead it is 0.015 mg/L.

<sup>i</sup>Each water system agency must certify, in writing, to the state (using third party or manufacturers' certification) that, when acrylamide and epichlorohydrin are used in drinking water systems, the combination (or product) of dose and monomer level does not exceed the levels specified, as follows.

- acrylamide = 0.05% dosed at 1 mg/L (or equivalent)
- epichlorohydrin = 0.01% dosed at 20 mg/L (or equivalent)

**APPENDIX 26.A**  
Properties of Chemicals Used in Water Treatment

chemical name	formula	use	molecular weight	equivalent weight
activated carbon	C	taste and odor control	12.0	—
aluminum hydroxide	Al(OH) <sub>3</sub>	—	78.0	26.0
aluminum sulfate (filter alum)	Al <sub>2</sub> (SO <sub>4</sub> ) <sub>3</sub> ·14.3H <sub>2</sub> O	coagulation	600	100
ammonia	NH <sub>3</sub>	chloramine disinfection	17.0	—

water	H <sub>2</sub> O	—	18.0	—

\*Exists only in aqueous form as a mixture of ions.

## APPENDIX 29.A

Selected *Ten States' Standards*<sup>\*</sup>

[11.243] **Hydraulic Load:** Use 100 gpcd (0.38 m<sup>3</sup>/d) for new systems in undeveloped areas unless other information is available.

[42.3] **Pumps:** At least two pumps are required. Both pumps should have the same capacity if only two pumps are used. This capacity must exceed the total design flow. If three or more pumps are used, the capacities may vary, but capacity (peak hourly flow) pumping must be possible with one pump out of service.

[42.7] **Pump Well Ventilation:** Provide 30 complete air changes per hour for both wet and dry wells using intermittent ventilation. For continuous ventilation, the requirement is reduced to 12 (for wet wells) and 6 (for dry wells) air changes per hour. In general, ventilation air should be forced in, as opposed to air being extracted and replaced by infiltration.

[61.12] **Racks and Bar Screens:** All racks and screens shall have openings less than 1.75 in (45 mm) wide. The smallest opening for manually cleaned screens is 1 in (2.54 cm). The smallest opening for mechanically cleaned screens may be smaller. Flow velocity must be 1.25–3.0 ft/sec (38–91 cm/s).

[62.2–62.3] **Grinders and Shredders:** Comminutors are required if there is no screening. Gravel traps or grit-removal equipment should precede comminutors.

[63.3–63.4] **Grit Chambers:** Grit chambers are required when combined storm and sanitary sewers are used. A minimum of two grit chambers in parallel should be used, with a provision for bypassing. For channel-type grit chambers, the optimum velocity is 1 ft/sec (30 cm/s) throughout. The detention time for channel-type grit chambers is dependent on the particle sizes to be removed.

[71–72] **Settling Tanks:** Multiple units are desirable, and multiple units must be provided if the average flow exceeds 100,000 gal/day (379 m<sup>3</sup>/d). For primary settling, the sidewater depth should be 10 ft (3.0 m) or greater. For tanks not receiving activated sludge, the design average overflow rate is 1000 gal/day-ft<sup>2</sup> (41 m<sup>3</sup>/d·m<sup>2</sup>); the maximum peak overflow rate is 1500–2000 gal/day-ft<sup>2</sup> (61–81 m<sup>3</sup>/d·m<sup>2</sup>). The maximum weir loading for flows greater than 1 MGD (3785 m<sup>3</sup>/d) is 30,000 gal/day-ft (375 m<sup>3</sup>/d·m). The basin size shall also be calculated based on the average design flow rate and a maximum settling rate of 1000 gal/day-ft<sup>2</sup> (41 m<sup>3</sup>/d·m<sup>2</sup>). The larger of the two sizes shall be used. If the flow rate is less than 1 MGD (3785 m<sup>3</sup>/d), the maximum weir loading is reduced to 20,000 gal/day-ft (250 m<sup>3</sup>/d·m).

For settling tanks following trickling filters and rotating biological contactors, the peak settling rate is 1500 gal/day-ft<sup>2</sup> (61 m<sup>3</sup>/d·m<sup>2</sup>).

For settling tanks following activated sludge processes, the maximum hydraulic loadings are: 1200 gal/day-ft<sup>2</sup> (49 m<sup>3</sup>/d·m<sup>2</sup>) for conventional, step, complete mix, and contact units; 1000 gal/day-ft<sup>2</sup> (41 m<sup>3</sup>/d·m<sup>2</sup>) for extended aeration units; and 800 gal/day-ft<sup>2</sup> (33 m<sup>3</sup>/d·m<sup>2</sup>) for separate two-stage nitrification units.

[84] **Anaerobic Digesters:** Multiple units are required. Minimum sidewater depth is 20 ft (6.1 m). For completely mixed digesters, maximum loading of volatile solids is 80 lbm/day-1000 ft<sup>3</sup> (1.3 kg/d·m<sup>3</sup>) of digester volume. For moderately mixed digesters, the limit is 40 lbm/day-1000 ft<sup>3</sup> (0.65 kg/d·m<sup>3</sup>).

[88.22] **Sludge Drying Beds:** For design purposes, the maximum sludge depth is 8 in (200 mm).

[91.3] **Trickling Filters:** All media should have a minimum depth of 6 ft (1.8 m). Rock media depth should not exceed 10 ft (3 m). Manufactured media depth should not exceed the manufacturer's recommendations. The rock media should be 1–4.5 in (2.5–11.4 cm) in size. Freeboard of 4 ft (1.2 ft) or more is required for manufactured media. The drain should slope at 1% or more, and the average drain velocity should be 2 ft/sec (0.6 m/s).

[92.3] **Activated Sludge Processes:** The maximum BOD loading shall be 40 lbm/day-1000 ft<sup>3</sup> (0.64 kg/d·m<sup>3</sup>) for conventional, step, and complete-mix units; 50 lbm/day-1000 ft<sup>3</sup> (0.8 kg/d·m<sup>3</sup>) for contact stabilization units; and 15 lbm/day-1000 ft<sup>3</sup> (0.24 kg/d·m<sup>3</sup>) for extended aeration units and oxidation ditch designs.

Aeration tank depths should be 10–30 ft (3–9 m). Freeboard should be 18 in (460 mm) or more. At least two aeration tanks shall be used. The dissolved oxygen content should not be allowed to drop below 2 mg/L at any time. The aeration rate should be 1500 ft<sup>3</sup> of oxygen per lbm of BOD<sub>5</sub> (94 m<sup>3</sup>/kg). For extended aeration, the rate should be 2050 ft<sup>3</sup> of oxygen per lbm of BOD<sub>5</sub> (128 m<sup>3</sup>/kg).

*(continued)*

**APPENDIX 29.A (continued)<sup>\*</sup>**  
**Selected Ten States' Standards**

[93] **Wastewater Treatment Ponds:** (Applicable to controlled-discharge, flow-through ( facultative), and aerated pond systems.) Pond bottoms must be at least 4 ft (1.2 m) above the highest water table elevation. Pond primary cells are designed based on average BOD<sub>5</sub> loads of 15–35 lbm/ac-day (17–40 kg/ha·d) at the mean operating depth. Detention time for controlled-discharge ponds shall be at least 180 days between a depth of 2 ft (0.61 m) and the maximum operating depth. Detention time for flow-through ( facultative) ponds should be 90–120 days, modified for cold weather. Detention time for aerated ponds may be estimated from the percentage,  $E$ , of BOD<sub>5</sub> to be removed:  $t_{\text{days}} = E/2.3k_1(100\% - E)$ , where  $k_1$  is the base-10 reaction coefficient, assumed to be 0.12/d at 68°F (20°C) and 0.06/d at 34°F (1°C). Although two cells can be used in very small systems, a minimum of three cells is normally required. Maximum cell size is 40 ac (16 ha). Ponds may be round, square, or rectangular (with length no greater than three times the width). Islands and sharp corners are not permitted. Dikes shall be at least 8 ft (2.4 m) wide at the top. Inner and outer dike slopes cannot be steeper than 1:3 (V:H). Inner slopes cannot be flatter than 1:4 (V:H). At least 3 ft (0.91 m) freeboard is required unless the pond system is very small, in which case 2 ft (0.6 m) is acceptable. Pond depth shall never be less than 2 ft (0.6 m). Depth shall be: (a) for controlled discharged and flow-through ( facultative) ponds, a maximum of 6 ft (1.8 m) for primary cells; greater for subsequent cells with mixing and aeration as required; and (b) for aerated ponds, a design depth of 10–15 ft (3–4.5 m).

[102.4] **Chlorination:** Minimum contact time is 15 min at peak flow.

\*Numbers in square brackets refer to sections in *Recommended Standards for Sewage Works*, 2004 ed., Great Lakes-Upper Mississippi River Board of State Sanitary Engineers, published by Health Education Service, NY, from which these guidelines were extracted. Refer to the original document for complete standards.

### USCS Soil Boring, Well, and Geotextile Symbols

## Geotextile symbols

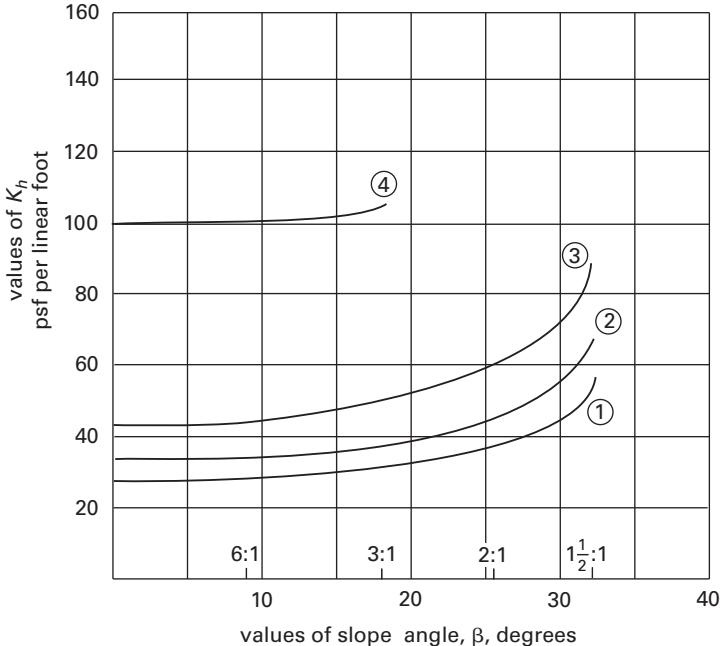

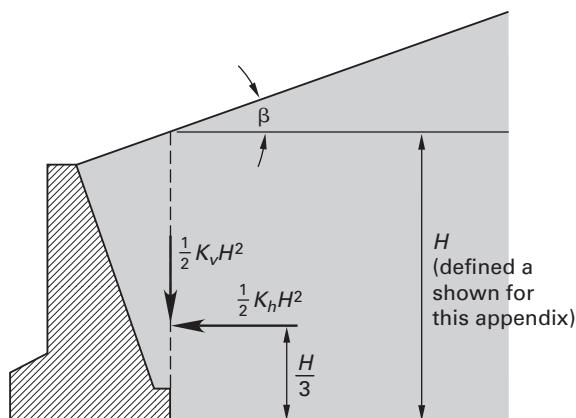

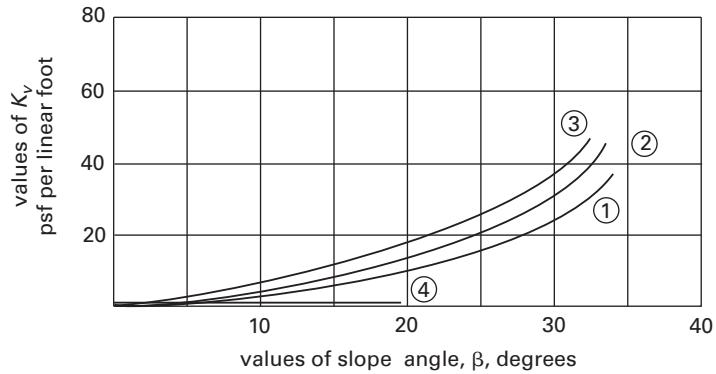

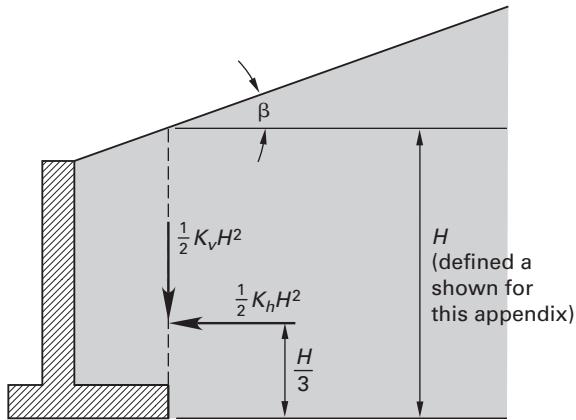

GT		geotextile
GM		geomembrane
GG		geogrid
GCD		geocomposite drain – with geotextile cover
GN		geonet
GCL		geocomposite clay liner
GEC		surficial geosynthetic erosion control
GL		geocell
GA		geomat
EKG		electrokinetic geosynthetic

The following function symbols may be used where a description of the role of the geosynthetic material is needed.

## APPENDIX 37.A

Active Components for Retaining Walls  
(straight slope backfill)  
(walls not over 20 ft high)  
(lbf/ft<sup>2</sup> per linear foot)

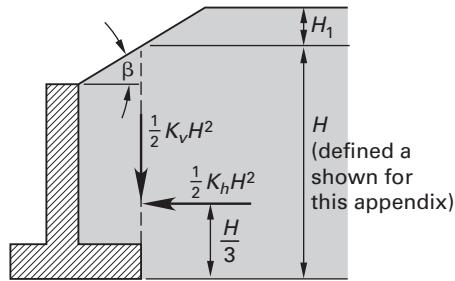

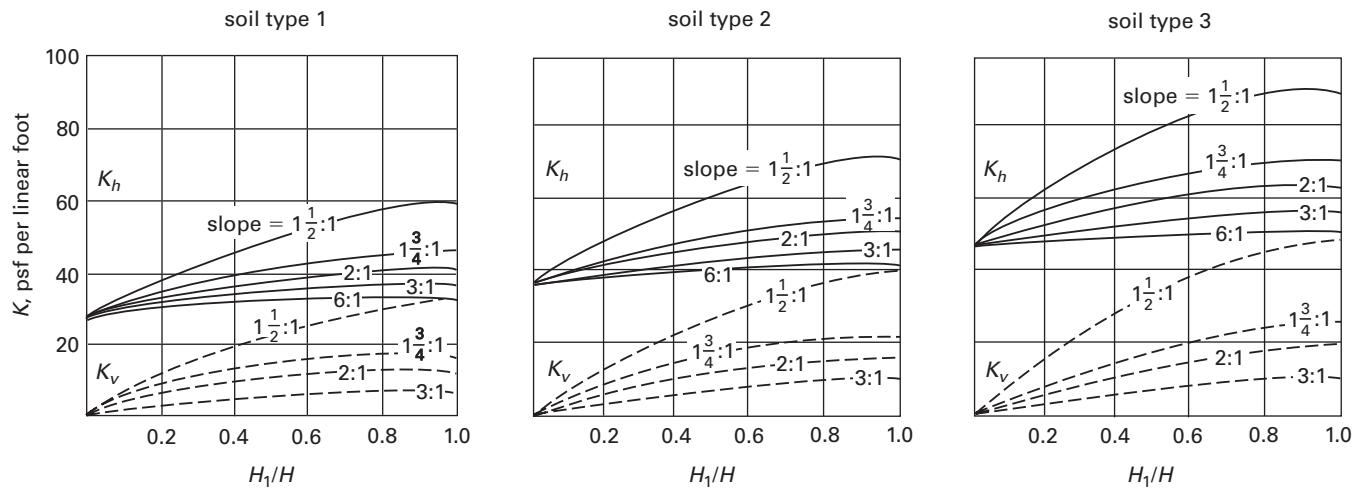

Circled numbers indicate the following soil types.

1. Clean sand and gravel: GW, GP, SW, SP.
2. Dirty sand and gravel of restricted permeability: GM, GM-GP, SM, SM-SP.
3. Stiff residual silts and clays, silty fine sands, and clayey sands and gravels CL, ML, CH, MH, SM, SC, GC.
4. Soft or very soft clay, organic silt, or silty clay.

AISI 1095, plain carbon steel, for handtools, music wire springs, leaf springs, knives, saws, and agricultural tools such as plows and disks	annealed hot rolled hardened	100 142 180	53 84 118
AISI 1330, manganese steel, for axles and drive shafts	annealed cold drawn hardened	97 113 122	83 93 100
AISI 4130, chromium-molybdenum steel, for high-strength aircraft structures	annealed hardened	81 161	52 137
AISI 4340, nickel-chromium-molybdenum steel, for large-scale, heavy-duty, high-strength structures	annealed as rolled hardened	119 192 220	99 147 200
AISI 2315, nickel steel, for carburized parts	as rolled cold drawn	85 95	56 75
AISI 2330, nickel steel	as rolled cold drawn annealed normalized	98 110 80 95	65 90 50 61
AISI 3115, nickel-chromium steel for carburized parts	cold drawn as rolled annealed	95 75 71	70 60 62
<b>STAINLESS STEELS</b>			
AISI 302, stainless steel, most widely used, same as 18-8	annealed cold drawn	90 105	35 60
AISI 303, austenitic stainless steel, good machineability	annealed cold worked	90 110	35 75
AISI 304, austenitic stainless steel, good machineability and weldability	annealed cold worked	85 110	30 75
AISI 309, stainless steel, good weldability, high strength at high temperatures, used in furnaces and ovens	annealed cold drawn	90 110	35 65
AISI 316, stainless steel, excellent corrosion resistance	annealed cold drawn	85 105	35 60
AISI 410, magnetic, martensitic, can be quenched and tempered to give varying strength	annealed cold drawn oil quenched and drawn	60 180 110	32 150 91
AISI 430, magnetic, ferritic, used for auto and architectural trim and for equipment in food and chemical industries	annealed cold drawn	60 100	35
AISI 502, magnetic, ferritic, low cost, widely used in oil refineries	annealed	60	25

(Multiply in/in-°F by 1.8 to obtain m/m·K.)

### APPENDIX 44.A

Elastic Beam Deflection Equations  
( $w$  is the load per unit length.)  
( $y$  is positive downward.)

#### Case 1: Cantilever with End Load

reactions:

$$R_l = 0$$

$$R_r = P$$

shear:

$$V = -P \text{ (constant)}$$

moments:

$$M_x = -Px$$

$$M_{\max} = -PL$$

end slope:

$$\phi_l = +\frac{PL^2}{2EI}$$

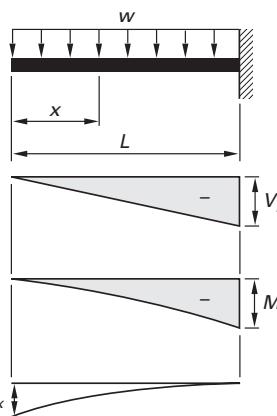

$$\phi_r = 0$$

deflection:

$$y_x = \left(\frac{P}{6EI}\right) \times (2L^3 - 3L^2x + x^3)$$

$$y_{\max} = \frac{PL^3}{3EI} \text{ at } x = 0$$

#### Case 2: Cantilever with Uniform Load

reactions:

$$R_l = 0$$

$$R_r = wL$$

shear:

$$V_x = -wx$$

$$V_{\max} = -wL = V_r$$

moments:

$$M_x = -\frac{wx^2}{2}$$

$$M_{\max} = -\frac{wL^2}{2} = M_r$$

end slope:

$$\phi_l = +\frac{wL^3}{6EI}$$

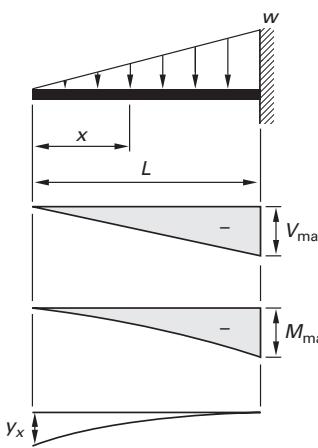

$$\phi_r = 0$$

deflection:

$$y_x = \left(\frac{w}{24EI}\right) \times (3L^4 - 4L^3x + x^4)$$

$$y_{\max} = \frac{wL^4}{8EI} \text{ at } x = 0$$

#### Case 3: Cantilever with Triangular Load

reactions:

$$R_l = 0$$

$$R_r = \frac{wL}{2}$$

shear:

$$V_x = -\frac{wx^2}{2L}$$

$$V_{\max} = \frac{wL}{2} \text{ at } x = L$$

moments:

$$M_x = -\frac{wx^3}{6L}$$

$$M_{\max} = \frac{wL^2}{6} \text{ at } x = L$$

end slope:

$$\phi_l = +\frac{wL^3}{24EI}$$

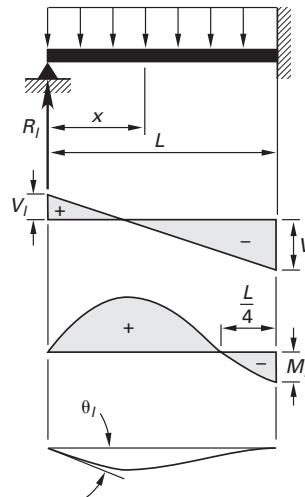

$$\phi_r = 0$$

deflection:

$$y_x = \left(\frac{w}{120EI}\right) \times (4L^5 - 5L^4x + x^5)$$

$$y_{\max} = \frac{wL^4}{30EI} \text{ at } x = 0$$

#### Case 4: Proppped Cantilever with Uniform Load

reactions:

$$R_l = \frac{3}{8}wL$$

$$R_r = \frac{5}{8}wL$$

shear:

$$V_l = -\frac{3}{8}wL$$

$$V_r = +\frac{5}{8}wL$$

$$V_x = w\left(\frac{3L}{8} - x\right)$$

moments:

$$M_r = M_{\max} = -\frac{wL^2}{8}$$

$$M_x = \left(-\frac{w}{8}\right)(3xL - 4x^2)$$

$$M = \frac{9wL^2}{128}$$

at  $x = 0.375L$

end slope:

$$\phi_l = +\frac{wL^3}{48EI}$$

$$\phi_r = 0$$

deflection:

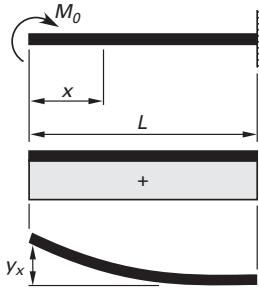

$$y_x = \left(\frac{w}{48EI}\right) \times (L^3x - 3Lx^3 + 2x^4)$$

$$y_{\max} = \frac{wL^4}{185EI}$$

at  $x = 0.4215L$

(continued)

**APPENDIX 44.A (continued)**  
**Elastic Beam Deflection Equations**  
 $(w$  is the load per unit length.)  
 $(y$  is positive downward.)

**Case 5: Cantilever with End Moment**

reactions:

$R_l = 0$

$R_r = 0$

shear:

$V = 0$

moments:

$M = M_0 = M_{\max}$

end slope:

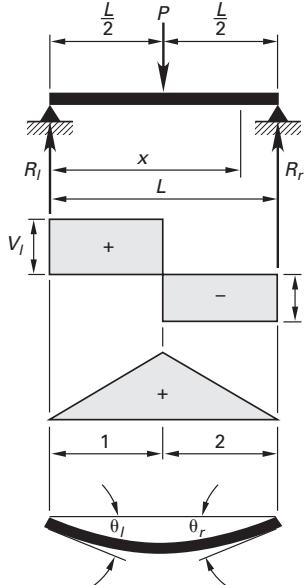

$\phi_l = -\frac{M_0 L}{EI}$

$\phi_r = 0$

deflection:

$y_x = \left(-\frac{M_0}{2EI}\right) (L^2 - 2xL + x^2)$

$y_{\max} = -\frac{M_0 L^2}{2EI}$

at  $x = 0$ **Case 6: Simple Beam with Center Load**

reactions:

$R_l = R_r = P/2$

shear:

$V_l = P/2$

$V_r = -P/2$

moments:

$M_{x1} = \frac{Px}{2}$

$M_{x2} = \frac{P}{2}(L-x)$

$M_{\max} = \frac{PL}{4}$

end slope:

$\phi_l = -\frac{PL^2}{16EI}$

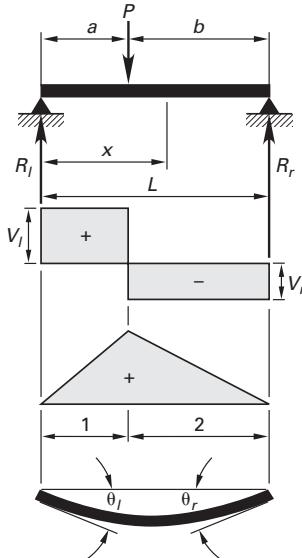

$\phi_r = +\frac{PL^2}{16EI}$

deflection:

$y_{x1} = \left(\frac{P}{48EI}\right)(3xL^2 - 4x^3)$

at  $x < L/2$ 

$y_{\max} = \left(\frac{PL^3}{48EI}\right)$  at  $x = L/2$

**Case 7: Simple Beam with Intermediate Load**

reactions:

$R_l = \frac{Pb}{L}$

$R_r = \frac{Pa}{L}$

shear:

$V_l = +\frac{Pb}{L}$

$V_r = -\frac{Pa}{L}$

moments:

$M_{x1} = \frac{Pbx}{L}$

$M_{x2} = \frac{Pa(L-x)}{L}$

$M_{\max} = \frac{Pab}{L}$  at  $x = a$

end slope:

$\phi_l = -\frac{Pab(1 + \frac{b}{L})}{6EI}$

$\phi_r = \frac{Pab(1 + \frac{a}{L})}{6EI}$

deflection:

$y_{x1} = \left(\frac{Pb}{6EI L}\right)(L^2 x - b^2 x - x^3)$

at  $x < a$ 

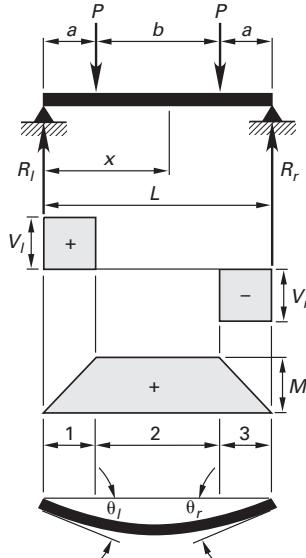

$y_{x2} = \left(\frac{Pb}{6EI L}\right) \left( \left(\frac{L}{b}\right)(x-a)^3 + (L^2 - b^2)x - x^3 \right)$

at  $x > a$ 

$y = \frac{Pa^2 b^2}{3EI L}$  at  $x = a$

$y_{\max} = \left(\frac{0.06415 Pb}{EIL}\right)(L^2 - b^2)^{3/2}$

$at x = \sqrt{\frac{a(L+b)}{3}}$

**Case 8: Simple Beam with Two Loads**

reactions:

$R_l = R_r = P$

shear:

$V_l = +P$

$V_r = -P$

moments:

$M_{x1} = Px$

$M_{x2} = Pa$

$M_{x3} = P(L-x)$

end slope:

$\phi_l = -\frac{Pa(a+b)}{2EI}$

$\phi_r = +\frac{Pa(a+b)}{2EI}$

deflection:

$y_{x1} = \left(\frac{P}{6EI}\right)(3Lax - 3a^2 x - x^3)$

at  $x < a$ 

$y_{x2} = \left(\frac{P}{6EI}\right)(3Lax - 3ax^2 - a^3)$

at  $a < x < a+b$ 

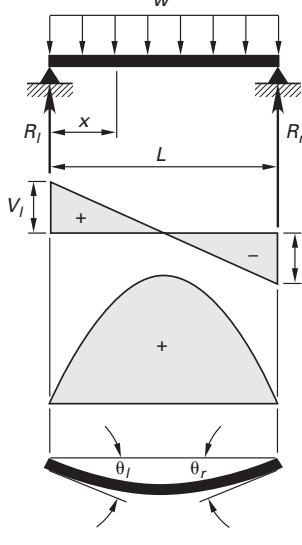

$y_{\max} = \left(\frac{P}{24EI}\right)(3L^2 a - 4a^3)$

at  $x = L/2$ 

(continued)

**APPENDIX 44.A (continued)**

Elastic Beam Deflection Equations  
( $w$  is the load per unit length.)  
( $y$  is positive downward.)

**Case 9: Simple Beam with Uniform Load**

reactions:

$$R_l = R_r = \frac{wL}{2}$$

shear:

$$V_l = +\frac{wL}{2}$$

$$V_r = -\frac{wL}{2}$$

moments:

$$M = \left(\frac{w}{2}\right)(Lx - x^2)$$

$$M_{\max} = \frac{wL^2}{8}$$

end slope:

$$\phi_l = \frac{-wL^3}{24EI}$$

$$\phi_r = +\frac{wL^3}{24EI}$$

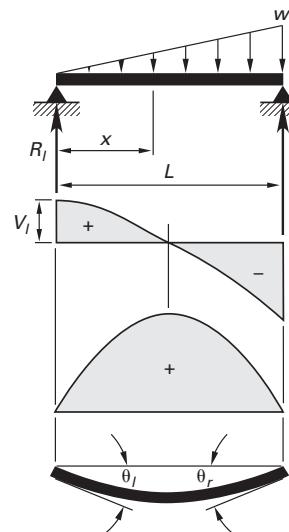

deflection:

$$y_x = \left(\frac{w}{24EI}\right) \times (L^3x - 2Lx^3 + x^4)$$

$$y_{\max} = \frac{5wL^4}{384EI}$$

 at  $x = \frac{L}{2}$ 
**Case 10: Simple Beam with Triangular Load**

( $w$  is the maximum loading per unit length at the right end, not the total load,  
 $W = \frac{1}{2}Lw$ .)

reactions:

$$R_l = \frac{wL}{6}$$

$$R_r = \frac{wL}{3}$$

shear:

$$V_l = +\frac{wL}{6}$$

$$V_r = -\frac{wL}{3}$$

$$V_x = \left(\frac{wL}{6}\right)\left(1 - 3\left(\frac{x}{L}\right)^2\right)$$

moments:

$$M_x = \left(\frac{w}{6}\right)\left(Lx - \frac{x^3}{L}\right)$$

$$M_{\max} = \frac{wL^2}{9\sqrt{3}} = 0.0642wL^2$$

 at  $x = 0.577L$ 

end slope:

$$\phi_l = \frac{-7wL^3}{360EI}$$

$$\phi_r = +\frac{wL^3}{45EI}$$

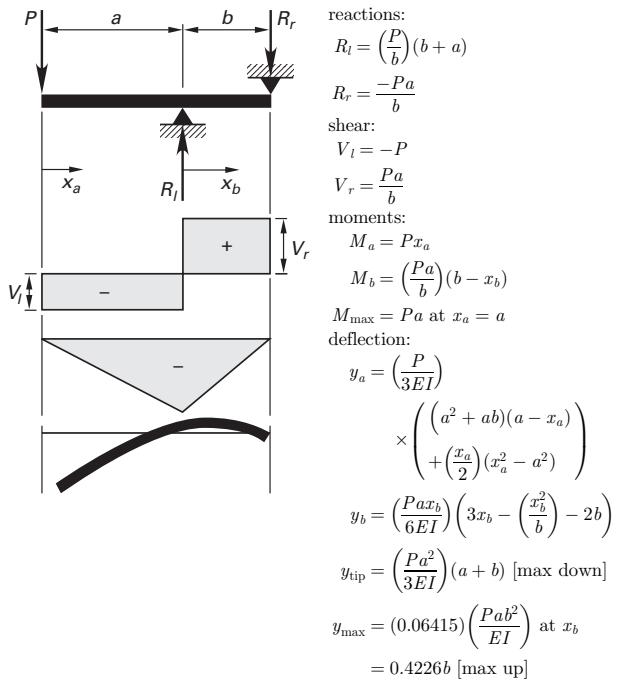

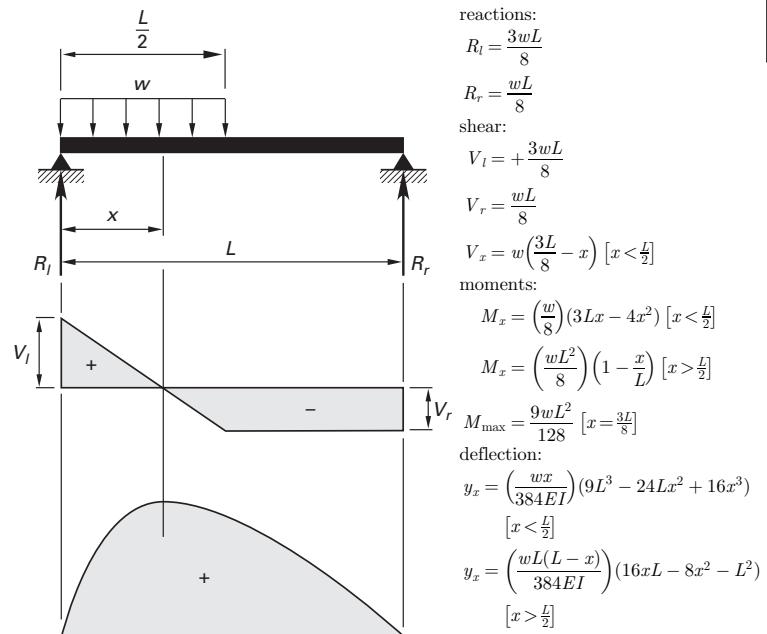

deflection:

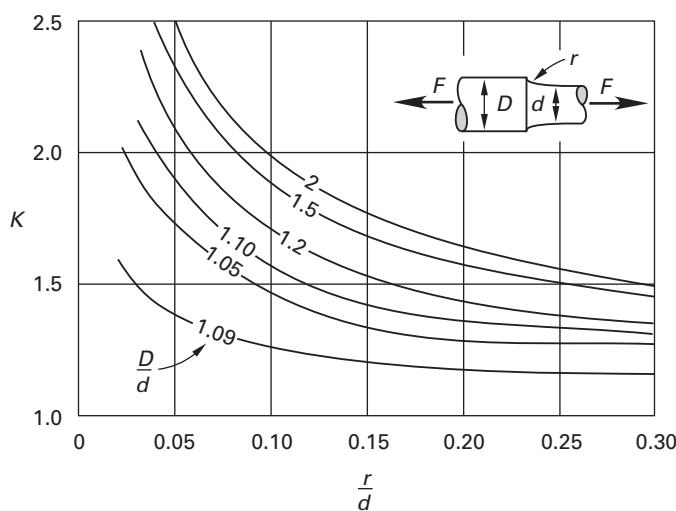

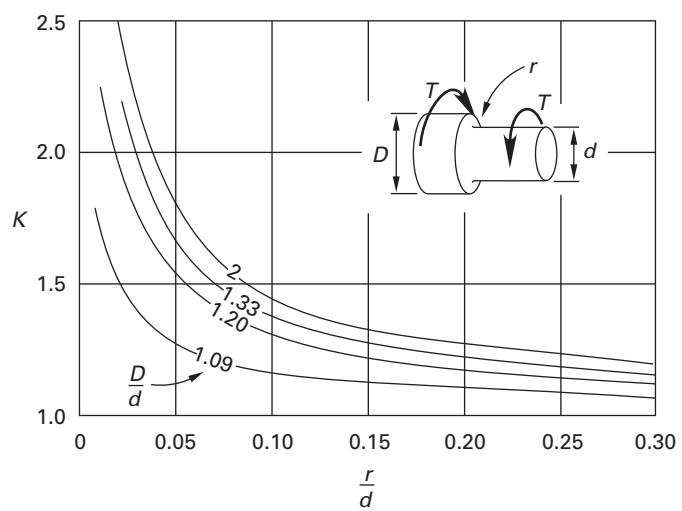

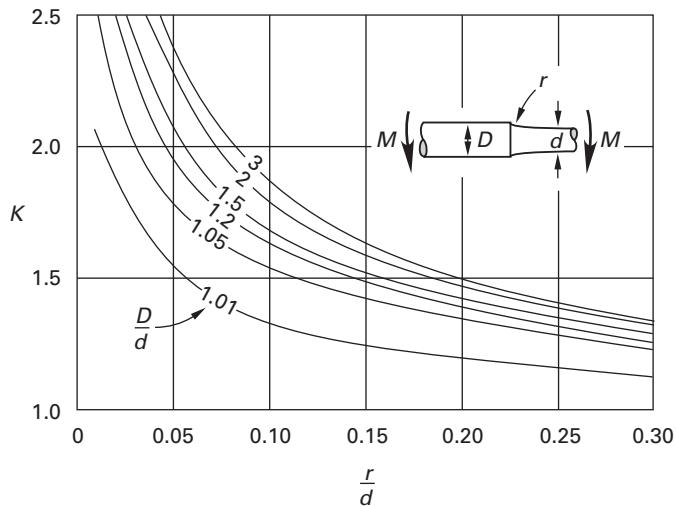

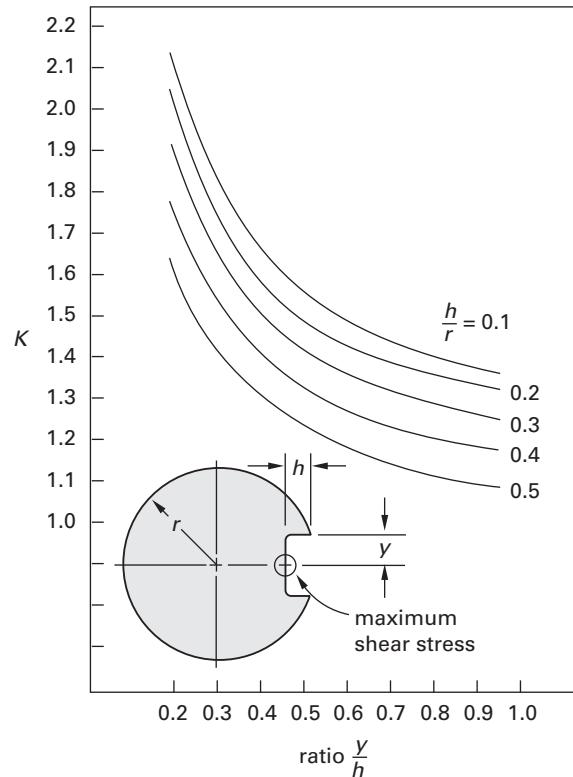

$$y_x = \left(\frac{w}{360EI}\right) \times \left(7L^3x - 10Lx^3 + \frac{3x^5}{L}\right)$$

$$y_{\max} = (0.00652)\left(\frac{wL^4}{EI}\right)$$

 at  $x = 0.519L$

**APPENDIX 58.A**  
Common Structural Steels

ASTM designation	type of steel	forms	recommended uses	minimum yield stress $F_y$ , (ksi) <sup>a</sup>	minimum tensile strength $F_u$ , (ksi) <sup>b</sup>
A36	carbon	shapes, bars, and plates	bolted or welded buildings and bridges and other structural uses	36, but 32 if thickness > 8 in	58–80
A529	carbon	shapes and plates to $\frac{1}{2}$ in	similar to A36	42–50	60–100
A572	high-strength low-alloy columbium-vanadium	shapes, plates, and bars to 6 in	bolted or welded construction; not for welded bridges for $F_y$ grades 55 and above	42–65	60–80
A242	atmospheric corrosion-resistant high-strength low-alloy	shapes, plates, and bars to 5 in	bolted or welded construction; welding technique very important	42–50	63–70
A588	atmospheric corrosion-resistant high-strength low-alloy	plates and bars to 4 in	bolted construction	42–50	63–70
A852	quenched and tempered alloy	plates only to 4 in	welded or bolted construction, primarily for welded bridges and buildings; welding technique of fundamental importance	70	90–110
A514	quenched and tempered low-alloy	plates only $2\frac{1}{2}$ to 6 in	welded structures with great attention technique, discouraged if ductility important	90–100	100–130
A992	high-strength low-alloy manganese-silicon-vanadium	shapes	wide flange shapes	42–65 (design 50)	60–80 (design 65)

(Multiply in by 25.4 to obtain mm.)

(Multiply ksi by 6.9 to obtain MPa.)

<sup>a</sup> $F_y$  values vary with thickness and group.

<sup>b</sup> $F_u$  values vary by grade and type.

**APPENDIX 78.A**  
 Oblique Triangle Equations

given	equation
$A, B, a$	$C = 180^\circ - (A + B)$ $b = \left(\frac{a}{\sin A}\right) \sin B$ $c = \left(\frac{a}{\sin A}\right) \sin(A + B) = \left(\frac{a}{\sin A}\right) \sin C$ $\text{area} = \frac{1}{2}ab \sin C = \frac{a^2 \sin B \sin C}{2 \sin A}$
$A, a, b$	$\sin B = \left(\frac{\sin A}{a}\right) b$ $C = 180^\circ - (A + B)$ $c = \left(\frac{a}{\sin A}\right) \sin C$ $\text{area} = \frac{1}{2}ab \sin C$
$C, a, b$	$c = \sqrt{a^2 + b^2 - 2ab \cos C}$ $\frac{1}{2}(A + B) = 90^\circ - \frac{1}{2}C$ $\tan \frac{1}{2}(A - B) = \left(\frac{a - b}{a + b}\right) \tan \frac{1}{2}(A + B)$ $A = \frac{1}{2}(A + B) + \frac{1}{2}(A - B)$ $B = \frac{1}{2}(A + B) - \frac{1}{2}(A - B)$ $c = (a + b) \left( \frac{\cos \frac{1}{2}(A + B)}{\cos \frac{1}{2}(A - B)} \right) = (a - b) \left( \frac{\sin \frac{1}{2}(A + B)}{\sin \frac{1}{2}(A - B)} \right)$ $\text{area} = \frac{1}{2}ab \sin C$
$a, b, c$	$\text{Let } s = \frac{a + b + c}{2}$ $\sin \frac{1}{2}A = \sqrt{\frac{(s - b)(s - c)}{bc}}$ $\cos \frac{1}{2}A = \sqrt{\frac{s(s - a)}{bc}}$ $\tan \frac{1}{2}A = \sqrt{\frac{(s - b)(s - c)}{s(s - a)}}$ $\sin A = 2 \sqrt{\frac{s(s - a)(s - b)(s - c)}{bc}}$ $\cos A = \frac{b^2 + c^2 - a^2}{2bc}$ $\text{area} = \sqrt{s(s - a)(s - b)(s - c)}$

**APPENDIX 84.A**  
Polyphase Motor Classifications and Characteristics

speed regulations	speed control	starting torque	breakdown torque	application
general-purpose squirrel cage (NEMA design B)				
Drops about 3% for large to 5% for small sizes.	None, except multispeed types, designed for two to four fixed speeds.	100% for large; 275% for 1 hp 4 pole unit.	200% of full load.	Constant-speed service where starting is not excessive. Fans, blowers, rotary compressors, and centrifugal pumps.
high-torque squirrel cage (NEMA design C)				
Drops about 3% for large to 6% for small sizes.	None, except multispeed types, designed for two and four fixed speeds.	250% of full load for high-speed to 200% for low-speed designs.	200% of full load.	Constant-speed where fairly high starting torque is required infrequently with starting current about 550% of full load. Reciprocating pumps and compressors, crushers, etc.
high-slip squirrel cage (NEMA design D)				
Drops about 10% to 15% from no load to full load.	None, except multispeed types, designed for two to four fixed speeds.	225% to 300% full load, depending on speed with rotor resistance.	200%. Will usually not stall until loaded to maximum torque, which occurs at standstill.	Constant-speed and high starting torque, if starting is not too frequent, and for high-peak loads with or without flywheels. Punch presses, shears, elevators, etc.
low-torque squirrel cage (NEMA design F)				
Drops about 3% for large to 5% for small sizes.	None, except multispeed types, designed for two to four fixed speeds.	50% of full load for high-speed to 90% for low-speed designs.	135% to 170% of full load.	Constant-speed service where starting duty is light. Fans, blowers, centrifugal pumps, and similar loads.
wound rotor				
With rotor rings short circuited, drops about 3% for large to 5% for small sizes.	Speed can be reduced to 50% by rotor resistance. Speed varies inversely as load.	Up to 300% depending on external resistance in rotor circuit and how distributed.	300% when rotor slip rings are short circuited.	Where high starting torque with low starting current or where limited speed control is required. Fans, centrifugal and plunger pumps, compressors, conveyors, hoists, cranes, etc.
synchronous				
Constant.	None, except special motors designed for two fixed speeds.	40% for slow to 160% for medium-speed 80% pf. Specials develop higher.	Unity-pf motors 170%, 80%-pf motors 225%. Specials, up to 300%	For constant-speed service, direct connection to slow-speed machines and where pf correction is required.

**APPENDIX 84.B**  
DC and Single-Phase Motor Classifications and Characteristics

speed regulations	speed control	starting torque	breakdown torque	application
series				
Varies inversely as load. Races on light loads and full voltage.	Zero to maximum depending on control and load.	High. Varies as square of voltage. Limited by commutation, heating, and line capacity.	High. Limited by commutation, heating, and line capacity.	Where high starting torque is required and speed can be regulated. Traction, bridges, hoists, gates, car dumpers, car retarders.
shunt				
Drops 3% to 5% from no load to full load.	Any desired range depending on design, type of system.	Good. With constant field, varies directly as voltage applied to armature.	High. Limited by commutation, heating, and line capacity.	Where constant or adjustable speed is required and starting conditions are not severe. Fans, blowers, centrifugal pumps, conveyors, wood and metal-working machines, elevators.
compound				
Drops 7% to 20% from no load to full load depending on amount of compounding.	Any desired range, depending on design, type of control.	Higher than for shunt, depending on amount of compounding.	High. Limited by commutation, heating and line capacity.	Where high starting torque and fairly constant speed is required. Plunger pumps, punch presses, shears, bending rolls, geared elevators, conveyors, hoists.
split-phase				
Drops about 10% from no load to full load.	None.	75% for large to 175% for small sizes.	150% for large to 200% for small sizes.	Constant-speed service where starting is easy. Small fans, centrifugal pumps and light-running machines, where polyphase is not available.
capacitor start				
Drops about 5% for large to 10% for small sizes.	None.	150% to 350% of full load depending on design and size.	50% for large to 200% for small sizes.	Constant-speed service for any starting duty and quiet operation, where polyphase current cannot be used.
commutator type				
Drops about 5% for large to 10% for small sizes.	Repulsion induction, none. Brush-shifting types, four to one at full load.	250% for large to 350% for small sizes.	150% for large to 250%.	Constant-speed service for any starting duty where speed control is required and polyphase current cannot be used.

\*This appendix is included to support general study and noncritical applications. NBS Circular 561 has been superseded by NBS Monograph 125, *Thermocouple Reference Tables Based on the IPTS-68: Reference Tables in degrees Fahrenheit for Thermoelements versus Platinum*, presenting the same information as British Standards Institution standard B.S. 4937. In the spirit of globalization, these have been superseded in other countries by IEC 584-1 (60584-1) *Thermocouples Part 1: Reference Tables*, published in 1995. In addition to being based on modern correlations and the 1990 International Temperature Scale (ITS), the 160-page IEC 60584-1 duplicates all text in English and French, refers only to the Celsius temperature scale, and is available only by purchase or licensing.

**APPENDIX 87.A**  
 Standard Cash Flow Factors

multiply by to obtain

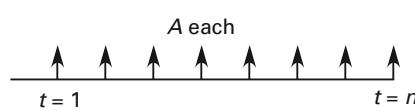

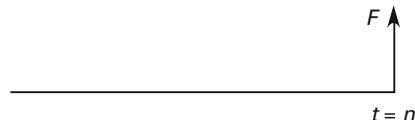

$$P = F(1 + i)^{-n}$$

$$(P/F, i\%, n)$$

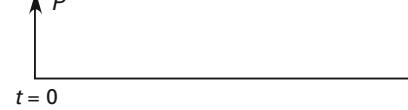

$$F = P(1 + i)^n$$

$$(F/P, i\%, n)$$

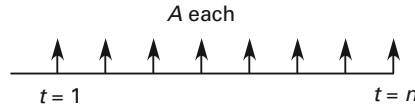

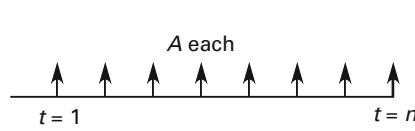

$$P = A \left( \frac{(1 + i)^n - 1}{i(1 + i)^n} \right)$$

$$(P/A, i\%, n)$$

$$A = P \left( \frac{i(1 + i)^n}{(1 + i)^n - 1} \right)$$

$$(A/P, i\%, n)$$

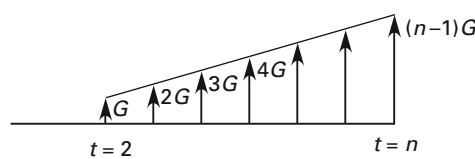

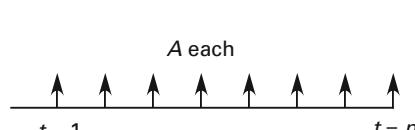

$$F = A \left( \frac{(1 + i)^n - 1}{i} \right)$$

$$(F/A, i\%, n)$$

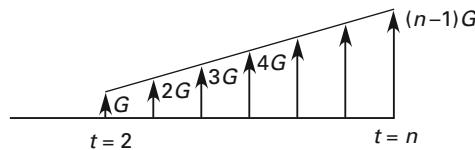

$$A = F \left( \frac{i}{(1 + i)^n - 1} \right)$$

$$(A/F, i\%, n)$$

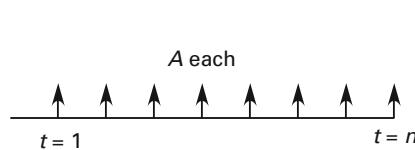

$$P = G \left( \frac{(1 + i)^n - 1}{i^2(1 + i)^n} - \frac{n}{i(1 + i)^n} \right)$$

$$(P/G, i\%, n)$$

$$A = G \left( \frac{1}{i} - \frac{n}{(1 + i)^n - 1} \right)$$

$$(A/G, i\%, n)$$

# Glossary

## A

**AASHTO:** American Association of State and Highway Transportation Officials.

**Abandonment:** The reversion of title to the owner of the underlying fee where an easement for highway purposes is no longer needed.

**Absorbed dose:** The energy deposited by radiation as it passes through a material.

**Absorption:** The process by which a liquid is drawn into and tends to fill permeable pores in a porous body. Also, the increase in weight of a porous solid body resulting from the penetration of liquid into its permeable pores.

**Accelerated flow:** A form of varied flow in which the velocity is increasing and the depth is decreasing.

**Acid:** Any compound that dissociates in water into H<sup>+</sup> ions. (The combination of H<sup>+</sup> and water, H<sub>3</sub>O<sup>+</sup>, is known as the hydronium ion.) Acids conduct electricity in aqueous solutions, have a sour taste, turn blue litmus paper red, have a pH between 0 and 7, and neutralize bases, forming salts and water.

**Active pressure:** Pressure causing a wall to move away from the soil.

**Adenosine triphosphate (ATP):** The macromolecule that functions as an energy carrier in cells. The energy is stored in a high-energy bond between the second and third phosphates.

**Adjudication:** A court proceeding to determine rights to the use of water on a particular stream or aquifer.

**Admixture:** Material added to a concrete mixture to increase its workability, strength, or imperviousness, or to lower its freezing point.

**Adsorbed water:** Water held near the surface of a material by electrochemical forces.

**Adsorption edge:** The pH range where solute adsorption changes sharply.

**Advection:** The transport of solutes along stream lines at the average linear seepage flow velocity.

**Aeration:** Mixing water with air, either by spraying water or diffusing air through water.

**Aerobe:** A microorganism whose growth requires free oxygen.

**Aerobic:** Requiring oxygen. Descriptive of a bacterial class that functions in the presence of free dissolved oxygen.

**Aggregate, coarse:** Aggregate retained on a no. 4 sieve.

**Aggregate, fine:** Aggregate passing the no. 4 sieve and retained on the no. 200 sieve.

**Aggregate, lightweight:** Aggregate having a dry density of 70 lbm/ft<sup>3</sup> (32 kg/m<sup>3</sup>) or less.

**Agonic line:** A line with no magnetic declination.

**Air change (Air flush):** A complete replacement of the air in a room or other closed space.

**Algae:** Simple photosynthetic plants having neither roots, stems, nor leaves.

**Alidade:** A tachometric instrument consisting of a telescope similar to a transit, an upright post that supports the standards of the horizontal axis of the telescope, and a straightedge whose edges are essentially in the same direction as the line of sight. An alidade is used in the field in conjunction with a plane table.

**Alkalinity:** A measure of the capacity of a water to neutralize acid without significant pH change. It is usually associated with the presence of hydroxyl, carbonate, and/or bicarbonate radicals in the water.

**Alluvial deposit:** A material deposited within the alluvium.

**Alluvium:** Sand, silt, clay, gravel, etc., deposited by running water.

**Alternate depths:** For a particular channel geometry and discharge, two depths at which water flows with the same specific energy in uniform flow. One depth corresponds to subcritical flow; the other corresponds to supercritical flow.

**Amictic:** Experiencing no overturns or mixing. Typical of polar lakes.

**Amphoteric behavior:** Ability of an aqueous complex or solid material to have a negative, neutral, or positive charge.

**Anabolism:** The phase of metabolism involving the formation of organic compounds; usually an energy-utilizing process.

**Anabanch:** The intertwining channels of a braided stream.

**Anaerobe:** A microorganism that grows only or best in the absence of free oxygen.

**Anaerobic:** Not requiring oxygen. Descriptive of a bacterial class that functions in the absence of free dissolved oxygen.

**Anion:** Negative ion that migrates to the positive electrode (anode) in an electrolytic solution.

**Anticinal spring:** A portion of an exposed aquifer (usually on a slope) between two impervious layers.

**Apparent specific gravity of asphalt mixture:** A ratio of the unit weight of an asphalt mixture (excluding voids permeable to water) to the unit weight of water.

**Appurtenance:** That which belongs with or is designed to complement something else. For example, a manhole is a sewer appurtenance.

**Apron:** An underwater “floor” constructed along the channel bottom to prevent scour. Aprons are almost always extensions of spillways and culverts.

**Aquiclude:** A saturated geologic formation with insufficient porosity to support any significant removal rate or contribute to the overall groundwater regime. In groundwater analysis, an aquiclude is considered to confine an aquifer at its boundaries.

**Aquifer:** Rock or sediment in a formation, group of formations, or part of a formation that is saturated and sufficiently permeable to transmit economic quantities of water to wells and springs.

**Aquifuge:** An underground geological formation that has absolutely no porosity or interconnected openings through which water can enter or be removed.

**Aquitard:** A saturated geologic unit that is permeable enough to contribute to the regional groundwater flow regime, but not permeable enough to supply a water well or other economic use.

**Arterial highway:** A general term denoting a highway primarily for through traffic, usually on a continuous route.

**Artesian formation:** An aquifer in which the piezometric height is greater than the aquifer height. In an artesian formation, the aquifer is confined and the water is under hydrostatic pressure.

**Artesian spring:** Water from an artesian formation that flows to the ground surface naturally, under hydrostatic pressure, due to a crack or other opening in the formation’s confining layer.

**Asphalt emulsion:** A mixture of asphalt cement with water. Asphalt emulsions are produced by adding a small amount of emulsifying soap to asphalt and water. The asphalt sets when the water evaporates.

**Atomic mass unit (AMU):** One AMU is one twelfth the atomic weight of carbon.

**Atomic number:** The number of protons in the nucleus of an atom.

**Atomic weight:** Approximately, the sum of the numbers of protons and neutrons in the nucleus of an atom.

**Autotroph:** An organism than can synthesize all of its organic components from inorganic sources.

**Auxiliary lane:** The portion of a roadway adjoining the traveled way for truck climbing, speed change, or other purposes supplementary to through traffic movement.

**Avogadro's law:** A gram-mole of any substance contains  $6.022 \times 10^{23}$  molecules.

**Azimuth:** The horizontal angle measured from the plane of the meridian to the vertical plane containing the line. The azimuth gives the direction of the line with respect to the meridian and is usually measured in a clockwise direction with respect to either the north or south meridian.

## B

**Backward pass:** The steps in a critical path analysis in which the latest start times are determined, usually after the earliest finish times have been determined in the forward pass.

**Backwater:** Water upstream from a dam or other obstruction that is deeper than it would normally be without the obstruction.

**Backwater curve:** A plot of depth versus location along the channel containing backwater.

**Base:** (a) A layer of selected, processed, or treated aggregate material of planned thickness and quality placed immediately below the pavement and above the subbase or subgrade soil. (b) Any compound that dissociates in water into  $\text{OH}^-$  ions. Bases conduct electricity in aqueous solutions, have a bitter taste, turn red litmus paper blue, have a pH between 7 and 14, and neutralize acids, forming salts and water.

**Base course:** The bottom portion of a pavement where the top and bottom portions are not the same composition.

**Base flow:** Component of stream discharge that comes from groundwater flow. Water infiltrates and moves through the ground very slowly; up to two years may elapse between precipitation and discharge.

**Batter pile:** A pile inclined from the vertical.

**Bed:** A layer of rock in the earth. Also the bottom of a body of water such as a river, lake, or sea.

**Bell:** An enlarged section at the base of a pile or pier used as an anchor.

**Belt highway:** An arterial highway carrying traffic partially or entirely around an urban area.

**Bent:** A supporting structure (usually of a bridge) consisting of a beam or girder transverse to the supported roadway and that is supported, in turn, by columns at each end, making an inverted "U" shape.

**Benthic zone:** The bottom zone of a lake, where oxygen levels are low.

**Benthos:** Organisms (typically anaerobic) occupying the benthic zone.

**Bentonite:** A volcanic clay that exhibits extremely large volume changes with moisture content changes.

**Berm:** A shelf, ledge, or pile.

**Bifurcation ratio:** The average number of streams feeding into the next side (order) waterway. The range is usually 2 to 4.

**Binary fission:** An asexual reproductive process in which one cell splits into two independent daughter cells.

**Bioaccumulation:** The process by which chemical substances are ingested and retained by organisms, either from the environment directly or through consumption of food containing the chemicals.

**Bioaccumulation factor:** *See Bioconcentration factor.*

**Bioactivation process:** A process using sedimentation, trickling filter, and secondary sedimentation before adding activated sludge. Aeration and final sedimentation are the follow-up processes.

**Bioassay:** The determination of kinds, quantities, or concentrations, and in some cases, the locations of material in the body, whether by direct measurement (*in vivo* counting) or by analysis and evaluation of materials excreted or removed (*in vitro*) from the body.

**Bioavailability:** A measure of what fraction, how much, or the rate that a substance (ingested, breathed in, dermal contact) is actually absorbed biologically. Bioavailability measurements are typically based on absorption into the blood or liver tissue.

**Biochemical oxygen demand (BOD):** The quantity of oxygen needed by microorganisms in a body of water to decompose the organic matter present. An index of water pollution.

**Bioconcentration:** The increase in concentration of a chemical in an organism resulting from tissue absorption (bioaccumulation) levels exceeding the rate of metabolism and excretion (biomagnification).

**Bioconcentration factor:** The ratio of chemical concentration in an organism to chemical concentration in the surrounding environment.

**Biodegradation:** The use of microorganisms to degrade contaminants.

**Biogas:** A mixture of approximately 55% methane and 45% carbon dioxide that results from the digestion of animal dung.

**Biomagnification:** The cumulative increase in the concentration of a persistent substance in successively higher levels of the food chain.

**Biomagnification factor:** *See Bioconcentration factor.*

**Biomass:** Renewable organic plant and animal material such as plant residue, sawdust, tree trimmings, rice straw, poultry litter and other animal wastes, some industrial wastes, and the paper component of municipal solid waste that can be converted to energy.

**Biosorption process:** A process that mixes raw sewage and sludge that have been pre-aerated in a separate tank.

**Biosphere:** The part of the world in which life exists.

**Biota:** All of the species of plants and animals indigenous to an area.

**Bleeding:** A form of segregation in which some of the water in the mix tends to rise to the surface of freshly placed concrete.

**Blind drainage:** Geographically large (with respect to the drainage basin) depressions that store water during a storm and therefore stop it from contributing to surface runoff.

**Bloom:** A phenomenon whereby excessive nutrients within a body of water results in an explosion of plant life, resulting in a depletion of oxygen and fish kill. Usually caused by urban runoff containing fertilizers.

**Bluff:** A high and steep bank or cliff.

**Body burden:** The total amount of a particular chemical in the body.

**Braided stream:** A wide, shallow stream with many anabanches.

**Branch sewer:** A sewer off the main sewer.

**Breaking chain:** A technique used when the slope is too steep to permit bringing the full length of the chain or tape to a horizontal position. When breaking chain, the distance is measured in partial tape lengths.

**Breakpoint chlorination:** Application of chlorine that results in a minimum of chloramine residuals. No significant free chlorine residual is produced unless the breakpoint is reached.

**Bulking:** *See Sludge bulking.*

**Bulk specific gravity of asphalt mixture:** Ratio of the unit weight of an asphalt mixture (including permeable and impermeable voids) to the unit weight of water.

**Butte:** A hill with steep sides that usually stands away from other hills.

**C**

**Caisson:** An airtight and watertight chamber used as a foundation and/or used to work or excavate below the water level.

**Capillary water:** Water just above the water table that is drawn up out of an aquifer due to capillary action of the soil.

**Carbonaceous demand:** Oxygen demand due to biological activity in a water sample, exclusive of nitrogenous demand.

**Carbonate hardness:** Hardness associated with the presence of bicarbonate radicals in the water.

**Carcinogen:** A cancer-causing agent.

**Carrier (biological):** An individual harboring a disease agent without apparent symptoms.

**Cascade impactor:** *See Impactor.*

**Cased hole:** An excavation whose sides are lined or sheeted.

**Catabolism:** The chemical reactions by which food materials or nutrients are converted into simpler substances for the production of energy and cell materials.

**Catena:** A group of soils of similar origin occurring in the same general locale but that differ slightly in properties.

**Cation:** Positive ion that migrates to the negative electrode (cathode) in an electrolytic solution.

**Cell wall:** The cell structure exterior to the cell membrane of plants, algae, bacteria, and fungi. It gives cells form and shape.

**Cement-treated base:** A base layer constructed with good-quality, well-graded aggregate mixed with up to 6% cement.

**CFR:** The Code of (U.S.) Federal Regulations, a compilation of all federal documents that have general applicability and legal effect, as published by the Office of the Federal Register.

**Channelization:** The separation or regulation of conflicting traffic movements into definite paths of travel by use of pavement markings, raised islands, or other means.

**Chat:** Small pieces of crushed rock and gravel. May be used for paving roads and roofs.

**Check:** A short section of built-up channel placed in a canal or irrigation ditch and provided with gates or flashboards to control flow or raise upstream level for diversion.

**Chelate:** A chemical compound into which a metallic ion (usually divalent) is tightly bound.

**Chelation:** (a) The process in which a compound or organic material attracts, combines with, and removes a metallic ion. (b) The process of removing metallic

contaminants by having them combine with special added substances.

**Chemical precipitation:** Settling out of suspended solids caused by adding coagulating chemicals.

**Chemocline:** A steep chemical (saline) gradient separating layers in meromictic lakes.

**Chloramine:** Compounds of chlorine and ammonia (e.g., NH<sub>2</sub>Cl, NHCl<sub>2</sub>, or NCl<sub>3</sub>).

**Chlorine demand:** The difference between applied chlorine and the chlorine residual. Chlorine demand is chlorine that has been reduced in chemical reactions and is no longer available for disinfection.

**Class:** A major taxonomic subdivision of a phylum. Each class is composed of one or more related orders.

**Clean-out:** A pipe through which snakes can be pushed to unplug a sewer.

**Clearance:** Distance between successive vehicles as measured between the vehicles, back bumper to front bumper.

**Coliform:** Gram-negative, lactose-fermenting rods, including escherichiae coli and similar species that normally inhabit the colon (large intestine). Commonly included in the coliform are Enterobacteria aerogenes, Klebsiella species, and other related bacteria.

**Colloid:** A fine particle ranging in size from 1 to 500 millimicrons. Colloids cause turbidity because they do not easily settle out.

**Combined residuals:** Compounds of an additive (such as chlorine) that have combined with something else. Chloramines are examples of combined residuals.

**Combined system:** A system using a single sewer for disposal of domestic waste and storm water.

**Comminutor:** A device that cuts solid waste into small pieces.

**Compaction:** Densification of soil by mechanical means, involving the expulsion of excess air.

**Compensation level:** In a lake, the depth of the limnetic area where oxygen production from light and photosynthesis are exactly balanced by depletion.

**Complete mixing:** Mixing accomplished by mechanical means (stirring).

**Compound:** A homogeneous substance composed of two or more elements that can be decomposed by chemical means only.

**Concrete:** A mixture of portland cement, fine aggregate, coarse aggregate, and water, with or without admixtures.

**Concrete, normal weight:** Concrete having a hardened density of approximately 150 lbm/ft<sup>3</sup>.

**Concrete, plain:** Concrete that is not reinforced with steel.

**Concrete, structural lightweight:** A concrete containing lightweight aggregate.

**Condemnation:** The process by which property is acquired for public purposes through legal proceedings under power of eminent domain.

**Cone of depression:** The shape of the water table around a well during and immediately after use. The cone's water surface level differs from the original water table by the well's drawdown.

**Confined water:** Artesian water overlaid with an impervious layer, usually under pressure.

**Confirmed test:** A follow-up test used if the presumptive test for coliforms is positive.

**Conflagration:** Total involvement or engulfment (as in a fire).

**Conjugate depths:** The depths on either side of a hydraulic jump.

**Connate water:** Pressurized water (usually, high in mineral content) trapped in the pore spaces of sedimentary rock at the time it was formed.

**Consolidation:** Densification of soil by mechanical means, involving expulsion of excess water.

**Contraction:** A decrease in the width or depth of flow caused by the geometry of a weir, orifice, or obstruction.

**Control of access:** The condition where the right of owners or occupants of abutting land or other persons to access in connection with a highway is fully or partially controlled by public authority.

**Critical depth:** The depth that minimizes the specific energy of flow.

**Critical flow:** Flow at the critical depth and velocity. Critical flow minimizes the specific energy and maximizes discharge.

**Critical slope:** The slope that produces critical flow.

**Critical velocity:** The velocity that minimizes specific energy. When water is moving at its critical velocity, a disturbance wave cannot move upstream since the wave moves at the critical velocity.

**Cuesta:** (From the Spanish word for cliff); a hill with a steep slope on one side and a gentle slope on the other.

**Cunette:** A small channel in the invert of a large combined sewer for dry weather flow.

**Curing:** The process and procedures used for promoting the hydration of cement. It consists of controlling the temperature and moisture from and into the concrete.

**Cyclone impactor:** *See* Impactor.

## D

**Dead load:** An inert, inactive load, primarily due to the structure's own weight.

**Decision sight distance:** Sight distance allowing for additional decision time in cases of complex conditions.

**Delta:** A deposit of sand and other sediment, usually triangular in shape. Deltas form at the mouths of rivers where the water flows into the sea.

**Deoxygenation:** The act of removing dissolved oxygen from water.

**Deposition:** The laying down of sediment such as sand, soil, clay, or gravel by wind or water. It may later be compacted into hard rock and buried by other sediment.

**Depression storage:** Initial storage of rain in small surface puddles.

**Depth-area-duration analysis:** A study made to determine the maximum amounts of rain within a given time period over a given area.

**Detrial mineral:** Mineral grain resulting from the mechanical disintegration of a parent rock.

**Dewatering:** Removal of excess moisture from sludge waste.

**Digestion:** Conversion of sludge solids to gas.

**Dilatancy:** The tendency of a material to increase in volume when undergoing shear.

**Dilution disposal:** Relying on a large water volume (lake or stream) to dilute waste to an acceptable concentration.

**Dimictic:** Experiencing two overturns per year. Dimictic lakes are usually found in temperate climates.

**Dimiper lake:** The freely circulating surface water with a small but variable temperature gradient.

**Dimple spring:** A depression in the earth below the water table.

**Distribution coefficient:** *See* Partition coefficient.

**Divided highway:** A highway with separated roadbeds for traffic in opposing directions.

**Domestic waste:** Waste that originates from households.

**Downpull:** A force on a gate, typically less at lower depths than at upper depths due to increased velocity, when the gate is partially open.

**Drainage density:** The total length of streams in a watershed divided by the drainage area.

**Drawdown:** The lowering of the water table level of an unconfined aquifer (or of the potentiometric surface of a confined aquifer) by pumping of wells.

**Drawdown curve:** *See* Cone of depression.

**Dredge line:** *See* Mud line.

**Dry weather flow:** *See* Base flow.

**Dystrophic:** Receiving large amounts of organic matter from surrounding watersheds, particularly humic

materials from wetlands that stain the water brown. Dystrophic lakes have low plankton productivity, except in highly productive littoral zones.

**E**

**Easement:** A right to use or control the property of another for designated purposes.

**Effective specific gravity of an asphalt mixture:** Ratio of the unit weight of an asphalt mixture (excluding voids permeable to asphalt) to the unit weight of water.

**Effluent:** That which flows out of a process.

**Effluent stream:** A stream that intersects the water table and receives groundwater. Effluent streams seldom go completely dry during rainless periods.

**Element:** A pure substance that cannot be decomposed by chemical means.

**Elutriation:** A countercurrent sludge washing process used to remove dissolved salts.

**Elutriator:** A device that purifies, separates, or washes material passing through it.

**Embankment:** A raised structure constructed of natural soil from excavation or borrow sources.

**Eminent domain:** The power to take private property for public use without the owner's consent upon payment of just compensation.

**Emulsion:** *See Asphalt emulsion.*

**Encroachment:** Use of the highway right-of-way for nonhighway structures or other purposes.

**Energy gradient:** The slope of the specific energy line (i.e., the sum of the potential and velocity heads).

**Enteric:** Intestinal.

**Enzyme:** An organic (protein) catalyst that causes changes in other substances without undergoing any alteration itself.

**Ephemeral stream:** A stream that goes dry during rainless periods.

**Epilimnion:** (Gr. for "upper lake"); the freely circulating surface water with a small but variable temperature gradient.

**Equivalent weight:** The amount of substance (in grams) that supplies one mole of reacting units. It is calculated as the molecular weight divided by the change in oxidation number experienced in a chemical reaction. An alternative calculation is the atomic weight of an element divided by its valence or the molecular weight of a radical or compound divided by its valence.

**Escarpmment:** A steep slope or cliff.

**Escherichiae coli (E. coli):** *See Coliform.*

**Estuary:** An area where fresh water meets salt water.

**Eutrophic:** Nutrient-rich; a eutrophic lake typically has a high surface area-to-volume ratio.

**Eutrophication:** The enrichment of water bodies by nutrients (e.g., phosphorus). Eutrophication of a lake normally contributes to a slow evolution into a bog, marsh, and ultimately, dry land.

**Evaporite:** Sediment deposited when sea water evaporates. Gypsum, salt, and anhydrite are evaporites.

**Evapotranspiration:** Evaporation of water from a study area due to all sources including water, soil, snow, ice, vegetation, and transpiration.

**F**

**Facultative:** Able to live under different or changing conditions. Descriptive of a bacterial class that functions either in the presence or absence of free dissolved oxygen.

**Fecal coliform:** Coliform bacterium present in the intestinal tracts and feces of warm-blooded animals.

**Fines:** Silt- and/or clay-sized particles.

**First-stage demand:** *See Carbonaceous demand.*

**Flexible pavement:** A pavement having sufficiently low bending resistance to maintain intimate contact with the underlying structure, yet having the required stability furnished by aggregate interlock, internal friction, and cohesion to support traffic.

**Float:** The amount of time that an activity can be delayed without delaying any succeeding activities.

**Floc:** Agglomerated colloidal particles.

**Flotation:** Addition of chemicals and bubbled air to liquid waste in order to get solids to float to the top as scum.

**Flow regime:** (a) Subcritical, critical, or supercritical.  
(b) Entrance control or exit control.

**Flowing well:** A well that flows under hydrostatic pressure to the surface (also called an Artesian well).

**Flume:** In general, any open channel for carrying water. More specifically, an open channel constructed above the earth's surface, usually supported on a trestle or on piers.

**Force main:** A sewer line that is pressurized.

**Forebay:** A reservoir holding water for subsequent use after it has been discharged from a dam.

**Forward pass:** The steps in a critical path analysis in which the earliest finish times are determined, usually before the latest start times are determined in the backward pass.

**Free residuals:** Ions or compounds not combined or reduced. The presence of free residuals signifies excess dosage.

**Freeboard distance:** The vertical distance between the water surface and the crest of a dam or top of a channel side. The distance the water surface can rise before it overflows.

**Freehaul:** Pertaining to hauling “for free” (i.e., without being able to bill an extra amount over the contract charge).

**Freeway:** A divided arterial highway with full control of access.

**Freeze (in piles):** A large increase in the ultimate capacity (and required driving energy) of a pile after it has been driven some distance.

**Friable:** Easily crumbled.

**Frontage road:** A local street or road auxiliary to and located on the side of an arterial highway for service to abutting property and adjacent areas, and for control of access.

**Frost susceptibility:** Susceptible to having water continually drawn up from the water table by capillary action, forming ice crystals below the surface (but above the frost line).

**Fulvic acid:** The alkaline-soluble portion of organic material (i.e., humus) that remains in solution at low pH and is of lower molecular weight. A breakdown product of cellulose from vascular plants.

**Fungi:** Aerobic, multicellular, nonphotosynthetic heterotrophic, eucaryote protists that degrade dead organic matter, releasing carbon dioxide and nitrogen.

## G

**Gap:** Corresponding time between successive vehicles (back bumper to front bumper) as they pass a point on a roadway.

**Gap-graded:** A soil with a discontinuous range of soil particle sizes; for example, containing large particles and small particles but no medium-sized particles.

**Geobar:** A polymeric material in the form of a bar.

**Geocell:** A three-dimensional, permeable, polymeric (synthetic or natural) honeycomb or web structure, made of alternating strips of geotextiles, geogrids, or geomembranes.

**Geocomposite:** A manufactured or assembled material using at least one geosynthetic product among the components.

**Geofoam:** A polymeric material that has been formed by the application of the polymer in semiliquid form through the use of a foaming agent. Results in a lightweight material with high void content.

**Geographic information system (GIS):** A digital database containing geographic information.

**Geogrid:** A planar, polymeric (synthetic or natural) structure consisting of a regular open network of integrally connected tensile elements that may be linked or formed by extrusion, bonding, or interlacing (knitting or lacing).

**Geomat:** A three-dimensional, permeable, polymeric (synthetic or natural) structure made of bonded filaments, used for soil protection and to bind roots and small plants in erosion control applications.

**Geomembrane:** A planar, relatively impermeable, polymeric (synthetic or natural) sheet. May be bituminous, elastomeric, or plastomeric.

**Geonet:** A planar, polymeric structure consisting of a regular dense network whose constituent elements are linked by knots or extrusions and whose openings are much larger than the constituents.

**Geopipe:** A polymeric pipe.

**Geospacer:** A three-dimensional polymeric structure with large void spaces.

**Geostrip:** A polymeric material in the form of a strip, with a width less than approximately 200 mm.

**Geosynthetic:** A planar, polymeric (synthetic or natural) material.

**Geotextile:** A planar, permeable, polymeric (synthetic or natural) textile material that may be woven, nonwoven, or knitted.

**Glacial till:** Soil resulting from a receding glacier, consisting of mixed clay, sand, gravel, and boulders.

**GMT:** *See UTC.*

**Gobar gas:** *See Biogas.*

**Gore:** The area immediately beyond the divergence of two roadways bounded by the edges of those roadways.

**Gradient:** The energy (head) loss per unit distance. *See also Slope.*

**Gravel:** Granular material retained on a no. 4 sieve.

**Gravitational water:** Free water in transit downward through the vadose (unsaturated) zone.

**Grillage:** A footing or part of a footing consisting of horizontally laid timbers or steel beams.

**Groundwater:** Loosely, all water that is underground as opposed to on the surface of the ground. Usually refers to water in the saturated zone below the water table.

**Gumbo:** Silty soil that becomes soapy, sticky, or waxy when wet.

## H

**Hard water:** Water containing dissolved salts of calcium and magnesium, typically associated with bicarbonates, sulfates, and chlorides.

**Hardpan:** A shallow layer of earth material that has become relatively hard and impermeable, usually through the decomposition of minerals.

**Head (Total hydraulic):** the sum of the elevation head, pressure head, and velocity head at a given point in an aquifer.

**Headwall:** Entrance to a culvert or sluiceway.

**Headway:** The time between successive vehicles as they pass a common point.

**Heat of hydration:** The exothermic heat given off by concrete as it cures.

**Horizon:** A layer of soil with different color or composition than the layers above and below it.

**HOV:** High-occupancy vehicle (e.g., bus).

**Humic acid:** The alkaline-soluble portion of organic material (i.e., humus) that precipitates from solution at low pH and is of higher molecular weight. A breakdown product of cellulose from vascular plants.

**Humus:** A grayish-brown sludge consisting of relatively large particle biological debris, such as the material sloughed off from a trickling filter.

**Hydration:** The chemical reaction between water and cement.

**Hydraulic depth:** Ratio of area in flow to the width of the channel at the fluid surface.

**Hydraulic jump:** An abrupt increase in flow depth that occurs when the velocity changes from supercritical to subcritical.

**Hydraulic radius:** Ratio of area in flow to wetted perimeter.

**Hydrogen ion:** The hydrogen atom stripped of its one orbital electron ( $H^+$ ). It associates with a water molecule to form the hydronium ion ( $H_3O^+$ ).

**Hydrological cycle:** The cycle experienced by water in its travel from the ocean, through evaporation and precipitation, percolation, runoff, and return to the ocean.

**Hydrometeor:** Any form of water falling from the sky.

**Hydronium ion:** *See* Hydrogen ion.

**Hydrophilic:** Seeking or liking water.

**Hydrophobic:** Avoiding or disliking water.

**Hygroscopic:** Absorbing moisture from the air.

**Hygroscopic water:** Moisture tightly adhering in a thin film to soil grains that is not removed by gravity or capillary forces.

**Hypolimnion:** (Gr. for “lower lake”); the deep, cold layer in a lake, below the epilimnion and metalimnion, cut off from the air above.

## I

**Igneous rock:** Rock that forms when molten rock (magma or lava) cools and hardens.

**Impactor:** An environmental device that removes and measures micron-sized dusts, particles, and aerosols from an air stream.

**Impervious layer:** A geologic layer through which no water can pass.

**Independent float:** The amount of time that an activity can be delayed without affecting the float on any preceding or succeeding activities.

**Infiltration:** (a) Groundwater that enters sewer pipes through cracks and joints. (b) The movement of water downward from the ground surface through the upper soil.

**Influent:** Flow entering a process.

**Influent stream:** A stream above the water table that contributes to groundwater recharge. Influent streams may go dry during the rainless season.

**Initial loss:** The sum of interception and depression loss, excluding blind drainage.

**In situ:** “In place”; without removal; in original location.

**Interception:** The process by which precipitation is captured on the surfaces of vegetation and other impervious surfaces and evaporates before it reaches the land surface.

**Interflow:** Infiltrated subsurface water that travels to a stream without percolating down to the water level.

**Intrusion:** An igneous rock formed from magma that pushed its way through other rock layers. Magma often moves through rock fractures, where it cools and hardens.

**Inverse condemnation:** The legal process that may be initiated by a property owner to compel the payment of fair compensation when the owner’s property has been taken or damaged for a public purpose.

**Inversion layer:** An extremely stable layer in the atmosphere in which temperature increases with elevation and mobility of airborne particles is restricted.

**Inverted siphon:** A sewer line that drops below the hydraulic grade line.

**In vitro:** Removed or obtained from an organism.

**In vivo:** Within an organism.

**Ion:** An atom that has either lost or gained one or more electrons, becoming an electrically charged particle.

**Isogonic line:** A line representing the magnetic declination.

**Isotopes:** Atoms of the same atomic number but having different atomic weights due to a variation in the number of neutrons.

**J**

**Jam density:** The density at which vehicles or pedestrians come to a halt.

**Juvenile water:** Water formed chemically within the earth from magma that has not participated in the hydrologic cycle.

**K**

**Kingdom:** A major taxonomic category consisting of several phyla or divisions.

**Krause process:** Mixing raw sewage, activated sludge, and material from sludge digesters.

**L**

**Lagging:** Heavy planking used to construct walls in excavations and braced cuts.

**Lamp holes:** Sewer inspection holes large enough to lower a lamp into but too small for a person.

**Lane occupancy (ratio):** The ratio of a lane's occupied time to the total observation time. Typically measured by a lane detector.

**Lapse rate, dry:** The rate that the atmospheric temperature decreases with altitude for a dry, adiabatic air mass.

**Lapse rate, wet:** The rate that the atmospheric temperature decreases with altitude for a moist, adiabatic air mass. The exact rate is a function of the moisture content.

**Lateral:** A sewer line that branches off from another.

**Lava:** Hot, liquid rock above ground. Also called lava once it has cooled and hardened.

**Limnetic:** Open water; extending down to the compensation level. Limnetic lake areas are occupied by suspended organisms (plankton) and free swimming fish.

**Limnology:** The branch of hydrology that pertains to the study of lakes.

**Lipids:** A group of organic compounds composed of carbon and hydrogen (e.g., fats, phospholipids, waxes, and steroids) that are soluble in a nonpolar, organic liquid (e.g., ether or chloroform); a constituent of living cells.

**Lipophilic:** Having an affinity for lipids.

**Littoral:** Shallow; heavily oxygenated. In littoral lake areas, light penetrates all the way through to the bottom, and the zone is usually occupied by a diversity of rooted plants and animals.

**Live load:** The weight of all nonpermanent objects in a structure, including people and furniture. Live load does not include seismic or wind loading.

**Loess:** A deposit of wind-blown silt.

**Lysimeter:** A container used to observe and measure percolation and mineral leaching losses due to water percolating through the soil in it.

**M**

**Magma:** Hot, liquid rock under the earth's surface.

**Main:** A large sewer at which all other branches terminate.

**Malodorous:** Offensive smelling.

**Marl:** An earthy substance containing 35% to 65% clay and 65% to 35% carbonate formed under marine or freshwater conditions.

**Meander corner:** A survey point set where boundaries intersect the bank of a navigable stream, wide river, or large lake.

**Meandering stream:** A stream with large curving changes of direction.

**Median:** The portion of a divided highway separating traffic traveling in opposite directions.

**Median lane:** A lane within the median to accommodate left-turning vehicles.

**Meridian:** A great circle of the earth passing through the poles.

**Meromictic lake:** A lake with a permanent hypolimnion layer that never mixes with the epilimnion. The hypolimnion layer is perennially stagnant and saline.

**Mesa:** A flat-topped hill with steep sides.

**Mesophyllic bacteria:** Bacteria growing between 10°C and 40°C, with an optimum temperature of 37°C. 40°C is, therefore, the upper limit for most wastewater processes.

**Metabolism:** All cellular chemical reactions by which energy is provided for vital processes and new cell substances are assimilated.

**Metalimnion:** A middle portion of a lake, between the epilimnion and hypolimnion, characterized by a steep and rapid decline in temperature (e.g., 1°C for each meter of depth).

**Metamorphic rock:** Rock that has changed from one form to another by heat or pressure.

**Meteoric water:** *See* Hydrometeor.

**Methylmercury:** A form of mercury that is readily absorbed through the gills of fish, resulting in large bioconcentration factors. Methylmercury is passed on to organisms higher in the food chain.

**Microorganism:** A microscopic form of life.

**Mixture:** A heterogeneous physical combination of two or more substances, each retaining its identity and specific properties.

Mohlman index: *See* Sludge volume index.

Mole: A quantity of substance equal to its molecular weight in grams (gmole or gram-mole) or in pounds (pmole or pound-mole).

Molecular weight: The sum of the atomic weights of all atoms in a molecule.

Monomictic: Experiencing one overturn per year. Monomictic lakes are typically very large and/or deep.

Mud line: The lower surface of an excavation or braced cut.

## N

Nephelometric turbidity unit: The unit of measurement for visual turbidity in water and other solutions.

Net rain: That portion of rain that contributes to surface runoff.

Nitrogen fixation: The formation of nitrogen compounds ( $\text{NH}_3$ , organic nitrogen) from free atmospheric nitrogen ( $\text{N}_2$ ).

Nitrogenous demand: Oxygen demand from nitrogen consuming bacteria.

Node: An activity in a precedence (critical path) diagram.

Nonpathogenic: Not capable of causing disease.

Nonpoint source: A pollution source caused by sediment, nutrients, and organic and toxic substances originating from land-use activities, usually carried to lakes and streams by surface runoff from rain or snowmelt. Nonpoint pollutants include fertilizers, herbicides, insecticides, oil and grease, sediment, salt, and bacteria. Non-point sources do not generally require NPDES permits.

Nonstriping sight distance: Nonstriping sight distances are in between stopping and passing distances, and they exceed the minimum sight distances required for marking no-passing zones. They provide a practical distance to complete the passing maneuver in a reasonably safe manner, eliminating the need for a no-passing zone pavement marking.

Normal depth: The depth of uniform flow. This is a unique depth of flow for any combination of channel conditions. Normal depth can be determined from the Manning equation.

Normally consolidated soil: Soil that has never been consolidated by a greater stress than presently existing.

NPDES: National Pollutant Discharge Elimination System.

NTU: *See* Nephelometric turbidity unit.

## O

Observation well: A nonpumping well used to observe the elevation of the water table or the potentiometric

surface. An observation well is generally of larger diameter than a piezometer well and typically is screened or slotted throughout the thickness of the aquifer.

Odor number: *See* Threshold odor number.

Oligotrophic: Nutrient-poor. Oligotrophic lakes typically have low surface area-to-volume ratios and largely inorganic sediments and are surrounded by nutrient-poor soil.

Order: In taxonomy, a major subdivision of a class. Each order consists of one or more related families.

Orthotropic bridge deck: A bridge deck, usually steel plate covered with a wearing surface, reinforced in one direction with integral cast-in-place concrete ribs. Used to reduce the bridge deck mass.

Orthotropic material: A material with different strengths (stiffnesses) along different axes.

Osmosis: The flow of a solvent through a semipermeable membrane separating two solutions of different concentrations.

Outcrop: A natural exposure of a rock bed at the earth's surface.

Outfall: A pipe that discharges treated wastewater into a lake, stream, or ocean.

Overchute: A flume passing over a canal to carry floodwaters away without contaminating the canal water below. An elevated culvert.

Overhaul: Pertaining to billable hauling (i.e., with being able to bill an extra amount over the contract charge).

Overland flow: Water that travels over the ground surface to a stream.

Overturn: (a) The seasonal (fall) increase in epilimnion depth to include the entire lake depth, generally aided by unstable temperature/density gradients. (b) The seasonal (spring) mixing of lake layers, generally aided by wind.

Oxidation: The loss of electrons in a chemical reaction. Opposite of *reduction*.

Oxidation number: An electrical charge assigned by a set of prescribed rules, used in predicting the formation of compounds in chemical reactions.

## P

Pan: A container used to measure surface evaporation rates.

Parkway: An arterial highway for noncommercial traffic, with full or partial control of access, usually located within a park or a ribbon of park-like development.

Partial treatment: Primary treatment only.

Partition coefficient: The ratio of the contaminant concentration in the solid (unabsorbed) phase to the contaminant concentration in the liquid (absorbed) phase

when the system is in equilibrium; typically represented as  $K_d$ .

**Passing sight distance:** The length of roadway ahead required to pass another vehicle without meeting an oncoming vehicle.

**Passive pressure:** A pressure acting to counteract active pressure.

**Pathogenic:** Capable of causing disease.

**Pathway:** An environmental route by which chemicals can reach receptors.

**Pay as you throw:** An administration scheme by which individuals are charged based on the volume of municipal waste discarded.

**Pedology:** The study of the formation, development, and classification of natural soils.

**Penetration treatment:** Application of light liquid asphalt to the roadbed material. Used primarily to reduce dust.

**Perched spring:** A localized saturated area that occurs above an impervious layer.

**Percolation:** The movement of water through the subsurface soil layers, usually continuing downward to the groundwater table.

**Permanent hardness:** Hardness that cannot be removed by heating.

**Person-rem:** A unit of the amount of total radiation received by a population. It is the product of the average radiation dose in rems times the number of people exposed in the population group.

**pH:** A measure of a solution's hydrogen ion concentration (acidity).

**Phreatic zone:** The layer the water table down to an impervious layer.

**Phreatophytes:** Plants that send their roots into or below the capillary fringe to access groundwater.

**Phytoplankton:** Small drifting plants.

**Pier shaft:** The part of a pier structure that is supported by the pier foundation.

**Piezometer:** A nonpumping well, generally of small diameter, that is used to measure the elevation of the water table or potentiometric surface. A piezometer generally has a short well screen through which water can enter.

**Piezometer nest:** A set of two or more piezometers set close to each other but screened to different depths.

**Piezometric level:** The level to which water will rise in a pipe due to its own pressure.

**Pile bent:** A supporting substructure of a bridge consisting of a beam or girder transverse to the roadway and that is supported, in turn, by a group of piles.

**Pitot tube traverse:** A volume or velocity measurement device that measures the impact energy of an air or liquid flow simultaneously at various locations in the flow area.

**Planimeter:** A device used to measure the area of a drawn shape.

**Plant mix:** A paving mixture that is not prepared at the paving site.

**Plat:** (a) A plan showing a section of land. (b) A small plot of land.

**pOH:** A measure of a solution's hydroxyl radical concentration (alkalinity).

**Point source:** A source of pollution that discharges into receiving waters from easily identifiable locations (e.g., a pipe or feedlot). Common point sources are factories and municipal sewage treatment plants. Point sources typically require NPDES permits.

**Pollutant:** Any solute or cause of change in physical properties that renders water, soil, or air unfit for a given use.

**Polymictic:** Experiencing numerous or continual overturns. Polymictic lakes, typically in the high mountains of equatorial regions, experience little seasonable temperature change.

**Porosity:** The ratio of pore volume to total rock, sediment, or formation volume.

**Post-chlorination:** Addition of chlorine after all other processes have been completed.

**Potable:** Suitable for human consumption.

**Prechlorination:** Addition of chlorine prior to sedimentation to help control odors and to aid in grease removal.

**Presumptive test:** A first-stage test in coliform fermentation. If positive, it is inconclusive without follow-up testing. If negative, it is conclusive.

**Prime coat:** The initial application of a low-viscosity liquid asphalt to an absorbent surface, preparatory to any subsequent treatment, for the purpose of hardening or toughening the surface and promoting adhesion between it and the superimposed constructed layer.

**Probable maximum rainfall:** The rainfall corresponding to some given probability (e.g., 1 in 100 years).

**Protium:** The stable  $^1\text{H}$  isotope of hydrogen.

**Protozoa:** Single-celled aquatic animals that reproduce by binary fission. Several classes are known pathogens.

**Putrefaction:** Anaerobic decomposition of organic matter with accompanying foul odors.

**Pycnometer:** A closed flask with graduations.

**Q**

*q*-curve: A plot of depth of flow versus quantity flowing for a channel with a constant specific energy.

**R**

Rad: Abbreviation for “radiation absorbed dose.” A unit of the amount of energy deposited in or absorbed by a material. A rad is equal to  $62.5 \times 10^6$  MeV per gram of material.

Radical: A charged group of atoms that act together as a unit in chemical reactions.

Ranger: *See* Wale.

Rapid flow: Flow at less than critical depth, typically occurring on steep slopes.

Rating curve: A plot of quantity flowing versus depth for a natural watercourse.

Reach: A straight section of a channel, or a section that is uniform in shape, depth, slope, and flow quantity.

Redox reaction: A chemical reaction in which oxidation and reduction occur.

Reduction: The loss of oxygen or the gain of electrons in a chemical reaction. Opposite of *oxidation*.

Refractory: Dissolved organic materials that are biologically resistant and difficult to remove.

Regulator: A weir or device that diverts large volume flows into a special high-capacity sewer.

Rem: Abbreviation for “Roentgen equivalent mammal.” A unit of the amount of energy absorbed by human tissue. It is the product of the absorbed dose (rad) times the quality factor.

Residual: A chemical that is left over after some of it has been combined or inactivated.

Resilient modulus: The modulus of elasticity of the soil.

Respiration: Any biochemical process in which energy is released. Respiration may be aerobic (in the presence of oxygen) or anaerobic (in the absence of oxygen).

Restraint: Any limitation (e.g., scarcity of resources, government regulation, or nonnegativity requirement) placed on a variable or combination of variables.

Resurfacing: A supplemental surface or replacement placed on an existing pavement to restore its riding qualities or increase its strength.

Retarded flow: A form of varied flow in which the velocity is decreasing and the depth is increasing.

Retrograde solubility: Solubility that decreases with increasing temperature. Typical of calcite (calcium carbonate,  $\text{CaCO}_3$ ) and radon.

Right of access: The right of an abutting land owner for entrance to or exit from a public road.

Rigid pavement: A pavement structure having portland cement concrete as one course.

Rip rap: Pieces of broken stone used as lining to protect the sides of waterways from erosion.

Road mix: A low-quality asphalt surfacing produced from liquid asphalts and used when plant mixes are not available or economically feasible and where volume is low.

Roadbed: That portion of a roadway extending from curb line to curb line or from shoulder line to shoulder line. Divided highways are considered to have two roadbeds.

Roentgen: The amount of energy absorbed in air by the passage of gamma or X-rays. A roentgen is equal to  $5.4 \times 10^7$  MeV per gram of air or 0.87 rad per gram of air and 0.96 rad per gram of tissue.

**S**

Safe yield: The maximum rate of water withdrawal that is economically, hydrologically, and ecologically feasible.

Sag pipe: *See* Inverted siphon.

Saline: Dominated by anionic carbonate, chloride, and sulfate ions.

Salt: An ionic compound formed by direct union of elements, reactions between acids and bases, reaction of acids and salts, and reactions between different salts.

Sand: Granular material passing through a no. 4 sieve but predominantly retained on a no. 200 sieve.

Sand trap: A section of channel constructed deeper than the rest of the channel to allow sediment to settle out.

Scour: Erosion typically occurring at the exit of an open channel or toe of a spillway.

Scrim: An open-weave, woven or nonwoven, textile product that is encapsulated in a polymer (e.g., polyester) material to provide strength and reinforcement to a watertight membrane.

Seal coat: An asphalt coating, with or without aggregate, applied to the surface of a pavement for the purpose of waterproofing and preserving the surface, altering the surface texture of the pavement, providing delineation, or providing resistance to traffic abrasion.

Second-stage demand: *See* Nitrogenous demand.

Sedimentary rock: Rocks formed from sediment, broken rocks, or organic matter. Sedimentary rocks are formed when wind or water deposits sediment into layers, which are pressed together by more layers of sediment above.

**Seed:** The activated sludge initially taken from a secondary settling tank and returned to an aeration tank to start the activated sludge process.

**Seep:** *See Spring.*

**Seiche, external:** An oscillation of the surface of a landlocked body of water.

**Seiche, internal:** An alternating pattern in the directions of layers of lake water movement.

**Sensitivity:** The ratio of a soil's undisturbed strength to its disturbed strength.

**Separate system:** A system with separate sewers for domestic and storm wastewater.

**Septic:** Produced by putrefaction.

**Settling basin:** A large, shallow basin through which water passes at low velocity, where most of the suspended sediment settles out.

**Sheeted pit:** *See Cased hole.*

**Shooting flow:** *See Rapid flow.*

**Sight distance:** The length of roadway that a driver can see.

**Sinkhole:** A natural dip or hole in the ground formed when underground salt or other rocks are dissolved by water and the ground above collapses into the empty space.

**Sinuosity:** The stream length divided by the valley length.

**Slickenside:** A surface (plane) in stiff clay that is a potential slip plane.

**Slope:** The tangent of the angle made by the channel bottom. *See also Gradient.*

**Sludge:** The precipitated solid matter produced by water and sewage treatment.

**Sludge bulking:** Failure of suspended solids to completely settle out.

**Sludge volume index (SVI):** The volume of sludge that settles in 30 min out of an original volume of 1000 mL. May be used as a measure of sludge bulking potential.

**Sol:** A homogenous suspension or dispersion of colloidal matter in a fluid.

**Soldier pile:** An upright pile used to hold lagging.

**Solution:** A homogeneous mixture of solute and solvent.

**Sorption:** A generic term covering the processes of absorption and adsorption.

**Space mean speed:** One of the measures of average speed of a number of vehicles over a common (fixed) distance. Determined as the inverse of the average time per unit distance. Usually less than time mean speed.

**Spacing:** Distance between successive vehicles, measured front bumper to front bumper.

**Specific activity:** The activity per gram of a radioisotope.

**Specific storage:** *See Specific yield.*

**Specific yield:** (a) The ratio of water volume that will drain freely (under gravity) from a sample to the total volume. Specific yield is always less than porosity. (b) The amount of water released from or taken into storage per unit volume of a porous medium per unit change in head.

**Split chlorination:** Addition of chlorine prior to sedimentation and after final processing.

**Spring:** A place where water flows or ponds on the surface due to the intersection of an aquifer with the earth surface.

**Stadia method:** Obtaining horizontal distances and differences in elevation by indirect geometric methods.

**Stage:** Elevation of flow surface above a fixed datum.

**Standing wave:** A stationary wave caused by an obstruction in a water course. The wave cannot move (propagate) because the water is flowing at its critical speed.

**Steady flow:** Flow in which the flow quantity does not vary with time at any location along the channel.

**Stilling basin:** An excavated pool downstream from a spillway used to decrease tailwater depth and to produce an energy-dissipating hydraulic jump.

**Stoichiometry:** The study of how elements combine in fixed proportions to form compounds.

**Stopping sight distance:** The distance that allows a driver traveling at the maximum speed to stop before hitting an observed object.

**Stratum:** Layer.

**Stream gaging:** A method of determining the velocity in an open channel.

**Stream order:** An artificial categorization of stream genealogy. Small streams are first order. Second-order streams are fed by first-order streams, third-order streams are fed by second-order streams, and so on.

**Stringer:** *See Wale.*

**Structural section:** The planned layers of specific materials, normally consisting of subbase, base, and pavement, placed over the subbase soil.

**Subbase:** A layer of aggregate placed on the existing soil as a foundation for the base.

**Subcritical flow:** Flow with depth greater than the critical depth and velocity less than the critical velocity.

**Subgrade:** The portion of a roadbed surface that has been prepared as specified, upon which a subbase, base, base course, or pavement is to be constructed.

Submain: *See Branch sewer.*

Substrate: A substance acted upon by an organism, chemical, or enzyme. Sometimes used to mean organic material.

Subsurface runoff: *See Interflow.*

Superchlorination: Chlorination past the breakpoint.

Supercritical flow: Flow with depth less than the critical depth and velocity greater than the critical velocity.

Superelevation: Roadway banking on a horizontal curve for the purpose of allowing vehicles to maintain the traveled speed.

Supernatant: The clarified liquid rising to the top of a sludge layer.

Surcharge: An additional loading. (a) In geotechnical work, any force loading added to the in situ soil load. (b) In water resources, any additional pressurization of a fluid in a pipe.

Surcharged sewer: (a) A sewer that is flowing under pressure (e.g., as a force main). (b) A sewer that is supporting an additional loading (e.g., a truck parked above it).

Surface detention: *See Surface retention.*

Surface retention: The part of a storm that does not contribute to runoff. Retention is made up of depression storage, interception, and evaporation.

Surface runoff: Water flow over the surface that reaches a stream after a storm.

Surficial: Pertaining to the surface.

Swale: (a) A low-lying portion of land, below the general elevation of the surroundings. (b) A natural ditch or long, shallow depression through which accumulated water from adjacent watersheds drains to lower areas.

## T

Tack coat: The initial application of asphalt material to an existing asphalt or concrete surface to provide a bond between the existing surface and the new material.

Tail race: An open waterway leading water out of a dam spillway and back to a natural channel.

Tailwater: The water into which a spillway or outfall discharges.

Taxonomy: The description, classification, and naming of organisms.

Temporary hardness: Hardness that can be removed by heating.

Theodolite: A survey instrument used to measure or lay off both horizontal and vertical angles.

Thermocline: The temperature gradient in the metalimnion.

Thermophilic bacteria: Bacteria that thrive in the 45°C to 75°C range. The optimum temperature is near 55°C.

Thixotropy: A property of a soil that regains its strength over time after being disturbed and weakened.

Threshold odor number: A measure of odor strength, typically the number of successive dilutions required to reduce an odorous liquid to undetectable (by humans) level.

Till: *See Glacial till.*

Time mean speed: One of the measures of average speed of a number of vehicles over a common (fixed) distance. Determined as the average vehicular speed over a distance. Usually greater than space mean speed.

Time of concentration: The time required for water to flow from the most distant point on a runoff area to the measurement or collection point.

TON: *See Threshold odor number.*

Topography: Physical features such as hills, valleys, and plains that shape the surface of the earth.

Total float: The amount of time that an activity in the critical path (e.g., project start) can be delayed without delaying the project completion date.

Township: A square parcel of land 6 mi on each side.

Toxin: A toxic or poisonous substance.

Tranquil flow: Flow at greater than the critical depth.

Transmissivity: The rate at which water moves through a unit width of an aquifer or confining bed under a unit hydraulic gradient. It is a function of properties of the liquid, the porous media, and the thickness of the porous media.

Transpiration: The process by which water vapor escapes from living plants (principally from the leaves) and enters the atmosphere.

Traveled way: The portion of the roadway for the movement of vehicles, exclusive of shoulders and auxiliary lanes.

Turbidity: (a) Cloudiness in water caused by suspended colloidal material. (b) A measure of the light-transmitting properties of water.

Turbidity unit: *See Nephelometric turbidity unit.*

Turnout: (a) A location alongside a traveled way where vehicles may stop off of the main road surface without impeding following vehicles. (b) A pipe placed through a canal embankment to carry water from the canal for other uses.

## U

Uniform flow: Flow that has constant velocity along a streamline. For an open channel, uniform flow implies

constant depth, cross-sectional area, and shape along its course.

**Unit process:** A process used to change the physical, chemical, or biological characteristics of water or wastewater.

**Unit stream power:** The product of velocity and slope, representing the rate of energy expenditure per unit mass of water.

**Uplift:** Elevation or raising of part of the earth's surface through forces within the earth.

**UTC:** Coordinated Universal Time, the international time standard; previously referred to as Greenwich Meridian Time (GMT).

## V

**Vadose water:** All underground water above the water table, including soil water, gravitational water, and capillary water.

**Vadose zone:** A zone above the water table containing both saturated and empty soil pores.

**Valence:** The relative combining capacity of an atom or group of atoms compared to that of the standard hydrogen atom. Essentially equivalent to the oxidation number.

**Varied flow:** Flow with different depths along the water course.

**Varve:** A layer of different material in the soil; fine layers of alluvium sediment deposited in glacial lakes.

**Vitrification:** Encapsulation in or conversion to an extremely stable, insoluble, glasslike solid by melting (usually electrically) and cooling. Used to destroy or immobilize hazardous compounds in soils.

**Volatile organic compounds (VOCs):** A class of toxic chemicals that easily evaporate or mix with the atmosphere and environment.

**Volatile solid:** Solid material in a water sample or in sludge that can be burned away or vaporized at high temperature.

**Volatilization:** The driving off or evaporation of a liquid in a solid or one or more phases in a liquid mixture.

## W

**Wah gas:** *See Biogas.*

**Wale:** A horizontal brace used to hold timbers in place against the sides of an excavation or to transmit the braced loads to the lagging.

**Wasteway:** A canal or pipe that returns excess irrigation water to the main channel.

**Water table:** The piezometric surface of an aquifer, defined as the locus of points where the water pressure is equal to the atmospheric pressure.

**Waving the rod:** A survey technique used when reading a rod for elevation data. By waving the rod (the rod is actually inclined toward the instrument and then brought more vertical), the lowest rod reading will indicate the point at which the rod is most vertical. The reading at that point is then used to determine the difference in elevation.

**Wet well:** A short-term storage tank from which liquid is pumped.

**Wetted perimeter:** The length of the channel cross section that has water contact. The air-water interface is not included in the wetted perimeter.

## X

**Xeriscape:** Creative landscaping for water and energy efficiency and lower maintenance.

**Xerophytes:** Drought-resistant plants, typically with root systems well above the water table.

## Z

**Zone of aeration:** *See Vadose zone.*

**Zone of saturation:** *See Phreatic zone.*

**Zoogloea:** The gelatinous film (i.e., "slime") of aerobic organisms that covers the exposed surfaces of a biological filter.

**Zooplankton:** Small, drifting animals capable of independent movement.
