- Topic I:** Background and Support
- Topic II:** Water Resources
- Topic III:** Environmental
- Topic IV:** Geotechnical
- Topic V:** Structural
- Topic VI:** Transportation
- Topic VII:** Construction
- Topic VIII:** Systems, Management, and Professional
- Topic IX:** Support Material

## **Where do I find practice problems to test what I've learned in this Reference Manual?**

The *Civil Engineering Reference Manual* provides a knowledge base that will prepare you for the Civil PE exam. But there's no better way to exercise your skills than to practice solving problems. To simplify your preparation, please consider *Practice Problems for the Civil Engineering PE Exam: A Companion to the Civil Engineering Reference Manual*. This publication provides you with more than 900 practice problems, each with a complete, step-by-step solution.

*Practice Problems for the Civil Engineering PE Exam* may be obtained from PPI at **[ppi2pass.com](http://ppi2pass.com)** or from your favorite retailer.

# Table of Contents

---

<b>Appendices Table of Contents</b>	vii
<b>Preface to the Fourteenth Edition</b>	xi
<b>Acknowledgments</b>	xv
<b>Codes and Standards</b>	xvii
<b>Introduction</b>	xix
<b>Topic I: Background and Support</b>	
Systems of Units	1-1
Engineering Drawing Practice	2-1
Algebra	3-1
Linear Algebra	4-1
Vectors	5-1
Trigonometry	6-1
Analytic Geometry	7-1
Differential Calculus	8-1
Integral Calculus	9-1
Differential Equations	10-1
Probability and Statistical Analysis of Data	11-1
Numerical Analysis	12-1
Energy, Work, and Power	13-1
<b>Topic II: Water Resources</b>	
Fluid Properties	14-1
Fluid Statics	15-1
Fluid Flow Parameters	16-1
Fluid Dynamics	17-1
Hydraulic Machines	18-1
Open Channel Flow	19-1
Meteorology, Climatology, and Hydrology	20-1
Groundwater	21-1
Inorganic Chemistry	22-1
Organic Chemistry	23-1
Combustion and Incineration	24-1
Water Supply Quality and Testing	25-1
Water Supply Treatment and Distribution	26-1
<b>Topic III: Environmental</b>	
Cellular Biology	27-1
Wastewater Quantity and Quality	28-1
Wastewater Treatment: Equipment and Processes	29-1
Activated Sludge and Sludge Processing	30-1
Municipal Solid Waste	31-1
Pollutants in the Environment	32-1
Storage and Disposition of Hazardous Materials	33-1
Environmental Remediation	34-1

## **Topic IV: Geotechnical**

Soil Properties and Testing	35-1
Shallow Foundations	36-1
Rigid Retaining Walls	37-1
Piles and Deep Foundations	38-1
Excavations	39-1
Special Soil Topics	40-1

## **Topic V: Structural**

Determinate Statics	41-1
Properties of Areas	42-1
Material Testing	43-1
Strength of Materials	44-1
Basic Elements of Design	45-1
Structural Analysis I	46-1
Structural Analysis II	47-1
Properties of Concrete and Reinforcing Steel	48-1
Concrete Proportioning, Mixing, and Placing	49-1
Reinforced Concrete: Beams	50-1
Reinforced Concrete: Slabs	51-1
Reinforced Concrete: Short Columns	52-1
Reinforced Concrete: Long Columns	53-1
Reinforced Concrete: Walls and Retaining Walls	54-1
Reinforced Concrete: Footings	55-1
Prestressed Concrete	56-1
Composite Concrete and Steel Bridge Girders	57-1
Structural Steel: Introduction	58-1
Structural Steel: Beams	59-1
Structural Steel: Tension Members	60-1
Structural Steel: Compression Members	61-1
Structural Steel: Beam-Columns	62-1
Structural Steel: Built-Up Sections	63-1
Structural Steel: Composite Beams	64-1
Structural Steel: Connectors	65-1
Structural Steel: Welding	66-1
Properties of Masonry	67-1
Masonry Walls	68-1
Masonry Columns	69-1

## **Topic VI: Transportation**

Properties of Solid Bodies	70-1
Kinematics	71-1
Kinetics	72-1
Roads and Highways: Capacity Analysis	73-1
Bridges: Condition and Rating	74-1
Highway Safety	75-1
Flexible Pavement Design	76-1
Rigid Pavement Design	77-1
Plane Surveying	78-1

Horizontal, Compound, Vertical, and  
Spiral Curves . . . . . 79-1

**Topic VII: Construction**

Construction Earthwork . . . . . 80-1  
Construction Staking and Layout . . . . . 81-1  
Building Codes and Materials Testing . . . . . 82-1  
Construction and Job Site Safety . . . . . 83-1

**Topic VIII: Systems, Management, and  
Professional**

Electrical Systems and Equipment . . . . . 84-1  
Instrumentation and Measurements . . . . . 85-1  
Project Management, Budgeting, and  
Scheduling . . . . . 86-1  
Engineering Economic Analysis . . . . . 87-1  
Professional Services, Contracts, and  
Engineering Law . . . . . 88-1  
Engineering Ethics . . . . . 89-1  
Engineering Licensing in the United States . . . . . 90-1

**Topic IX: Support Material**

Appendices . . . . . A-1  
Glossary . . . . . G-1  
Index . . . . . I-1

# Appendices

## Table of Contents

---

1.A	Conversion Factors . . . . .	A-1
1.B	Common SI Unit Conversion Factors . . . . .	A-3
7.A	Mensuration of Two-Dimensional Areas . . . . .	A-7
7.B	Mensuration of Three-Dimensional Volumes . . . . .	A-9
9.A	Abbreviated Table of Indefinite Integrals . . . . .	A-10
10.A	Laplace Transforms . . . . .	A-11
11.A	Areas Under the Standard Normal Curve . . . . .	A-12
11.B	Chi-Squared Distribution . . . . .	A-13
11.C	Values of $t_C$ for Student's $t$ -Distribution . . . . .	A-14
11.D	Values of the Error Function and Complementary Error Function . . . . .	A-15
14.A	Properties of Water at Atmospheric Pressure (customary U.S. units) . . . . .	A-16
14.B	Properties of Ordinary Liquid Water (SI units) . . . . .	A-17
14.C	Viscosity of Water in Other Units (customary U.S. units) . . . . .	A-20
14.D	Properties of Air at Atmospheric Pressure (customary U.S. units) . . . . .	A-21
14.E	Properties of Air at Atmospheric Pressure (SI units) . . . . .	A-22
14.F	Properties of Common Liquids . . . . .	A-23
14.G	Viscosities Versus Temperature of Hydrocarbons, Lubricants, Fuels, and Heat Transfer Fluids . . . . .	A-24
14.H	Properties of Uncommon Fluids . . . . .	A-25
14.I	Vapor Pressure of Various Hydrocarbons and Water (Cox Chart) . . . . .	A-26
14.J	Specific Gravity of Hydrocarbons . . . . .	A-27
14.K	Viscosity Conversion Chart (Approximate Conversions for Newtonian Fluids) . . . . .	A-28
14.L	Viscosity Index Chart: 0–100 VI . . . . .	A-29
16.A	Area, Wetted Perimeter, and Hydraulic Radius of Partially Filled Circular Pipes . . . . .	A-30
16.B	Dimensions of Welded and Seamless Steel Pipe (customary U.S. units) . . . . .	A-31
16.C	Dimensions of Welded and Seamless Steel Pipe (SI units) . . . . .	A-35
16.D	Dimensions of Rigid PVC and CPVC Pipe (customary U.S. units) . . . . .	A-38
16.E	Dimensions of Large Diameter, Nonpressure, PVC Sewer and Water Pipe (customary U.S. units) . . . . .	A-39
16.F	Dimensions and Weights of Concrete Sewer Pipe (customary U.S. units) . . . . .	A-42
16.G	Dimensions of Cast-Iron and Ductile Iron Pipe Standard Pressure Classes (customary U.S. units) . . . . .	A-44
16.H	Dimensions of Ductile Iron Pipe Special Pressure Classes (customary U.S. units) . . . . .	A-45
16.I	Standard ASME/ANSI Z32.2.3 Piping Symbols . . . . .	A-46
16.J	Dimensions of Copper Water Tubing (customary U.S. units) . . . . .	A-47
16.K	Dimensions of Brass and Copper Tubing (customary U.S. units) . . . . .	A-48
16.L	Dimensions of Seamless Steel Boiler (BWG) Tubing (customary U.S. units) . . . . .	A-49
17.A	Specific Roughness and Hazen-Williams Constants for Various Water Pipe Materials . . . . .	A-50
17.B	Darcy Friction Factors (turbulent flow) . . . . .	A-51
17.C	Water Pressure Drop in Schedule-40 Steel Pipe . . . . .	A-55
17.D	Equivalent Length of Straight Pipe for Various (Generic) Fittings . . . . .	A-56
17.E	Hazen-Williams Nomograph ( $C=100$ ) . . . . .	A-57
17.F	Corrugated Metal Pipe . . . . .	A-58
18.A	International Standard Atmosphere . . . . .	A-59
18.B	Properties of Saturated Steam by Temperature (customary U.S. units) . . . . .	A-60
18.C	Properties of Saturated Steam by Pressure (customary U.S. units) . . . . .	A-63
18.D	Properties of Superheated Steam (customary U.S. units) . . . . .	A-65
18.E	Properties of Saturated Steam by Temperature (SI units) . . . . .	A-70
18.F	Properties of Saturated Steam by Pressure (SI units) . . . . .	A-70
18.G	Properties of Superheated Steam (SI units) . . . . .	A-72
19.A	Manning's Roughness Coefficient (design use) .	A-73
19.B	Manning Equation Nomograph . . . . .	A-74
19.C	Circular Channel Ratios . . . . .	A-75
19.D	Critical Depths in Circular Channels . . . . .	A-76
19.E	Conveyance Factor, $K$ . . . . .	A-77
19.F	Conveyance Factor, $K'$ . . . . .	A-79
20.A	Rational Method Runoff $C$ -Coefficients . . . . .	A-81
20.B	Random Numbers . . . . .	A-82
22.A	Atomic Numbers and Weights of the Elements . . . . .	A-65

22.B	Periodic Table of the Elements (referred to carbon-12) . . . . .	A-84
22.C	Water Chemistry $\text{CaCO}_3$ Equivalents . . . . .	A-85
22.D	Saturation Concentrations of Dissolved Oxygen in Water . . . . .	A-87
22.E	Names and Formulas of Important Chemicals . . . . .	A-88
22.F	Approximate Solubility Product Constants at $25^\circ\text{C}$ . . . . .	A-89
22.G	Dissociation Constants of Acids at $25^\circ\text{C}$ . . . . .	A-92
22.H	Dissociation Constants of Bases at $25^\circ\text{C}$ . . . . .	A-93
24.A	Heats of Combustion for Common Compounds . . . . .	A-94
24.B	Approximate Properties of Selected Gases . . . . .	A-95
25.A	National Primary Drinking Water Regulations . . . . .	A-96
26.A	Properties of Chemicals Used in Water Treatment . . . . .	A-103
29.A	Selected <i>Ten States' Standards</i> . . . . .	A-104
35.A	USCS Soil Boring, Well, and Geotextile Symbols . . . . .	A-106
37.A	Active Components for Retaining Walls (straight slope backfill) . . . . .	A-108
37.B	Active Components for Retaining Walls (broken slope backfill) . . . . .	A-109
37.C	Curves for Determining Active and Passive Earth Pressure Coefficients, $k_a$ and $k_p$ (with inclined wall face, $\theta$ , wall friction, $\delta$ , and horizontal backfill) . . . . .	A-110
37.D	Curves for Determining Active and Passive Earth Pressure Coefficients, $k_a$ and $k_p$ (with vertical face, wall friction, $\delta$ , and sloping backfill, $\beta$ ) . . . . .	A-111
40.A	Boussinesq Stress Contour Chart (infinitely long and square footings) . . . . .	A-112
40.B	Boussinesq Stress Contour Chart (uniformly loaded circular footings) . . . . .	A-113
42.A	Centroids and Area Moments of Inertia for Basic Shapes . . . . .	A-114
43.A	Typical Properties of Structural Steel, Aluminum, and Magnesium . . . . .	A-115
43.B	Typical Mechanical Properties of Representative Metals . . . . .	A-116
43.C	Typical Mechanical Properties of Thermoplastic Resins and Composites (room temperature, after post-mold annealing) . . . . .	A-119
44.A	Elastic Beam Deflection Equations . . . . .	A-120
44.B	Stress Concentration Factors . . . . .	A-124
45.A	Properties of Weld Groups . . . . .	A-125
47.A	Elastic Fixed-End Moments . . . . .	A-126
47.B	Indeterminate Beam Formulas . . . . .	A-128
47.C	Moment Distribution Worksheet . . . . .	A-133
48.A	ASTM Standards for Wire Reinforcement . . . . .	A-134
52.A	Reinforced Concrete Interaction Diagram, $\gamma = 0.60$ (round, 4 ksi concrete, 60 ksi steel) . . . . .	A-135
52.B	Reinforced Concrete Interaction Diagram, $\gamma = 0.70$ (round, 4 ksi concrete, 60 ksi steel) . . . . .	A-136
52.C	Reinforced Concrete Interaction Diagram, $\gamma = 0.75$ (round, 4 ksi concrete, 60 ksi steel) . . . . .	A-137
52.D	Reinforced Concrete Interaction Diagram, $\gamma = 0.80$ (round, 4 ksi concrete, 60 ksi steel) . . . . .	A-138
52.E	Reinforced Concrete Interaction Diagram, $\gamma = 0.90$ (round, 4 ksi concrete, 60 ksi steel) . . . . .	A-139
52.F	Reinforced Concrete Interaction Diagram, $\gamma = 0.60$ (square, 4 ksi concrete, 60 ksi steel) . . . . .	A-140
52.G	Reinforced Concrete Interaction Diagram, $\gamma = 0.70$ (square, 4 ksi concrete, 60 ksi steel) . . . . .	A-141
52.H	Reinforced Concrete Interaction Diagram, $\gamma = 0.75$ (square, 4 ksi concrete, 60 ksi steel) . . . . .	A-142
52.I	Reinforced Concrete Interaction Diagram, $\gamma = 0.80$ (square, 4 ksi concrete, 60 ksi steel) . . . . .	A-143
52.J	Reinforced Concrete Interaction Diagram, $\gamma = 0.90$ (square, 4 ksi concrete, 60 ksi steel) . . . . .	A-144
52.K	Reinforced Concrete Interaction Diagram, $\gamma = 0.60$ (uniplane, 4 ksi concrete, 60 ksi steel) . . . . .	A-145
52.L	Reinforced Concrete Interaction Diagram, $\gamma = 0.70$ (uniplane, 4 ksi concrete, 60 ksi steel) . . . . .	A-146
52.M	Reinforced Concrete Interaction Diagram, $\gamma = 0.75$ (uniplane, 4 ksi concrete, 60 ksi steel) . . . . .	A-147
52.N	Reinforced Concrete Interaction Diagram, $\gamma = 0.80$ (uniplane, 4 ksi concrete, 60 ksi steel) . . . . .	A-148
52.O	Reinforced Concrete Interaction Diagram, $\gamma = 0.90$ (uniplane, 4 ksi concrete, 60 ksi steel) . . . . .	A-149
58.A	Common Structural Steels . . . . .	A-150
58.B	Properties of Structural Steel at High Temperatures . . . . .	A-151
59.A	Values of $C_b$ for Simply-Supported Beams . . . . .	A-152
68.A	Section Properties of Masonry Horizontal Cross Sections . . . . .	A-153
68.B	Section Properties of Masonry Vertical Cross Sections . . . . .	A-155
68.C	UngROUTed Wall Section Properties . . . . .	A-157
68.D	Grouted Wall Section Properties . . . . .	A-158
69.A	Column Interaction Diagram (compression controls, $g = 0.4$ ) . . . . .	A-159
69.B	Column Interaction Diagram (compression controls, $g = 0.6$ ) . . . . .	A-160
69.C	Column Interaction Diagram (compression controls, $g = 0.8$ ) . . . . .	A-161

69.D	Column Interaction Diagram (tension controls, $g = 0.4$ ) . . . . .	A-162
69.E	Column Interaction Diagram (tension controls, $g = 0.6$ ) . . . . .	A-163
69.F	Column Interaction Diagram (tension controls, $g = 0.8$ ) . . . . .	A-164
70.A	Mass Moments of Inertia . . . . .	A-165
76.A	Axle Load Equivalency Factors for Flexible Pavements (single axles and $p_t$ of 2.5) . . . . .	A-166
76.B	Axle Load Equivalency Factors for Flexible Pavements (tandem axles and $p_t$ of 2.5) . . . . .	A-167
76.C	Axle Load Equivalency Factors for Flexible Pavements (triple axles and $p_t$ of 2.5) . . . . .	A-168
77.A	Axle Load Equivalency Factors for Rigid Pavements (single axles and $p_t$ of 2.5) . . . . .	A-169
77.B	Axle Load Equivalency Factors for Rigid Pavements (double axles and $p_t$ of 2.5) . . . . .	A-170
77.C	Axle Load Equivalency Factors for Rigid Pavements (triple axles and $p_t$ of 2.5) . . . . .	A-171
78.A	Oblique Triangle Equations . . . . .	A-172
84.A	Polyphase Motor Classifications and Characteristics . . . . .	A-173
84.B	DC and Single-Phase Motor Classifications and Characteristics . . . . .	A-174
85.A	Thermoelectric Constants for Thermocouples . . . . .	A-175
87.A	Standard Cash Flow Factors . . . . .	A-177
87.B	Cash Flow Equivalent Factors . . . . .	A-178

---

# Preface to the Fifteenth Edition

---

As I mentioned in the preface to the fourteenth edition, I am chagrined to admit that I never read a single preface while I was in college. Out of the prefaces of 100 or so textbooks written by witty, clever, dedicated, and famous experts, I never read a single word. Since then, I have added hundreds of additional books to my library, and I have only read a few of their prefaces. I certainly have never written to an author and said, "Hey, I loved your preface." Nor have I ever received such a communication about any book that I have written. So, why does a book even need a preface?

The preface usually explains (a) why the author wanted to write the book, (b) why the book turned out the way it did, and (c) how the book differs from the previous edition. Whereas subsequent chapters after the preface constitute a book's brain, the preface constitutes a book's heart and soul. You do not have to read its preface for a book to have utility. The real "value" is in the subsequent chapters. However, if you want a special connection with the book, if you want to get inside the author's head, if you want to feel what you are learning, you should start by reading its preface.

New books are written for a variety of reasons; new editions less so. Typically, new editions are written to replace old editions that have become somehow inadequate. Although I have read some that come close, authors do not intentionally write books to be inadequate when they are first published; instead, their books just evolve into obsolescence and inadequacy over time. Now and then, however, the reason behind publishing a new edition is more complex.

For example, sometimes a perfectly good book can become suddenly obsolete due to an external event. This book has had many "sudden" new editions (and this fifteenth edition is no exception), which were triggered by some change to the civil PE exam. Typical exam changes that have required publishing a new edition of this book include revisions to the codes and standards on which the civil PE exam is based, as well as changes to the exam's body of knowledge, format, administration, and emphasis on (i.e., number of questions for) each subject.

Other times, new editions are driven by an author's desire to add new material or to improve preexisting material. Sometimes they are driven by a need to incorporate accumulated corrections.

This fifteenth edition of the *Civil Engineering Reference Manual* represents a complex agglomeration of the

reasons mentioned: revisions to exam codes and standards, addition of new and improved material, and changes in how the exam is administered.

The reasons this fifteenth edition turned out the way that it did are as complex as the reasons why it was written in the first place. First, like its predecessors, this edition was developed in an ethical and professional manner, which means that only the NCEES published outline of exam subjects guided me when I wrote this edition. It may seem strange to you that a book designed to help you pass the civil PE exam would not be based on the actual exam content; however, though not associated with NCEES in any way, both PPI and I share its passion for exam security. Therefore, no actual exam content is present in this book.

Second, as a professional engineer, I understand it is my responsibility to protect the public, while still helping qualified applicants to prepare for their future careers as engineers. To help you review and learn the engineering concepts necessary to pass the civil PE exam (and thus, go on to protect the public), PPI went far beyond industry standards in getting content checked and reviewed, edited, and proofread.

Finally, this book is the way that it is because I wrote it to be the kind of textbook I would want to help me learn the concepts needed to pass the civil PE exam. You will not have to go very far to find someone who will tell you that this book goes beyond the subjects covered on the civil PE exam. This is true. I have my own idea of what engineering concepts the civil PE exam should cover, and I have woven those concepts into this book. You may disagree with this practice. Indeed, history has shown that my expectations of what an engineer with a minimum of four years of experience should know are very high. (You would probably have to read trade and industry publications every day to have the knowledge that I want you to have when you take your civil PE exam.) However, I have incorporated those concepts because I do not just want you to review or learn "some engineering" from this book. Instead, I actually want you to be a better engineer for having read it. Think of passing your exam as icing on the cake of being a great engineer.

Regardless of why I wrote this edition, or why this edition turned out the way that it did, inevitably, PPI's Customer Care (what PPI calls "Customer Service") department will need to answer the pre-purchase questions such as, "What has changed?" and "Do I really need to

purchase this book?" and "I have the 12th edition. Can I use it?" This department also has to deal with irate customers who purchased the previous edition 25 months ago and swear they would have waited if they had known that Michael R. Lindeburg was writing a new edition. (Hey, everyone: I'm always writing a new edition. But, only the publisher knows when it is coming out.)

To answer those questions and to help the Customer Care department answer such questions, I am writing this script: "Yes. You absolutely need to get this new edition. The author did not write it for nothing. He wrote it because the exam changed. He wrote it because it is better. He wrote it because it is more helpful, easier to understand, more complete, and better organized. This edition differs from the 10th (or 11th, or 12th, etc.) edition in several hundred thousand ways. No, a zillion ways. You will not know everything that has changed, but you will benefit from the changes. You do not use obsolete technology like a buggy whip, leaded fuel, a rotary-dial phone, carbon paper, or an IBM Selectric typewriter any more, do you? Instead, you drive a motorized car, use unleaded fuel, talk "hands-free" on your cell phone, send emails (from this same phone!), and type on your personal laptop or tablet. Still not convinced you need this edition? Let me put it another way: You would not study for your driver's license test using a 1968 copy of your state's DMV driver handbook, would you? No, you would not. So, why then, would you take a book based on obsolete material into the most important exam of your career? Do not be penny-wise and pound-foolish. In fact, do not be foolish, period. You need this fifteenth edition."

To satisfy the marketing department, which inevitably wants to know what has changed since the fourteenth edition, I will say: "This book is completely consistent with the NCEES exam content and breadth-and-depth format, and it is equally representative of the codes and standards NCEES has adopted for the exam. In fact, the largest replacement of content that took place in this edition occurred in order to make material consistent with NCEES-adopted codes and standards." (The actual codes and standards used by this book are listed in this book's "Codes Used to Prepare This Book" section of the front matter.)

In addition to the 15 new appendices and the usual slate of reader-suggested improvements, updates, and inevitable errata, this fifteenth edition incorporates changes in structural design. For example, the concrete chapters were updated to the 2011 ACI 318; the steel chapters were updated to the 2011 AISC fourteenth edition; the masonry chapters were updated to the 2012 IBC and the 2011 ACI 530/530.1, including deleting the one-third allowable stress increase for wind and seismic loads; and the traffic and transportation chapters were updated to the 2012 *Highway Capacity Manual*. A lot of new material has been added from AASHTO's first-ever 2010 *Highway Safety Manual*, which is now listed by NCEES as a civil PE exam standard/code reference. Four structural chapters have been augmented with

additional material from the 2012 *AASHTO LRFD Bridge Design Specifications*. Statistics on new content are listed in Sidebar S1 at the end of this preface.

The geotechnical chapters reflect NCEES's reliance on specific editions and/or parts of *Minimum Design Loads for Buildings and Other Structures* (ASCE/SEI7), and *Occupational Safety and Health Standards for the Construction Industry* (OSHA 1926).

The structural chapters reflect NCEES's reliance on specific editions and releases of *Building Code Requirements for Structural Concrete* (ACI 318); *Building Code Requirements and Specification for Masonry Structures* (ACI 530/530.1); *Steel Construction Manual* (*AISC Manual*); *Minimum Design Loads for Buildings and Other Structures* (ASCE/SEI7); *International Building Code* (IBC); *National Design Specification for Wood Construction ASD/LRFD* (NDS); *PCI Design Handbook: Precast and Prestressed Concrete* (PCI); and *AASHTO LRFD Bridge Design Specifications* (AASHTO LRFD).

For concrete, solutions based on ACI 318 App. C may not be used on the exam. This book provides solutions using only ACI 318 Chap. 9 (the so-called unified) methods.

For steel, you may still use either load and resistance factor design (LRFD) or allowable stress design (ASD) methods on the exam. Therefore, this book presents both solving methods in parallel so regardless of which method you choose to study, you will be supported.

For masonry, only ASD may be used on the exam, with the exception that the strength design (SD) method covered in ACI 530 Sec. 3.3.5 is the only method permitted to be used for slender walls with out-of-plane loads. This book provides ASD solutions, followed by SD solutions for additional reference.

As with the fourteenth edition, this book contains a chapter covering some bridge topics. Bridge rating is not specifically identified by NCEES as an exam subject, although bits and pieces of bridge design, analysis, and construction are implicit in other civil engineering activities that are covered on the exam. Given the great likelihood of future transportation funding shortfalls, even with the ongoing dedicated and noble efforts of our state departments of transportation, I feel that all professional engineers should be able to speak about the U.S. transportation infrastructure. This bridges chapter is a stub that I intend to continue to flesh out in future editions according to my own observations.

The transportation chapters reflect NCEES's reliance on specific editions of *A Policy on Geometric Design of Highways and Streets* (AASHTO Green Book); *AASHTO Guide for Design of Pavement Structures* (AASHTO GDPS-4-M); *AASHTO Roadside Design Guide*; *Mechanistic-Empirical Pavement Design Guide: A Manual of Practice* (AASHTO MEPDG); *Guide for the Planning, Design, and Operation of Pedestrian Facilities* (AASHTO Pedestrian); *Highway Safety*

*Manual* (HSM); AI *The Asphalt Handbook* (MS-4); NRC *Highway Capacity Manual* (HCM); *Manual on Uniform Traffic Control Devices* (MUTCD); *Design and Control of Concrete Mixtures*; and *Hydraulic Design of Highway Culverts*.

The construction chapters reflect NCEES's reliance on specific editions of ACI 318; *Guide to Formwork for Concrete* (ACI 347); *Formwork for Concrete* (ACI SP-4); *AISC Manual, Design Loads on Structures During Construction* (ASCE 37); NDS, CMWB *Standard Practice for Bracing Masonry Walls Under Construction*; and *Occupational Safety and Health Standards for the Construction Industry* (OSHA 1926). Still, the majority of what NCEES considers to be "construction" was already present in this book and continues to be covered in other chapters. Earthwork, foundations, slope stability, compaction, temporary structures, and other geotechnical subjects are in their own chapters, as are formwork, engineering economics, construction law, and many other construction subjects. Although there is no single chapter titled "Construction" that contains everything NCEES thinks you should know, this book presents the construction topic to the same degree of detail as other topics—regardless of where you read it.

Sidebar S.1 contains the statistics of what distinguishes this edition from the previous editions.

**Sidebar S.1 New Edition Statistics**

chapters with new material, 11  
new equations, 21  
new tables, 8  
new appendices, 15  
new figures, 12  
new index entries, 275

You and I are associates in the same honorable profession, and we are also members of the same species. In those regards, we exist to help each other. Helping you review and learn the subjects in the chapters that follow was always foremost in my mind. With every word that I wrote, I wanted to help you conduct an ethical review that would make both of us proud. This book is proof that I have been here for you. Now, you should go do your best to serve humanity. That starts by passing the PE exam.

Michael R. Lindeburg, PE

---

# Acknowledgments

---

Every new edition is a lot of work, for someone. Sometimes, as when new content is needed, the work of bringing out a new edition falls to the author; sometimes the work falls to the publisher's editorial and production staff, as when existing content is reformatted and reorganized; and sometimes the work falls to one or more subject matter experts, as when specialized knowledge is required to integrate changes in standards, codes, and federal legislation. Sometimes, one player shoulders a disproportionate share of the load; sometimes one player gets off easier than another.

This fifteenth edition was one of those new editions where a lot of people contributed. If anything, the author got off the easiest (my hand is up). Yes, there is new content. However, the biggest content changes were updates to the structural and transportation chapters. Regarding those changes, this book is the beneficiary of Akash Rao, PE, LEED AP BD+C; Kent A. Harries; Joshua T. Frohman, PE; Alfredo Cely, PE; Norman R. Voigt, PE, PLS; and Ralph Arcena. Mr. Rao developed content for the structural chapters in accordance with *AASHTO LRFD Bridge Design Specifications* (AASHTO *LRFD*), sixth edition; *National Design Specification for Wood Construction ASD/LRFD* (NDS), 2012 edition; *Steel Construction Manual* (AISC), fourteenth edition; and *Building Code Requirements for Structural Concrete* (ACI 318), 2011 edition. Mr. Harries reviewed and revised content for the structural chapters to be consistent with *AASHTO LRFD*. Mr. Frohman developed content for Chap. 75, Highway Safety, in accordance with *Highway Safety Manual* (HSM), first edition. Mr. Cely and Mr. Voight contributed their time and engineering expertise to Chap. 75 by reviewing the added HSM content. I would also like to thank Mr. Arcena for meticulously checking calculations throughout this edition.

Now, I would like to introduce you to the "I could not have done it without you" crew. The talented team at PPI that produced this edition is the same team that produced the new edition of *Practice Problems for the Civil Engineering PE Exam*, and the team members deserve just as many accolades here as I gave them in the Acknowledgments of that book. As it turns out, producing two new books is not twice as hard as producing one new book. Considering all of the connections between the two books, producing this edition is greatly complicated by the need for consistency with and cross-references to the *Practice Problems*. Producing a set of interrelated books is not a task for the faint of heart.

At PPI, the task of making the vision of a new edition into a reality fell to a Product Development and Implementation Department team that consisted of Sam Webster, editorial manager; Serena Cavanaugh, acquisitions editor; Nicole Evans, associate project manager; Tracy Katz, lead editor; Thomas Bliss, David Chu, Tyler Hayes, Sierra Cirimelli-Low, Julia Lopez, Scott Marley, Ellen Nordman, and Ian A. Walker, copy editors; Tom Bergstrom, production associate and technical illustrator; Kate Hayes, production associate; Cathy Schrott, production services manager; and Sarah Hubbard, director of product development and implementation. I wish to thank Jenny Lindeburg King, associate editor-in-chief, for her instrumental role in ensuring this edition met PPI's quality standards.

I also wish to recognize and honor Kate Hayes, who retired from PPI in October of 2015. Kate is a 20-year employee whose fingers have competently transposed, formed, programmed, and paginated all of my books. However, this fifteenth edition of the *Civil Engineering Reference Manual* will be her last Michael R. Lindeburg book—at least for a little while. I am grateful for and humbled by her attitude toward and dedication to the PPI cause, and I am amazed at her professionalism. But, her legacy is not defined by the hundreds of new books, new editions, and reprints that she has worked on over the past two decades. It is not even defined by the millions of engineers, architects, surveyors, interior designers, and other building and construction professionals on whose careers she has had an impact. Her true, lasting legacy is defined by the relationships she formed with PPI's coworkers, past and present, who have found her to be respectful, helpful, caring, and infinitely delightful to work and play with. What a role model! What an inspiration! What a friend! I miss her already. I am looking forward to the day when PPI pushes a project in her direction (to be worked on in the comfort of her sofa, of course).

This edition incorporates the comments, questions, suggestions, and errata submitted by many people who have used the previous edition for their own preparations. As an author, I am humbled to know that these individuals have read the previous edition in such detail as to notice typos, illogic, and other errata, and that they subsequently took the time to share their observations with me. Their suggestions have been incorporated into this edition, and their attention to detail will benefit you and all future readers. The following is a partial list (in

alphabetical order) of some of those who have improved this book through their comments.

Alex Bachowski; Mike Berkey; Robert Bernard; Laura Buchanan; Rebecca Carmine; Waqar Cheema; Redi Gjecka; Jacqueline Gonsalves; Joel Hinnenkamp; Peter Kauffmann; Paul Lefebvre; Yarrow Murphy; Dominic Pontarolo; Aliasgar Rangwala; Jeffrey Rodgers; Ken Sanoski; Sean Shigenaga; Ahmed Thabet; Julian Vaduva; and Bernard Vannoy

This edition shares a common developmental heritage with all of its previous editions. There are hundreds of additional people that I mentioned by name in the acknowledgments of those books. They are not forgotten, and their names will live on in the tens of thousands of old editions that remain in widespread circulation. For this edition, though, there is not a single contributor that I intentionally excluded. Still, I could have slipped up and forgotten to mention you. I hope you will let me know if you should have been credited, but were inadvertently left out. I would appreciate the opportunity to list your name in the next printing of this edition.

Near the end of the acknowledgments, after mentioning many people who contributed to the book and, therefore, could be blamed for a variety of types of errors, it is common for an author to say something like, “I take responsibility for all of the errors you find in this book.” Or, “All of the mistakes are mine.” This is certainly true, given the process of publishing, since the author sees and approves the final version before his or her book goes to the printer. You would think that after more than 35 years of writing, I would have figured out how to write something without making a mistake and how to proofread without missing those blunders that are so obvious to readers. However, such perfection continues to elude me. So, yes, the finger points straight at me.

All I can say instead is that I will do my best to respond to any suggestions and errata that you report through PPI’s website, [ppi2pass.com/errata](http://ppi2pass.com/errata). I would love to see your name in the acknowledgments for the next edition.

Thank you, everyone!

Michael R. Lindeburg, PE

# Codes and Standards

The information that was used to write and update this book was based on the exam specifications at the time of publication. However, as with engineering practice itself, the PE exam is not always based on the most current codes or cutting-edge technology. Similarly, codes, standards, and regulations adopted by state and local agencies often lag issuance by several years. It is likely that the codes that are most current, the codes that you use in practice, and the codes that are the basis of your exam will all be different.

PPI lists on its website the dates and editions of the codes, standards, and regulations on which NCEES has announced the PE exams are based. It is your responsibility to find out which codes are relevant to your exam.

## CONSTRUCTION DESIGN STANDARDS

ACI 318: *Building Code Requirements for Structural Concrete*, 2011. American Concrete Institute, Farmington Hills, MI.

ACI 347: *Guide to Formwork for Concrete*, 2004. American Concrete Institute, Farmington Hills, MI. (as an appendix of ACI SP-4, Seventh ed.)

ACI SP-4: *Formwork for Concrete*, Seventh ed., 2005. American Concrete Institute, Farmington Hills, MI.

AISC: *Steel Construction Manual*, Fourteenth ed., 2011. American Institute of Steel Construction, Inc., Chicago, IL.

ASCE 37: *Design Loads on Structures During Construction*, 2002. American Society of Civil Engineers, Reston, VA.

CMWB: *Standard Practice for Bracing Masonry Walls Under Construction*, 2012. Council for Masonry Wall Bracing, Mason Contractors Association of America, Lombard, IL.

MUTCD-Pt 6: *Manual on Uniform Traffic Control Devices*—Part 6, Temporary Traffic Control, 2009. U.S. Department of Transportation, Federal Highway Administration, Washington, DC.

NDS: *National Design Specification for Wood Construction ASD/LRFD*, 2012 ed. American Wood Council, Washington, DC.

OSHA 1926: *Occupational Safety and Health Regulations for the Construction Industry* (U.S. Federal version). U.S. Department of Labor, Washington, DC.

## GEOTECHNICAL DESIGN STANDARDS

ASCE/SEI7: *Minimum Design Loads for Buildings and Other Structures*, 2010. American Society of Civil Engineers, Reston, VA.

OSHA 1926: *Occupational Safety and Health Regulations for the Construction Industry* (U.S. Federal version). U.S. Department of Labor, Washington, DC.

## STRUCTURAL DESIGN STANDARDS

AASHTO LRFD: *AASHTO LRFD Bridge Design Specifications*, Sixth ed., 2012. American Association of State Highway and Transportation Officials, Washington, DC.

ACI 318<sup>1</sup>: *Building Code Requirements for Structural Concrete*, 2011. American Concrete Institute, Farmington Hills, MI.

ACI 530/530.1<sup>2</sup>: *Building Code Requirements and Specification for Masonry Structures* (and companion commentaries), 2011. The Masonry Society, Boulder, CO; American Concrete Institute, Detroit, MI; and Structural Engineering Institute of the American Society of Civil Engineers, Reston, VA.

AISC: *Steel Construction Manual*, Fourteenth ed., 2011. American Institute of Steel Construction, Inc., Chicago, IL.

ASCE/SEI7: *Minimum Design Loads for Buildings and Other Structures*, 2010. American Society of Civil Engineers, Reston, VA.

AWS D1.1/D1.1M<sup>3</sup>: *Structural Welding Code—Steel*, Twenty-second ed., 2010. American Welding Society, Miami, FL.

AWS D1.2/D1.2M<sup>4</sup>: *Structural Welding Code—Aluminum*, Sixth ed., 2014. American Welding Society, Miami, FL.

<sup>1</sup>ACI 318 App. C does not apply to the Civil PE structural depth exam.

<sup>2</sup>Only the Allowable Stress Design (ASD) method may be used on the exam, except that ACI 530 Sec. 3.3.5 (strength design) may be used for walls with out-of-plane loads.

<sup>3</sup>ACI 31.1, AWS D1.2, and AWS D1.4 are listed in the Codes, Standards, and Documents subsection of NCEES's Civil PE structural depth exam specifications.

<sup>4</sup>See Ftn. 3.

AWS D1.4/D1.4M<sup>5</sup>: *Structural Welding Code—Reinforcing Steel*, Seventh ed., 2011. American Welding Society, Miami, FL.

IBC: *2012 International Building Code* (without supplements). International Code Council, Inc., Falls Church, VA.

NDS<sup>6</sup>: *National Design Specification for Wood Construction ASD/LRFD*, 2012 ed., and *National Design Specification Supplement, Design Values for Wood Construction*, 2012 ed. American Wood Council, Washington, DC.

OSHA 1910<sup>7</sup>: *Occupational Safety and Health Standards* (U.S. Federal version). U.S. Department of Labor, Washington, DC.

OSHA 1926: *Occupational Safety and Health Regulations for the Construction Industry* (U.S. Federal version) Subpart E, Personal Protective and Life Saving Equipment, 1926.95–1926.107; Subpart M, Fall Protection, 1926.500–1926.503, App. A–E; Subpart Q, Concrete and Masonry Construction, 1926.700–1926.706, with App. A; and Subpart R, Steel Erection, 1926.750–1926.761, with App. A–H. U.S. Department of Labor, Washington, DC.

PCI: *PCI Design Handbook: Precast and Prestressed Concrete*, Seventh ed., 2010. Precast/Prestressed Concrete Institute, Chicago, IL.

HSM: *Highway Safety Manual*, First ed., 2010. American Association of State Highway and Transportation Officials, Washington, DC.

AASHTO MEPDG: *Mechanistic-Empirical Pavement Design Guide: A Manual of Practice*, Interim ed., 2008. American Association of State Highway and Transportation Officials, Washington, DC.

AASHTO: *Roadside Design Guide*, Fourth ed., 2011. American Association of State Highway and Transportation Officials, Washington, DC.

AI: *The Asphalt Handbook* (MS-4), Seventh ed., 2007. Asphalt Institute, Lexington, KY.

FHWA: *Hydraulic Design of Highway Culverts*, Hydraulic Design Series no. 5, Publication no. FHWA-HIF-12-026, Third ed., 2012. U.S. Department of Transportation, Federal Highway Administration, Washington, DC.

HCM: *Highway Capacity Manual*, 2010 ed. Transportation Research Board, National Research Council, Washington, DC.

MUTCD: *Manual on Uniform Traffic Control Devices*, 2009 (including Revisions 1 and 2, May 2012). U.S. Department of Transportation, Federal Highway Administration, Washington, DC.

PCA: *Design and Control of Concrete Mixtures*, Fifteenth ed., 2011. Portland Cement Association, Skokie, IL.

## **TRANSPORTATION DESIGN STANDARDS**

AASHTO GDPS: *AASHTO Guide for Design of Pavement Structures* (GDPS-4-M), 1993, and 1998 supplement. American Association of State Highway and Transportation Officials, Washington, DC.

AASHTO Green Book: *A Policy on Geometric Design of Highways and Streets*, Sixth ed., 2011. American Association of State Highway and Transportation Officials, Washington, DC.

AASHTO: *Guide for the Planning, Design, and Operation of Pedestrian Facilities*, First ed., 2004. American Association of State Highway and Transportation Officials, Washington, DC.

---

<sup>5</sup>See Ftn. 3.

<sup>6</sup>Only the ASD method may be used for wood design on the exam.

<sup>7</sup>Part 1910 is listed in the Codes, Standards, and Documents subsection of NCEES's Civil PE structural depth exam specifications.

# Introduction

## PART 1: HOW YOU CAN USE THIS BOOK

### QUICKSTART

If you never read the material at the front of your books anyway, if you are in a hurry to begin, and you only want to read one paragraph, here it is:

Most chapters in this book are independent. Start with any one and look through it. Use the index extensively. Decide if you are going to work problems in that topic. If so, solve as many problems in that topic as time allows. Do not stop studying until the exam. Start right now! Quickly! Good luck.

However, if you want to begin a thorough review, you should probably try to find out everything there is to know about the National Council of Examiners for Engineering and Surveying (NCEES) Civil PE exam. The rest of this Introduction is for you.

### IF YOU ARE A PRACTICING ENGINEER

If you are a practicing engineer and have obtained this book as a general reference handbook, it will probably sit in your bookcase until you have a specific need.

However, if you are preparing for the PE exam in civil engineering, the following suggestions may help.

- Find out the current edition of this book. You might be reading this book long after it was published. **Newer editions mean that the codes, standards, and regulations on which the exam is based are not represented in the older edition, that the exam body of knowledge has changed, and/or the exam format and policies have changed.** Older editions are no longer appropriate for the current exam, and it is not reasonable for you to expect an older edition to serve your needs when it is out of date.
- Be reasonable in what you expect from this book. Much like any textbook, this book is a compilation of material designed to help you learn certain subjects—in this case, subjects on the exam. This book does not contain “everything” that you need to know to pass the exam, particularly the afternoon part of the exam. (PPI has published reference manuals specifically for the afternoon parts.) You will need to assemble a library of other references. This book is not a substitute for the experience, general knowledge, and judgment that engineers are expected to demonstrate on the exam. This book will help you learn subjects. It will not help you pass the exam if you go into the exam unprepared or unqualified.
- Become intimately familiar with this book. This means knowing the order of the chapters, the approximate locations of important figures and tables, what appendices are available, and so on.
- Use the subject title tabs along the side of each page. The tab names correspond to the exam organization.
- Use Table 1 and Table 2 of this Introduction to learn which subjects in this book are not specific exam subjects. Some chapters in this book are supportive and do not cover specific exam topics. However, these chapters provide background and support for the other chapters.
- Some engineers read every page in a chapter. Some merely skim through a chapter and its appendices. In either case, you must familiarize yourself with the subjects before starting to solve practice problems.
- Identify and obtain a set of 10–30 solved practice problems for each of the exam subjects. I have written an accompanying book, *Practice Problems for the Civil Engineering PE Exam*, for this purpose. Other resources include the *Civil PE Practice Exam*, books in the *Six-Minute Solutions* series, and the Civil PE Exam Cafe, all published by PPI. You may use problem sets from your old textbooks, college notes, or review course if they are more convenient. Regardless of the resources you use, you should know that you will encounter two types of practice problems. Some problems look like exam problems. They are short and have multiple-choice answers. These types of problems are good for familiarizing yourself with the exam format. However, they are not very effective at exposing you to the integration of multiple concepts in problem solving, for familiarizing you with this book, and for making sure you have seen all of the “gotchas” that are possible in a subject. To address those requirements, you will need some longer problems. *Practice Problems for the Civil Engineering PE Exam* contains both types of problems.
- Most of the problems in *Practice Problems for the Civil Engineering PE Exam* are presented in both customary U.S. units (also known as the “U.S. Customary System” or “USCS,” “English units,” inch-pound units, and “British units”) and the International System of

Units (SI). Initially, work through the problems in U.S. units. (All structural engineering problems on the exam use U.S. units.) If you have time at the end of your review, start over and solve all of the problems in SI units.

- Set a reasonable limit on the time you spend on each subject. It is not necessary to solve an infinite number of practice problems. The number of practice problems you attempt will depend on how much time you have and how skilled you are in the subject.
- If it is not already your habit, practice carrying units along in all calculations. Many errors are caused by, and many incorrect exam answer options are based on, common mistakes with units. Pounds do not work in  $F = ma$ ; and  $\text{ft}^3/\text{sec}$  does not cancel gpm. When working in U.S. units, you will find equations in this book in which the quantity  $g/g_c$  appears. For calculations at standard gravity, the numerical value of this fraction is 1.00. Therefore, it is necessary to incorporate this quantity only in calculations with a nonstandard gravity or when you are being meticulous with units.
- Use the solutions to your practice problems to check your work. If your answer is not correct, figure out why.
- To minimize time spent in searching for often-used formulas and data, prepare a one-page summary of all the important formulas and information in each subject area. You can then use these summaries during the exam instead of searching in this book. You may want to consider *Quick Reference for the Civil Engineering PE Exam*, which PPI has published for this type of use.
- Use the index extensively. Every significant term, law, theorem, and concept has been indexed in every conceivable way—backward and forward—using fuzzy logic synonyms in anticipation of frantic exam searches. If you do not recognize a term used, look for it in the index. Many engineers bring a separate copy of the index with them to the exam.
- Some subjects appear in more than one chapter. (Construction engineering is a good example of a subject that resists single-chapter organization.) Use the index liberally to learn all there is to know about a particular subject.

## IF YOU ARE AN INSTRUCTOR

---

The first two editions of this book consisted of a series of handouts prepared for the benefit of my PE review courses. These editions were intended to be compilations of all the long formulas, illustrations, and tables of data that I did not have time to put on the chalkboard. You can use this edition in the same way.

If you are teaching a review course for the PE exam, you can use the material in this book as a guide to prepare your lectures.

I have always tried to overprepare my students. For that reason, the homework problems (i.e., example problems in this book and practice problems in *Practice Problems for the Civil Engineering PE Exam*) are often more difficult and more varied than actual exam questions. Also, you will appreciate the fact that it is more efficient to cover several procedural steps in one problem than to ask simple “one-liners” or definition questions. That is the reason that the example and homework problems are often harder and longer than actual exam problems.

To do all the homework for some chapters requires approximately 15 to 20 hours. If you are covering one or more chapters per week, that is a lot of homework. “Capacity assignment” is the goal in my review courses. If you assign 20 hours of homework and a student is able to put in only 10 hours that week, that student will have worked to his or her capacity. After the PE exam, that student will honestly say that he or she could not have prepared any more than he or she did in your course. For that reason, you have to assign homework on the basis of what is required to become proficient in the subjects of your lecture. You must resist assigning only the homework that you think can be completed in an arbitrary number of hours.

Homework assignments in my review courses are not individually graded. Instead, students are permitted to make use of existing solutions to learn procedures and techniques to the problems in their homework set, such as those in *Practice Problems for the Civil Engineering PE Exam* book, which contains solutions to all practice problems. However, each student must turn in a completed set of problems for credit each week. Though I do not correct the homework problems, I address comments or questions emailed to me, posted on the course forum, or written on the assignments.

I believe that students should start preparing for the PE exam at least six months before the exam date. However, most wait until three or four months before getting serious. Because of that, I have found that a 13- or 14-week format works well for a live PE review course. It is a little rushed, but the course is over before everyone gets bored with my jokes. Each week, there is a three-hour meeting, which includes a lecture and a short break. Table 1 outlines a course format that might work for you. If you can add more course time, your students will appreciate it. Another lecture covering water resources or environmental engineering would be wonderful. However, I do not think you can cover the full breadth of material in much less time or in fewer weeks.

I have tried to order the subjects in a logical, progressive manner, keeping my eye on “playing the high-probability subjects.” I cover the subjects that everyone can learn (e.g., fluids and soils) early in the course.

I leave the subjects that only daily practitioners should attempt (e.g., concrete, steel, and highway capacity) to the end.

**Table 1** Typical PE Exam Review Course Format

meeting	subject covered	chapters
1	Introduction to the Exam, Engineering Economics	90, 87
2	Fluids, Conduit Flow, and Pumps	14–18
3	Open Channel Flow	19
4	Hydrology	20–21
5	Water Supply	25–26
6	Wastewater and the Environment	28–30, 31–34
7	Soils, Foundations, Settlement, and Retaining Walls	35–40
8	Surveying and Concrete Mixing	78, 49
9	Highway Design and Traffic Analysis	73, 75, 79
10	Construction Engineering	80–83
11	Mechanics of Materials	41–47
12	Concrete Design	48–50
13	Steel Design	59, 61–62

Lecture coverage of some exam subjects is necessarily brief; other subjects are not covered at all. These omissions are intentional; they are not the result of scheduling omissions. Why? First, time is not on our side in a review course. Second, some subjects rarely contribute to the exam. Third, some subjects are not well-received by the students. For example, I have found that very few people try to become proficient in bridges, timber, and masonry if they do not already work in those areas. Most nonstructural civil engineers stick with the non-structural basics: fluids, soils, surveying, water supply, and wastewater. Most structural engineers stick with structural subjects. Unless you have six months in which to teach your PE review, your students' time can be better spent covering other subjects.

All the skipped chapters and any related practice problems are presented as floating assignments to be made up in the students' "free time."

I strongly believe in exposing my students to a realistic sample exam, but I no longer administer an in-class mock exam. Since the review course usually ends only a few days before the real PE exam, I hesitate to make students sit for several hours in the late evening to take a "final exam." Rather, I distribute and assign a take-home practice exam at the first meeting of the review course.

If the practice exam is to be used as an indication of preparedness, caution your students not to look at the practice exam prior to taking it. Looking at the practice exam, or otherwise using it to direct their review, will produce unwarranted specialization in subjects contained in the practice exam.

There are many ways to organize a PE review course, depending on your available time, budget, intended audience, facilities, and enthusiasm. However, all good course formats have the same result: The students struggle with the workload during the course, and then they breeze through the exam after the course.

## **PART 2: EVERYTHING YOU EVER WANTED TO KNOW ABOUT THE PE EXAM**

### **WHAT IS THE FORMAT OF THE PE EXAM?**

The NCEES PE exam in civil engineering consists of two four-hour sessions separated by a one-hour lunch period. The morning "breadth" session is taken by all examinees. There are five afternoon "depth" modules: construction, geotechnical, structural, transportation, and water resources and environmental. (The depth modules may be referred to as "discipline-specific," or DS, modules, borrowing a term from the FE exam.) You must be approved by your state licensing board before you can register for the exam using the "MyNCEES" system on the NCEES website. You select your depth module when you register for the exam. At the exam, you will receive an exam booklet for the depth module you selected during registration. Switching modules is not possible. Your answer sheet will be scored based on the module you selected during registration.

Both the morning and afternoon sessions contain 40 questions in multiple-choice (i.e., "objective") format. As this is a "no-choice" exam, you must answer all questions in each session correctly to receive full credit. There are no optional questions.

### **WHAT SUBJECTS ARE ON THE PE EXAM?**

NCEES has published a description of subjects on the exam. Irrespective of the published exam structure, the exact number of questions that will appear in each subject area cannot be predicted reliably.

There is no guarantee that any single subject will occur in any quantity. One of the reasons for this is that some of the questions span several disciplines. You might consider a pump selection question to come from the subject of fluids, while NCEES might categorize it as engineering economics.

**Table 2** Detailed Analysis of Tested Subjects**MORNING SESSION**  
(40 multiple-choice questions)

*Project planning:* quantity take-off methods; cost estimating; project schedules; activity identification and sequencing  
*Means and methods:* construction loads; construction methods; temporary structures and facilities

*Soil mechanics:* lateral earth pressure; soil consolidation; effective and total stresses; bearing capacity; foundation settlement; slope stability; shear (e.g., forces and stresses); axial (e.g., forces and stresses); combined stresses; deflection; beams; columns; slabs; footings; retaining walls

*Structural mechanics:* dead and live loads; trusses; bending (e.g., moments and stresses); shear (e.g., forces and stresses); axial (e.g., forces and stresses); combined stresses; deflection; beams; columns; slabs; footings; retaining walls

*Hydraulics and hydrology:* open-channel flow; stormwater collection and drainage (e.g., culvert, stormwater inlets, gutter flow, street flow, storm sewer pipes); storm characteristics (e.g., storm frequency, rainfall measurement, and distribution); runoff analysis (e.g., rational and SCS/NRCS methods, hydrographic application, runoff time of concentration); detention/retention ponds; pressure conduit (e.g., single pipe, force mains, Hazen-Williams, Darcy Weisbach, major and minor losses); energy and/or continuity equation (e.g., Bernoulli)

*Geometrics:* basic circular curve elements (e.g., middle ordinate, length, chord, radius); basic vertical curve elements; traffic volume (e.g., vehicle mix, flow, and speed)

*Materials:* soil classification and boring log interpretations; soil properties (e.g., strength, permeability, compressibility, phase relationships); concrete (e.g., nonreinforced, reinforced); structural steel; material test methods and specification conformance; compaction

*Site development:* excavation and embankment (e.g., cut and fill); construction site layout and control; temporary and permanent soil erosion and sediment control (e.g., construction erosion control and permits, sediment transport, channel/outlet protection); impact of construction on adjacent facilities; safety (e.g., construction, roadside, work zone)

**AFTERNOON SESSIONS**  
(40 multiple-choice questions)\***CIVIL/CONSTRUCTION DEPTH EXAM**

*Earthwork construction and layout* (6): excavation and embankment (e.g., cut and fill); borrow pit volumes; site layout and control; earthwork mass diagrams and haul distance; site and subsurface investigations

*Estimating quantities and costs* (6): quantity take-off methods; cost estimating; cost analysis for resource selection; work measurement and productivity

*Construction operations and methods* (7): lifting and rigging; crane stability; dewatering and pumping; equipment operations (e.g., selection, production, economics); deep foundation installation

*Scheduling* (5): construction sequencing; activity time analysis; critical path method (CPM) analysis; resource scheduling and leveling; time-cost trade-off

*Material quality control and production* (6): material properties and testing (e.g., soils, concrete, asphalt); weld and bolt installation; quality control process (QA/QC); concrete proportioning and placement; concrete maturity and early strength evaluation

*Temporary structures* (7): construction loads, codes, and standards; formwork; falsework and scaffolding; shoring and reshoring; bracing and anchorage for stability; temporary support of excavation

*Health and safety* (3): OSHA regulations and hazard identification/abatement; safety management and statistics; work zone and public safety

**CIVIL/GEOTECHNICAL DEPTH EXAM**

*Site characterization* (5): interpretation of available existing site data and proposed site development data (e.g., aerial photography, geologic and topographic maps, GIS data, as-built plans, planning studies and reports); subsurface exploration planning; geophysics (e.g., GPR, resistivity, seismic methods); drilling techniques (e.g., hollow stem auger, cased boring, mud rotary, air rotary, rock coring, sonic drilling); sampling techniques (e.g., split-barrel sampling, thin-walled tube sampling, handling and storage); in situ testing (e.g., standard penetration testing, cone penetration testing, pressure meter testing, dilatometer testing, field vane shear); description and classification of soils (e.g., Burmeister, Unified Soil Classification System, AASHTO, USDA); rock classification and characterization (e.g., recovery, rock quality designation, RMR, weathering, orientation); groundwater exploration, sampling, and characterization

*Soil mechanics, laboratory testing, and analysis* (5): index properties and testing; strength testing of soil and rock; stress-strain testing of soil and rock; permeability testing properties of soil and rock; effective and total stresses

\*The numbers in parentheses reflect the approximate number of questions for a given exam topic.

(continued)

**Table 2** Detailed Analysis of Tested Subjects (continued)

- Field materials testing, methods, and safety* (3): excavation and embankment, borrow source studies, laboratory and field compaction; trench and construction safety; geotechnical instrumentation (e.g., inclinometer, settlement plates, piezometer, vibration monitoring)
- Earthquake engineering and dynamic loads* (2): liquefaction analysis and mitigation techniques; seismic site characterization, including site classification using ASCE/SEI7; pseudo-static analysis and earthquake loads
- Earth structures* (4): slab on grade; ground improvement (e.g., grouting, soil mixing, preconsolidation/wicks, lightweight materials); geosynthetic applications (e.g., separation, strength, filtration, drainage, reinforced soil slopes, internal stability of MSE); slope stability and slope stabilization; earth dams, levees, and embankments; landfills and caps (e.g., interface stability, drainage systems, lining systems); pavement structures (rigid, flexible, or unpaved), including equivalent single-axle load (ESAL), pavement thickness, subgrade testing, subgrade preparation, maintenance and rehabilitation treatments; settlement
- Groundwater and seepage* (3): seepage analysis/groundwater flow; dewatering design, methods, and impact on nearby structures; drainage design/infiltration; grouting and other methods of reducing seepage
- Problematic soil and rock conditions* (3): Karst; collapsible, expansive, and sensitive soils; reactive/corrosive soils; frost susceptibility
- Earth retaining structures* (ASD or LRFD) (5): lateral earth pressure; load distribution; rigid retaining wall stability analysis (e.g., CIP, gravity, external stability of MSE, crib, bin); flexible retaining wall stability analysis (e.g., soldier pile and lagging, sheet pile, secant pile, tangent pile, diaphragm walls, temporary support of excavation, braced and anchored walls); cofferdams; underpinning (e.g., effects on adjacent construction); ground anchors, tie-backs, soil nails, and rock anchors for foundations and slopes
- Shallow foundations* (ASD or LRFD) (5): bearing capacity; settlement, including vertical stress distribution
- Deep foundations* (ASD or LRFD) (5): single-element axial capacity (e.g., driven pile, drilled shaft, micropile, helical screw piles, auger cast piles); lateral load and deformation analysis; single-element settlement; downdrag; group effects (e.g., axial capacity, settlement, lateral deflection); installation methods/hammer selection; pile dynamics (e.g., wave equation, high-strain dynamic testing, signal matching); pile and drilled-shaft load testing; integrity testing methods (e.g., low-strain impact integrity testing, ultrasonic cross-hole testing, coring, thermal integrity testing)

## CIVIL/STRUCTURAL DEPTH EXAM

### Analysis of Structures (14)

*Loads and load applications* (4): dead loads; live loads; construction loads; wind loads; seismic loads; moving loads (e.g., vehicular, cranes); snow, rain, ice; impact loads; earth pressure and surcharge loads; load paths (e.g., lateral and vertical); load combinations; tributary areas

*Forces and load effects* (10): diagrams (e.g., shear and moment); axial (e.g., tension and compression); shear; flexure; deflection; special topics (e.g., torsion, buckling, fatigue, progressive collapse, thermal deformation, bearing)

### Design and Details of Structures (20)

*Materials and material properties* (5): concrete (e.g., plain, reinforced, cast-in-place, precast, pretensioned, post-tensioned); steel (e.g., structural, reinforcing, cold-formed); timber; masonry (e.g., brick veneer, CMU)

*Component design and detailing* (15): horizontal members (e.g., beams, slabs, diaphragms); vertical members (e.g., columns, bearing walls, shear walls); systems (e.g., trusses, braces, frames, composite construction); connections (e.g., bearing, bolted, welded, embedded, anchored); foundations (e.g., retaining walls, footings, combined footings, slabs, mats, piers, piles, caissons, drilled shafts)

### Codes and Construction (6)

*Codes, standards, and guidance documents* (4): *International Building Code* (IBC); *Building Code Requirements for Structural Concrete* (ACI 318); *Building Code Requirements and Specification for Masonry Structures* (ACI 530/530.1); *PCI Design Handbook: Precast and Prestressed Concrete* (PCI); *Steel Construction Manual* (AISC); *National Design Specification for Wood Construction ASD/LRFD* (NDS); *AASHTO LRFD Bridge Design Specifications* (AASHTO LRFD); *Minimum Design Loads for Buildings and Other Structures* (ASCE/SEI7); *Structural Welding Code—Steel* (AWS D1.1); *Structural Welding Code—Aluminum* (AWS D1.2); *Structural Welding Code—Reinforcing Steel* (AWS D1.4); *Occupational Safety and Health Standards* (OSHA 1910); *Safety and Health Regulations for Construction* (OSHA 1926)

*Temporary structures and other topics* (2): special inspections; submittals; formwork; falsework and scaffolding; shoring and reshoring; concrete maturity and early strength evaluation; bracing; anchorage; OSHA regulations; safety management

(continued)

**Table 2** Detailed Analysis of Tested Subjects (*continued*)**CIVIL/TRANSPORTATION DEPTH EXAM**

- Traffic engineering (capacity analysis and transportation planning)* (11): uninterrupted flow (e.g., level of service, capacity); street segment interrupted flow (e.g., level of service, running time, travel speed); intersection capacity (e.g., at grade, signalized, roundabout, interchange); traffic analysis (e.g., volume studies, peak hour factor, speed studies, modal split); trip generation and traffic impact studies; accident analysis (e.g., conflict analysis, accident rates, collision diagrams); nonmotorized facilities (e.g., pedestrian, bicycle); traffic forecast; highway safety analysis (e.g., crash modification factors, *Highway Safety Manual*)
- Horizontal design* (4): basic curve elements (e.g., middle ordinate, length, chord, radius); sight distance considerations; superelevation (e.g., rate, transitions, method, components); special horizontal curves (e.g., compound/reverse curves, curve widening, coordination with vertical geometry)
- Vertical design* (4): vertical curve geometry; stopping and passing sight distance (e.g., crest curve, sag curve); vertical clearance
- Intersection geometry* (4): intersection sight distance; interchanges (e.g., freeway merge, entrance and exit design, horizontal design, vertical design); at-grade intersection layout, including roundabouts
- Roadside and cross-section design* (4): forgiving roadside concepts (e.g., clear zone, recoverable slopes, roadside obstacles); barrier design (e.g., barrier types, end treatments, crash cushions); cross-section elements (e.g., lane widths, shoulders, bike lane, sidewalks); Americans with Disabilities Act (ADA) design considerations
- Signal design* (3): signal timing (e.g., clearance intervals, phasing, pedestrian crossing timing, railroad preemption); signal warrants
- Traffic control design* (3): signs and pavement markings; temporary traffic control
- Geotechnical and pavement* (4): design traffic analysis (e.g., equivalent single-axle load (ESAL); sampling and testing (e.g., subgrade resilient modulus, CBR, R-values, field tests); mechanistic design procedures (e.g., flexible and rigid pavement); pavement evaluation and maintenance measures (e.g., skid, roughness, structural capacity, rehabilitation treatments); settlement and compaction; soil stabilization techniques; excavation, embankment, and mass balance
- Drainage* (2): hydrology (e.g., rational method, hydrographs, SCS/NRCS method); culvert design, including hydraulic energy dissipation; stormwater collection systems (e.g., inlet capacities, pipe flow); gutter flow; open-channel flow; runoff detention/retention/water quality mitigation measures
- Alternatives analysis* (1): economic analysis (e.g., present worth, lifecycle costs)

**CIVIL/WATER RESOURCES AND ENVIRONMENTAL DEPTH EXAM**

- Analysis and design* (4): mass balance; hydraulic loading; solids loading (e.g., sediment loading, sludge); hydraulic flow measurement
- Hydraulics—closed conduit* (5): energy and/or continuity equation (e.g., Bernoulli, momentum equation); pressure conduit (e.g., single pipe, force mains, Hazen-Williams, Darcy-Weisbach, major and minor losses); pump application and analysis, including wet wells, lift stations, and cavitation; pipe network analysis (e.g., series, parallel, and loop networks)
- Hydraulics—open channel* (5): open-channel flow; hydraulic energy dissipation; stormwater collection and drainage (e.g., culvert, stormwater inlets, gutter flow, street flow, storm sewer pipes); subcritical and supercritical flow
- Hydrology* (7): storm characteristics (e.g., storm frequency, rainfall measurement, and distribution); runoff analysis (e.g., rational and SCS/NRCS methods); hydrograph development and applications, including synthetic hydrographs; rainfall intensity, duration, and frequency; time of concentration; rainfall and stream gauging stations; depletions (e.g., evaporation, detention, percolation, and diversions); stormwater management (e.g., detention ponds, retention ponds, infiltration systems, and swales)
- Groundwater and wells* (3): aquifers; groundwater flow; well analysis—steady state
- Wastewater collection and treatment* (6): wastewater collection systems (e.g., lift stations, sewer networks, infiltration, inflow, smoke testing, maintenance, and odor control); wastewater treatment processes; wastewater flow rates; preliminary treatment; primary treatment; secondary treatment (e.g., physical, chemical, and biological processes); nitrification/denitrification; phosphorus removal; solids treatment, handling, and disposal; digestion; disinfection; advanced treatment (e.g., physical, chemical, and biological processes)
- Water quality* (3): stream degradation; oxygen dynamics; total maximum daily load (TMDL) (e.g., nutrient contamination, DO, load allocation); biological contaminants; chemical contaminants, including bioaccumulation
- Drinking water distribution and treatment* (6): drinking water distribution systems; drinking water treatment processes; demands; storage; sedimentation; taste and odor control; rapid mixing (e.g., coagulation); flocculation; filtration; disinfection, including disinfection byproducts; hardness and softening
- Engineering economics analysis* (1): economic analysis (e.g., present worth, lifecycle costs, comparison of alternatives)

Table 2 describes the subjects in detail. Most examinees find the list to be formidable in appearance. The problem counts in Table 2 are according to NCEES, but these problem counts are approximate. NCEES adds,

The exam is developed with questions that will require a variety of approaches and methodologies, including design, analysis, and application. Some problems may require knowledge of engineering economics. The knowledge areas specified as examples of kinds of knowledge are not exclusive or exhaustive categories.

As Table 2 shows, the subjects in morning and afternoon sessions overlap. However, the depth of required knowledge is not the same within and between sessions. Therefore, Table 2 provides some guidance as to just “what” each of these subjects means.

### **WHAT IS THE TYPICAL QUESTION FORMAT?**

Almost all of the questions are standalone—that is, they are completely independent. However, NCEES allows that some sets of questions may start with a statement of a “situation” that will apply to (typically) two to five following questions. Such grouped questions are increasingly rare, however.

Each of the questions will have four answer options labeled “A,” “B,” “C,” and “D.” If the answer options are numerical, they will be displayed in increasing value. One of the answer options is correct (or, will be “most nearly correct,” as described in the following section). The remaining answer options are incorrect and may consist of one or more “logical distractors,” the term used by NCEES to designate incorrect options that look correct.

NCEES intends the questions to be unrelated. Questions are independent or start with new given data. A mistake on one of the questions should not cause you to get a subsequent question wrong. However, considerable time may be required to repeat previous calculations with a new set of given data.

### **HOW MUCH “LOOK-UP” IS REQUIRED ON THE EXAM?**

Since the questions are multiple-choice in design, all required data will appear in the situation statement. Since the exam would be unfair if it was possible to arrive at an incorrect answer after making valid assumptions or using plausible data, you will not generally be required to come up with numerical data that might affect your success on the problem. There will also be superfluous information in the majority of questions.

### **WHAT DOES “MOST NEARLY” REALLY MEAN?**

One of the more disquieting aspects of these questions is that the available answer choices are seldom exact. Answer choices generally have only two or three

significant digits. Exam questions ask, “Which answer choice is most nearly the correct value?” or they instruct you to complete the sentence, “The value is approximately ...” A lot of self-confidence is required to move on to the next question when you do not find an exact match for the answer you calculated, or if you have had to split the difference because no available answer option is close.

NCEES has described it like this:

Many of the questions on NCEES exams require calculations to arrive at a numerical answer. Depending on the method of calculation used, it is very possible that examinees working correctly will arrive at a range of answers. The phrase “most nearly” is used to accommodate answers that have been derived correctly but that may be slightly different from the correct answer choice given on the exam. You should use good engineering judgment when selecting your choice of answer. For example, if the question asks you to calculate an electrical current or determine the load on a beam, you should literally select the answer option that is most nearly what you calculated, regardless of whether it is more or less than your calculated value. However, if the question asks you to select a fuse or circuit breaker to protect against a calculated current or to size a beam to carry a load, you should select an answer option that will safely carry the current or load. Typically, this requires selecting a value that is closest to but larger than the current or load.

The difference is significant. Suppose you were asked to calculate “most nearly” the volumetric pure water flow required to dilute a contaminated stream to an acceptable concentration. Suppose, also, that you calculated 823 gpm. If the answer options were (A) 600 gpm, (B) 800 gpm, (C) 1000 gpm, and (D) 1200 gpm, you would go with answer option (B), because it is most nearly what you calculated. If, however, you were asked to select a pump or pipe with the same rated capacities, you would have to go with option (C) because an 800 gpm pump would not be sufficient. Got it?

### **HOW MUCH MATHEMATICS IS NEEDED FOR THE EXAM?**

There are no pure mathematics questions (algebra, geometry, trigonometry, etc.) on the exam. However, you will need to apply your knowledge of these subjects to the exam questions.

Generally, only simple algebra, trigonometry, and geometry are needed on the PE exam. You will need to use the trigonometric, logarithm, square root, exponentiation, and similar buttons on your calculator. There is no need to use any other method for these functions.

Except for simple quadratic equations, you will probably not need to find the roots of higher-order equations.

For second-order (quadratic) equations, NCEES does not care if you find roots by factoring, completing the square, using the quadratic equation, or using your calculator's root finder. Occasionally, it will be convenient to use the equation-solving capability of your calculator. However, other solution methods exist.

There is essentially no use of calculus on the exam. Rarely, you may need to take a simple derivative to find a maximum or minimum of some simple algebraic function. Even rarer is the need to integrate to find an average, moment of inertia, statical moment, or shear flow.

There is essentially no need to solve differential equations. Questions involving radioactive decay, seismic vibrations, control systems, chemical reactions, and fluid mixing have appeared from time to time. However, these applications are extremely rare, have typically been first-order, and could usually be handled without having to solve differential equations.

Basic statistical analysis of observed data may be necessary. Statistical calculations are generally limited to finding means, medians, standard deviations, variances, percentiles, and confidence limits. Since the problems are multiple-choice, you will not have to draw a histogram, although you might have to interpret one. Usually, the only population distribution you need to be familiar with is the normal curve. Probability, reliability, hypothesis testing, and statistical quality control are not explicit exam subjects, though their concepts may appear peripherally in some problems. Although the term "least squares" may appear in surveying problems, you will not have to use linear or nonlinear regression and other curve-fitting techniques to correlate data.

Quantitative optimization methods, such as linear, dynamic, and integer programming, generally associated with the field of operations research, are not exam subjects. However, elements of simple queuing theory are integrated into some traffic and transportation subjects, so you should have a basic familiarity with the terminology of queues.

The PE exam is concerned with numerical answers, not with proofs or derivations. You will not be asked to prove or derive formulas, use deductive reasoning, or validate theorems, corollaries, or lemmas.

Inasmuch as first assumptions can significantly affect the rate of convergence, problems requiring trial-and-error solutions are unlikely. Rarely, a calculation may require an iterative solution method. Generally, there is no need to complete more than two iterations. You will not need to program your calculator to obtain an "exact" answer, nor will you generally need to use complex numerical methods.

### **STRAIGHT TALK: STRUCTURAL TOPICS**

---

There are four specialized structural subjects that require special consideration in your review: masonry, timber, bridge, and seismic design. These subjects appear

regularly (i.e., on every exam). (Yes, there are simple seismic design questions on the NCEES Civil PE exam!) Even if you do not intend to work in the Civil PE structural depth module, you will have to know a little something about these subjects for the morning breadth session.

Bridge, timber, and seismic design are specialized structural fields that are covered in separate PPI publications. These publications are *Timber Design for the Civil and Structural PE Exams*, and *Seismic Design of Building Structures*.

### **MASONRY: ASD AND SD**

---

The masonry chapters in this book are introductions to basic concepts and the most common design applications. Exam questions often go far beyond wall and column design. If you intend to be ready for any masonry question, I recommend that you supplement your study of these chapters. For masonry, only allowable stress design (ASD) solving methods may be used on the exam, with the exception that the strength design (SD) method may be used for walls with out-of-plane loads (ACI 530 Sec. 3.3.5). However, because the SD method is still reliable for masonry construction, and it is used in industry practice, this book provides both ASD and SD methods for your additional (and post-exam) reference. Where design methods differ, this book presents the ASD method first.

### **STEEL: ASD AND LRFD**

---

Either ASD or load and resistance factor design (LRFD) methods may be used, as there will be "parallel" questions adapted to both. It is not necessary to learn both systems of design. This book provides both ASD and LRFD solving methods in parallel.

### **CONCRETE: ACI 318 CHAP. 9 AND APP. C**

---

For concrete, ACI 318 App. C may not be used on the structural depth exam. Only ACI 318 Chap. 9 methods may be used.

### **WHICH BUILDING CODE?**

---

Building codes may be needed, but only to a limited extent (e.g., for wind and seismic loadings). Since the PE exam is a national exam, you are not required to use a regional building code. NCEES has adopted the IBC as the basis of its code-related questions. The code edition (year, version, etc.) tested is a thorny issue, however. The exam can be years behind the most recently adopted code, and many years behind the latest codes being published and distributed.

Occasionally, the International Code Council will modify, augment, and delete parts of the primary standard. For example, IBC contains provisions that differ slightly from those in ACI 530. While this is a

valid practical concern, NCEES is aware of the differences, and questions that have ambiguous correct answers are rare on the exam.

### HOW ABOUT ENGINEERING ECONOMICS?

For most of the early years of engineering licensing, questions on engineering economics appeared frequently on the exams. This is no longer the case. However, in its outline of exam subjects, NCEES notes: "Some questions may require knowledge of engineering economics." What this means is that engineering economics might appear in several questions on the exam, or the subject might be totally absent. While the degree of engineering economics knowledge may have decreased somewhat, the basic economic concepts (e.g., time value of money, present worth, nonannual compounding, comparison of alternatives, etc.) are still valid test subjects.

If engineering economics is incorporated into other questions, its "disguise" may be totally transparent. For example, you might need to compare the economics of buying and operating two blowers for remediation of a hydrocarbon spill—blowers whose annual costs must be calculated from airflow rates and heads. Also, you may need to use engineering economics concepts and tables in problems that do not even mention "dollars" (e.g., when you need to predict future water demand, population growth, or traffic volume).

### WHAT ABOUT PROFESSIONALISM AND ETHICS?

For many decades, NCEES has considered adding professionalism and ethics questions to the PE exam. However, these subjects are not part of the test outline, and there has yet to be an ethics question in the exam. Construction engineering questions dealing with obligations related to contracts, bidding, estimating, inspection, and regulations sometimes get pretty close to the subject of professional practice. However, you will not encounter the phrase "ethical obligation" in the exam.

### IS THE EXAM TRICKY?

Other than providing superfluous data, the PE exam is not a "tricky exam." The exam does not overtly try to get you to fail. Examinees manage to fail on a regular basis with perfectly straightforward questions. The exam questions are difficult in their own right. NCEES does not need to provide misleading or conflicting statements. However, you will find that commonly made mistakes are represented in the available answer choices. Thus, the alternative answers (known as distractors) will be logical.

Questions are generally practical, dealing with common and plausible situations that you might experience in your job. You will not be asked to design a structure for reduced gravity on the moon, to design a mud-brick road, to analyze the effects of a nuclear bomb blast on a structure, or to use bamboo for tension reinforcement.

### DOES NCEES WRITE EXAM QUESTIONS AROUND THIS BOOK?

Only NCEES knows what NCEES uses to write its exam questions. However, it is irrelevant, because this book is not intended to (1) be everything you need to pass the exam, (2) expose exam secrets or exam questions, or (3) help you pass when you do not deserve to pass. NCEES knows about this book, but worrying about NCEES writing exam questions based on information that is or is not in this book means you are placing too much dependency on this book. This book, for example, will teach you how to use aspects of many standards and codes. Expecting that this book will replace those standards and codes is unrealistic. This book will provide instruction in certain principles. Expecting that you will not need to learn anything else is unrealistic. This book presents many facts, definitions, and numerical values. Expecting that you will not need to know other facts, definitions, and numerical values is unrealistic. What NCEES uses to write exam questions will not have any effect on what you need to do to prepare for the exam.

### WHAT MAKES THE QUESTIONS DIFFICULT?

Some questions are difficult because the pertinent theory is not obvious. There may be only one acceptable procedure, and it may be heuristic (or defined by a code) such that nothing else will be acceptable. Many highway capacity questions are this way.

Some questions are difficult because the data needed is hard to find. Some data just is not available unless you happen to have brought the right reference book. Many of the structural questions are of this nature. There is no way to solve most structural steel questions without the *AISC Manual*. Designing an eccentrically loaded concrete column without published interaction diagrams is nearly impossible to do in six minutes. If you did not bring OSHA regulations to the exam, you are not going to be able to answer many safety questions.

Some questions are difficult because they defy the imagination. Three-dimensional structural questions and some surveying curve questions fit this description. If you cannot visualize the question, you probably cannot solve it.

Some questions are difficult because the computational burden is high, and they just take a long time. Pipe networking questions solved with the Hardy Cross method fall into this category.

Some questions are difficult because the terminology is obscure, and you just do not know what the terms mean. This can happen in almost any subject.

### DOES THE PE EXAM USE SI UNITS?

The PE exam in civil engineering primarily uses customary U.S. units although SI and a variety of other metric systems are also used. Questions use the units that

correspond to commonly accepted industry standards. Structural problems use customary U.S. units exclusively. Some questions, such as those in structural, soils, surveying, and traffic subjects, primarily use units of pounds, feet, seconds, gallons, and degrees Fahrenheit. Metric units are used in chemical-related subjects, including electrical power (watts) and water concentration (mg/L) questions. Either system can be used for fluids, although the use of metric units is still rare.

Unlike this book, the exam does not differentiate between lbf (pounds-force) and lbm (pounds-mass). Similarly, the exam does not follow this book's practice of meticulously separating the concepts of mass and weight; density and specific weight; and gravity,  $g$ , and the gravitational constant,  $g_c$ .

### **WHY DOES NCEES REUSE SOME QUESTIONS?**

NCEES reuses some of the more reliable questions from each exam. The percentage of repeat questions is not high—no more than 25% of the exam. NCEES repeats questions in order to equate the performance of one group of examinees with the performance of an earlier group. The repeated questions are known as *equaters*, and together, they are known as the *equating subtest*.

Occasionally, a new question appears on the exam that very few of the examinees do well on. Usually, the reason for this is that the subject is too obscure or the question is too difficult. Questions on water chemistry, timber, masonry, control systems, and some engineering management subjects (e.g., linear programming) fall into this category. Also, there have been cases where a low percentage of the examinees get the answer correct because the question was inadvertently stated in a poor or confusing manner. Questions that everyone gets correct are also considered defective.

NCEES tracks the usage and “success” of each of the exam questions. “Rogue” questions are not repeated without modification. This is one of the reasons historical analysis of question types should not be used as the basis of your review.

### **DOES NCEES USE THE EXAM TO PRE-TEST FUTURE QUESTIONS?**

NCEES does not use the PE exam to “pre-test” or qualify future questions. (It does use this procedure on the FE exam, however.) All of the questions you work will contribute toward your final score.

### **ARE THE EXAMPLE PROBLEMS IN THIS BOOK REPRESENTATIVE OF THE EXAM?**

The example problems in this book are intended to be instructional and informative. They were written to illustrate how their respective concepts can be implemented.

Example problems are not intended to represent exam problems or provide guidance on what you should study.

### **ARE THE PRACTICE PROBLEMS REPRESENTATIVE OF THE EXAM?**

The practice problems in the companion book, *Practice Problems for the Civil Engineering PE Exam*, were chosen to cover the most likely exam subjects. Some of the practice problems are multiple-choice, and some require free-format solutions. However, they are generally more comprehensive and complex than actual exam problems, regardless of their formats. Some of the practice problems are marked “*Time limit: one hour.*” Compared to the six-minute problems on the PE exam, such one-hour problems are considerably more time-consuming.

Practice problems in the companion book were selected to complement subjects in the *Civil Engineering Reference Manual*. Over the many editions of both books, the practice problems have developed into a comprehensive review of the most important civil engineering subjects covered on the exam.

All of the practice problems are original. Since NCEES does not release old exams, none of the practice problems are actual exam problems.

### **WHAT REFERENCE MATERIAL IS PERMITTED IN THE EXAM?**

The PE exam is an open-book exam. Most states do not have any limits on the numbers and types of books you can use. Personal notes in a three-ring binder and other semipermanent covers can usually be used.

Some states use a “shake test” to eliminate loose papers from binders. Make sure that nothing escapes from your binders when they are inverted and shaken.

The references you bring into the exam room in the morning do not have to be the same as the references you use in the afternoon. However, you cannot share books with other examinees during the exam.

A few states do not permit collections of solved problems such as *Schaum’s Outlines* series, sample exams, and solutions manuals. A few states maintain a formal list of banned books.

Strictly speaking, loose paper and scratch pads are not permitted in the examination room. Certain types of preprinted graphs and logarithmically scaled graph papers (which are almost never needed) should be three-hole punched and brought in a three-ring binder. An exception to this restriction may be made for laminated and oversize charts, graphs, and tables that are commonly needed for particular types of questions. However, there probably are not any such items for the civil PE exam.

It is a good idea to check with your state board to learn what is and is not permitted in the examination room.

PPI provides information about each state board on the PPI website ([ppi2pass.com/faqs/state-boards](http://ppi2pass.com/faqs/state-boards)).

### HOW MANY BOOKS SHOULD YOU BRING?

Except for codes and standards, you should not need many books in the examination room, particularly in the morning breadth session. The trouble is, you cannot know in advance which ones you will need. That is the reason why many examinees show up with boxes and boxes of books. Since this book is not a substitute for your own experience and knowledge, without a doubt, there are things that you will need that are not in this book. But there are not so many that you need to bring your company's entire library. The exam is very fast-paced. You will not have time to use books with which you are not thoroughly familiar. The exam does not require you to know obscure solution methods or to use difficult-to-find data. You will not need articles printed in an industry magazine; you will not need doctoral theses or industry proceedings; and you will not need to know about recent industry events.

So, it really is unnecessary to bring a large quantity of books with you. Essential books are identified in Table 3 in this Introduction, and you should be able to decide which support you need for the areas in which you intend to work. This book and five to 10 other references of your choice should be sufficient for most of the questions you answer.<sup>1</sup>

### MAY TABS BE PLACED ON PAGES?

It is common to tab pages in your books in an effort to reduce the time required to locate useful sections. Inasmuch as some states consider Post-it® notes to be "loose paper," your tabs should be of the more permanent variety. Although you can purchase tabs with gummed attachment points, it is also possible simply to use transparent tape to secure the Post-its you have already placed in your books.

### CAN YOU WRITE AND MARK IN YOUR BOOKS?

During your preparation, you may write anything you want, anywhere in your books, including this one. You can use pencil, pen, or highlighter in order to further your understanding of the content. However, during the exam, you must avoid the appearance of taking notes about the exam. This means that you should write only on the scratch paper that is provided. During the exam, other than drawing a line across a wide table of

<sup>1</sup>For decades, this Introduction has recommended that you bring an engineering/scientific dictionary with you, but this recommendation is no longer valid. Printed engineering/scientific dictionaries appear to be things of the past. Those that still exist are not very good, and none are targeted enough to be helpful with the modern afternoon depth exams.

numbers, or using your pencil to follow a line on a graph, you should not write in your books.

### WHAT ABOUT CALCULATORS?

The exam requires the use of a scientific calculator. However, it may not be obvious that you should bring a spare calculator with you to the exam. It is always unfortunate when an examinee is not able to finish because his or her calculator was dropped or stolen or stopped working for some unknown reason.

To protect the integrity of its exams, NCEES has banned communicating and text-editing calculators from the exam site. NCEES provides a list of calculator models acceptable for use during the exam. Calculators not included in the list are not permitted. Check the current list of permissible devices at the PPI website ([ppi2pass.com/calculators](http://ppi2pass.com/calculators)). Contact your state board to determine if nomographs and specialty slide rules are permitted.

The exam has not been optimized for any particular brand or type of calculator. In fact, for most calculations, a \$15 scientific calculator will produce results as satisfactory as those from a \$200 calculator. There are definite benefits to having built-in statistical functions, graphing, unit-conversion, and equation-solving capabilities. However, these benefits are not so great as to give anyone an unfair advantage.

It is essential that a calculator used for the civil PE exam have the following functions.

- trigonometric and inverse trigonometric functions
- hyperbolic and inverse hyperbolic functions
- $\pi$
- $\sqrt{x}$  and  $x^2$
- both common and natural logarithms
- $y^x$  and  $e^x$

For maximum speed and utility, your calculator should also have or be programmed for the following functions.

- interpolation
- extracting roots of quadratic and higher-order equations
- calculating factors for economic analysis questions

You may not share calculators with other examinees. Be sure to take your calculator with you whenever you leave the exam room for any length of time.

Laptop and tablet computers, and electronic readers are not permitted in the examination room. Their use has been considered, but no states actually permit them. However, considering the nature of the exam questions, it is very unlikely that these devices would provide any advantage.

- Steel Construction Manual* (AISC). American Institute of Steel Construction, Inc.

\* Although any edition can be used to learn the subject, the exam is "edition sensitive." Since the code version, edition, or year that is tested on the exam can change without notice, this information is available at PPI's website, [ppi2pass.com/cefaq](http://ppi2pass.com/cefaq).

## **ARE MOBILE DEVICES PERMITTED?**

You may not possess or use a cell phone, laptop or tablet computer, electronic reader, or other communications or text-messaging device during the exam, regardless of whether it is on. You will not be frisked upon entrance to the exam, but should a proctor discover that you are in possession of a communications device, you should expect to be politely excluded from the remainder of the exam.

## **HOW YOU SHOULD GUESS**

There is no deduction for incorrect answers, so guessing is encouraged. However, since NCEES produces defensible licensing exams, there is no pattern to the placement of correct responses. Since the quantitative responses are sequenced according to increasing values, the placement of a correct answer among other numerical distractors is a function of the distractors, not of some statistical normalizing routine. Therefore, it is irrelevant whether you choose all “A,” “B,” “C,” or “D” when you get into guessing mode during the last minute or two of the exam period.

The proper way to guess is as an engineer. You should use your knowledge of the subject to eliminate illogical answer choices. Illogical answer choices are those that violate good engineering principles, that are outside normal operating ranges, or that require extraordinary assumptions. Of course, this requires you to have some basic understanding of the subject in the first place. Otherwise, you go back to random guessing. That is the reason that the minimum passing score is higher than 25%.

You will not get any points using the “test-taking skills” that helped you in college. You will not be able to eliminate any [verb] answer choices from “Which [noun] ...” questions. You will not find problems with options of the “more than 50” and “less than 50” variety. You will not find one answer choice among the four that has a different number of significant digits, or has a verb in a different tense, or has some singular/plural discrepancy with the stem. The distractors will always match the stem, and they will be logical.

## **HOW IS THE EXAM GRADED AND SCORED?**

The maximum number of points you can earn on the civil engineering PE exam is 80. The minimum number of points for passing (referred to by NCEES as the *cut score*) varies from exam to exam. The cut score is determined through a rational procedure, without the benefit of knowing examinees’ performance on the exam. That is, the exam is not graded on a curve. The cut score is selected based on what you are expected to know, not based on passing a certain percentage of engineers.

Each of the questions is worth one point. Grading is straightforward, since a computer grades your score sheet. Either you get the question right or you do not. If you

mark two or more answers for the same problem, no credit is given for the problem.

You will receive the results of your exam from your state board (not NCEES) online through your MyNCEES account or by mail, depending on your state. Eight to ten weeks will pass before NCEES releases the results to the state boards. However, the state boards take varying amounts of additional time before notifying examinees. You should allow three to four months for notification.

Your score may or may not be revealed to you, depending on your state’s procedure. Even if the score is reported to you, it may have been scaled or normalized to 100%. It may be difficult to determine whether the reported score is out of 80 points or is out of 100%.

## **HOW IS THE CUT SCORE ESTABLISHED?**

The raw cut score may be established by NCEES before or after the exam is administered. Final adjustments may be made following the exam date.

NCEES uses a process known as the *Modified Angoff* procedure to establish the cut score. This procedure starts with a small group (the cut score panel) of professional engineers and educators selected by NCEES. Each individual in the group reviews each problem and makes an estimate of its difficulty. Specifically, each individual estimates the number of minimally qualified engineers out of a hundred examinees who should know the correct answer to the problem. (This is equivalent to predicting the percentage of minimally qualified engineers who will answer correctly.)

Next, the panel assembles, and the estimates for each problem are openly compared and discussed. Eventually, a consensus value is obtained for each. When the panel has established a consensus value for every problem, the values are summed and divided by 100 to establish the cut score.

Various minor adjustments can be made to account for examinee population (as characterized by the average performance on any equate questions) and any flawed problems. Rarely, security breaches result in compromised problems or exams. How equate questions, exam flaws, and security issues affect examinee performance is not released by NCEES to the public.

## **WHAT IS THE HISTORICAL PASSING RATE?**

Before the civil engineering PE exam became a no-choice, breadth-and-depth (B&D) exam with multiple-choice questions, the passing rate for first-timers varied considerably. It might have been 40% for one exam and 80% for the next. The passing rate for repeat examinees was even lower. The no-choice, objective, B&D format has reduced the variability in the passing rate considerably. Within a few percentage points, 60–65% of first-time exam takers pass the civil engineering PE exam. The passing rate for

repeat exam takers is less than half of the first-time exam taker passing rate.

### **ARE ALL OF THE DEPTH MODULES EQUAL IN DIFFICULTY?**

---

Nothing in the Modified Angoff procedure ensures that the cut score will be the same in all of the depth modules. Thus, each depth module may have a different cut score. The easier the questions, the higher the cut score will be. Accordingly, the cut scores and passing rates are different for each depth module.

### **CHEATING AND EXAM SUBVERSION**

---

There are not very many ways to cheat on an open-book test. The proctors are well trained in spotting the few ways that do exist. It goes without saying that you should not talk to other examinees in the room, nor should you pass notes back and forth. You should not write anything into your books or take notes on the contents of the exam. You should not use your cell phone. The number of people who are released to use the restroom may be limited to prevent discussions.

NCEES regularly reuses problems that have appeared on previous exams. Therefore, exam integrity is a serious issue with NCEES, which goes to great lengths to make sure nobody copies the questions. You may not keep your exam booklet or scratch paper, enter the text of questions into your calculator, or copy problems into your own material.

NCEES has become increasingly unforgiving about loss of its intellectual property. NCEES routinely prosecutes violators and seeks financial redress for loss of its exam problems, as well as invalidating any engineering license you may have earned by taking one of its exams while engaging in prohibited activities. Your state board may impose additional restrictions on your right to retake any exam if you are convicted of such activities. In addition to tracking down the sources of any exam problem compilations that it becomes aware of, NCEES is also aggressive in pursuing and prosecuting examinees who disclose the contents of the exam in online forum and "chat" environments. Your constitutional rights to free speech and expression will not protect you from civil prosecution for violating the nondisclosure agreement that NCEES requires you to sign before taking the exam. If you wish to participate in a dialogue about a particular exam subject, you must do so in such a manner that does not violate the essence of your nondisclosure agreement. This requires decoupling your discussion from the exam and reframing the question to avoid any exam particulars.

The proctors are concerned about exam subversion, which generally means activity that might invalidate the exam or the examination process. The most common form of exam subversion involves trying to copy exam problems for future use. However, in their zeal to enforce

and protect, proctors have shown unforgiving intolerance of otherwise minor infractions such as using your own pencil, using a calculator not on the approved list, possessing a cell phone, or continuing to write for even an instant after "pencils down" is called. For such infractions, you should expect to have the results of your exam invalidated, and all of your pleas and arguments in favor of forgiveness to be ignored. Even worse, since you will summarily be considered to have cheated, your state board will most likely prohibit you from retaking the exam for a number of exam cycles. There is no mercy built into the NCEES and state board procedures.

## **PART 3: HOW TO PREPARE FOR AND PASS THE PE EXAM IN CIVIL ENGINEERING**

---

### **WHAT SHOULD YOU STUDY?**

---

The exam covers many diverse subjects. Strictly speaking, you do not have to study every subject on the exam in order to pass. However, the more subjects you study, the more you will improve your chances of passing. You should decide early in the preparation process which subjects you are going to study. The strategy you select will depend on your background. Following are the four most common strategies.

A broad approach is the key to success for examinees who have recently completed their academic studies. This strategy is to review the fundamentals in a broad range of undergraduate subjects (which means studying all or most of the chapters in this book). The exam includes enough fundamentals problems to make this strategy worthwhile. Overall, it is the best approach.

Engineers who have little time for preparation tend to concentrate on the subject areas in which they hope to find the most problems. By studying the list of exam subjects, some have been able to focus on those subjects that will give them the highest probability of finding enough problems that they can answer. This strategy works as long as the exam cooperates and has enough of the types of questions they need. Too often, though, examinees who pick and choose subjects to review cannot find enough problems to complete the exam.

Engineers who have been away from classroom work for a long time tend to concentrate on the subjects in which they have had extensive experience, in the hope that the exam will feature lots of problems in those subjects. This method is seldom successful.

Some engineers plan on modeling their solutions from similar problems they have found in textbooks, collections of solutions, and old exams. These engineers often spend a lot of time compiling and indexing the example and sample problem types in all of their books. This is not a legitimate preparation method, and it is almost never successful.

## **DO YOU NEED A CLASSROOM REVIEW COURSE?**

Approximately 60% of first-time PE examinees take an instructor-led review course of some form. Live classroom and internet courses of various types, as well as previously recorded lessons, are available for some or all of the exam topics. Live courses and instructor-moderated internet courses provide several significant advantages over self-directed study, some of which may apply to you.

- A course structures and paces your review. It ensures that you keep going forward without getting bogged down in one subject.
- A course focuses you on a limited amount of material. Without a course, you might not know which subjects to study.
- A course provides you with the questions you need to solve. You will not have to spend time looking for them.
- A course spoon-feeds you the material. You may not need to read the book!
- The course instructor can answer your questions when you are stuck.

You probably already know if any of these advantages apply to you. A review course will be less valuable if you are thorough, self-motivated, and highly disciplined.

## **HOW LONG SHOULD YOU STUDY?**

We have all heard stories of the person who did not crack a book until the week before the exam and still passed it with flying colors. Yes, these people really exist. However, I am not one of them, and you probably are not either. In fact, after having taught thousands of engineers in my own classes, I am convinced that these people are as rare as the ones who have taken the exam five times and still have not passed it.

A thorough review takes approximately 300 hours. Most of this time is spent solving problems. Some of it may be spent in class; some is spent at home. Some examinees spread this time over a year. Others try to cram it all into two months. Most classroom review courses last for three or four months. The best time to start studying will depend on how much time you can spend per week.

## **WHAT THE WELL-HEELED CIVIL ENGINEER SHOULD BEGIN ACCUMULATING**

There are many references and resources that you should begin to assemble for review and for use in the exam.

It is unlikely that you could pass the PE exam without accumulating other books and resources. There certainly is not much margin for error if you show up with only one book. True, references are not needed to answer some

fluids, hydrology, and soils questions. However, there are many afternoon depth questions that require knowledge, data, and experience that are presented and described only in codes, standards, and references dedicated to a single subject. You would have to be truly lucky to go in “bare,” find the right mix of questions, and pass.

Few examinees are able to accumulate all of the references needed to support the exam’s entire body of knowledge. The accumulation process is too expensive and time-consuming, and the sources are too diverse. Like purchasing an insurance policy, what you end up with will be more a function of your budget than of your needs. In some cases, one book will satisfy several needs.

The list in Table 3 was compiled from approximately 70 administrations of the civil engineering PE exam. The books and other items listed are regularly cited by examinees as being particularly useful to them. This listing only includes the major “named” books that have become standard references in the industry. These books are in addition to any textbooks or resources that you might choose to bring.

## **ADDITIONAL REVIEW MATERIAL**

In addition to this book and its accompanying *Practice Problems for the Civil Engineering PE Exam*, PPI can provide you with many targeted references and study aids, some of which are listed here. All of these books have stood the test of time, which means that examinees continually report their usefulness and that PPI keeps them up to date.

- *Civil PE Practice Examination*
- *Quick Reference for the Civil Engineering PE Exam*
- *Engineering Unit Conversions*
- *Civil Engineering Solved Problems*
- *Seismic Design of Building Structures*
- *Surveying Principles for Civil Engineers*
- *Timber Design for the Civil and Structural PE Exams*
- PPI books in the *Six-Minute Solutions* series

## **DOWNLOAD FOR ADDITIONAL ENGINEERING EXAM SUPPORT**

Many of the tables and appendices in this book are representative abridgments with just enough data to (a) do the practice problems in the companion book and (b) give you a false sense of security. You can download or link to additional data, explanations, and references by visiting PPI’s website, [ppi2pass.com/CEwebrefs](http://ppi2pass.com/CEwebrefs).

## **WHAT YOU WILL NOT NEED**

Generally, people bring too many things to the exam. One general rule is that you should not bring books that you have not looked at during your review. If you did not

need a book while doing the practice problems in this book, you will not need it during the exam.

There are some other things that you will not need.

- Books on basic and introductory subjects: You will not need books that cover trigonometry, geometry, or calculus.
- Books that cover background engineering subjects that appear on the exam, such as fluids, thermodynamics, and chemistry: The exam is more concerned with the applications of these bodies of knowledge than with the bodies of knowledge themselves.
- Books on non-exam subjects: Such subjects as materials science, statics, dynamics, mechanics of materials, drafting, history, the English language, geography, and philosophy are not part of the exam.
- Books on mathematical analysis, numerical analysis, or extensive mathematics tabulations
- Extensive collections of properties: You will not be expected to know the properties and characteristics of chemical compounds, obscure or exotic alloys, uncommon liquids and gases, or biological organisms. Most characteristics affecting performance are provided as part of the problem statement.
- Plumbing, electrical, or fire codes
- Obscure books and materials: Books that are in foreign languages, doctoral theses, and papers presented at technical societies will not be needed during the exam.
- Old textbooks or obsolete, rare, and ancient books: NCEES exam committees are aware of which textbooks are in use. Material that is available only in out-of-print publications and old editions will not be used.
- Handbooks in other disciplines: You probably will not need a mechanical, electrical, or industrial engineering handbook.
- The *CRC Handbook of Chemistry and Physics*
- Computer science books: You will not need to bring books covering computer logic, programming, algorithms, program design, or subroutines for BASIC, Fortran, C, Pascal, HTML, Java, or any other programming language.
- Crafts- and trades-oriented books: The exam does not expect you to have detailed knowledge of trades or manufacturing operations (e.g., carpentry, plumbing, electrical wiring, roofing, sheetrocking, foundry, metal turning, sheet-metal forming, or designing jigs and fixtures).
- Manufacturer's literature and catalogs: No part of the exam requires you to be familiar with products that are proprietary to any manufacturer.

- U.S. government publications: With the exceptions of the publications mentioned and referenced in this book, no government publications are required for the PE exam.
- The text of federal acts, policies, and treaties such as the Clean Air Act, Clean Water Act, Resource Conservation and Recovery Act, Oil Pollution Act, Atomic Energy Act, and Nuclear Waste Policy Act
- Your state's laws: The PE exam is a national exam. Nothing unique to your state will appear on it. (However, federal legislation affecting engineers, particularly in environmental areas, is fair game.)
- Local or state building codes

## SHOULD YOU LOOK FOR OLD EXAMS?

---

The traditional approach to preparing for standardized tests includes working sample tests. However, NCEES does not release old tests or questions after they are used. Therefore, there are no official questions or tests available from legitimate sources. NCEES publishes booklets of sample questions and solutions to illustrate the format of the exam. However, these questions have been compiled from various previous exams, and the resulting publication is not a true "old exam." Furthermore, NCEES sometimes constructs its sample questions books from questions that have been pulled from active use for various reasons, including poor performance. Such marginal questions, while accurately reflecting the format of the exam, are not always representative of actual exam subjects.

## WHAT SHOULD YOU MEMORIZIZE?

---

You get lucky here, because it is not necessary to memorize anything. The exam is open-book, so you can look up any procedure, formula, or piece of information that you need. You can speed up your problem-solving response time significantly if you do not have to look up the conversion from gal/min to ft<sup>3</sup>/sec, the definition of the sine of an angle, and the chemical formula for carbon dioxide, but you do not even have to memorize these kinds of things. As you work practice problems in the companion book, *Practice Problems for the Civil Engineering PE Exam*, you will automatically memorize the things that you come across more than a few times.

## DO YOU NEED A REVIEW SCHEDULE?

---

It is important that you develop and adhere to a review outline and schedule. Once you have decided which subjects you are going to study, you can allocate the available time to those subjects in a manner that makes sense to you. If you are not taking a classroom review course (where the order of preparation is determined by the lectures), you should make an outline of subjects for self-study to use for scheduling your preparation.

A fill-in-the-dates schedule is provided in Table 4 at the end of this Introduction. If you purchased this book directly from PPI, you also have access to an interactive, adjustable, and personalized study schedule. Log in to your PPI account to access your custom study schedule.

### **A SIMPLE PLANNING SUGGESTION**

Designate some location (a drawer, a corner, a cardboard box, or even a paper shopping bag left on the floor) as your “exam catchall.” Use your catchall during the months before the exam when you have revelations about things you should bring with you. For example, you might realize that the plastic ruler marked off in tenths of an inch that is normally kept in the kitchen junk drawer can help you with some soil pressure questions. Or, you might decide that a certain book is particularly valuable, that it would be nice to have dental floss after lunch, or that large rubber bands and clips are useful for holding books open.

It is not actually necessary to put these treasured items in the catchall during your preparation. You can, of course, if it is convenient. But if these items will have other functions during the time before the exam, at least write yourself a note and put the note into the catchall. When you go to pack your exam kit a few days before the exam, you can transfer some items immediately, and the notes will be your reminders for the other items that are back in the kitchen drawer.

### **HOW YOU CAN MAKE YOUR REVIEW REALISTIC**

In the exam, you must be able to recall solution procedures, formulas, and important data quickly. You must remain sharp for eight hours or more. When you played a sport back in school, your coach tried to put you in game-related situations. Preparing for the PE exam is not much different from preparing for a big game. Some part of your preparation should be realistic and representative of the exam environment.

There are several things you can do to make your review more representative. For example, if you gather most of your review resources (i.e., books) in advance and try to use them exclusively during your review, you will become more familiar with them. (Of course, you can also add to or change your references if you find inadequacies.)

Learning to use your time wisely is one of the most important lessons you can learn during your review. You will undoubtedly encounter questions that end up taking much longer than you expected. In some instances, you will cause your own delays by spending too much time looking through books for things you need (or just by looking for the books themselves!). Other times, the questions will entail too much work.

Learn to recognize these situations so that you can make an intelligent decision about skipping such questions in the exam.

### **WHAT TO DO A FEW DAYS BEFORE THE EXAM**

There are a few things you should do a week or so before the exam. You should arrange for childcare and transportation. Since the exam does not always start or end at the designated time, make sure that your childcare and transportation arrangements are flexible.

Check PPI’s website for last-minute updates and errata to any PPI books you might have and are bringing to the exam.

Prepare a separate copy of this book’s index. You may be able to photocopy the actual index; alternatively, you may download the index to the current edition of this book at [ppi2pass.com/ermindex](http://ppi2pass.com/ermindex).

If you have not already done so, read the “Advice from Civil PE Examinees” section of PPI’s website.

If it is convenient, visit the exam location in order to find the building, parking areas, exam room, and restrooms. If it is not convenient, you may find driving directions and/or site maps online.

Take the battery cover off your calculator and check to make sure you are bringing the correct size replacement batteries. Some calculators require a different kind of battery for their “permanent” memories. Put the cover back on and secure it with a piece of masking tape. Write your name on the tape to identify your calculator.

If your spare calculator is not the same as your primary calculator, spend a few minutes familiarizing yourself with how it works. In particular, you should verify that your spare calculator is functional.

### **PREPARE YOUR CAR**

- [ ] Gather snow chains, a shovel, and tarp to kneel on while installing chains.
- [ ] Check tire pressure.
- [ ] Check your spare tire.
- [ ] Check for tire installation tools.
- [ ] Verify that you have the vehicle manual.
- [ ] Check fluid levels (oil, gas, water, brake fluid, transmission fluid, window-washing solution).
- [ ] Fill up with gas.
- [ ] Check battery and charge if necessary.
- [ ] Know something about your fuse system (where fuses are, how to replace them, etc.).
- [ ] Assemble all required maps.
- [ ] Fix anything that might slow you down (missing wiper blades, etc.).
- [ ] Check your taillights.

- [ ] Affix the current DMV vehicle registration tag.
- [ ] Fix anything that might get you pulled over on the way to the exam (burned-out taillight or headlight, broken lenses, bald tires, missing license plate, noisy muffler).
- [ ] Treat the inside windows with anti-fog solution.
- [ ] Put a roll of paper towels in the back seat.
- [ ] Gather exact change for any bridge tolls or toll roads.
- [ ] Find and install your electronic toll tag, if applicable.
- [ ] Put \$20 in your glove box.
- [ ] Check for current vehicle registration and proof of insurance.
- [ ] Locate a spare door and ignition key.
- [ ] Find your AAA or other roadside-assistance cards and phone numbers.
- [ ] Plan alternate routes.

### **PREPARE YOUR EXAM KITS**

Second in importance to your scholastic preparation is the preparation of your two exam kits. The first kit consists of a bag, box (plastic milk crates hold up better than cardboard in the rain), or wheeled travel suitcase containing items to be brought with you into the exam room.

- [ ] your exam authorization notice
- [ ] current, signed government-issued photographic identification (e.g., driver's license, not a student ID card)
- [ ] this book
- [ ] a separate, bound copy of this book's index (a printable copy can be downloaded at [ppi2pass.com/cermindex](http://ppi2pass.com/cermindex))
- [ ] other textbooks and reference books
- [ ] regular dictionary
- [ ] review course notes in a three-ring binder
- [ ] cardboard boxes or plastic milk crates to use as bookcases
- [ ] primary calculator
- [ ] spare calculator
- [ ] instruction booklets for your calculators
- [ ] extra calculator batteries
- [ ] two straightedges (e.g., ruler, scale, triangle, protractor)
- [ ] protractor
- [ ] scissors
- [ ] stapler
- [ ] transparent tape
- [ ] magnifying glass
- [ ] small (jeweler's) screwdriver for fixing your glasses or for removing batteries from your calculator
- [ ] unobtrusive (quiet) snacks or candies, already unwrapped

- [ ] two small plastic bottles of water
- [ ] travel pack of tissue (keep in your pocket)
- [ ] handkerchief
- [ ] headache remedy
- [ ] personal medication
- [ ] \$5.00 in assorted coinage
- [ ] spare contact lenses and multipurpose contact lens cleaning solution
- [ ] backup reading glasses (no case)
- [ ] eye drops
- [ ] light, comfortable sweater
- [ ] loose shoes or slippers
- [ ] cushion for your chair
- [ ] earplugs
- [ ] wristwatch with alarm
- [ ] several large trash bags ("raincoats" for your boxes of books)
- [ ] roll of paper towels
- [ ] wire coat hanger (to hang up your jacket or to get back into your car in an emergency)
- [ ] extra set of car keys on a string around your neck

The second kit consists of the following items and should be left in a separate bag or box in your car in case it is needed.

- [ ] copy of your exam authorization notice
- [ ] light lunch
- [ ] beverage in thermos or can
- [ ] sunglasses
- [ ] extra pair of prescription glasses
- [ ] raincoat, boots, gloves, hat, and umbrella
- [ ] street map of the exam area
- [ ] parking permit
- [ ] battery-powered desk lamp
- [ ] your cell phone
- [ ] length of rope

The following items cannot be used during the exam and should be left at home.

- [ ] personal pencils and erasers (NCEES distributes mechanical pencils at the exam.)
- [ ] fountain pens
- [ ] radio, CD player, MP3 player, or other media player
- [ ] battery charger
- [ ] extension cords
- [ ] scratch paper
- [ ] notepads
- [ ] drafting compass
- [ ] circular ("wheel") slide rules

### **PREPARE FOR THE WORST**

All of the occurrences listed in this section have happened to examinees. Granted, you cannot prepare for every eventuality. But, even though each of these

occurrences taken individually is a low-probability event, taken together, they are worth considering in advance.

- Imagine getting a flat tire, getting stuck in traffic, or running out of gas on the way to the exam.
- Imagine rain and snow as you are carrying your cardboard boxes of books into the exam room.
- Imagine arriving late. Can you get into the exam without having to make two trips from your car?
- Imagine having to park two blocks from the exam site. How are you going to get everything to the exam room? Can you actually carry everything that far? Could you use a furniture dolly, a supermarket basket, or perhaps a helpmate?
- Imagine a Star Trek convention, square-dancing contest, construction, or an auction in the next room.
- Imagine a site without any heat, with poor lighting, or with sunlight streaming directly into your eyes.
- Imagine a hard folding chair and a table with one short leg.
- Imagine a site next to an airport with frequent take-offs, or next to a construction site with a pile driver, or next to the NHRA State Championship.
- Imagine a seat where someone nearby chews gum with an open mouth; taps his pencil or drums her fingers; or wheezes, coughs, and sneezes for eight hours.
- Imagine the distraction of someone crying or of proctors evicting yelling and screaming examinees who have been found cheating.
- Imagine the tragedy of another examinee's serious medical emergency.
- Imagine a delay of an hour while you wait for someone to unlock the building, turn on the heat, or wait for the head proctor to bring instructions.
- Imagine a power outage occurring sometime during the exam.
- Imagine a proctor who (a) tells you that one of your favorite books cannot be used in the exam, (b) accuses you of cheating, or (c) calls "time up" without giving you any warning.
- Imagine not being able to get your lunch out of your car or find a restaurant.
- Imagine getting sick or nervous in the exam.
- Imagine someone stealing your calculator during lunch.

### **WHAT TO DO THE DAY BEFORE THE EXAM**

Take the day before the exam off from work to relax. Do not cram. A good night's sleep is the best way to start

the exam. If you live a considerable distance from the exam site, consider getting a hotel room in which to spend the night.

Practice setting up your exam work environment. Carry your boxes to the kitchen table. Arrange your "book-cases" and supplies. Decide what stays on the floor in boxes and what gets an "honored position" on the tabletop.

Use your checklist to make sure you have everything. Make sure your exam kits are packed and ready to go. Wrap your boxes in plastic bags in case it is raining when you carry them from the car to the examination room.

Calculate your wake-up time and set the alarms on two bedroom clocks. Select and lay out your clothing items. (Dress in layers.) Select and lay out your breakfast items.

If it is going to be hot on exam day, put your (plastic) bottles of water in the freezer.

Make sure you have gas in your car and money in your wallet.

### **WHAT TO DO THE DAY OF THE EXAM**

Turn off the quarterly and hourly alerts on your wrist-watch. Leave your cell phone in the car. If you must bring it, set it on silent mode. Bring a morning newspaper.

You should arrive at least 30 minutes before the exam starts. This will allow time for finding a convenient parking place, bringing your materials to the exam room, making room and seating changes, and calming down. Be prepared, though, to find that the exam room is not open or ready at the designated time.

Once you have arranged the materials around you on your table, take out your morning newspaper and look cool. (Only nervous people work crossword puzzles.)

### **WHAT TO DO DURING THE EXAM**

All of the procedures typically associated with timed, proctored, machine-graded assessment tests will be in effect when you take the PE exam.

The proctors will distribute the exam booklets and answer sheets if they are not already on your tables. However, you should not open the booklets until instructed to do so. You may read the information on the front and back covers, and you should write your name in any appropriate blank spaces.

Listen carefully to everything the proctors say. Do not ask your proctors any engineering questions. Even if they are knowledgeable in engineering, they will not be permitted to answer your questions.

Answers to questions are recorded on an answer sheet contained in the test booklet. The proctors will guide you through the process of putting your name and other biographical information on this sheet when the time comes, which will take approximately 15 minutes. You will be given the full four hours to answer questions. Time to initialize the answer sheet is not part of your four hours.

The common suggestions to “completely fill the bubbles and erase completely” apply here. NCEES provides each examinee with a mechanical pencil with HB lead. Use of ballpoint pens and felt-tip markers is prohibited.

If you finish the exam early and there are still more than 30 minutes remaining, you will be permitted to leave the room. If you finish less than 30 minutes before the end of the exam, you may be required to remain until the end. This is done to be considerate of the people who are still working.

Be prepared to stop working immediately when the proctors call “pencils down” or “time is up.” Continuing to work for even a few seconds will completely invalidate your exam.

When you leave, you must return your examination booklet. You may not keep the examination booklet for later review.

If there are any questions that you think were flawed, in error, or unsolvable, ask a proctor for a “reporting form” on which you can submit your comments. Follow your proctor’s advice in preparing this document.

### **WHAT ABOUT EATING AND DRINKING IN THE EXAMINATION ROOM?**

---

The official rule is probably the same in every state: no eating or drinking during the exam. That makes sense, for a number of reasons. Some examination sites do not want (or do not permit) stains and messes. Others do not want crumbs to attract ants and rodents. Your table partners do not want spills or smells. Nobody wants the distractions. Your proctors cannot give you a new exam booklet when the first one is ruined with coffee.

How this rule is administered varies from site to site and from proctor to proctor. Some proctors enforce the letter of law, threatening to evict you from the examination room when they see you chewing gum. Others may permit you to have bottled water, as long as you store the bottles on the floor where any spills will not harm what is on the table. No one is going to let you crack peanuts while you work on the exam, but I cannot see anyone complaining about a hard candy melting away in your mouth. You will just have to find out when you get there.

### **HOW TO SOLVE MULTIPLE-CHOICE QUESTIONS**

---

When you begin each session of the exam, observe the following suggestions:

- Use only the pencil provided.
- Do not spend an inordinate amount of time on any single question. If you have not answered a question in a reasonable amount of time, make a note of it and move on.
- Set your wristwatch alarm for five minutes before the end of each four-hour session, and use that remaining time to guess at all of the remaining questions. Odds are that you will be successful with about 25% of your guesses, and these points will more than make up for the few points that you might earn by working during the last five minutes.
- Make mental notes about any question for which you cannot find a correct response, that appears to have two correct responses, or that you believe has some technical flaw. Errors in the exam are rare, but they do occur. Such errors are usually discovered during the scoring process and discounted from the exam, so it is not necessary to tell your proctor, but be sure to mark the one best answer before moving on.
- Make sure all of your responses on the answer sheet are dark, and completely fill the bubbles.

### **SOLVE QUESTIONS CAREFULLY**

---

Many points are lost to carelessness. Keep the following items in mind when you are solving practice problems. Hopefully, these suggestions will be automatic in the exam.

- [ ] Did you recheck your mathematical equations?
- [ ] Do the units cancel out in your calculations?
- [ ] Did you convert between radius and diameter?
- [ ] Did you convert between feet and inches?
- [ ] Did you convert from gage to absolute pressures?
- [ ] Did you convert between pounds and kips, or between kPa and Pa?
- [ ] Did you recheck all data obtained from other sources, tables, and figures? (In finding the friction factor, did you enter the Moody diagram at the correct Reynolds number?)

### **SHOULD YOU TALK TO OTHER EXAMINEES AFTER THE EXAM?**

---

The jury is out on this question. People react quite differently to the examination experience. Some people are energized. Most are exhausted. Some people need to unwind by talking with other examinees, describing every

detail of their experience, and dissecting every exam question. Other people need lots of quiet space, and prefer just to get into a hot tub to soak and sulk. Most engineers, apparently, are in this latter category.

Since everyone who took the exam has seen it, you will not be violating your “oath of silence” if you talk about the details with other examinees immediately after the exam. It is difficult not to ask how someone else approached a question that had you completely stumped. However, keep in mind that it is very disquieting to think you answered a question correctly, only to have someone tell you where you went wrong.

To ensure you do not violate the nondisclosure agreement you signed before taking the exam, make sure you do not discuss any exam particulars with people who have not also taken the exam.

### **AFTER THE EXAM**

Yes, there is something to do after the exam. Most people return home, throw their exam “kits” into the corner, and collapse. A week later, when they can bear to think about the experience again, they start integrating their exam kits back into their normal lives. The calculators go back into the desk, the books go back on the shelves, the \$5.00 in change goes back into the piggy bank, and all of the miscellaneous stuff you brought with you to the exam is put back wherever it came.

Here is what I suggest you do as soon as you get home.

- [ ] Thank your spouse and children for helping you during your preparation.
- [ ] Take any paperwork you received on exam day out of your pocket, purse, or wallet. Put this inside your *Civil Engineering Reference Manual*.
- [ ] Reflect on any statements regarding exam secrecy to which you signed your agreement in the exam.
- [ ] If you participated in a PPI Passing Zone, log on one last time to thank the instructors. (Passing Zones remain open for a week after the exam.)
- [ ] Call your employer and tell him/her that you need to take a mental health day off on Monday.

A few days later, when you can face the world again, do the following.

- [ ] Make notes about anything you would do differently if you had to take the exam over again.
- [ ] Consolidate all of your application paperwork, correspondence to/from your state, and any paperwork that you received on exam day.
- [ ] If you took a live review course, call or email the instructor (or write a note) to say, “Thanks.”
- [ ] Return any books you borrowed.
- [ ] Write thank-you notes to all of the people who wrote letters of recommendation or reference for you.

- [ ] Find and read the chapter in this book that covers ethics. There were no ethics questions on your PE exam, but it does not make any difference. Ethical behavior is expected of a PE in any case. Spend a few minutes reflecting on how your performance (obligations, attitude, presentation, behavior, appearance, etc.) might be about to change once you are licensed. Consider how you are going to be a role model for others around you.
- [ ] Put all of your review books, binders, and notes someplace where they will be out of sight.

### **FINALLY**

By the time you have “undone” all of your preparations, you might have thought of a few things that could help future examinees. If you have any sage comments about how to prepare, any suggestions about what to do in or bring to the exam, any comments on how to improve this book, or any funny anecdotes about your experience, I hope you will share these with me. By this time, you will be the “expert,” and I will be your biggest fan.

### **AND THEN, THERE'S THE WAIT ...**

Waiting for the exam results is its own form of mental torture.

Yes, I know the exam is 100% multiple-choice, and grading should be almost instantaneous. But, you are going to wait, nevertheless. There are many reasons for the delay.

Although the actual machine grading “only takes seconds,” consider the following facts: (a) NCEES prepares multiple exams for each administration, in case one becomes unusable (i.e., is inappropriately released) before the exam date. (b) Since the actual version of the exam used is not known until after it is finally given, the cut score determination occurs after the exam date.

I would not be surprised to hear that NCEES receives dozens, if not hundreds, of claims from well-meaning examinees who were 100% certain that the exams they took were seriously flawed to some degree—that there was not a correct answer for such-and-such question, that there were two answers for such-and-such question, or even, perhaps, that such-and-such question was missing from their examination booklet altogether. Each of these claims must be considered as a potential adjustment to the cut score.

Then, the exams must actually be graded. Since grading nearly 50,000 exams (counting all the FE and PE exams) requires specialized equipment, software, and training not normally possessed by the average employee, as well as time to do the work (also not normally possessed by the average employee), grading is invariably outsourced.

Outsourced grading cannot begin until all of the states have returned their score sheets to NCEES and NCEES has sorted, separated, organized, and consolidated the score sheets into whatever “secret sauce sequence” is best. During grading, some of the score sheets “pop out” with any number of abnormalities that demand manual scoring.

After the individual exams are scored, the results are analyzed in a variety of ways. Some of the analysis looks at passing rates by such delineators as degree, major, university, site, and state. Part of the analysis looks for similarities between physically adjacent examinees (to look for cheating). Part of the analysis looks for examination sites that have statistically abnormal group performance. And, some of the analysis looks for exam questions that have a disproportionate fraction of successful or unsuccessful examinees. Anyway, you get the idea: Grading is not merely a matter of putting your examination booklet and answer sheet in an electronic reader. All of these steps have to be completed for 100% of the examinees before any results can be delivered.

Once NCEES has graded your test and notified your state, when you hear about it depends on when the work is done by your state. Some states have to approve the results at a board meeting; others prepare the certificates before sending out notifications. Some states are more computerized than others. Some states have 50 examinees, while others have 10,000. Some states are shut down by blizzards and hurricanes; others are administratively challenged—understaffed, inadequately trained, or over budget.

There is no pattern to the public release of results. None. The exam results are not released to all states simultaneously. (The states with the fewest examinees often receive their results soonest.) They are not released by discipline. They are not released alphabetically by state or examinee name. The examinees who did not pass are not notified first (or last). Your coworker might receive his or her notification today, and you might be waiting another three weeks for yours.

Some states post the names of the successful examinees, or unsuccessful examinees, or both on their official state websites before the results go out. Others update their websites after the results go out. Some states do not list much of anything on their websites.

Remember, too, that the size or thickness of the envelope you receive from your state does not mean anything. Some states send a big congratulations package and certificate. Others send a big package with a new application to repeat the exam. Some states send a postcard. Some send a one-page letter. Some states send you an invoice for your license fees. (Ahh, what a welcome bill!) You just have to open it to find out.

Check the Engineering Exam Forum on the PPI website regularly to find out which states have released their results. You will find many other anxious examinees there and any number of humorous conspiracy theories and rumors.

While you are waiting, I hope you will become a “Forum” regular. Log on often and help other examinees by sharing your knowledge, experiences, and wisdom.

### **AND WHEN YOU PASS ...**

---

- [ ] Celebrate.
- [ ] Notify the people who wrote letters of recommendation or reference for you.
- [ ] Read “FAQs about What Happens After You Pass the Exam” on PPI’s website.
- [ ] Ask your employer for a raise.
- [ ] Tell the folks at PPI (who have been rootin’ for you all along) the good news.

20. Dimensional Analysis .....	1-8

## 1. INTRODUCTION

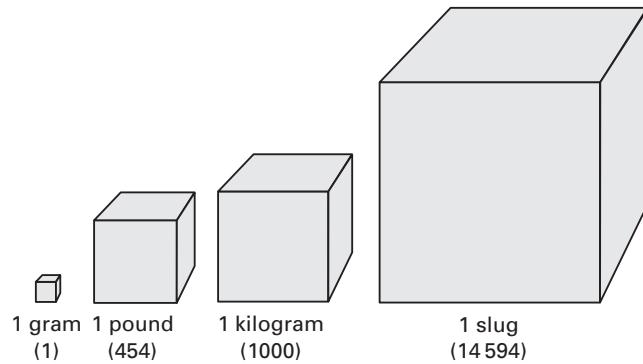

The purpose of this chapter is to eliminate some of the confusion regarding the many units available for each engineering variable. In particular, an effort has been made to clarify the use of the so-called English systems, which for years have used the *pound* unit both for force and mass—a practice that has resulted in confusion even for those familiar with it.

## 2. COMMON UNITS OF MASS

The choice of a mass unit is the major factor in determining which system of units will be used in solving a problem. It is obvious that one will not easily end up with a force in pounds if the rest of the problem is stated in meters and kilograms. Actually, the choice of a mass unit determines more than whether a conversion factor will be necessary to convert from one system to another (e.g., between SI and English units). An inappropriate choice of a mass unit may actually require a conversion factor *within* the system of units.

The common units of mass are the gram, pound, kilogram, and slug.<sup>1</sup> There is nothing mysterious about these units. All represent different quantities of matter, as Fig. 1.1 illustrates. In particular, note that the pound and slug do not represent the same quantity of matter.<sup>2</sup>

**Figure 1.1** Common Units of Mass

## 3. MASS AND WEIGHT

In SI, *kilograms* are used for mass and *newtons* for weight (force). The units are different, and there is no confusion between the variables. However, for years the term *pound* has been used for both mass and weight. This usage has obscured the distinction between the two: mass is a constant property of an object; weight varies with the gravitational field. Even the conventional use of the abbreviations *lbm* and *lbf* (to distinguish between pounds-mass and pounds-force) has not helped eliminate the confusion.

It is true that an object with a mass of one pound will have an earthly weight of one pound, but this is true only on the earth. The weight of the same object will be much less on the moon. Therefore, care must be taken when working with mass and force in the same problem.

The relationship that converts mass to weight is familiar to every engineering student.

$$W = mg \quad 1.1$$

<sup>1</sup>Normally, one does not distinguish between a unit and a multiple of that unit, as is done here with the gram and the kilogram. However, these two units actually are bases for different consistent systems.

<sup>2</sup>A slug is approximately equal to 32.1740 pounds-mass.

Equation 1.1 illustrates that an object's weight will depend on the local acceleration of gravity as well as the object's mass. The mass will be constant, but gravity will depend on location. Mass and weight are not the same.

#### 4. ACCELERATION OF GRAVITY

Gravitational acceleration on the earth's surface is usually taken as 32.2 ft/sec<sup>2</sup> or 9.81 m/s<sup>2</sup>. These values are rounded from the more precise values of 32.1740 ft/sec<sup>2</sup> and 9.80665 m/s<sup>2</sup>. However, the need for greater accuracy must be evaluated on a problem-by-problem basis. Usually, three significant digits are adequate, since gravitational acceleration is not constant anyway but is affected by location (primarily latitude and altitude) and major geographical features.

The term *standard gravity*,  $g_0$ , is derived from the acceleration at essentially any point at sea level and approximately 45° N latitude. If additional accuracy is needed, the gravitational acceleration can be calculated from Eq. 1.2. This equation neglects the effects of large land and water masses.  $\phi$  is the latitude in degrees.

$$\begin{aligned} g_{\text{surface}} &= g' \left( 1 + (5.3024 \times 10^{-3}) \sin^2 \phi \right. \\ &\quad \left. - (5.8 \times 10^{-6}) \sin^2 2\phi \right) \\ g' &= 32.08769 \text{ ft/sec}^2 \\ &= 9.780327 \text{ m/s}^2 \end{aligned} \quad 1.2$$

If the effects of the earth's rotation are neglected, the gravitational acceleration at an altitude  $h$  above the earth's surface is given by Eq. 1.3.  $r_e$  is the earth's radius.

$$\begin{aligned} g_h &= g_{\text{surface}} \left( \frac{r_e}{r_e + h} \right)^2 \\ r_e &= 3959 \text{ mi} \\ &= 6.3781 \times 10^6 \text{ m} \end{aligned} \quad 1.3$$

#### 5. CONSISTENT SYSTEMS OF UNITS

A set of units used in a calculation is said to be *consistent* if no conversion factors are needed.<sup>3</sup> For example, a moment is calculated as the product of a force and a lever arm length.

$$M = Fr \quad 1.4$$

A calculation using Eq. 1.4 would be consistent if  $M$  was in newton-meters,  $F$  was in newtons, and  $r$  was in meters. The calculation would be inconsistent if  $M$  was in ft-kips,  $F$  was in kips, and  $r$  was in inches (because a conversion factor of 1/12 would be required).

<sup>3</sup>The terms *homogeneous* and *coherent* are also used to describe a consistent set of units.

The concept of a consistent calculation can be extended to a system of units. A *consistent system of units* is one in which no conversion factors are needed for any calculation. For example, Newton's second law of motion can be written without conversion factors. Newton's second law simply states that the force required to accelerate an object is proportional to the acceleration of the object. The constant of proportionality is the object's mass.

$$F = ma \quad 1.5$$

Equation 1.5 is  $F = ma$ , not  $F = Wa/g$  or  $F = ma/g_c$ . Equation 1.5 is consistent: it requires no conversion factors. This means that in a consistent system where conversion factors are not used, once the units of  $m$  and  $a$  have been selected, the units of  $F$  are fixed. This has the effect of establishing units of work and energy, power, fluid properties, and so on.

The decision to work with a consistent set of units is desirable but not necessary. Problems in fluid flow and thermodynamics are routinely solved in the United States with inconsistent units. This causes no more of a problem than working with inches and feet when calculating a moment. It is necessary only to use the proper conversion factors.

#### 6. THE ENGLISH ENGINEERING SYSTEM

Through common and widespread use, pounds-mass (lbm) and pounds-force (lbf) have become the standard units for mass and force in the *English Engineering System*. (The English Engineering System is used in this book.)

There are subjects in the United States in which the use of pounds for mass is firmly entrenched. For example, most thermodynamics, fluid flow, and heat transfer problems have traditionally been solved using the units of lbm/ft<sup>3</sup> for density, Btu/lbm for enthalpy, and Btu/lbm·°F for specific heat. Unfortunately, some equations contain both lbm-related and lbf-related variables, as does the steady flow conservation of energy equation, which combines enthalpy in Btu/lbm with pressure in lbf/ft<sup>2</sup>.

The units of pounds-mass and pounds-force are as different as the units of gallons and feet, and they cannot be canceled. A mass conversion factor,  $g_c$ , is needed to make the equations containing lbf and lbm dimensionally consistent. This factor is known as the *gravitational constant* and has a value of 32.1740 lbm-ft/lbf-sec<sup>2</sup>. The numerical value is the same as the standard acceleration of gravity, but  $g_c$  is not the local gravitational acceleration,  $g$ .<sup>4</sup>  $g_c$  is a conversion constant, just as 12.0 is the conversion factor between feet and inches.

The English Engineering System is an inconsistent system as defined according to Newton's second law.

<sup>4</sup>It is acceptable (and recommended) that  $g_c$  be rounded to the same number of significant digits as  $g$ . Therefore, a value of 32.2 for  $g_c$  would typically be used.

$F = ma$  cannot be written if lbf, lbm, and ft/sec<sup>2</sup> are the units used. The  $g_c$  term must be included.

$$F \text{ in lbf} = \frac{(m \text{ in lbm})(a \text{ in } \frac{\text{ft}}{\text{sec}^2})}{g_c \text{ in } \frac{\text{lbm-ft}}{\text{lbf-sec}^2}} \quad 1.6$$

In Eq. 1.6,  $g_c$  does more than "fix the units." Since  $g_c$  has a numerical value of 32.1740, it actually changes the calculation numerically. A force of 1.0 pound will not accelerate a 1.0-pound mass at the rate of 1.0 ft/sec<sup>2</sup>.

In the English Engineering System, work and energy are typically measured in ft-lbf (mechanical systems) or in British thermal units, Btu (thermal and fluid systems). One Btu is equal to 778.17 ft-lbf.

### Example 1.1

Calculate the weight in lbf of a 1.00 lbm object in a gravitational field of 27.5 ft/sec<sup>2</sup>.

*Solution*

From Eq. 1.6,

$$F = \frac{ma}{g_c} = \frac{(1.00 \text{ lbm})(27.5 \frac{\text{ft}}{\text{sec}^2})}{32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2}} \\ = 0.854 \text{ lbf}$$

### 7. OTHER FORMULAS AFFECTED BY INCONSISTENCY

It is not a significant burden to include  $g_c$  in a calculation, but it may be difficult to remember when  $g_c$  should be used. Knowing when to include the gravitational constant can be learned through repeated exposure to the formulas in which it is needed, but it is safer to carry the units along in every calculation.

The following is a representative (but not exhaustive) listing of formulas that require the  $g_c$  term. In all cases, it is assumed that the standard English Engineering System units will be used.

- kinetic energy

$$E = \frac{mv^2}{2g_c} \quad (\text{in ft-lbf}) \quad 1.7$$

- potential energy

$$E = \frac{mgz}{g_c} \quad (\text{in ft-lbf}) \quad 1.8$$

- pressure at a depth

$$p = \frac{\rho gh}{g_c} \quad (\text{in lbf/ft}^2) \quad 1.9$$

### Example 1.2

A rocket that has a mass of 4000 lbm travels at 27,000 ft/sec. What is its kinetic energy in ft-lbf?

*Solution*

From Eq. 1.7,

$$E_k = \frac{mv^2}{2g_c} = \frac{(4000 \text{ lbm})(27,000 \frac{\text{ft}}{\text{sec}})^2}{(2)(32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2})} \\ = 4.53 \times 10^{10} \text{ ft-lbf}$$

### 8. WEIGHT AND WEIGHT DENSITY

Weight,  $W$ , is a force exerted on an object due to its placement in a gravitational field. If a consistent set of units is used, Eq. 1.1 can be used to calculate the weight of a mass. In the English Engineering System, however, Eq. 1.10 must be used.

$$W = \frac{mg}{g_c} \quad 1.10$$

Both sides of Eq. 1.10 can be divided by the volume of an object to derive the *weight density*,  $\gamma$ , of the object. Equation 1.11 illustrates that the weight density (in units of lbf/ft<sup>3</sup>) can also be calculated by multiplying the mass density (in units of lbm/ft<sup>3</sup>) by  $g/g_c$ . Since  $g$  and  $g_c$  usually have the same numerical values, the only effect of Eq. 1.12 is to change the units of density.

$$\frac{W}{V} = \left(\frac{m}{V}\right)\left(\frac{g}{g_c}\right) \quad 1.11$$

$$\gamma = \frac{W}{V} = \left(\frac{m}{V}\right)\left(\frac{g}{g_c}\right) = \frac{\rho g}{g_c} \quad 1.12$$

Weight does not occupy volume. Only mass has volume. The concept of weight density has evolved to simplify certain calculations, particularly fluid calculations. For example, pressure at a depth is calculated from Eq. 1.13. (Compare this with Eq. 1.9.)

$$p = \gamma h \quad 1.13$$

### 9. THE ENGLISH GRAVITATIONAL SYSTEM

Not all English systems are inconsistent. Pounds can still be used as the unit of force as long as pounds are not used as the unit of mass. Such is the case with the consistent *English Gravitational System*.

If acceleration is given in ft/sec<sup>2</sup>, the units of mass for a consistent system of units can be determined from Newton's second law. The combination of units in Eq. 1.14 is known as a *slug*.  $g_c$  is not needed at all since this system

is consistent. It would be needed only to convert slugs to another mass unit.

$$\text{units of } m = \frac{\text{units of } F}{\text{units of } a} = \frac{\text{lbf}}{\frac{\text{ft}}{\text{sec}^2}} = \frac{\text{lbf}\cdot\text{sec}^2}{\text{ft}} \quad 1.14$$

Slugs and pounds-mass are not the same, as Fig. 1.1 illustrates. However, both are units for the same quantity: mass. Equation 1.15 will convert between slugs and pounds-mass.

$$\text{no. of slugs} = \frac{\text{no. of lbm}}{g_c} \quad 1.15$$

The number of slugs is not derived by dividing the number of pounds-mass by the local gravity.  $g_c$  is used regardless of the local gravity. The conversion between feet and inches is not dependent on local gravity; neither is the conversion between slugs and pounds-mass.

Since the English Gravitational System is consistent, Eq. 1.16 can be used to calculate weight. The local gravitational acceleration is used.

$$W \text{ in lbf} = (m \text{ in slugs}) \left( g \text{ in } \frac{\text{ft}}{\text{sec}^2} \right) \quad 1.16$$

## 10. THE ABSOLUTE ENGLISH SYSTEM

The obscure *Absolute English System* takes the approach that mass must have units of pounds-mass (lbm) and the units of force can be derived from Newton's second law. The units for  $F$  cannot be simplified any more than they are in Eq. 1.17. This particular combination of units is known as a *poundal*.<sup>5</sup> A poundal is not the same as a pound.

$$\begin{aligned} \text{units of } F &= (\text{units of } m)(\text{units of } a) \\ &= (\text{lbm}) \left( \frac{\text{ft}}{\text{sec}^2} \right) \\ &= \frac{\text{lbm}\cdot\text{ft}}{\text{sec}^2} \end{aligned} \quad 1.17$$

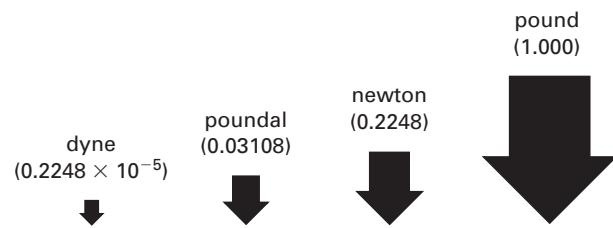

Poundals have not seen widespread use in the United States. The English Gravitational System (using slugs for mass) has greatly eclipsed the Absolute English System in popularity. Both are consistent systems, but there seems to be little need for poundals in modern engineering. Figure 1.2 shows the poundal in comparison to other common units of force.

## 11. METRIC SYSTEMS OF UNITS

Strictly speaking, a *metric system* is any system of units that is based on meters or parts of meters. This broad definition includes *mks systems* (based on meters,

<sup>5</sup>A poundal is equal to 0.03108 pounds-force.

Figure 1.2 Common Force Units

kilograms, and seconds) as well as *cgs systems* (based on centimeters, grams, and seconds).

Metric systems avoid the pounds-mass versus pounds-force ambiguity in two ways. First, a unit of weight is not established at all. All quantities of matter are specified as mass. Second, force and mass units do not share a common name.

The term *metric system* is not explicit enough to define which units are to be used for any given variable. For example, within the cgs system there is variation in how certain electrical and magnetic quantities are represented (resulting in the ESU and EMU systems). Also, within the mks system, it is common practice in some industries to use kilocalories as the unit of thermal energy, while the SI unit for thermal energy is the joule. This shows a lack of uniformity even within the metricated engineering community.<sup>6</sup>

The “metric” parts of this book use SI, which is the most developed and codified of the so-called metric systems.<sup>7</sup> There will be occasional variances with local engineering custom, but it is difficult to anticipate such variances within a book that must itself be consistent.

## 12. THE cgs SYSTEM

The cgs system is used widely by chemists and physicists. It is named for the three primary units used to construct its derived variables: the centimeter, the gram, and the second.

When Newton's second law is written in the cgs system, the following combination of units results.

$$\begin{aligned} \text{units of force} &= (m \text{ in g}) \left( a \text{ in } \frac{\text{cm}}{\text{s}^2} \right) \\ &= \text{g}\cdot\text{cm}/\text{s}^2 \end{aligned} \quad 1.18$$

<sup>6</sup>In the “field test” of the metric system conducted over the past 200 years, other conventions are to use kilograms-force (kgf) instead of newtons and kgf/cm<sup>2</sup> for pressure (instead of pascals).

<sup>7</sup>SI units are an outgrowth of the *General Conference of Weights and Measures*, an international treaty organization that established the *Système International d'Unités* (*International System of Units*) in 1960. The United States subscribed to this treaty in 1975.

This combination of units for force is known as a *dyne*. Energy variables in the cgs system have units of dyne·cm or, equivalently, g·cm<sup>2</sup>/s<sup>2</sup>. This combination is known as an *erg*. There is no uniformly accepted unit of power in the cgs system, although calories per second is frequently used.

The fundamental volume unit in the cgs system is the cubic centimeter (cc). Since this is the same volume as one thousandth of a liter, units of milliliters (mL) are also used.

### 13. SI UNITS (THE mks SYSTEM)

*SI units* comprise an *mks system* (so named because it uses the meter, kilogram, and second as base units). All other units are derived from the base units, which are completely listed in Table 1.1. This system is fully consistent, and there is only one recognized unit for each physical quantity (variable).

**Table 1.1** SI Base Units

quantity	name	symbol
length	meter	m
mass	kilogram	kg
time	second	s
electric current	ampere	A
temperature	kelvin	K
amount of substance	mole	mol
luminous intensity	candela	cd

Two types of units are used: base units and derived units. The *base units* are dependent only on accepted standards or reproducible phenomena. The *derived units* (Table 1.2 and Table 1.3) are made up of combinations of base units. Prior to 1995, radians and steradians were classified as *supplementary units*.

In addition, there is a set of non-SI units that may be used. This concession is primarily due to the significance and widespread acceptance of these units. Use of the non-SI units listed in Table 1.4 will usually create an inconsistent expression requiring conversion factors.

The SI unit of force can be derived from Newton's second law. This combination of units for force is known as a *newton*.

$$\text{units of force} = (m \text{ in kg}) \left( a \text{ in } \frac{\text{m}}{\text{s}^2} \right) \\ = \text{kg} \cdot \text{m/s}^2 \quad 1.19$$

Energy variables in SI units have units of N·m or, equivalently, kg·m<sup>2</sup>/s<sup>2</sup>. Both of these combinations are known as a *joule*. The units of power are joules per second, equivalent to a *watt*.

**Table 1.2** Some SI Derived Units with Special Names

quantity	name	symbol	expressed in terms of other units
frequency	hertz	Hz	1/s
force	newton	N	kg·m/s <sup>2</sup>
pressure, stress	pascal	Pa	N/m <sup>2</sup>
energy, work, quantity of heat	joule	J	N·m
power, radiant flux	watt	W	J/s
quantity of electricity, electric charge	coulomb	C	
electric potential, potential difference, electromotive force	volt	V	W/A
electric capacitance	farad	F	C/V
electric resistance	ohm	Ω	V/A
electric conductance	siemens	S	A/V
magnetic flux	weber	Wb	V·s
magnetic flux density	tesla	T	Wb/m <sup>2</sup>
inductance	henry	H	Wb/A
luminous flux	lumen	lm	
illuminance	lux	lx	lm/m <sup>2</sup>
plane angle	radian	rad	—
solid angle	steradian	sr	—

### Example 1.3

A 10 kg block hangs from a cable. What is the tension in the cable? (Standard gravity equals 9.81 m/s<sup>2</sup>.)

*Solution*

$$F = mg \\ = (10 \text{ kg}) \left( 9.81 \frac{\text{m}}{\text{s}^2} \right) \\ = 98.1 \text{ kg} \cdot \text{m/s}^2 \quad (98.1 \text{ N})$$

### Example 1.4

A 10 kg block is raised vertically 3 m. What is the change in potential energy?

*Solution*

$$\Delta E_p = mg\Delta h \\ = (10 \text{ kg}) \left( 9.81 \frac{\text{m}}{\text{s}^2} \right) (3 \text{ m}) \\ = 294 \text{ kg} \cdot \text{m}^2/\text{s}^2 \quad (294 \text{ J})$$

### 14. RULES FOR USING SI UNITS

In addition to having standardized units, the set of SI units also has rigid syntax rules for writing the units and combinations of units. Each unit is abbreviated with a

**Table 1.3** Some SI Derived Units

quantity	description	symbol
area	square meter	$\text{m}^2$
volume	cubic meter	$\text{m}^3$
speed—linear	meter per second	$\text{m}/\text{s}$
speed—angular	radian per second	$\text{rad}/\text{s}$
acceleration—linear	meter per second squared	$\text{m}/\text{s}^2$
acceleration—angular	radian per second squared	$\text{rad}/\text{s}^2$
density, mass density	kilogram per cubic meter	$\text{kg}/\text{m}^3$
concentration (of amount of substance)	mole per cubic meter	$\text{mol}/\text{m}^3$
specific volume	cubic meter per kilogram	$\text{m}^3/\text{kg}$
luminance	candela per square meter	$\text{cd}/\text{m}^2$
absolute viscosity	pascal second	$\text{Pa}\cdot\text{s}$
kinematic viscosity	square meters per second	$\text{m}^2/\text{s}$
moment of force	newton meter	$\text{N}\cdot\text{m}$
surface tension	newton per meter	$\text{N}/\text{m}$
heat flux density, irradiance	watt per square meter	$\text{W}/\text{m}^2$
heat capacity, entropy	joule per kelvin	$\text{J}/\text{K}$
specific heat capacity, specific entropy	joule per kilogram kelvin	$\text{J}/\text{kg}\cdot\text{K}$
specific energy	joule per kilogram	$\text{J}/\text{kg}$
thermal conductivity	watt per meter kelvin	$\text{W}/\text{m}\cdot\text{K}$
energy density	joule per cubic meter	$\text{J}/\text{m}^3$
electric field strength	volt per meter	$\text{V}/\text{m}$
electric charge density	coulomb per cubic meter	$\text{C}/\text{m}^3$
surface density of charge, flux density	coulomb per square meter	$\text{C}/\text{m}^2$
permittivity	farad per meter	$\text{F}/\text{m}$
current density	ampere per square meter	$\text{A}/\text{m}^2$
magnetic field strength	ampere per meter	$\text{A}/\text{m}$
permeability	henry per meter	$\text{H}/\text{m}$
molar energy	joule per mole	$\text{J}/\text{mol}$
molar entropy, molar heat capacity	joule per mole kelvin	$\text{J}/\text{mol}\cdot\text{K}$
radiant intensity	watt per steradian	$\text{W}/\text{sr}$

specific symbol. The following rules for writing and combining these symbols should be adhered to.

- The expressions for derived units in symbolic form are obtained by using the mathematical signs of multiplication and division. For example, units of velocity are  $\text{m}/\text{s}$ . Units of torque are  $\text{N}\cdot\text{m}$  (not  $\text{N}\cdot\text{m}$  or  $\text{Nm}$ ).
- Scaling of most units is done in multiples of 1000.

**Table 1.4** Acceptable Non-SI Units

quantity	unit name	symbol or abbreviation	relationship to SI unit
area	hectare	ha	$1 \text{ ha} = 10000 \text{ m}^2$
energy	kilowatt-hour	$\text{kW}\cdot\text{h}$	$1 \text{ kW}\cdot\text{h} = 3.6 \text{ MJ}$
mass	metric ton <sup>a</sup>	t	$1 \text{ t} = 1000 \text{ kg}$
plane angle	degree (of arc)	°	$1^\circ = 0.017453 \text{ rad}$
speed of rotation	revolution per minute	$\text{r}/\text{min}$	$1 \text{ r}/\text{min} = 2\pi/60 \text{ rad/s}$
temperature interval	degree Celsius	°C	$1^\circ\text{C} = 1\text{K}$
time	minute	min	$1 \text{ min} = 60 \text{ s}$
	hour	h	$1 \text{ h} = 3600 \text{ s}$
	day (mean solar)	d	$1 \text{ d} = 86400 \text{ s}$
	year (calendar)	a	$1 \text{ a} = 31536000 \text{ s}$
velocity	kilometer per hour	$\text{km}/\text{h}$	$1 \text{ km}/\text{h} = 0.278 \text{ m/s}$
volume	liter <sup>b</sup>	L	$1 \text{ L} = 0.001 \text{ m}^3$

<sup>a</sup>The international name for metric ton is *tonne*. The metric ton is equal to the *megagram* (Mg).

<sup>b</sup>The international symbol for liter is the lowercase l, which can be easily confused with the numeral 1. Several English-speaking countries have adopted the script ℥ or uppercase L (as does this book) as a symbol for liter in order to avoid any misinterpretation.

- The symbols are always printed in roman type, regardless of the type used in the rest of the text. The only exception to this is in the use of the symbol for liter, where the use of the lower case “el” (l) may be confused with the numeral one (1). In this case, “liter” should be written out in full, or the script ℥ or L used. (L is used in this book.)
- Symbols are not pluralized: 45 kg (not 45 kgs).
- A period after a symbol is not used, except when the symbol occurs at the end of a sentence.
- When symbols consist of letters, there must always be a full space between the quantity and the symbols: 45 kg (not 45kg). However, for planar angle designations, no space is left:  $42^\circ 12' 45''$  (not  $42^\circ 12' 45''$ ).
- All symbols are written in lowercase, except when the unit is derived from a proper name: m for meter, s for second, A for ampere, Wb for weber, N for newton, W for watt.
- Prefixes are printed without spacing between the prefix and the unit symbol (e.g., km is the symbol for kilometer). Table 1.5 lists common prefixes, their symbols, and their values.
- In text, when no number is involved, the unit should be spelled out. Example: Carpet is sold by the square meter, not by the  $\text{m}^2$ .
- Where a decimal fraction of a unit is used, a zero should always be placed before the decimal marker: 0.45 kg (not .45 kg). This practice draws attention to the decimal marker and helps avoid errors of scale.

- A practice in some countries is to use a comma as a decimal marker, while the practice in North America, the United Kingdom, and some other countries is to use a period as the decimal marker. Furthermore, in some countries that use the decimal comma, a period is frequently used to divide long numbers into groups of three. Because of these differing practices, spaces must be used instead of commas to separate long lines of digits into easily readable blocks of three digits with respect to the decimal marker: 32 453.246 072 5. A space (half-space preferred) is optional with a four-digit number: 1 234 or 1234.
- The word *ton* has multiple meanings. In the United States and Canada, the *short ton* of 2000 lbm (907.18 kg; 8896.44 N) is used. Previously, for commerce within the United Kingdom, a *long ton* of 2240 lbm (1016.05 kg) was used. A *metric ton* (or, *tonne*) is 1000 kg ( $10^6$  Mg; 2205 lbm). In air conditioning industries, a *ton of refrigeration* is equivalent to a cooling rate of 200 Btu/min (12,000 Btu/hr). For explosives, a *ton of explosive power* is approximately the energy given off by 2000 lbm of TNT, standardized by international convention as  $10^9$  cal (1 Gcal; 4.184 GJ) for both “ton” and “tonne” designations. Various definitions are used in shipping, where *freight ton* (*measurement ton* or MTON) refers to volume, usually 40 ft<sup>3</sup>. Many other specialty definitions are also in use.

**Table 1.5** SI Prefixes\*

prefix	symbol	value
exa	E	$10^{18}$
peta	P	$10^{15}$
tera	T	$10^{12}$
giga	G	$10^9$
mega	M	$10^6$
kilo	k	$10^3$
hecto	h	$10^2$
deka (or deca)	da	$10^1$
deci	d	$10^{-1}$
centi	c	$10^{-2}$
milli	m	$10^{-3}$
micro	$\mu$	$10^{-6}$
nano	n	$10^{-9}$
pico	p	$10^{-12}$
femto	f	$10^{-15}$
atto	a	$10^{-18}$

\*There is no “B” (billion) prefix. In fact, the word “billion” means  $10^9$  in the United States but  $10^{12}$  in most other countries. This unfortunate ambiguity is handled by avoiding the use of the term “billion.”

## 15. UNCOMMON UNITS ENCOUNTERED IN THE UNITED STATES

Table 1.6 lists some units and their abbreviations that may be encountered in the United States. These units are found in specific industries and engineering specialty areas. In some cases, they may be archaic.

**Table 1.6** Uncommon Units Encountered in the United States (by abbreviation)

abbreviation or symbol	meaning
$\text{G}$	reciprocal of ohms (SI siemens)
$\square'$	square feet
$\square$	square feet
barn	area of a uranium nucleus ( $10^{-28}$ square meters)
BeV	billions ( $10^9$ ) of electron-volts (SI GeV)
csf	hundreds of square feet
kBh	thousands of Btus per hour (ambiguous)
MBh	thousands of Btus per hour (ambiguous)
MeV	millions ( $10^6$ ) of electron volts
mho	reciprocal of ohms (SI siemens)
MMBtuh	millions ( $10^6$ ) of Btus per hour
square	100 square feet (roofing)

## 16. PRIMARY DIMENSIONS

Regardless of the system of units chosen, each variable representing a physical quantity will have the same *primary dimensions*. For example, velocity may be expressed in miles per hour (mph) or meters per second (m/s), but both units have dimensions of length per unit time. Length and time are two of the primary dimensions, as neither can be broken down into more basic dimensions. The concept of primary dimensions is useful when converting little-used variables between different systems of units, as well as in correlating experimental results (i.e., dimensional analysis).

There are three different sets of primary dimensions in use.<sup>8</sup> In the *MLθT* system, the primary dimensions are mass (*M*), length (*L*), time ( $\theta$ ), and temperature (*T*). All symbols are uppercase. In order to avoid confusion between time and temperature, the Greek letter theta is used for time.<sup>9</sup>

All other physical quantities can be derived from these primary dimensions.<sup>10</sup> For example, work in SI units has units of N·m. Since a newton is a kg·m/s<sup>2</sup>, the primary dimensions of work are *ML<sup>2</sup>/θ<sup>2</sup>*. The primary dimensions for many important engineering variables are shown in Table 1.7. If it is more convenient to stay with traditional English units, it may be more desirable to work in the *FMLθTQ* system (sometimes called the *engineering dimensional system*). This system adds the primary dimensions of force (*F*) and heat (*Q*). Work (ft-lbf in the English system) has the primary dimensions of *FL*.

<sup>8</sup>One of these, the *FLθT* system, is not discussed here.

<sup>9</sup>This is the most common usage. There is a lack of consistency in the engineering world about the symbols for the primary dimensions in dimensional analysis. Some writers use *t* for time instead of  $\theta$ . Some use *H* for heat instead of *Q*. And, in the worst mix-up of all, some have reversed the use of *T* and  $\theta$ .

<sup>10</sup>A *primary dimension* is the same as a *base unit* in the SI set of units. The SI units add several other base units, as shown in Table 1.1, to deal with variables that are difficult to derive in terms of the four primary base units.

**Table 1.7** Dimensions of Common Variables

variable (common symbol)	dimensional system		
	$ML\theta T$	$FL\theta T$	$FML\theta TQ$
mass ( $m$ )	$M$	$F\theta^2/L$	$M$
force ( $F$ )	$ML/\theta^2$	$F$	$F$
length ( $L$ )	$L$	$L$	$L$
time ( $\theta$ or $t$ )	$\theta$	$\theta$	$\theta$
temperature ( $T$ )	$T$	$T$	$T$
work ( $W$ )	$ML^2/\theta^2$	$FL$	$FL$
heat ( $Q$ )	$ML^2/\theta^2$	$FL$	$Q$
acceleration ( $a$ )	$L/\theta^2$	$L/\theta^2$	$L/\theta^2$
frequency ( $n$ or $f$ )	$1/\theta$	$1/\theta$	$1/\theta$
area ( $A$ )	$L^2$	$L^2$	$L^2$
coefficient of thermal expansion ( $\beta$ )	$1/T$	$1/T$	$1/T$
density ( $\rho$ )	$M/L^3$	$F\theta^2/L^4$	$M/L^3$
dimensional constant ( $g_c$ )	1.0	1.0	$ML/\theta^2 F$
specific heat at constant pressure ( $c_p$ ); at constant volume ( $c_v$ )	$L^2/\theta^2 T$	$L^2/\theta^2 T$	$Q/MT$
heat transfer coefficient ( $h$ ); overall ( $U$ )	$M/\theta^3 T$	$F/\theta LT$	$Q/\theta L^2 T$
power ( $P$ )	$ML^2/\theta^3$	$FL/\theta$	$FL/\theta$
heat flow rate ( $\dot{Q}$ )	$ML^2/\theta^3$	$FL/\theta$	$Q/\theta$
kinematic viscosity ( $\nu$ )	$L^2/\theta$	$L^2/\theta$	$L^2/\theta$
mass flow rate ( $\dot{m}$ )	$M/\theta$	$F\theta/L$	$M/\theta$
mechanical equivalent of heat ( $J$ )	—	—	$FL/Q$
pressure ( $p$ )	$M/L\theta^2$	$F/L^2$	$F/L^2$
surface tension ( $\sigma$ )	$M/\theta^2$	$F/L$	$F/L$
angular velocity ( $\omega$ )	$1/\theta$	$1/\theta$	$1/\theta$
volumetric flow rate ( $\dot{m}/\rho = \dot{V}$ )	$L^3/\theta$	$L^3/\theta$	$L^3/\theta$
conductivity ( $k$ )	$ML/\theta^3 T$	$F/\theta T$	$Q/L\theta T$
thermal diffusivity ( $\alpha$ )	$L^2/\theta$	$L^2/\theta$	$L^2/\theta$
velocity ( $v$ )	$L/\theta$	$L/\theta$	$L/\theta$
viscosity, absolute ( $\mu$ )	$M/L\theta$	$F\theta/L^2$	$F\theta/L^2$
volume ( $V$ )	$L^3$	$L^3$	$L^3$

(Compare this with the primary dimensions for work in the  $ML\theta T$  system.) Thermodynamic variables are similarly simplified.

Dimensional analysis will be more conveniently carried out when one of the four-dimension systems ( $ML\theta T$  or  $FL\theta T$ ) is used. Whether the  $ML\theta T$ ,  $FL\theta T$ , or  $FML\theta TQ$  system is used depends on what is being derived and who will be using it, and whether or not a consistent set of variables is desired. Conversion constants such as  $g_c$  and  $J$  will almost certainly be required if the  $ML\theta T$  system is used to generate variables for use in the English systems. It is also much more convenient to use the  $FML\theta TQ$  system when working in the fields of thermodynamics, fluid flow, heat transfer, and so on.

## 17. DIMENSIONLESS GROUPS

A dimensionless group is derived as a ratio of two forces or other quantities. Considerable use of dimensionless groups is made in certain subjects, notably fluid mechanics and heat transfer. For example, the Reynolds number, Mach number, and Froude number are used to distinguish between distinctly different flow regimes in pipe flow, compressible flow, and open channel flow, respectively.

Table 1.8 contains information about the most common dimensionless groups used in fluid mechanics and heat transfer.

## 18. LINEAL AND BOARD FOOT MEASUREMENTS

The term *lineal* is often mistaken as a typographical error for *linear*. Although “lineal” has its own specific meaning very different from “linear,” the two are often used interchangeably by engineers.<sup>11</sup> The adjective *lineal* is often encountered in the building trade (e.g., 12 lineal feet of lumber), where the term is used to distinguish it from board feet measurement.

A *board foot* (abbreviated bd-ft) is not a measure of length. Rather, it is a measure of volume used with lumber. Specifically, a board foot is equal to 144 in<sup>3</sup> ( $2.36 \times 10^{-3} \text{ m}^3$ ). The name is derived from the volume of a board 1 foot square and 1 inch thick. In that sense, it is parallel in concept to the acre-foot. Since lumber cost is directly related to lumber weight and volume, the board foot unit is used in determining the overall lumber cost.

## 19. AREAL MEASUREMENTS

*Areal* is an adjective that means “per unit area.” For example, “areal bolt density” is the number of bolts per unit area. In computer work, the *areal density* of a magnetic disk is the number of bits per square inch (square centimeter).

## 20. DIMENSIONAL ANALYSIS

*Dimensional analysis* is a means of obtaining an equation that describes some phenomenon without understanding the mechanism of the phenomenon. The most serious limitation is the need to know beforehand which variables influence the phenomenon. Once these are known or assumed, dimensional analysis can be applied by a routine procedure.

The first step is to select a system of primary dimensions. (See Sec. 1.16.) Usually the  $ML\theta T$  system is used, although this choice may require the use of  $g_c$  and  $J$  in the final results.

<sup>11</sup> *Lineal* is best used when discussing a line of succession (e.g., a lineal descendant of a particular person). *Linear* is best used when discussing length (e.g., a linear dimension of a room).

**Table 1.8** Common Dimensionless Groups

name	symbol	formula	interpretation
Biot number	Bi	$\frac{hL}{k_s}$	$\frac{\text{surface conductance}}{\text{internal conduction of solid}}$
Cauchy number	Ca	$\frac{v^2}{B_s} = \frac{v^2}{\rho a^2}$	$\frac{\text{inertia force}}{\text{compressive force}} = \text{Mach number}^2$
Eckert number	Ec	$\frac{v^2}{2c_p\Delta T}$	$\frac{\text{temperature rise due to energy conversion}}{\text{temperature difference}}$
Eötvös number	Eo	$\frac{\rho g L^2}{\sigma}$	$\frac{\text{buoyancy}}{\text{surface tension}}$

Reynolds number	Re	$\frac{\rho v L}{\mu} = \frac{v L}{\nu}$	$\frac{\text{inertia force}}{\text{viscous force}}$
Schmidt number	Sc	$\frac{\mu}{\rho D_c} = \frac{\nu}{D_c}$	$\frac{\text{diffusion of momentum}}{\text{diffusion of mass}}$
Sherwood number*	Sh	$\frac{k_D L}{D_c}$	$\frac{\text{mass diffusivity}}{\text{molecular diffusivity}}$
Stanton number	St	$\frac{h}{v\rho c_p G} = \frac{h}{c_p G}$	$\frac{\text{heat transfer at wall}}{\text{energy transported by stream}}$
Stokes number	Sk	$\frac{\Delta p L}{\mu v}$	$\frac{\text{pressure force}}{\text{viscous force}}$
Strouhal number*	Sl	$\frac{L}{tv} = \frac{L\omega}{v}$	$\frac{\text{frequency of vibration}}{\text{characteristic frequency}}$
Weber number	We	$\frac{\rho v^2 L}{\sigma}$	$\frac{\text{inertia force}}{\text{surface tension force}}$

\*Multiple definitions exist, most often the square or square root of the formula shown.

The second step is to write a functional relationship between the dependent variable and the independent variable,  $x_i$ .

$$y = f(x_1, x_2, \dots, x_m) \quad 1.20$$

This function can be expressed as an exponentiated series. The  $C_i$ ,  $a_i$ ,  $b_i$ , ...,  $z_i$  in Eq. 1.21 are unknown constants.

$$y = C_1 x_1^{a_1} x_2^{b_1} x_3^{c_1} \cdots x_m^{z_1} + C_2 x_1^{a_2} x_2^{b_2} x_3^{c_2} \cdots x_m^{z_2} + \cdots \quad 1.21$$

The key to solving Eq. 1.21 is that each term on the right-hand side must have the same dimensions as  $y$ . Simultaneous equations are used to determine some of the  $a_i$ ,  $b_i$ ,  $c_i$ , and  $z_i$ . Experimental data are required to determine the  $C_i$  and remaining exponents. In most analyses, it is assumed that the  $C_i = 0$  for  $i \geq 2$ .

Since this method requires working with  $m$  different variables and  $n$  different independent dimensional quantities (such as  $M$ ,  $L$ ,  $\theta$ , and  $T$ ), an easier method is desirable. One simplification is to combine the  $m$  variables into dimensionless groups called *pi-groups*. (See Table 1.7.)

If these dimensionless groups are represented by  $\pi_1$ ,  $\pi_2$ ,  $\pi_3$ , ...,  $\pi_k$ , the equation expressing the relationship between the variables is given by the *Buckingham π-theorem*.

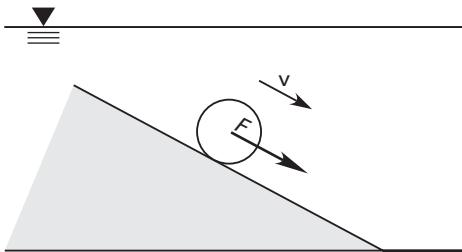

$$f(\pi_1, \pi_2, \pi_3, \dots, \pi_k) = 0 \quad 1.22$$

$$k = m - n \quad 1.23$$

The dimensionless pi-groups are usually found from the  $m$  variables according to an intuitive process.

### Example 1.5

A solid sphere rolls down a submerged incline. Find an equation for the velocity,  $v$ .

### Solution

Assume that the velocity depends on the force,  $F$ , due to gravity, the diameter of the sphere,  $D$ , the density of the fluid,  $\rho$ , and the viscosity of the fluid,  $\mu$ .

$$v = f(F, D, \rho, \mu) = CF^a D^b \rho^c \mu^d$$

This equation can be written in terms of the primary dimensions of the variables.

$$\frac{L}{\theta} = C \left( \frac{ML}{\theta^2} \right)^a L^b \left( \frac{M}{L^3} \right)^c \left( \frac{M}{L\theta} \right)^d$$

Since  $L$  on the left-hand side has an implied exponent of one, a necessary condition is

$$1 = a + b - 3c - d \quad (L)$$

Similarly, the other necessary conditions are

$$-1 = -2a - d \quad (\theta)$$

$$0 = a + c + d \quad (M)$$

Solving simultaneously yields

$$b = -1$$

$$c = a - 1$$

$$d = 1 - 2a$$

$$v = CF^a D^{-1} \rho^{a-1} \mu^{1-2a}$$

$$= C \left( \frac{\mu}{D\rho} \right) \left( \frac{F\rho}{\mu^2} \right)^a$$

$C$  and  $a$  must be determined experimentally.

## 1. NORMAL VIEWS OF LINES AND PLANES

A *normal view* of a line is a perpendicular projection of the line onto a viewing plane parallel to the line. In the normal view, all points of the line are equidistant from the observer. Therefore, the true length of a line is viewed and can be measured.

Generally, however, a line will be viewed from an oblique position and will appear shorter than it actually is. The normal view can be constructed by drawing an auxiliary view from the orthographic view.<sup>1</sup> (See Sec. 2.5.)

Similarly, a normal view of a plane figure is a perpendicular projection of the figure onto a viewing plane parallel to the plane of the figure. All points of the plane are equidistant from the observer. Therefore, the true size and shape of any figure in the plane can be determined.

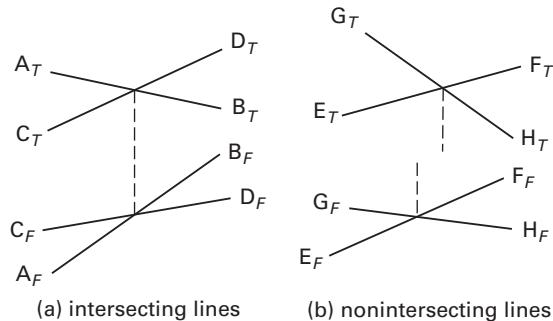

## 2. INTERSECTING AND PERPENDICULAR LINES

A single orthographic view is not sufficient to determine whether two lines intersect. However, if two or more views show the lines as having the same common point (i.e., crossing at the same position in space), then the lines intersect. In Fig. 2.1, the subscripts *F* and *T* refer to front and top views, respectively.

According to the *perpendicular line principle*, two perpendicular lines appear perpendicular only in a normal view of either one or both of the lines. Conversely, if two lines appear perpendicular in any view, the lines are perpendicular only if the view is a normal view of one or both of the lines.

<sup>1</sup>The technique for constructing a normal view is covered in engineering drafting texts.

**Figure 2.1** Intersecting and NonIntersecting Lines

## 3. TYPES OF VIEWS

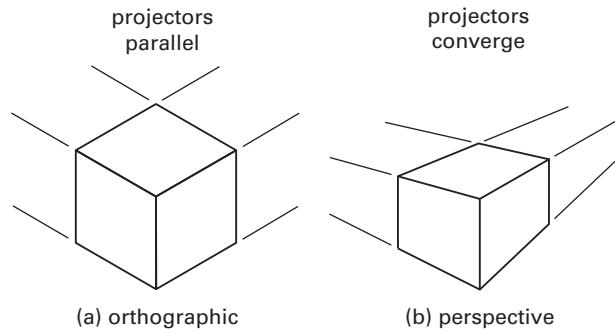

Objects can be illustrated in several different ways depending on the number of views, the angle of observation, and the degree of artistic latitude taken for the purpose of simplifying the drawing process.<sup>2</sup> Table 2.1 categorizes the types of views.

**Table 2.1** Types of Views of Objects

orthographic views
principal views
auxiliary views
oblique views
cavalier projection
cabinet projection
clinographic projection
axonometric views
isometric
dimetric
trimetric
perspective views
parallel perspective
angular perspective

The different types of views are easily distinguished by their *projectors* (i.e., projections of parallel lines on the object). For a cube, there are three sets of projectors corresponding to the three perpendicular axes. In an *orthographic (orthogonal)* view, the projectors are parallel. In a *perspective (central)* view, some or all of the projectors converge to a point. Figure 2.2 illustrates the orthographic and perspective views of a block.

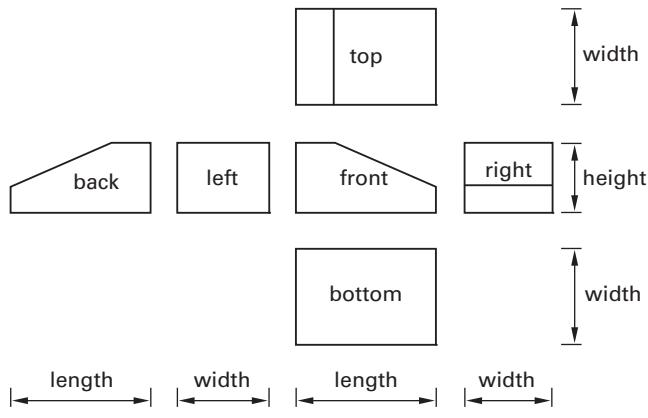

<sup>2</sup>The omission of perspective from a drawing is an example of a step taken to simplify the drawing process.

**Figure 2.2** Orthographic and Perspective Views of a Block

#### 4. PRINCIPAL (ORTHOGRAPHIC) VIEWS

In a *principal view* (also known as a *planar view*), one of the sets of projectors is normal to the view. That is, one of the planes of the object is seen in a normal view. The other two sets of projectors are orthogonal and are usually oriented horizontally and vertically on the paper. Because background details of an object may not be visible in a principal view, it is necessary to have at least three principal views to completely illustrate a symmetrical object. At most, six principal views will be needed to illustrate complex objects.

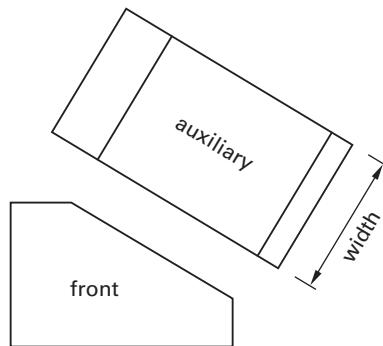

The relative positions of the six views have been standardized and are shown in Fig. 2.3, which also defines the *width* (also known as *depth*), *height*, and *length* of the object. The views that are not needed to illustrate features or provide dimensions (i.e., *redundant views*) can be omitted. The usual combination selected consists of the top, front, and right side views.

**Figure 2.3** Positions of Standard Orthographic Views

It is common to refer to the front, side, and back views as *elevations* and to the top and bottom views as *plan views*. These terms are not absolute since any plane can be selected as the front.

#### 5. AUXILIARY (ORTHOGRAPHIC) VIEWS

An *auxiliary view* is needed when an object has an inclined plane or curved feature or when there are more details than can be shown in the six principal views. As with the other orthographic views, the auxiliary view is a normal (face-on) view of the inclined plane. Figure 2.4 illustrates an auxiliary view.

**Figure 2.4** Auxiliary View

The projectors in an auxiliary view are perpendicular to only one of the directions in which a principal view is observed. Accordingly, only one of the three dimensions of width, height, and depth can be measured (scaled). In a *profile auxiliary view*, the object's width can be measured. In a *horizontal auxiliary view (auxiliary elevation)*, the object's height can be measured. In a *frontal auxiliary view*, the depth of the object can be measured.

#### 6. OBLIQUE (ORTHOGRAPHIC) VIEWS

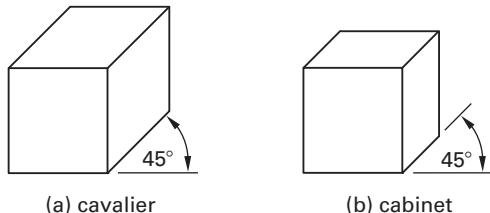

If the object is turned so that three principal planes are visible, it can be completely illustrated by a single *oblique view*.<sup>3</sup> In an oblique view, the direction from which the object is observed is not (necessarily) parallel to any of the directions from which principal and auxiliary views are observed.

In two common methods of oblique illustration, one of the view planes coincides with an orthographic view plane. Two of the drawing axes are at right angles to each other; one of these is vertical, and the other (the *oblique axis*) is oriented at 30° or 45° (originally chosen to coincide with standard drawing triangles). The ratio of scales used for the horizontal, vertical, and oblique axes can be 1:1:1 or 1:1: $\frac{1}{2}$ . The latter ratio helps to overcome the visual distortion due to the absence of perspective in the oblique direction.

<sup>3</sup>Oblique views are not unique in this capability—perspective drawings share it. Oblique and perspective drawings are known as *pictorial drawings* because they give depth to the object by illustrating it in three dimensions.

*Cavalier* ( $45^\circ$  oblique axis and 1:1:1 scale ratio) and *cabinet* ( $45^\circ$  oblique axis and 1:1: $\frac{1}{2}$  scale ratio) *projections* are the two common types of oblique views that incorporate one of the orthographic views. If an angle of  $9.5^\circ$  is used (as in illustrating crystalline lattice structures), the technique is known as *clinographic projection*. Figure 2.5 illustrates cavalier and cabinet oblique drawings of a perfect cube.

Figure 2.5 Cavalier and Cabinet Oblique Drawings

## 7. AXONOMETRIC (ORTHOGRAPHIC OBLIQUE) VIEWS

In axonometric views, the view plane is not parallel to any of the principal orthographic planes. Figure 2.6 illustrates types of axonometric views for a perfect cube. Axonometric views and axonometric drawings are not the same. In a *view (projection)*, one or more of the face lengths is foreshortened. In a *drawing*, the lengths are drawn full length, resulting in a distorted illustration. Table 2.2 lists the proper ratios that should be observed.

In an *isometric view*, the three projectors intersect at equal angles ( $120^\circ$ ) with the plane. This simplifies construction with standard  $30^\circ$  drawing triangles. All of the faces are foreshortened by the same amount, to  $\sqrt{2}/3$ , or approximately 81.6%, of the true length. In a *dimetric view*, two of the projectors intersect at equal angles, and only two of the faces are equally reduced in length. In a *trimetric view*, all three intersection angles are different, and all three faces are reduced by different amounts.

## 8. PERSPECTIVE VIEWS

In a *perspective view*, one or more sets of projectors converge to a fixed point known as the *center of vision*. In the *parallel perspective*, all vertical lines remain vertical in the picture; all horizontal frontal lines remain horizontal. Therefore, one face is parallel to the observer and only one set of projectors converges. In the *angular perspective*, two sets of projectors converge. In the little-used *oblique perspective*, all three sets of projectors converge. Figure 2.7 illustrates types of perspective views.

Figure 2.6 Types of Axonometric Views

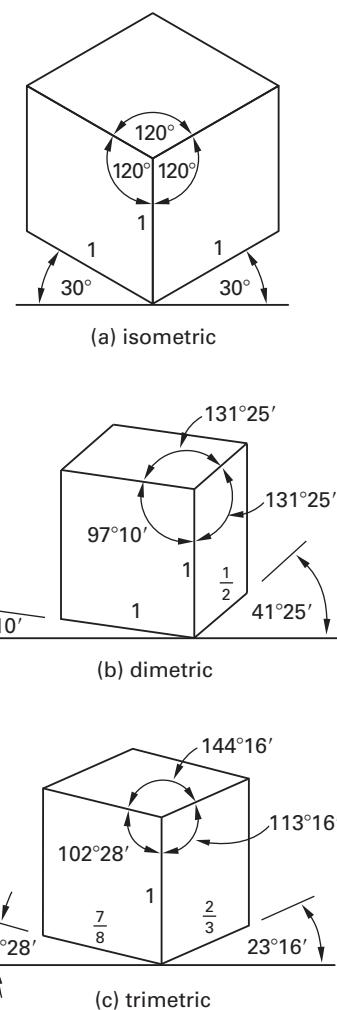

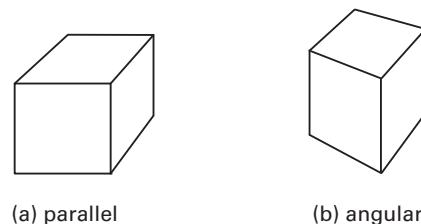

Table 2.2 Axonometric Foresightening

view	projector intersection angles	proper ratio of sides
isometric	$120^\circ, 120^\circ, 120^\circ$	$0.82:0.82:0.82$
dimetric	$131^\circ25', 131^\circ25', 97^\circ10'$ $103^\circ38', 103^\circ38', 152^\circ44'$	$1:1:\frac{1}{2}$ $\frac{3}{4}:\frac{3}{4}:1$
trimetric	$102^\circ28', 144^\circ16', 113^\circ16'$ $138^\circ14', 114^\circ46', 107^\circ$	$1:\frac{2}{3}:\frac{7}{8}$ $1:\frac{3}{4}:\frac{7}{8}$

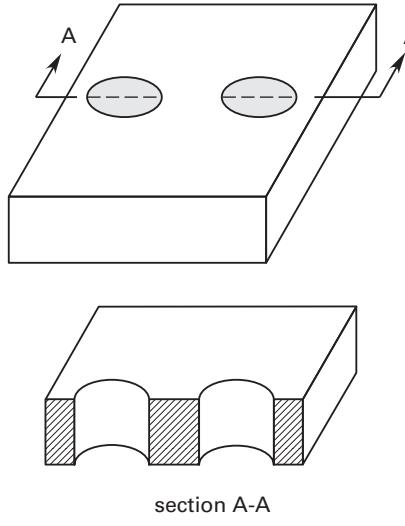

Figure 2.7 Types of Perspective Views

## 9. SECTIONS

A *section* is an imaginary cut taken through an object to reveal the shape or interior construction.<sup>4</sup> Figure 2.8 illustrates the standard symbol for a *sectioning cut* and the resulting sectional view. Section arrows are perpendicular to the cutting plane and indicate the viewing direction.

**Figure 2.8** Sectioning Cut Symbol and Sectional View

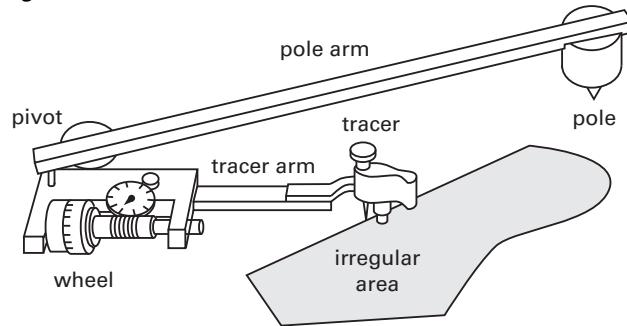

## 10. PLANIMETERS

A *planimeter* is a table-mounted device used to measure irregular areas on a map, photograph, or illustration through mechanical integration. (See Fig. 2.9.) It typically has two arms. The pole arm rotates freely around the pole, which is fixed on the table. The tracer arm rotates around the pivot, which is where it joins the polar arm. The pointer on the other end of the tracer arm is used to trace the perimeter of the region. Near the pivot is a wheel which simply rolls and slides along the table. In operation, the area to be measured is traced clockwise with the tracer. As the area is traced, the measuring wheel rolls and accumulates the total distance on a dial. An optional support wheel may maintain balance. The number of turns recorded on the dial is proportional to the area of the region traced out.

*Green's theorem* (*Green's law*) relates a double integral over a closed region to a line integral over its boundary. Although the mathematics necessary to prove how planimeters measure area functions can be complex, the actual usage is not. Equation 2.1 is the governing equation of planimeter area.  $r$  is the radius of the wheel,  $N$  is

<sup>4</sup>The term *section* is also used to mean a *cross section*—a slice of finite but negligible thickness that is taken from an object to show the cross section or interior construction at the plane of the slice.

**Figure 2.9** Planimeter

the number of wheel revolutions, and  $L$  is the length of the tracer arm. The traced area,  $A$ , has the same units as  $r$  and  $L$ . This area is multiplied by the square of the illustration scale to determine the feature's true area.

$$A = 2\pi rNL \quad 2.1$$

## 11. TOLERANCES

The *tolerance* for a dimension is the total permissible variation or difference between the acceptable limits. The tolerance for a dimension can be specified in two ways: either as a general rule in the title block (e.g.,  $\pm 0.001$  in unless otherwise specified) or as specific limits that are given with each dimension (e.g.,  $2.575$  in  $\pm 0.005$  in).

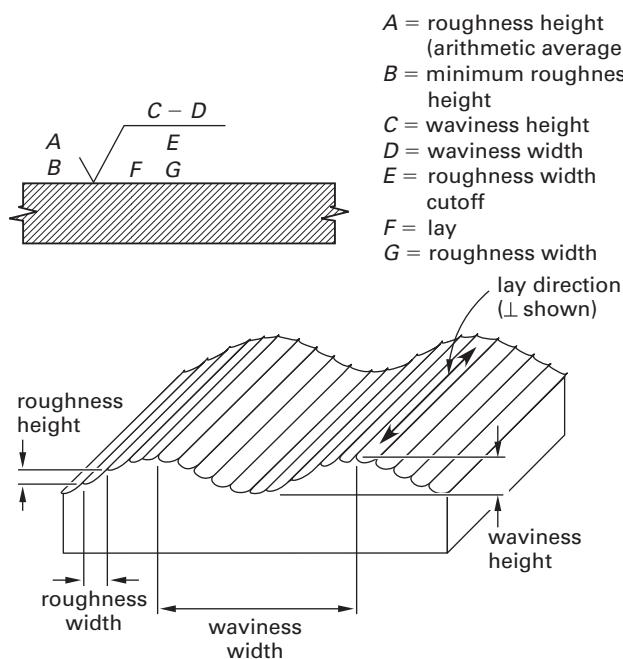

## 12. SURFACE FINISH

ANSI B46.1 specifies surface finish by a combination of parameters.<sup>5</sup> The basic symbol for designating these factors is shown in Fig. 2.10. In the symbol,  $A$  is the maximum *roughness height index*,  $B$  is the optional minimum *roughness height*,  $C$  is the peak-to-valley *waviness height*,  $D$  is the optional peak-to-valley *waviness spacing (width)* rating,  $E$  is the optional *roughness width cutoff (roughness sampling length)*,  $F$  is the *lay*, and  $G$  is the *roughness width*. Unless minimums are specified, all parameters are maximum allowable values, and all lesser values are permitted.

Since the roughness varies, the waviness height is an arithmetic average within a sampled square, and the designation  $A$  is known as the *roughness weight*,  $R_a$ .<sup>6</sup> Values are normally given in micrometers ( $\mu m$ ) or microinches ( $\mu in$ ) in SI or customary U.S. units, respectively. A value for the roughness width cutoff of

<sup>5</sup>Specification does not indicate appearance (i.e., color or luster) or performance (i.e., hardness, corrosion resistance, or microstructure).

<sup>6</sup>The symbol  $R_a$  is the same as the AA (arithmetic average) and CLA (centerline average) terms used in other (and earlier) standards.

**Figure 2.10** Surface Finish Designations

0.80 mm (0.03 in) is assumed when *E* is not specified. Other standard values in common use are 0.25 mm (0.010 in) and 0.08 mm (0.003 in). The lay symbol, *F*, can be = (parallel to indicated surface),  $\perp$  (perpendicular), C (circular), M (multidirectional), P (pitted), R (radial), or X (crosshatch).

If a small circle is placed at the *A* position, no machining is allowed and only cast, forged, die-cast, injection-molded, and other unfinished surfaces are acceptable.

### 1. INTRODUCTION

Engineers working in design and analysis encounter mathematical problems on a daily basis. Although algebra and simple trigonometry are often sufficient for routine calculations, there are many instances when certain advanced subjects are needed. This chapter and the following, in addition to supporting the calculations used in other chapters, consolidate the mathematical concepts most often needed by engineers.

### 2. SYMBOLS USED IN THIS BOOK

Many symbols, letters, and Greek characters are used to represent variables in the formulas used throughout this book. These symbols and characters are defined in the nomenclature section of each chapter. However, some of the other symbols in this book are listed in Table 3.2.

### 3. GREEK ALPHABET

Table 3.1 lists the Greek alphabet.

**Table 3.1** The Greek Alphabet

uppercase	lowercase	Greek name	uppercase	lowercase	Greek name
A	$\alpha$	alpha	N	$\nu$	nu
B	$\beta$	beta	$\Xi$	$\xi$	xi
$\Gamma$	$\gamma$	gamma	O	$\circ$	omicron
$\Delta$	$\delta$	delta	$\Pi$	$\pi$	pi
E	$\epsilon$	epsilon	P	$\rho$	rho
Z	$\zeta$	zeta	$\Sigma$	$\sigma$	sigma
H	$\eta$	eta	T	$\tau$	tau
$\Theta$	$\theta$	theta	$\Upsilon$	$\upsilon$	upsilon
I	$\iota$	iota	$\Phi$	$\phi$	phi
K	$\kappa$	kappa	X	$\chi$	chi
$\Lambda$	$\lambda$	lambda	$\Psi$	$\psi$	psi
M	$\mu$	mu	$\Omega$	$\omega$	omega

### 4. TYPES OF NUMBERS

The *numbering system* consists of three types of numbers: real, imaginary, and complex. *Real numbers*, in turn, consist of rational numbers and irrational numbers. *Rational real numbers* are numbers that can be written as the ratio of two integers (e.g., 4,  $\frac{2}{5}$ , and  $\frac{1}{3}$ ).<sup>1</sup> *Irrational real numbers* are nonterminating, nonrepeating numbers that cannot be expressed as the ratio of two integers (e.g.,  $\pi$  and  $\sqrt{2}$ ). Real numbers can be positive or negative.

*Imaginary numbers* are square roots of negative numbers. The symbols  $i$  and  $j$  are both used to represent the square root of  $-1$ .<sup>2</sup> For example,  $\sqrt{-5} = \sqrt{5}\sqrt{-1} = \sqrt{5}i$ . *Complex numbers* consist of combinations of real and imaginary numbers (e.g.,  $3 - 7i$ ).

### 5. SIGNIFICANT DIGITS

The significant digits in a number include the leftmost, nonzero digits to the rightmost digit written. Final answers from computations should be rounded off to the number of decimal places justified by the data. The answer can be no more accurate than the least accurate number in the data. Of course, rounding should be done on final calculation results only. It should not be done on interim results.

<sup>1</sup>Notice that 0.333333... is a nonterminating number, but as it can be expressed as a ratio of two integers (i.e.,  $1/3$ ), it is a rational number.

<sup>2</sup>The symbol  $j$  is used to represent the square root of  $-1$  in electrical calculations to avoid confusion with the current variable,  $i$ .

**Table 3.2** Symbols Used in This Book

symbol	name	use	example
$\Sigma$	sigma	series summation	$\sum_{i=1}^3 x_i = x_1 + x_2 + x_3$
$\pi$	pi	3.1415926...	$P = \pi D$
$e$	base of natural logs	2.71828...	
$\prod$	pi	series multiplication	$\prod_{i=1}^3 x_i = x_1 x_2 x_3$
$\Delta$	delta	change in quantity	$\Delta h = h_2 - h_1$
$\bar{}$	over bar	average value	$\bar{x}$
$\cdot$	over dot	per unit time	$\dot{m}$ = mass flowing per second
!	factorial <sup>a</sup>		$x! = x(x-1)(x-2) \cdots (2)(1)$
$  $	absolute value <sup>b</sup>		$  -3   = +3$
$\sim$	similarity		$\Delta ABC \sim \Delta DEF$
$\approx$	approximately equal to		$x \approx 1.5$
$\cong$	congruency		$ST \cong UV$
$\propto$	proportional to		$x \propto y$
$\equiv$	equivalent to		$a + bi \equiv re^{i\theta}$
$\infty$	infinity		$x \rightarrow \infty$
log	base-10 logarithm		$\log 5.74$
ln	natural logarithm		$\ln 5.74$
exp	exponential power		$\exp(x) \equiv e^x$
rms	root-mean-square		$V_{\text{rms}} = \sqrt{\frac{1}{n} \sum_{i=1}^n V_i^2}$
$\angle$	phasor or angle		$53^\circ$
$\in$	element of	set/membership	$Y = \sum_{j \in \{0,1,2,\dots,n\}} y_j$

<sup>a</sup>Zero factorial ( $0!$ ) is frequently encountered in the form of  $(n - n)!$  when calculating permutations and combinations. Zero factorial is defined as 1.

<sup>b</sup>The notation  $\text{abs}(x)$  is also used to indicate the absolute value.

There are two ways that significant digits can affect calculations. For the operations of multiplication and division, the final answer is rounded to the number of significant digits in the least significant multiplicand, divisor, or dividend. So,  $2.0 \times 13.2 = 26$  since the first multiplicand (2.0) has two significant digits only.

For the operations of addition and subtraction, the final answer is rounded to the position of the least significant digit in the addenda, minuend, or subtrahend. So,  $2.0 + 13.2 = 15.2$  because both addenda are significant to the tenth's position; however,  $2 + 13.4 = 15$  since the 2 is significant only in the ones' position.

The multiplication rule should not be used for addition or subtraction, as this can result in strange answers. For example, it would be incorrect to round  $1700 + 0.1$  to 2000 simply because 0.1 has only one significant digit. Table 3.3 gives examples of significant digits.

## 6. EQUATIONS

An *equation* is a mathematical statement of equality, such as  $5 = 3 + 2$ . *Algebraic equations* are written in terms of *variables*. In the equation  $y = x^2 + 3$ , the value of variable  $y$  depends on the value of variable  $x$ . Therefore,  $y$  is the *dependent variable* and  $x$  is the *independent variable*. The dependency of  $y$  on  $x$  is clearer when the equation is written in *functional form*:  $y = f(x)$ .

**Table 3.3** Examples of Significant Digits

number as written	number of significant digits	implied range
341	3	340.5–341.5
34.1	3	34.05–34.15
0.00341	3	0.003405–0.003415
$341 \times 10^7$	3	$340.5 \times 10^7$ – $341.5 \times 10^7$
$3.41 \times 10^{-2}$	3	$3.405 \times 10^{-2}$ – $3.415 \times 10^{-2}$
3410	3	3405–3415
3410*	4	3409.5–3410.5
341.0	4	340.95–341.05

\*It is permitted to write "3410." to distinguish the number from its three-significant-digit form, although this is rarely done.

A *parametric equation* uses one or more independent variables (*parameters*) to describe a function.<sup>3</sup> For example, the parameter  $\theta$  can be used to write the parametric equations of a unit circle.

$$x = \cos \theta \quad 3.1$$

$$y = \sin \theta \quad 3.2$$

<sup>3</sup>As used in this section, there is no difference between a parameter and an independent variable. However, the term *parameter* is also used as a descriptive measurement that determines or characterizes the form, size, or content of a function. For example, the radius is a parameter of a circle, and mean and variance are parameters of a probability distribution. Once these parameters are specified, the function is completely defined.

A unit circle can also be described by a *nonparametric equation*.<sup>4</sup>

$$x^2 + y^2 = 1 \quad 3.3$$

## 7. FUNDAMENTAL ALGEBRAIC LAWS

Algebra provides the rules that allow complex mathematical relationships to be expanded or condensed. Algebraic laws may be applied to complex numbers, variables, and real numbers. The general rules for changing the form of a mathematical relationship are given as follows.

- commutative law for addition

$$A + B = B + A \quad 3.4$$

- commutative law for multiplication

$$AB = BA \quad 3.5$$

- associative law for addition

$$A + (B + C) = (A + B) + C \quad 3.6$$

- associative law for multiplication

$$A(BC) = (AB)C \quad 3.7$$

- distributive law

$$A(B + C) = AB + AC \quad 3.8$$

## 8. POLYNOMIALS

A *polynomial* is a rational expression—usually the sum of several variable terms known as *monomials*—that does not involve division. The *degree of the polynomial* is the highest power to which a variable in the expression is raised. The following *standard polynomial forms* are useful when trying to find the roots of an equation.

$$(a + b)(a - b) = a^2 - b^2 \quad 3.9$$

$$(a \pm b)^2 = a^2 \pm 2ab + b^2 \quad 3.10$$

$$(a \pm b)^3 = a^3 \pm 3a^2b + 3ab^2 \pm b^3 \quad 3.11$$

$$(a^3 \pm b^3) = (a \pm b)(a^2 \mp ab + b^2) \quad 3.12$$

$$(a^n - b^n) = (a - b) \left( a^{n-1} + a^{n-2}b + a^{n-3}b^2 + \dots + b^{n-1} \right) \quad [n \text{ is any positive integer}] \quad 3.13$$

$$(a^n + b^n) = (a + b) \left( a^{n-1} - a^{n-2}b + a^{n-3}b^2 - \dots + b^{n-1} \right) \quad [n \text{ is any positive odd integer}] \quad 3.14$$

<sup>4</sup>Since only the coordinate variables are used, this equation is also said to be in *Cartesian equation form*.

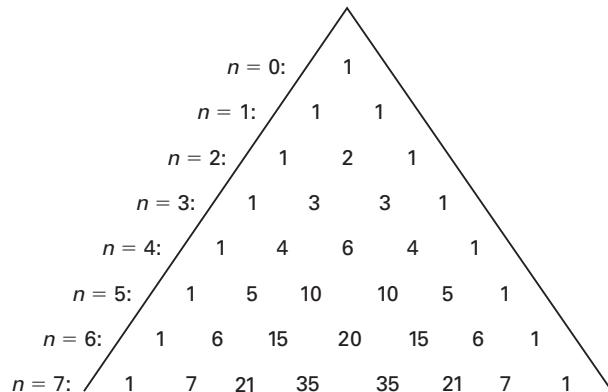

The *binomial theorem* defines a polynomial of the form  $(a + b)^n$ .

$$\begin{aligned} (a + b)^n &= \sum_{i=0}^n a^{n-i} b^i + C_1 a^{n-1} b^1 + C_2 a^{n-2} b^2 + \dots \\ &\quad + C_i a^{n-i} b^i + \dots + n a b^{n-1} + b^n \end{aligned} \quad 3.15$$

$$C_i = \frac{n!}{i!(n-i)!} \quad [i = 0, 1, 2, \dots, n] \quad 3.16$$

The coefficients of the expansion can be determined quickly from *Pascal's triangle*—each entry is the sum of the two entries directly above it. (See Fig. 3.1.)

**Figure 3.1** Pascal's Triangle

The values  $r_1, r_2, \dots, r_n$  of the independent variable  $x$  that satisfy a polynomial equation  $f(x) = 0$  are known as *roots* or *zeros* of the polynomial. A polynomial of degree  $n$  with real coefficients will have at most  $n$  real roots, although they need not all be distinctly different.

## 9. ROOTS OF QUADRATIC EQUATIONS

A *quadratic equation* is an equation of the general form  $ax^2 + bx + c = 0$  [ $a \neq 0$ ]. The *roots*,  $x_1$  and  $x_2$ , of the equation are the two values of  $x$  that satisfy it.

$$x_1, x_2 = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} \quad 3.17$$

$$x_1 + x_2 = -\frac{b}{a} \quad 3.18$$

$$x_1 x_2 = \frac{c}{a} \quad 3.19$$

The types of roots of the equation can be determined from the *discriminant* (i.e., the quantity under the radical in Eq. 3.17).

- If  $b^2 - 4ac > 0$ , the roots are real and unequal.
- If  $b^2 - 4ac = 0$ , the roots are real and equal. This is known as a *double root*.
- If  $b^2 - 4ac < 0$ , the roots are complex and unequal.

## 10. ROOTS OF GENERAL POLYNOMIALS

It is difficult to find roots of cubic and higher-degree polynomials because few general techniques exist. *Cardano's formula (method)* uses closed-form equations to laboriously calculate roots for general cubic (3rd degree) polynomials. Compromise methods are used when solutions are needed on the spot.

- *inspection and trial and error:* Finding roots by inspection is equivalent to making reasonable guesses about the roots and substituting into the polynomial.
- *graphing:* If the value of a polynomial  $f(x)$  is calculated and plotted for different values of  $x$ , an approximate value of a root can be determined as the value of  $x$  at which the plot crosses the  $x$ -axis.
- *factoring:* If at least one root (say,  $x = r$ ) of a polynomial  $f(x)$  is known, the quantity  $x - r$  can be factored out of  $f(x)$  by long division. The resulting quotient will be lower by one degree, and the remaining roots may be easier to determine. This method is particularly applicable if the polynomial is in one of the standard forms presented in Sec. 3.8.
- *special cases:* Certain polynomial forms can be simplified by substitution or solved by standard formulas if they are recognized as being special cases. (The standard solution to the quadratic equation is such a special case.) For example,  $ax^4 + bx^2 + c = 0$  can be reduced to a polynomial of degree 2 if the substitution  $u = x^2$  is made.
- *numerical methods:* If an approximate value of a root is known, numerical methods (bisection method, Newton's method, etc.) can be used to refine the value. The more efficient techniques are too complex to be performed by hand.

## 11. EXTRANEous ROOTS

With simple equalities, it may appear possible to derive roots by basic algebraic manipulations.<sup>5</sup> However, multiplying each side of an equality by a power of a variable may introduce *extraneous roots*. Such roots do not satisfy the original equation even though they are derived according to the rules of algebra. Checking a calculated root is always a good idea, but is particularly necessary if the equation has been multiplied by one of its own variables.

### Example 3.1

Use algebraic operations to determine a value that satisfies the following equation. Determine if the value is a valid or extraneous root.

$$\sqrt{x-2} = \sqrt{x} + 2$$

<sup>5</sup>In this sentence, *equality* means a combination of two expressions containing an equal sign. Any two expressions can be linked in this manner, even those that are not actually equal. For example, the expressions for two nonintersecting ellipses can be equated even though there is no intersection point. Finding extraneous roots is more likely when the underlying equality is false to begin with.

*Solution*

Square both sides.

$$x - 2 = x + 4\sqrt{x} + 4$$

Subtract  $x$  from each side, and combine the constants.

$$4\sqrt{x} = -6$$

Solve for  $x$ .

$$x = \left(\frac{-6}{4}\right)^2 = \frac{9}{4}$$

Substitute  $x = 9/4$  into the original equation.

$$\begin{aligned}\sqrt{\frac{9}{4}-2} &= \sqrt{\frac{9}{4}+2} \\ \frac{1}{2} &= \frac{7}{2}\end{aligned}$$

Since the equality is not established,  $x = 9/4$  is an extraneous root.

## 12. DESCARTES' RULE OF SIGNS

*Descartes' rule of signs* determines the maximum number of positive (and negative) real roots that a polynomial will have by counting the number of sign reversals (i.e., changes in sign from one term to the next) in the polynomial. The polynomial  $f(x) = 0$  must have real coefficients and must be arranged in terms of descending powers of  $x$ .

- The number of positive roots of the polynomial equation  $f(x) = 0$  will not exceed the number of sign reversals.
- The difference between the number of sign reversals and the number of positive roots is an even number.
- The number of negative roots of the polynomial equation  $f(x) = 0$  will not exceed the number of sign reversals in the polynomial  $f(-x)$ .
- The difference between the number of sign reversals in  $f(-x)$  and the number of negative roots is an even number.

### Example 3.2

Determine the possible numbers of positive and negative roots that satisfy the following polynomial equation.

$$4x^5 - 5x^4 + 3x^3 - 8x^2 - 2x + 3 = 0$$

*Solution*

There are four sign reversals, so up to four positive roots exist. To keep the difference between the number of positive roots and the number of sign reversals an even number, the number of positive real roots is limited to zero, two, and four.

Substituting  $-x$  for  $x$  in the polynomial results in

$$-4x^5 - 5x^4 - 3x^3 - 8x^2 + 2x + 3 = 0$$

There is only one sign reversal, so the number of negative roots cannot exceed one. There must be exactly one negative real root in order to keep the difference to an even number (zero in this case).

### 13. RULES FOR EXPONENTS AND RADICALS

In the expression  $b^n = a$ ,  $b$  is known as the *base* and  $n$  is the *exponent* or *power*. In Eq. 3.20 through Eq. 3.33,  $a$ ,  $b$ ,  $m$ , and  $n$  are any real numbers with limitations listed.

$$b^0 = 1 \quad [b \neq 0] \quad 3.20$$

$$b^1 = b \quad 3.21$$

$$b^{-n} = \frac{1}{b^n} = \left(\frac{1}{b}\right)^n \quad [b \neq 0] \quad 3.22$$

$$\left(\frac{a}{b}\right)^n = \frac{a^n}{b^n} \quad [b \neq 0] \quad 3.23$$

$$(ab)^n = a^n b^n \quad 3.24$$

$$b^{m/n} = \sqrt[n]{b^m} = (\sqrt[n]{b})^m \quad 3.25$$

$$(b^n)^m = b^{nm} \quad 3.26$$

$$b^m b^n = b^{m+n} \quad 3.27$$

$$\frac{b^m}{b^n} = b^{m-n} \quad [b \neq 0] \quad 3.28$$

$$\sqrt[n]{b} = b^{1/n} \quad 3.29$$

$$(\sqrt[n]{b})^n = (b^{1/n})^n = b \quad 3.30$$

$$\sqrt[n]{ab} = \sqrt[n]{a}\sqrt[n]{b} = a^{1/n}b^{1/n} = (ab)^{1/n} \quad 3.31$$

$$\sqrt[n]{\frac{a}{b}} = \frac{\sqrt[n]{a}}{\sqrt[n]{b}} = \left(\frac{a}{b}\right)^{1/n} \quad [b \neq 0] \quad 3.32$$

$$\sqrt[m]{\sqrt[n]{b}} = \sqrt[mn]{b} = b^{1/mn} \quad 3.33$$

### 14. LOGARITHMS

Logarithms can be considered to be exponents. For example, the exponent  $n$  in the expression  $b^n = a$  is the logarithm of  $a$  to the base  $b$ . Therefore, the two expressions  $\log_b a = n$  and  $b^n = a$  are equivalent.

The base for *common logs* is 10. Usually, “log” will be written when common logs are desired, although “ $\log_{10}$ ” appears occasionally. The base for *natural (Napierian) logs* is 2.71828..., a number that is given the symbol  $e$ . When natural logs are desired, usually “ln” is written, although “ $\log_e$ ” is also used.

Most logarithms will contain an integer part (the *characteristic*) and a decimal part (the *mantissa*). The common and natural logarithms of any number less than one are negative. If the number is greater than one, its common and natural logarithms are positive. Although the logarithm may be negative, the mantissa is always positive. For negative logarithms, the characteristic is found by expressing the logarithm as the sum of a negative characteristic and a positive mantissa.

For common logarithms of numbers greater than one, the characteristics will be positive and equal to one less than the number of digits in front of the decimal. If the number is less than one, the characteristic will be negative and equal to one more than the number of zeros immediately following the decimal point.

If a negative logarithm is to be used in a calculation, it must first be converted to *operational form* by adding the characteristic and mantissa. The operational form should be used in all calculations and is the form displayed by scientific calculators.

The logarithm of a negative number is a complex number.

#### Example 3.3

Use logarithm tables to determine the operational form of  $\log_{10} 0.05$ .

*Solution*

Since the number is less than one and there is one leading zero, the characteristic is found by observation to be  $-2$ . From a book of logarithm tables, the mantissa of 5.0 is 0.699. Two ways of expressing the combination of mantissa and characteristic are used.

*method 1:*  $\bar{2}.699$

*method 2:*  $8.699 - 10$

The operational form of this logarithm is  $-2 + 0.699 = -1.301$ .

### 15. LOGARITHM IDENTITIES

Prior to the widespread availability of calculating devices, logarithm identities were used to solve complex calculations by reducing the solution method to table lookup, addition, and subtraction. Logarithm identities are still useful in simplifying expressions containing exponentials and other logarithms. In Eq. 3.34 through Eq. 3.45,  $a \neq 1$ ,  $b \neq 1$ ,  $x > 0$ , and  $y > 0$ .

$$\log_b b = 1 \quad 3.34$$

$$\log_b 1 = 0 \quad 3.35$$

$$\log_b b^n = n \quad 3.36$$

$$\log x^a = a \log x \quad 3.37$$

$$\log \sqrt[n]{x} = \log x^{1/n} = \frac{\log x}{n} \quad 3.38$$

$$b^{n \log_b x} = x^n = \text{antilog}(n \log_b x) \quad 3.39$$

$$b^{\log_b x/n} = x^{1/n} \quad 3.40$$

$$\log xy = \log x + \log y \quad 3.41$$

$$\log \frac{x}{y} = \log x - \log y \quad 3.42$$

$$\log_a x = \log_b x \log_a b \quad 3.43$$

$$\ln x = \ln 10 \log_{10} x \approx 2.3026 \log_{10} x \quad 3.44$$

$$\log_{10} x = \log_{10} \ln x e \approx 0.4343 \ln x \quad 3.45$$

**Example 3.4**

The surviving fraction,  $f$ , of a radioactive isotope is given by  $f = e^{-0.005t}$ . For what value of  $t$  will the surviving percentage be 7%?

*Solution*

$$f = 0.07 = e^{-0.005t}$$

Take the natural log of both sides.

$$\ln 0.07 = \ln e^{-0.005t}$$

From Eq. 3.36,  $\ln e^x = x$ . Therefore,

$$-2.66 = -0.005t$$

$$t = 532$$

**16. PARTIAL FRACTIONS**

The method of *partial fractions* is used to transform a proper polynomial fraction of two polynomials into a sum of simpler expressions, a procedure known as *resolution*.<sup>6,7</sup> The technique can be considered to be the act of “unadding” a sum to obtain all of the addends.

Suppose  $H(x)$  is a proper polynomial fraction of the form  $P(x)/Q(x)$ . The object of the resolution is to determine the partial fractions  $u_1/v_1$ ,  $u_2/v_2$ , and so on, such that

$$H(x) = \frac{P(x)}{Q(x)} = \frac{u_1}{v_1} + \frac{u_2}{v_2} + \frac{u_3}{v_3} + \dots \quad 3.46$$

The form of the denominator polynomial  $Q(x)$  will be the main factor in determining the form of the partial fractions. The task of finding the  $u_i$  and  $v_i$  is simplified by categorizing the possible forms of  $Q(x)$ .

*case 1:*  $Q(x)$  factors into  $n$  different linear terms.

$$Q(x) = (x - a_1)(x - a_2) \cdots (x - a_n) \quad 3.47$$

Then,

$$H(x) = \sum_{i=1}^n \frac{A_i}{x - a_i} \quad 3.48$$

*case 2:*  $Q(x)$  factors into  $n$  identical linear terms.

$$Q(x) = (x - a)(x - a) \cdots (x - a) \quad 3.49$$

Then,

$$H(x) = \sum_{i=1}^n \frac{A_i}{(x - a)^i} \quad 3.50$$

<sup>6</sup>To be a *proper polynomial fraction*, the degree of the numerator must be less than the degree of the denominator. If the polynomial fraction is improper, the denominator can be divided into the numerator to obtain whole and fractional polynomials. The method of partial fractions can then be used to reduce the fractional polynomial.

<sup>7</sup>This technique is particularly useful for calculating integrals and inverse Laplace transforms in subsequent chapters.

*case 3:*  $Q(x)$  factors into  $n$  different quadratic terms,  $x^2 + p_i x + q_i$ .

Then,

$$H(x) = \sum_{i=1}^n \frac{A_i x + B_i}{x^2 + p_i x + q_i} \quad 3.51$$

*case 4:*  $Q(x)$  factors into  $n$  identical quadratic terms,  $x^2 + px + q$ .

Then,

$$H(x) = \sum_{i=1}^n \frac{A_i x + B_i}{(x^2 + px + q)^i} \quad 3.52$$

Once the general forms of the partial fractions have been determined from inspection, the *method of undetermined coefficients* is used. The partial fractions are all cross multiplied to obtain  $Q(x)$  as the denominator, and the coefficients are found by equating  $P(x)$  and the cross-multiplied numerator.

**Example 3.5**

Resolve  $H(x)$  into partial fractions.

$$H(x) = \frac{x^2 + 2x + 3}{x^4 + x^3 + 2x^2}$$

*Solution*

Here,  $Q(x) = x^4 + x^3 + 2x^2$  factors into  $x^2(x^2 + x + 2)$ . This is a combination of cases 2 and 3.

$$H(x) = \frac{A_1}{x} + \frac{A_2}{x^2} + \frac{A_3 + A_4 x}{x^2 + x + 2}$$

Cross multiplying to obtain a common denominator yields

$$\frac{(A_1 + A_4)x^3 + (A_1 + A_2 + A_3)x^2 + (2A_1 + A_2)x + 2A_2}{x^4 + x^3 + 2x^2}$$

Since the original numerator is known, the following simultaneous equations result.

$$A_1 + A_4 = 0$$

$$A_1 + A_2 + A_3 = 1$$

$$2A_1 + A_2 = 2$$

$$2A_2 = 3$$

The solutions are  $A_1 = 0.25$ ;  $A_2 = 1.50$ ;  $A_3 = -0.75$ ; and  $A_4 = -0.25$ .

$$H(x) = \frac{1}{4x} + \frac{3}{2x^2} - \frac{x + 3}{4(x^2 + x + 2)}$$

## 17. SIMULTANEOUS LINEAR EQUATIONS

A *linear equation* with  $n$  variables is a polynomial of degree 1 describing a geometric shape in  $n$ -space. A *homogeneous linear equation* is one that has no constant term, and a *nonhomogeneous linear equation* has a constant term.

A solution to a set of simultaneous linear equations represents the intersection point of the geometric shapes in  $n$ -space. For example, if the equations are limited to two variables (e.g.,  $y = 4x - 5$ ), they describe straight lines. The solution to two simultaneous linear equations in 2-space is the point where the two lines intersect. The set of the two equations is said to be a *consistent system* when there is such an intersection.<sup>8</sup>

Simultaneous equations do not always have unique solutions, and some have none at all. In addition to crossing in 2-space, lines can be parallel or they can be the same line expressed in a different equation format (i.e., dependent equations). In some cases, parallelism and dependency can be determined by inspection. In most cases, however, matrix and other advanced methods must be used to determine whether a solution exists. A set of linear equations with no simultaneous solution is known as an *inconsistent system*.

Several methods exist for solving linear equations simultaneously by hand.<sup>9</sup>

- *graphing:* The equations are plotted and the intersection point is read from the graph. This method is possible only with two-dimensional problems.
- *substitution:* An equation is rearranged so that one variable is expressed as a combination of the other variables. The expression is then substituted into the remaining equations wherever the selected variable appears.
- *reduction:* All terms in the equations are multiplied by constants chosen to eliminate one or more variables when the equations are added or subtracted. The remaining sum can then be solved for the other variables. This method is also known as *eliminating the unknowns*.
- *Cramer's rule:* This is a procedure in linear algebra that calculates determinants of the original coefficient matrix **A** and of the  $n$  matrices resulting from the systematic replacement of column **A** by the constant matrix **B**.

### Example 3.6

Solve the following set of linear equations by (a) substitution and (b) reduction.

$$2x + 3y = 12 \quad [\text{Eq. I}]$$

$$3x + 4y = 8 \quad [\text{Eq. II}]$$

<sup>8</sup>A homogeneous system always has at least one solution: the *trivial solution*, in which all variables have a value of zero.

<sup>9</sup>Other matrix and numerical methods exist, but they require a computer.

*Solution*

- (a) From Eq. I, solve for variable  $x$ .

$$x = 6 - 1.5y \quad [\text{Eq. III}]$$

Substitute  $6 - 1.5y$  into Eq. II wherever  $x$  appears.

$$(3)(6 - 1.5y) + 4y = 8$$

$$18 - 4.5y + 4y = 8$$

$$y = 20$$

Substitute 20 for  $y$  in Eq. III.

$$x = 6 - (1.5)(20) = -24$$

The solution  $(-24, 20)$  should be checked to verify that it satisfies both original equations.

- (b) Eliminate variable  $x$  by multiplying Eq. I by 3 and Eq. II by 2.

$$3 \times \text{Eq. I: } 6x + 9y = 36 \quad [\text{Eq. I}']$$

$$2 \times \text{Eq. II: } 6x + 8y = 16 \quad [\text{Eq. II}']$$

Subtract Eq. II' from Eq. I'.

$$y = 20 \quad [\text{Eq. I}' - \text{Eq. II}']$$

Substitute  $y = 20$  into Eq. I'.

$$6x + (9)(20) = 36$$

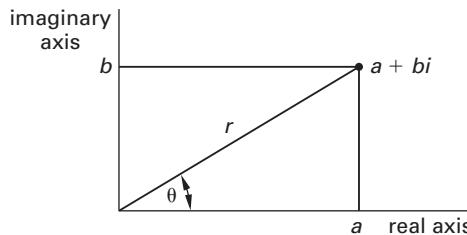

$$x = -24$$

The solution  $(-24, 20)$  should be checked to verify that it satisfies both original equations.

## 18. COMPLEX NUMBERS

A *complex number*,  $Z$ , is a combination of real and imaginary numbers. When expressed as a sum (e.g.,  $a + bi$ ), the complex number is said to be in *rectangular* or *trigonometric form*. The complex number can be plotted on the real-imaginary coordinate system known as the *complex plane*, as illustrated in Fig. 3.2.

**Figure 3.2** A Complex Number in the Complex Plane

The complex number  $\mathbf{Z} = a + bi$  can also be expressed in *exponential form*.<sup>10</sup> The quantity  $r$  is known as the *modulus* of  $\mathbf{Z}$ ;  $\theta$  is the *argument*.

$$a + bi \equiv re^{i\theta} \quad 3.53$$

$$r = \text{mod } \mathbf{Z} = \sqrt{a^2 + b^2} \quad 3.54$$

$$\theta = \arg \mathbf{Z} = \arctan \frac{b}{a} \quad 3.55$$

Similarly, the *phasor form* (also known as the *polar form*) is

$$\mathbf{Z} = r \angle \theta \quad 3.56$$

The *rectangular form* can be determined from  $r$  and  $\theta$ .

$$a = r \cos \theta \quad 3.57$$

$$b = r \sin \theta \quad 3.58$$

$$\begin{aligned} \mathbf{Z} &= a + bi = r \cos \theta + ir \sin \theta \\ &= r(\cos \theta + i \sin \theta) \end{aligned} \quad 3.59$$

The *cis form* is a shorthand method of writing a complex number in rectangular (trigonometric) form.

$$a + bi = r(\cos \theta + i \sin \theta) = r \text{cis } \theta \quad 3.60$$

*Euler's equation*, as shown in Eq. 3.61, expresses the equality of complex numbers in exponential and trigonometric form.

$$e^{i\theta} = \cos \theta + i \sin \theta \quad 3.61$$

Related expressions are

$$e^{-i\theta} = \cos \theta - i \sin \theta \quad 3.62$$

$$\cos \theta = \frac{e^{i\theta} + e^{-i\theta}}{2} \quad 3.63$$

$$\sin \theta = \frac{e^{i\theta} - e^{-i\theta}}{2i} \quad 3.64$$

### Example 3.7

What is the exponential form of the complex number  $\mathbf{Z} = 3 + 4i$ ?

*Solution*

$$\begin{aligned} r &= \sqrt{a^2 + b^2} = \sqrt{3^2 + 4^2} = \sqrt{25} \\ &= 5 \end{aligned}$$

$$\begin{aligned} \theta &= \arctan \frac{b}{a} = \arctan \frac{4}{3} = 0.927 \text{ rad} \\ \mathbf{Z} &= re^{i\theta} = 5e^{i(0.927)} \end{aligned}$$

## 19. OPERATIONS ON COMPLEX NUMBERS

Most algebraic operations (addition, multiplication, exponentiation, etc.) work with complex numbers, but notable exceptions are the inequality operators. The concept of one complex number being less than or greater than another complex number is meaningless.

When adding two complex numbers, real parts are added to real parts, and imaginary parts are added to imaginary parts.

$$(a_1 + ib_1) + (a_2 + ib_2) = (a_1 + a_2) + i(b_1 + b_2) \quad 3.65$$

$$(a_1 + ib_1) - (a_2 + ib_2) = (a_1 - a_2) + i(b_1 - b_2) \quad 3.66$$

Multiplication of two complex numbers in rectangular form is accomplished by the use of the algebraic distributive law and the definition  $i^2 = -1$ .

Division of complex numbers in rectangular form requires the use of the *complex conjugate*. The complex conjugate of the complex number  $(a + bi)$  is  $(a - bi)$ . By multiplying the numerator and the denominator by the complex conjugate, the denominator will be converted to the real number  $a^2 + b^2$ . This technique is known as *rationalizing* the denominator and is illustrated in Ex. 3.8(c).

Multiplication and division are often more convenient when the complex numbers are in exponential or phasor forms, as Eq. 3.67 and Eq. 3.68 show.

$$(r_1 e^{i\theta_1})(r_2 e^{i\theta_2}) = r_1 r_2 e^{i(\theta_1 + \theta_2)} \quad 3.67$$

$$\frac{r_1 e^{i\theta_1}}{r_2 e^{i\theta_2}} = \left( \frac{r_1}{r_2} \right) e^{i(\theta_1 - \theta_2)} \quad 3.68$$

Taking powers and roots of complex numbers requires *de Moivre's theorem*, Eq. 3.69 and Eq. 3.70.

$$\mathbf{Z}^n = (re^{i\theta})^n = r^n e^{in\theta} \quad 3.69$$

$$\sqrt[n]{\mathbf{Z}} = (re^{i\theta})^{1/n} = \sqrt[n]{r} e^{i(\theta + k360^\circ / n)} \quad [k = 0, 1, 2, \dots, n-1] \quad 3.70$$

### Example 3.8

Perform the following complex arithmetic.

$$(a) (3 + 4i) + (2 + i)$$

$$(b) (7 + 2i)(5 - 3i)$$

$$(c) \frac{2 + 3i}{4 - 5i}$$

*Solution*

$$(a) \quad (3 + 4i) + (2 + i) = (3 + 2) + (4 + 1)i \\ = 5 + 5i$$

$$\begin{aligned} (b) \quad (7 + 2i)(5 - 3i) &= (7)(5) - (7)(3i) + (2i)(5) \\ &\quad - (2i)(3i) \\ &= 35 - 21i + 10i - 6i^2 \\ &= 35 - 21i + 10i - (6)(-1) \\ &= 41 - 11i \end{aligned}$$

<sup>10</sup>The terms *polar form*, *phasor form*, and *exponential form* are all used somewhat interchangeably.

- (c) Multiply the numerator and denominator by the complex conjugate of the denominator.

$$\begin{aligned}\frac{2+3i}{4-5i} &= \frac{(2+3i)(4+5i)}{(4-5i)(4+5i)} = \frac{-7+22i}{(4)^2+(5)^2} \\ &= \frac{-7}{41} + i\frac{22}{41}\end{aligned}$$

## 20. LIMITS

A *limit* (*limiting value*) is the value a function approaches when an independent variable approaches a target value. For example, suppose the value of  $y = x^2$  is desired as  $x$  approaches 5. This could be written as

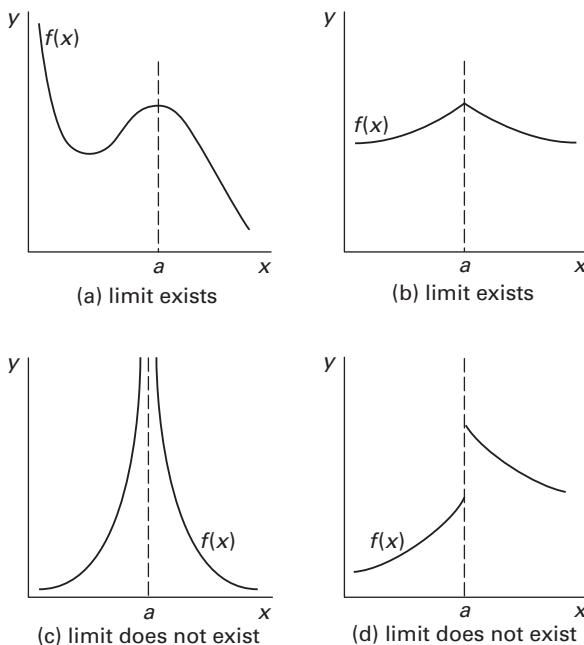

$$\lim_{x \rightarrow 5} x^2 \quad 3.71$$

The power of limit theory is wasted on simple calculations such as this but is appreciated when the function is undefined at the target value. The object of limit theory is to determine the limit without having to evaluate the function at the target. The general case of a limit evaluated as  $x$  approaches the target value  $a$  is written as

$$\lim_{x \rightarrow a} f(x) \quad 3.72$$

It is not necessary for the actual value  $f(a)$  to exist for the limit to be calculated. The function  $f(x)$  may be undefined at point  $a$ . However, it is necessary that  $f(x)$  be defined on both sides of point  $a$  for the limit to exist. If  $f(x)$  is undefined on one side, or if  $f(x)$  is discontinuous at  $x = a$  (as in Fig. 3.3(c) and Fig. 3.3(d)), the limit does not exist.

**Figure 3.3** Existence of Limits

The following theorems can be used to simplify expressions when calculating limits.

$$\lim_{x \rightarrow a} x = a \quad 3.73$$

$$\lim_{x \rightarrow a} (mx + b) = ma + b \quad 3.74$$

$$\lim_{x \rightarrow a} b = b \quad 3.75$$

$$\lim_{x \rightarrow a} (kF(x)) = k \lim_{x \rightarrow a} F(x) \quad 3.76$$

$$\begin{aligned}\lim_{x \rightarrow a} \left( F_1(x) \begin{cases} + \\ - \\ \times \\ \div \end{cases} F_2(x) \right) \\ = \lim_{x \rightarrow a} (F_1(x)) \begin{cases} + \\ - \\ \times \\ \div \end{cases} \lim_{x \rightarrow a} (F_2(x))\end{aligned} \quad 3.77$$

The following identities can be used to simplify limits of trigonometric expressions.

$$\lim_{x \rightarrow 0} \sin x = 0 \quad 3.78$$

$$\lim_{x \rightarrow 0} \left( \frac{\sin x}{x} \right) = 1 \quad 3.79$$

$$\lim_{x \rightarrow 0} \cos x = 1 \quad 3.80$$

The following standard methods (tricks) can be used to determine limits.

- If the limit is taken to infinity, all terms can be divided by the largest power of  $x$  in the expression. This will leave at least one constant. Any quantity divided by a power of  $x$  vanishes as  $x$  approaches infinity.
- If the expression is a quotient of two expressions, any common factors should be eliminated from the numerator and denominator.
- L'Hôpital's rule*, Eq. 3.81, should be used when the numerator and denominator of the expression both approach zero or both approach infinity.<sup>11</sup>  $P^k(x)$  and  $Q^k(x)$  are the  $k$ th derivatives of the functions  $P(x)$  and  $Q(x)$ , respectively. (L'Hôpital's rule can be applied repeatedly as required.)

$$\lim_{x \rightarrow a} \left( \frac{P(x)}{Q(x)} \right) = \lim_{x \rightarrow a} \left( \frac{P^k(x)}{Q^k(x)} \right) \quad 3.81$$

<sup>11</sup>L'Hôpital's rule should not be used when only the denominator approaches zero. In that case, the limit approaches infinity regardless of the numerator.

**Example 3.9**

Evaluate the following limits.

$$(a) \lim_{x \rightarrow 3} \left( \frac{x^3 - 27}{x^2 - 9} \right)$$

$$(b) \lim_{x \rightarrow \infty} \left( \frac{3x - 2}{4x + 3} \right)$$

$$(c) \lim_{x \rightarrow 2} \left( \frac{x^2 + x - 6}{x^2 - 3x + 2} \right)$$

*Solution*

(a) Factor the numerator and denominator. (L'Hôpital's rule can also be used.)

$$\begin{aligned} \lim_{x \rightarrow 3} \left( \frac{x^3 - 27}{x^2 - 9} \right) &= \lim_{x \rightarrow 3} \left( \frac{(x-3)(x^2+3x+9)}{(x-3)(x+3)} \right) \\ &= \lim_{x \rightarrow 3} \left( \frac{x^2+3x+9}{x+3} \right) \\ &= \frac{(3)^2 + (3)(3) + 9}{3+3} \\ &= 9/2 \end{aligned}$$

(b) Divide through by the largest power of  $x$ . (L'Hôpital's rule can also be used.)

$$\begin{aligned} \lim_{x \rightarrow \infty} \left( \frac{3x - 2}{4x + 3} \right) &= \lim_{x \rightarrow \infty} \left( \frac{3 - \frac{2}{x}}{4 + \frac{3}{x}} \right) \\ &= \frac{3 - \frac{2}{\infty}}{4 + \frac{3}{\infty}} = \frac{3 - 0}{4 + 0} \\ &= 3/4 \end{aligned}$$

(c) Use L'Hôpital's rule. (Factoring can also be used.) Take the first derivative of the numerator and denominator.

$$\begin{aligned} \lim_{x \rightarrow 2} \left( \frac{x^2 + x - 6}{x^2 - 3x + 2} \right) &= \lim_{x \rightarrow 2} \left( \frac{2x+1}{2x-3} \right) \\ &= \frac{(2)(2)+1}{(2)(2)-3} = \frac{5}{1} \\ &= 5 \end{aligned}$$

**21. SEQUENCES AND PROGRESSIONS**

A sequence,  $\{A\}$ , is an ordered progression of numbers,  $a_i$ , such as 1, 4, 9, 16, 25, ... The terms in a sequence can be all positive, all negative, or of alternating signs.  $a_n$  is known as the general term of the sequence.

$$\{A\} = \{a_1, a_2, a_3, \dots, a_n\} \quad 3.82$$

A sequence is said to *diverge* (i.e., be *divergent*) if the terms approach infinity or if the terms fail to approach any finite value, and it is said to *converge* (i.e., be *convergent*) if the terms approach any finite value (including zero). That is, the sequence converges if the limit defined by Eq. 3.83 exists.

$$\lim_{n \rightarrow \infty} a_n \begin{cases} \text{converges if the limit is finite} \\ \text{diverges if the limit is infinite} \\ \text{or does not exist} \end{cases} \quad 3.83$$

The main task associated with a sequence is determining the next (or the general) term. If several terms of a sequence are known, the next (unknown) term must usually be found by intuitively determining the pattern of the sequence. In some cases, though, the method of *Rth-order differences* can be used to determine the next term. This method consists of subtracting each term from the following term to obtain a set of differences. If the differences are not all equal, the next order of differences can be calculated.

**Example 3.10**

What is the general term of the sequence  $\{A\}$ ?

$$\{A\} = \left\{ 3, \frac{9}{2}, \frac{27}{6}, \frac{81}{24}, \dots \right\}$$

*Solution*

The solution is purely intuitive. The numerator is recognized as a power series based on the number 3. The denominator is recognized as the factorial sequence. The general term is

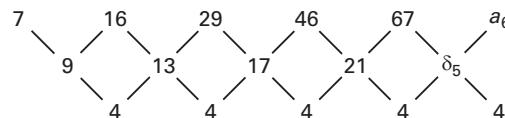

$$a_n = \frac{3^n}{n!}$$

**Example 3.11**

Find the sixth term in the sequence  $\{A\} = \{7, 16, 29, 46, 67, a_6\}$ .

*Solution*

The sixth term is not intuitively obvious, so the method of *Rth-order differences* is tried. The pattern is not obvious from the first order differences, but the second order differences are all 4.

$$\delta_5 - 21 = 4$$

$$\delta_5 = 25$$

$$a_6 - 67 = \delta_5 = 25$$

$$a_6 = 92$$

**Example 3.12**

Does the sequence with general term  $e^n/n$  converge or diverge?

*Solution*

See if the limit exists.

$$\lim_{n \rightarrow \infty} \left( \frac{e^n}{n} \right) = \frac{\infty}{\infty}$$

Since  $\infty/\infty$  is inconclusive, apply L'Hôpital's rule. Take the derivative of both the numerator and the denominator with respect to  $n$ .

$$\lim_{n \rightarrow \infty} \left( \frac{e^n}{1} \right) = \frac{\infty}{1} = \infty$$

The sequence diverges.

**22. STANDARD SEQUENCES**

There are four standard sequences: geometric, arithmetic, harmonic, and  $p$ -sequence.

- The *geometric sequence* converges for  $-1 < r \leq 1$  and diverges otherwise.  $a$  is known as the *first term*;  $r$  is known as the *common ratio*.

$$a_n = ar^{n-1} \quad \begin{cases} a \text{ is a constant} \\ n = 1, 2, 3, \dots, \infty \end{cases} \quad 3.84$$

*example:*  $\{1, 2, 4, 8, 16, 32\}$  ( $a = 1$ ,  $r = 2$ )

- The *arithmetic sequence* always diverges.

$$a_n = a + (n - 1)d \quad \begin{cases} a \text{ and } d \text{ are constants} \\ n = 1, 2, 3, \dots, \infty \end{cases} \quad 3.85$$

*example:*  $\{2, 7, 12, 17, 22, 27\}$  ( $a = 2$ ,  $d = 5$ )

- The *harmonic sequence* always converges.

$$a_n = \frac{1}{n} \quad [n = 1, 2, 3, \dots, \infty] \quad 3.86$$

*example:*  $\{1, \frac{1}{2}, \frac{1}{3}, \frac{1}{4}, \frac{1}{5}, \frac{1}{6}\}$

- The *p-sequence* converges if  $p \geq 0$  and diverges if  $p < 0$ . (This is different from the *p-series*, whose convergence depends on the sum of its terms.)

$$a_n = \frac{1}{n^p} \quad [n = 1, 2, 3, \dots, \infty] \quad 3.87$$

*example:*  $\{1, \frac{1}{4}, \frac{1}{9}, \frac{1}{16}, \frac{1}{25}, \frac{1}{36}\}$  ( $p = 2$ )

**23. APPLICATION: GROWTH RATES**

Models of *population growth* commonly assume arithmetic or geometric growth rates over limited periods of time.<sup>12</sup> *Arithmetic growth rate*, also called *constant growth rate* and *linear growth rate*, is appropriate when a population increase involves limited resources or occurs at specific intervals. Means of subsistence, such as areas of farmable land by generation, and budgets and enrollments by year, for example, are commonly assumed to increase arithmetically with time. Arithmetic growth is equivalent to simple interest compounding. Given a starting population,  $P_0$ , that increases every period by a constant *growth rate amount*,  $R$ , the population after  $t$  periods is

$$P_t = P_0 + tR \quad [\text{arithmetic}] \quad 3.88$$

The *average annual growth rate* is conventionally defined as

$$r_{\text{ave}, \%} = \frac{P_t - P_0}{tP_0} \times 100\% = \frac{R}{P_0} \times 100\% \quad 3.89$$

*Geometric growth (Malthusian growth)* is appropriate when resources to support growth are infinite. The population changes by a fixed *growth rate fraction*,  $r$ , each period. Geometric growth is equivalent to discrete period interest compounding, and  $(F/P, r\%, t)$  economic interest factors can be used. The population at time  $t$  (i.e., after  $t$  periods) is

$$P_t = P_0(1 + r)^t \equiv P_0(F/P, r\%, t) \quad [\text{geometric}] \quad 3.90$$

Geometric growth can be expressed in terms of a time constant,  $\tau_b$ , associated with a specific base,  $b$ . Commonly, only three bases are used. For  $b = 2$ ,  $\tau$  is the *doubling time*,  $T$ . For  $b = 1/2$ ,  $\tau$  is the *half-life*,  $t_{1/2}$ . For  $b = e$ ,  $\tau$  is the *e-folding time*, or just *time constant*,  $\tau$ . Base- $e$  growth is known as *exponential growth* or *instantaneous growth*. It is appropriate for continuous growth (not discrete time periods) and is equivalent to continuous interest compounding.

$$\begin{aligned} P_t &= P_0(1 + r)^t = P_0 e^{t/\tau} = P_0(2)^{t/T} \\ &= P_0 \left(\frac{1}{2}\right)^{t/t_{1/2}} \quad [\text{geometric}] \end{aligned} \quad 3.91$$

Taking the logarithm of Eq. 3.90 results in a *log-linear form*. Log-linear functions graph as straight lines.

$$\log P_t = \log P_0 + t \log(1 + r) \quad 3.92$$

**24. SERIES**

A *series* is the sum of terms in a sequence. There are two types of series. A *finite series* has a finite number of terms, and an *infinite series* has an infinite number of

<sup>12</sup>Another population growth model is the logistic (S-shaped) curve.

terms.<sup>13</sup> The main tasks associated with series are determining the sum of the terms and whether the series converges. A series is said to *converge* (be *convergent*) if the sum,  $S_n$ , of its term exists.<sup>14</sup> A finite series is always convergent.

The performance of a series based on standard sequences (defined in Sec. 3.22) is well known.

- *geometric series:*

$$S_n = \sum_{i=1}^n ar^{i-1} = \frac{a(1 - r^n)}{1 - r} \quad [\text{finite series}] \quad 3.93$$

$$S_n = \sum_{i=1}^{\infty} ar^{i-1} = \frac{a}{1 - r} \quad \begin{cases} \text{infinite series} \\ -1 < r < 1 \end{cases} \quad 3.94$$

- *arithmetic series:* The infinite series diverges unless  $a = d = 0$ .

$$\begin{aligned} S_n &= \sum_{i=1}^n (a + (i - 1)d) \\ &= \frac{n(2a + (n - 1)d)}{2} \quad [\text{finite series}] \end{aligned} \quad 3.95$$

- *harmonic series:* The infinite series diverges.
- *p-series:* The infinite series diverges if  $p \leq 1$ . The infinite series converges if  $p > 1$ . (This is different from the *p*-sequence whose convergence depends only on the last term.)

## 25. TESTS FOR SERIES CONVERGENCE

It is obvious that all finite series (i.e., series having a finite number of terms) converge. That is, the sum,  $S_n$ , defined by Eq. 3.96 exists.

$$S_n = \sum_{i=1}^n a_i \quad 3.96$$

Convergence of an infinite series can be determined by taking the limit of the sum. If the limit exists, the series converges; otherwise, it diverges.

$$\lim_{n \rightarrow \infty} S_n = \lim_{n \rightarrow \infty} \sum_{i=1}^n a_i \quad 3.97$$

In most cases, the expression for the general term  $a_n$  will be known, but there will be no simple expression for the sum  $S_n$ . Therefore, Eq. 3.97 cannot be used to determine convergence. It is helpful, but not conclusive, to look at the limit of the general term. If the limit, as defined in Eq. 3.98, is nonzero, the series

<sup>13</sup>The term *infinite series* does not imply the sum is infinite.

<sup>14</sup>This is different from the definition of convergence for a sequence where only the last term was evaluated.

diverges. If the limit equals zero, the series may either converge or diverge. Additional testing is needed in that case.

$$\lim_{n \rightarrow \infty} a_n \begin{cases} = 0 & \text{inconclusive} \\ \neq 0 & \text{diverges} \end{cases} \quad 3.98$$

Two tests can be used independently or after Eq. 3.98 has proven inconclusive: the ratio and comparison tests. The *ratio test* calculates the limit of the ratio of two consecutive terms.

$$\lim_{n \rightarrow \infty} \frac{a_{n+1}}{a_n} \begin{cases} < 1 & \text{converges} \\ = 1 & \text{inconclusive} \\ > 1 & \text{diverges} \end{cases} \quad 3.99$$

The *comparison test* is an indirect method of determining convergence of an unknown series. It compares a standard series (geometric and *p*-series are commonly used) against the unknown series. If all terms in a positive standard series are smaller than the terms in the unknown series and the standard series diverges, the unknown series must also diverge. Similarly, if all terms in the standard series are larger than the terms in the unknown series and the standard series converges, then the unknown series also converges.

In mathematical terms, if  $A$  and  $B$  are both series of positive terms such that  $a_n < b_n$  for all values of  $n$ , then (a)  $B$  diverges if  $A$  diverges, and (b)  $A$  converges if  $B$  converges.

### Example 3.13

Does the infinite series  $A$  converge or diverge?

$$A = 3 + \frac{9}{2} + \frac{27}{6} + \frac{81}{24} + \dots$$

*Solution*

The general term was found in Ex. 3.10 to be

$$a_n = \frac{3^n}{n!}$$

Since limits of factorials are not easily determined, use the ratio test.

$$\begin{aligned} \lim_{n \rightarrow \infty} \left( \frac{a_{n+1}}{a_n} \right) &= \lim_{n \rightarrow \infty} \left( \frac{\frac{3^{n+1}}{(n+1)!}}{\frac{3^n}{n!}} \right) = \lim_{n \rightarrow \infty} \left( \frac{3}{n+1} \right) = \frac{3}{\infty} \\ &= 0 \end{aligned}$$

Since the limit is less than 1, the infinite series converges.

**Example 3.14**

Does the infinite series  $A$  converge or diverge?

$$A = 2 + \frac{3}{4} + \frac{4}{9} + \frac{5}{16} + \dots$$

*Solution*

By observation, the general term is

$$a_n = \frac{1+n}{n^2}$$

The general term can be expanded by partial fractions to

$$a_n = \frac{1}{n} + \frac{1}{n^2}$$

However,  $1/n$  is the harmonic series. Since the harmonic series is divergent and this series is larger than the harmonic series (by the term  $1/n^2$ ), this series also diverges.

**26. SERIES OF ALTERNATING SIGNS<sup>15</sup>**

Some series contain both positive and negative terms. The ratio and comparison tests can both be used to determine if a series with alternating signs converges. If a series containing all positive terms converges, then the same series with some negative terms also converges. Therefore, the all-positive series should be tested for convergence. If the all-positive series converges, the original series is said to be *absolutely convergent*. (If the all-positive series diverges and the original series converges, the original series is said to be *conditionally convergent*.)

Alternatively, the ratio test can be used with the absolute value of the ratio. The same criteria apply.

$$\lim_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right| \begin{cases} < 1 & \text{converges} \\ = 1 & \text{inconclusive} \\ > 1 & \text{diverges} \end{cases} \quad 3.100$$

<sup>15</sup>This terminology is commonly used even though it is not necessary that the signs strictly alternate.

## 1. MATRICES

A *matrix* is an ordered set of *entries* (*elements*) arranged rectangularly and set off by brackets.<sup>1</sup> The entries can be variables or numbers. A matrix by itself has no particular value—it is merely a convenient method of representing a set of numbers.

The size of a matrix is given by the number of rows and columns, and the nomenclature  $m \times n$  is used for a matrix with  $m$  rows and  $n$  columns. For a *square matrix*, the number of rows and columns will be the same, a quantity known as the *order* of the matrix.

Bold uppercase letters are used to represent matrices, while lowercase letters represent the entries. For example,  $a_{23}$  would be the entry in the second row and third column of matrix **A**.

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix}$$

A *submatrix* is the matrix that remains when selected rows or columns are removed from the original matrix.<sup>2</sup> For example, for matrix **A**, the submatrix remaining

<sup>1</sup>The term *array* is synonymous with *matrix*, although the former is more likely to be used in computer applications.

<sup>2</sup>By definition, a matrix is a submatrix of itself.

after the second row and second column have been removed is

$$\begin{bmatrix} a_{11} & a_{13} \\ a_{31} & a_{33} \end{bmatrix}$$

An *augmented matrix* results when the original matrix is extended by repeating one or more of its rows or columns or by adding rows and columns from another matrix. For example, for the matrix **A**, the augmented matrix created by repeating the first and second columns is

$$\left[ \begin{array}{ccc|cc} a_{11} & a_{12} & a_{13} & | & a_{11} & a_{12} \\ a_{21} & a_{22} & a_{23} & | & a_{21} & a_{22} \\ a_{31} & a_{32} & a_{33} & | & a_{31} & a_{32} \end{array} \right]$$

## 2. SPECIAL TYPES OF MATRICES

Certain types of matrices are given special designations.

- *cofactor matrix*: the matrix formed when every entry is replaced by the cofactor of that entry (see Sec. 4.4)
- *column matrix*: a matrix with only one column
- *complex matrix*: a matrix with complex number entries
- *diagonal matrix*: a square matrix with all zero entries except for the  $a_{ij}$  for which  $i = j$
- *echelon matrix*: a matrix in which the number of zeros preceding the first nonzero entry of a row increases row by row until only zero rows remain. A *row-reduced echelon matrix* is an echelon matrix in which the first nonzero entry in each row is a 1 and all other entries in the columns are zero.
- *identity matrix*: a diagonal (square) matrix with all nonzero entries equal to 1, usually designated as **I**, having the property that  $\mathbf{AI} = \mathbf{IA} = \mathbf{A}$
- *null matrix*: the same as a zero matrix
- *row matrix*: a matrix with only one row
- *scalar matrix*:<sup>3</sup> a diagonal (square) matrix with all diagonal entries equal to some scalar  $k$

<sup>3</sup>Although the term *complex matrix* means a matrix with complex entries, the term *scalar matrix* means more than a matrix with scalar entries.

- *singular matrix*: a matrix whose determinant is zero (see Sec. 4.10)
- *skew symmetric matrix*: a square matrix whose transpose is equal to the negative of itself (i.e.,  $\mathbf{A} = -\mathbf{A}^t$ ) (see Sec. 4.9)
- *square matrix*: a matrix with the same number of rows and columns (i.e.,  $m = n$ )
- *symmetric(al) matrix*: a square matrix whose transpose is equal to itself (i.e.,  $\mathbf{A}^t = \mathbf{A}$ ), which occurs only when  $a_{ij} = a_{ji}$
- *triangular matrix*: a square matrix with zeros in all positions above or below the diagonal
- *unit matrix*: the same as the identity matrix
- *zero matrix*: a matrix with all zero entries

Figure 4.1 shows examples of special matrices.

**Figure 4.1 Examples of Special Matrices**

$\begin{bmatrix} 9 & 0 & 0 & 0 \\ 0 & -6 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 5 \end{bmatrix}$ (a) diagonal	$\begin{bmatrix} 2 & 18 & 2 & 18 \\ 0 & 0 & 1 & 9 \\ 0 & 0 & 0 & 9 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ (b) echelon	$\begin{bmatrix} 1 & 9 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$ (c) row-reduced echelon
$\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$ (d) identity	$\begin{bmatrix} 3 & 0 & 0 & 0 \\ 0 & 3 & 0 & 0 \\ 0 & 0 & 3 & 0 \\ 0 & 0 & 0 & 3 \end{bmatrix}$ (e) scalar	$\begin{bmatrix} 2 & 0 & 0 & 0 \\ 7 & 6 & 0 & 0 \\ 9 & 1 & 1 & 0 \\ 8 & 0 & 4 & 5 \end{bmatrix}$ (f) triangular

### 3. ROW EQUIVALENT MATRICES

A matrix  $\mathbf{B}$  is said to be *row equivalent* to a matrix  $\mathbf{A}$  if it is obtained by a finite sequence of *elementary row operations* on  $\mathbf{A}$ :

- interchanging the  $i$ th and  $j$ th rows
- multiplying the  $i$ th row by a nonzero scalar
- replacing the  $i$ th row by the sum of the original  $i$ th row and  $k$  times the  $j$ th row

However, two matrices that are row equivalent as defined do not necessarily have the same determinants. (See Sec. 4.5.)

*Gauss-Jordan elimination* is the process of using these elementary row operations to row-reduce a matrix to echelon or row-reduced echelon forms, as illustrated in Ex. 4.8. When a matrix has been converted to a row-reduced echelon matrix, it is said to be in *row canonical form*. The phrases *row-reduced echelon form* and *row canonical form* are synonymous.

### 4. MINORS AND COFACTORS

Minors and cofactors are determinants of submatrices associated with particular entries in the original square matrix. The *minor* of entry  $a_{ij}$  is the determinant of a submatrix resulting from the elimination of the single row  $i$  and the single column  $j$ . For example, the minor corresponding to entry  $a_{12}$  in a  $3 \times 3$  matrix  $\mathbf{A}$  is the determinant of the matrix created by eliminating row 1 and column 2.

$$\text{minor of } a_{12} = \begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix} \quad 4.1$$

The *cofactor* of entry  $a_{ij}$  is the minor of  $a_{ij}$  multiplied by either +1 or -1, depending on the position of the entry. (That is, the cofactor either exactly equals the minor or it differs only in sign.) The sign is determined according to the following positional matrix.<sup>4</sup>

$$\begin{bmatrix} +1 & -1 & +1 & \dots \\ -1 & +1 & -1 & \dots \\ +1 & -1 & +1 & \dots \\ \vdots & \vdots & \vdots & \ddots \end{bmatrix}$$

For example, the cofactor of entry  $a_{12}$  in matrix  $\mathbf{A}$  (described in Sec. 4.4) is

$$\text{cofactor of } a_{12} = - \begin{vmatrix} a_{21} & a_{23} \\ a_{31} & a_{33} \end{vmatrix} \quad 4.2$$

#### Example 4.1

What is the cofactor corresponding to the -3 entry in the following matrix?

$$\mathbf{A} = \begin{bmatrix} 2 & 9 & 1 \\ -3 & 4 & 0 \\ 7 & 5 & 9 \end{bmatrix}$$

*Solution*

The minor's submatrix is created by eliminating the row and column of the -3 entry.

$$\mathbf{M} = \begin{bmatrix} 9 & 1 \\ 5 & 9 \end{bmatrix}$$

<sup>4</sup>The sign of the cofactor  $a_{ij}$  is positive if  $(i+j)$  is even and is negative if  $(i+j)$  is odd.

The minor is the determinant of  $\mathbf{M}$ .

$$|\mathbf{M}| = (9)(9) - (5)(1) = 76$$

The sign corresponding to the  $-3$  position is negative. Therefore, the cofactor is  $-76$ .

## 5. DETERMINANTS

A *determinant* is a scalar calculated from a square matrix. The determinant of matrix  $\mathbf{A}$  can be represented as  $D\{\mathbf{A}\}$ ,  $\text{Det}(\mathbf{A})$ ,  $\Delta\mathbf{A}$ , or  $|\mathbf{A}|$ .<sup>5</sup> The following rules can be used to simplify the calculation of determinants.

- If  $\mathbf{A}$  has a row or column of zeros, the determinant is zero.
- If  $\mathbf{A}$  has two identical rows or columns, the determinant is zero.
- If  $\mathbf{B}$  is obtained from  $\mathbf{A}$  by adding a multiple of a row (column) to another row (column) in  $\mathbf{A}$ , then  $|\mathbf{B}| = |\mathbf{A}|$ .
- If  $\mathbf{A}$  is triangular, the determinant is equal to the product of the diagonal entries.
- If  $\mathbf{B}$  is obtained from  $\mathbf{A}$  by multiplying one row or column in  $\mathbf{A}$  by a scalar  $k$ , then  $|\mathbf{B}| = k|\mathbf{A}|$ .
- If  $\mathbf{B}$  is obtained from the  $n \times n$  matrix  $\mathbf{A}$  by multiplying by the scalar matrix  $k$ , then  $|k\mathbf{A}| = k^n|\mathbf{A}|$ .
- If  $\mathbf{B}$  is obtained from  $\mathbf{A}$  by switching two rows or columns in  $\mathbf{A}$ , then  $|\mathbf{B}| = -|\mathbf{A}|$ .

Calculation of determinants is laborious for all but the smallest or simplest of matrices. For a  $2 \times 2$  matrix, the formula used to calculate the determinant is easy to remember.

$$\mathbf{A} = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

$$|\mathbf{A}| = \begin{vmatrix} a & b \\ c & d \end{vmatrix} = ad - bc \quad 4.3$$

Two methods are commonly used for calculating the determinant of  $3 \times 3$  matrices by hand. The first uses an augmented matrix constructed from the original matrix and the first two columns (as shown in Sec. 4.1).<sup>6</sup> The determinant is calculated as the sum of the products in the left-to-right downward diagonals less the sum of the products in the left-to-right upward diagonals.

<sup>5</sup>The vertical bars should not be confused with the square brackets used to set off a matrix, nor with absolute value.

<sup>6</sup>It is not actually necessary to construct the augmented matrix, but doing so helps avoid errors.

$$\mathbf{A} = \begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix}$$

augmented  $\mathbf{A} = \begin{bmatrix} a & b & c & | & a & b \\ d & e & f & | & d & e \\ g & h & i & | & g & h \end{bmatrix}$

4.4

$$|\mathbf{A}| = aei + bfg + cdh - gec - hfa - idb \quad 4.5$$

The second method of calculating the determinant is somewhat slower than the first for a  $3 \times 3$  matrix but illustrates the method that must be used to calculate determinants of  $4 \times 4$  and larger matrices. This method is known as *expansion by cofactors*. One row (column) is selected as the base row (column). The selection is arbitrary, but the number of calculations required to obtain the determinant can be minimized by choosing the row (column) with the most zeros. The determinant is equal to the sum of the products of the entries in the base row (column) and their corresponding cofactors.

$$\mathbf{A} = \begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix}$$

$$|\mathbf{A}| = a \begin{vmatrix} e & f \\ h & i \end{vmatrix} - d \begin{vmatrix} b & c \\ h & i \end{vmatrix} + g \begin{vmatrix} b & c \\ e & f \end{vmatrix} \quad 4.6$$

### Example 4.2

Calculate the determinant of matrix  $\mathbf{A}$  (a) by cofactor expansion, and (b) by the augmented matrix method.

$$\mathbf{A} = \begin{bmatrix} 2 & 3 & -4 \\ 3 & -1 & -2 \\ 4 & -7 & -6 \end{bmatrix}$$

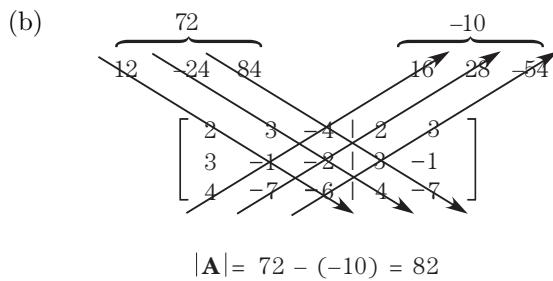

### Solution

- (a) Since there are no zero entries, it does not matter which row or column is chosen as the base. Choose the first column as the base.

$$|\mathbf{A}| = 2 \begin{vmatrix} -1 & -2 \\ -7 & -6 \end{vmatrix} - 3 \begin{vmatrix} 3 & -4 \\ -7 & -6 \end{vmatrix} + 4 \begin{vmatrix} 3 & -4 \\ -1 & -2 \end{vmatrix}$$

$$= (2)(6 - 14) - (3)(-18 - 28) + (4)(-6 - 4)$$

$$= 82$$

## 6. MATRIX ALGEBRA<sup>7</sup>

Matrix algebra differs somewhat from standard algebra.

- *equality*: Two matrices,  $\mathbf{A}$  and  $\mathbf{B}$ , are equal only if they have the same numbers of rows and columns and if all corresponding entries are equal.
- *inequality*: The  $>$  and  $<$  operators are not used in matrix algebra.
- *commutative law of addition*:

$$\mathbf{A} + \mathbf{B} = \mathbf{B} + \mathbf{A} \quad 4.7$$

- *associative law of addition*:

$$\mathbf{A} + (\mathbf{B} + \mathbf{C}) = (\mathbf{A} + \mathbf{B}) + \mathbf{C} \quad 4.8$$

- *associative law of multiplication*:

$$(\mathbf{AB})\mathbf{C} = \mathbf{A}(\mathbf{BC}) \quad 4.9$$

- *left distributive law*:

$$\mathbf{A}(\mathbf{B} + \mathbf{C}) = \mathbf{AB} + \mathbf{AC} \quad 4.10$$

- *right distributive law*:

$$(\mathbf{B} + \mathbf{C})\mathbf{A} = \mathbf{BA} + \mathbf{CA} \quad 4.11$$

- *scalar multiplication*:

$$k(\mathbf{AB}) = (k\mathbf{A})\mathbf{B} = \mathbf{A}(k\mathbf{B}) \quad 4.12$$

Except for trivial and special cases, matrix multiplication is not commutative. That is,

$$\mathbf{AB} \neq \mathbf{BA}$$

## 7. MATRIX ADDITION AND SUBTRACTION

Addition and subtraction of two matrices is possible only if both matrices have the same numbers of rows and columns (i.e., order). They are accomplished by adding or subtracting the corresponding entries of the two matrices.

<sup>7</sup>Since matrices are used to simplify the presentation and solution of sets of linear equations, matrix algebra is also known as *linear algebra*.

## 8. MATRIX MULTIPLICATION AND DIVISION

A matrix can be multiplied by a scalar, an operation known as *scalar multiplication*, in which case all entries of the matrix are multiplied by that scalar. For example, for the  $2 \times 2$  matrix  $\mathbf{A}$ ,

$$k\mathbf{A} = \begin{bmatrix} ka_{11} & ka_{12} \\ ka_{21} & ka_{22} \end{bmatrix}$$

A matrix can be multiplied by another matrix, but only if the left-hand matrix has the same number of columns as the right-hand matrix has rows. *Matrix multiplication* occurs by multiplying the elements in each left-hand matrix row by the entries in each right-hand matrix column, adding the products, and placing the sum at the intersection point of the participating row and column.

*Matrix division* can be accomplished only by multiplying by the inverse of the denominator matrix. There is no specific division operation in matrix algebra.

### Example 4.3

Determine the product matrix  $\mathbf{C}$ .

$$\mathbf{C} = \begin{bmatrix} 1 & 4 & 3 \\ 5 & 2 & 6 \end{bmatrix} \begin{bmatrix} 7 & 12 \\ 11 & 8 \\ 9 & 10 \end{bmatrix}$$

*Solution*

The left-hand matrix has three columns, and the right-hand matrix has three rows. Therefore, the two matrices can be multiplied.

The first row of the left-hand matrix and the first column of the right-hand matrix are worked with first. The corresponding entries are multiplied, and the products are summed.

$$c_{11} = (1)(7) + (4)(11) + (3)(9) = 78$$

The intersection of the top row and left column is the entry in the upper left-hand corner of the matrix  $\mathbf{C}$ .

The remaining entries are calculated similarly.

$$c_{12} = (1)(12) + (4)(8) + (3)(10) = 74$$

$$c_{21} = (5)(7) + (2)(11) + (6)(9) = 111$$

$$c_{22} = (5)(12) + (2)(8) + (6)(10) = 136$$

The product matrix is

$$\mathbf{C} = \begin{bmatrix} 78 & 74 \\ 111 & 136 \end{bmatrix}$$

## 9. TRANSPOSE

The *transpose*,  $\mathbf{A}^t$ , of an  $m \times n$  matrix  $\mathbf{A}$  is an  $n \times m$  matrix constructed by taking the  $i$ th row and making it the  $i$ th column. The diagonal is unchanged. For example,

$$\mathbf{A} = \begin{bmatrix} 1 & 6 & 9 \\ 2 & 3 & 4 \\ 7 & 1 & 5 \end{bmatrix}$$

$$\mathbf{A}^t = \begin{bmatrix} 1 & 2 & 7 \\ 6 & 3 & 1 \\ 9 & 4 & 5 \end{bmatrix}$$

Transpose operations have the following characteristics.

$$(\mathbf{A}^t)^t = \mathbf{A} \quad 4.13$$

$$(k\mathbf{A})^t = k(\mathbf{A}^t) \quad 4.14$$

$$\mathbf{I}^t = \mathbf{I} \quad 4.15$$

$$(\mathbf{AB})^t = \mathbf{B}^t \mathbf{A}^t \quad 4.16$$

$$(\mathbf{A} + \mathbf{B})^t = \mathbf{A}^t + \mathbf{B}^t \quad 4.17$$

$$|\mathbf{A}^t| = |\mathbf{A}| \quad 4.18$$

## 10. SINGULARITY AND RANK

A *singular matrix* is one whose determinant is zero. Similarly, a *nonsingular matrix* is one whose determinant is nonzero.

The *rank* of a matrix is the maximum number of linearly independent row or column vectors.<sup>8</sup> A matrix has rank  $r$  if it has at least one nonsingular square submatrix of order  $r$  but has no nonsingular square submatrix of order more than  $r$ . While the submatrix must be square (in order to calculate the determinant), the original matrix need not be.

The rank of an  $m \times n$  matrix will be, at most, the smaller of  $m$  and  $n$ . The rank of a null matrix is zero. The ranks of a matrix and its transpose are the same. If a matrix is in echelon form, the rank will be equal to the number of rows containing at least one nonzero entry. For a  $3 \times 3$  matrix, the rank can be 3 (if it is nonsingular), 2 (if any one of its  $2 \times 2$  submatrices is nonsingular), 1 (if it and all  $2 \times 2$  submatrices are singular), or 0 (if it is null).

The determination of rank is laborious if done by hand. Either the matrix is reduced to echelon form by using elementary row operations, or exhaustive enumeration is used to create the submatrices and many determinants are calculated. If a matrix has more rows than columns and row-reduction is used, the work required to put the matrix in echelon form can be reduced by working with the transpose of the original matrix.

<sup>8</sup>The *row rank* and *column rank* are the same.

## Example 4.4

What is the rank of matrix  $\mathbf{A}$ ?

$$\mathbf{A} = \begin{bmatrix} 1 & -2 & -1 \\ -3 & 3 & 0 \\ 2 & 2 & 4 \end{bmatrix}$$

*Solution*

Matrix  $\mathbf{A}$  is singular because  $|\mathbf{A}| = 0$ . However, there is at least one  $2 \times 2$  nonsingular submatrix.

$$\begin{vmatrix} 1 & -2 \\ -3 & 3 \end{vmatrix} = (1)(3) - (-3)(-2) = -3$$

Therefore, the rank is 2.

## Example 4.5

Determine the rank of matrix  $\mathbf{A}$  by reducing it to echelon form.

$$\mathbf{A} = \begin{bmatrix} 7 & 4 & 9 & 1 \\ 0 & 2 & -5 & 3 \\ 0 & 4 & -10 & 6 \end{bmatrix}$$

*Solution*

By inspection, the matrix can be row-reduced by subtracting two times the second row from the third row. The matrix cannot be further reduced. Since there are two nonzero rows, the rank is 2.

$$\begin{bmatrix} 7 & 4 & 9 & 1 \\ 0 & 2 & -5 & 3 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

## 11. CLASSICAL ADJOINT

The *classical adjoint* is the transpose of the cofactor matrix. (See Sec. 4.2.) The resulting matrix can be designated as  $\mathbf{A}_{\text{adj}}$ ,  $\text{adj}\{\mathbf{A}\}$ , or  $\mathbf{A}^{\text{adj}}$ .

## Example 4.6

What is the classical adjoint of matrix  $\mathbf{A}$ ?

$$\mathbf{A} = \begin{bmatrix} 2 & 3 & -4 \\ 0 & -4 & 2 \\ 1 & -1 & 5 \end{bmatrix}$$

**Solution**

The matrix of cofactors is determined to be

$$\begin{bmatrix} -18 & 2 & 4 \\ -11 & 14 & 5 \\ -10 & -4 & -8 \end{bmatrix}$$

The transpose of the matrix of cofactors is

$$\mathbf{A}_{\text{adj}} = \begin{bmatrix} -18 & -11 & -10 \\ 2 & 14 & -4 \\ 4 & 5 & -8 \end{bmatrix}$$

**12. INVERSE**

The product of a matrix  $\mathbf{A}$  and its inverse,  $\mathbf{A}^{-1}$ , is the identity matrix,  $\mathbf{I}$ . Only square matrices have inverses, but not all square matrices are invertible. A matrix has an inverse if and only if it is nonsingular (i.e., its determinant is nonzero).

$$\mathbf{AA}^{-1} = \mathbf{A}^{-1}\mathbf{A} = \mathbf{I} \quad 4.19$$

$$(\mathbf{AB})^{-1} = \mathbf{B}^{-1}\mathbf{A}^{-1} \quad 4.20$$

The inverse of a  $2 \times 2$  matrix is most easily determined by formula.

$$\mathbf{A} = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$$

$$\mathbf{A}^{-1} = \frac{1}{|A|} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix} \quad 4.21$$

For any matrix, the inverse is determined by dividing every entry in the classical adjoint by the determinant of the original matrix.

$$\mathbf{A}^{-1} = \frac{\mathbf{A}_{\text{adj}}}{|\mathbf{A}|} \quad 4.22$$

**Example 4.7**

What is the inverse of matrix  $\mathbf{A}$ ?

$$\mathbf{A} = \begin{bmatrix} 4 & 5 \\ 2 & 3 \end{bmatrix}$$

**Solution**

The determinant is calculated as

$$|\mathbf{A}| = (4)(3) - (2)(5) = 2$$

Using Eq. 4.22, the inverse is

$$\mathbf{A}^{-1} = \frac{1}{2} \begin{bmatrix} 3 & -5 \\ -2 & 4 \end{bmatrix} = \begin{bmatrix} \frac{3}{2} & -\frac{5}{2} \\ -1 & 2 \end{bmatrix}$$

Check.

$$\begin{aligned} \mathbf{AA}^{-1} &= \begin{bmatrix} 4 & 5 \\ 2 & 3 \end{bmatrix} \begin{bmatrix} \frac{3}{2} & -\frac{5}{2} \\ -1 & 2 \end{bmatrix} = \begin{bmatrix} 6 - 5 & -10 + 10 \\ 3 - 3 & -5 + 6 \end{bmatrix} \\ &= \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \\ &= \mathbf{I} \quad [\text{OK}] \end{aligned}$$

**13. WRITING SIMULTANEOUS LINEAR EQUATIONS IN MATRIX FORM**

Matrices are used to simplify the presentation and solution of sets of simultaneous linear equations. For example, the following three methods of presenting simultaneous linear equations are equivalent.

$$a_{11}x_1 + a_{12}x_2 = b_1$$

$$a_{21}x_1 + a_{22}x_2 = b_2$$

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \end{bmatrix}$$

$$\mathbf{AX} = \mathbf{B}$$

In the second and third representations,  $\mathbf{A}$  is known as the *coefficient matrix*,  $\mathbf{X}$  as the *variable matrix*, and  $\mathbf{B}$  as the *constant matrix*.

Not all systems of simultaneous equations have solutions, and those that do may not have unique solutions. The existence of a solution can be determined by calculating the determinant of the coefficient matrix. Solution-existence rules are summarized in Table 4.1.

- If the system of linear equations is homogeneous (i.e.,  $\mathbf{B}$  is a zero matrix) and  $|\mathbf{A}|$  is zero, there are an infinite number of solutions.
- If the system is homogeneous and  $|\mathbf{A}|$  is nonzero, only the trivial solution exists.

- If the system of linear equations is nonhomogeneous (i.e.,  $\mathbf{B}$  is not a zero matrix) and  $|\mathbf{A}|$  is nonzero, there is a unique solution to the set of simultaneous equations.
- If  $|\mathbf{A}|$  is zero, a nonhomogeneous system of simultaneous equations may still have a solution. The requirement is that the determinants of all substitutional matrices are zero, in which case there will be an infinite number of solutions. (See Sec. 4.14.) Otherwise, no solution exists.

**Table 4.1** Solution-Existence Rules for Simultaneous Equations

	$\mathbf{B} = 0$	$\mathbf{B} \neq 0$
$ \mathbf{A}  = 0$	infinite number of solutions (linearly dependent equations)	either an infinite number of solutions or no solution at all
$ \mathbf{A}  \neq 0$	trivial solution only ( $x_i = 0$ )	unique nonzero solution

## 14. SOLVING SIMULTANEOUS LINEAR EQUATIONS

*Gauss-Jordan elimination* can be used to obtain the solution to a set of simultaneous linear equations. The coefficient matrix is augmented by the constant matrix. Then, elementary row operations are used to reduce the coefficient matrix to canonical form. All of the operations performed on the coefficient matrix are performed on the constant matrix. The variable values that satisfy the simultaneous equations will be the entries in the constant matrix when the coefficient matrix is in canonical form.

Determinants are used to calculate the solution to linear simultaneous equations through a procedure known as *Cramer's rule*.

The procedure is to calculate determinants of the original coefficient matrix  $\mathbf{A}$  and of the  $n$  matrices resulting from the systematic replacement of a column in  $\mathbf{A}$  by the constant matrix  $\mathbf{B}$ . For a system of three equations in three unknowns, there are three substitutional matrices,  $\mathbf{A}_1$ ,  $\mathbf{A}_2$ , and  $\mathbf{A}_3$ , as well as the original coefficient matrix, for a total of four matrices whose determinants must be calculated.

The values of the unknowns that simultaneously satisfy all of the linear equations are

$$x_1 = \frac{|\mathbf{A}_1|}{|\mathbf{A}|} \quad 4.23$$

$$x_2 = \frac{|\mathbf{A}_2|}{|\mathbf{A}|} \quad 4.24$$

$$x_3 = \frac{|\mathbf{A}_3|}{|\mathbf{A}|} \quad 4.25$$

### Example 4.8

Use Gauss-Jordan elimination to solve the following system of simultaneous equations.

$$2x + 3y - 4z = 1$$

$$3x - y - 2z = 4$$

$$4x - 7y - 6z = -7$$

#### Solution

The augmented matrix is created by appending the constant matrix to the coefficient matrix.

$$\left[ \begin{array}{ccc|c} 2 & 3 & -4 & 1 \\ 3 & -1 & -2 & 4 \\ 4 & -7 & -6 & -7 \end{array} \right]$$

Elementary row operations are used to reduce the coefficient matrix to canonical form. For example, two times the first row is subtracted from the third row. This step obtains the 0 needed in the  $a_{31}$  position.

$$\left[ \begin{array}{ccc|c} 2 & 3 & -4 & 1 \\ 3 & -1 & -2 & 4 \\ 0 & -13 & 2 & -9 \end{array} \right]$$

This process continues until the following form is obtained.

$$\left[ \begin{array}{ccc|c} 1 & 0 & 0 & 3 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 2 \end{array} \right]$$

$x = 3$ ,  $y = 1$ , and  $z = 2$  satisfy this system of equations.

### Example 4.9

Use Cramer's rule to solve the following system of simultaneous equations.

$$2x + 3y - 4z = 1$$

$$3x - y - 2z = 4$$

$$4x - 7y - 6z = -7$$

**Solution**

The determinant of the coefficient matrix is

$$|\mathbf{A}| = \begin{vmatrix} 2 & 3 & -4 \\ 3 & -1 & -2 \\ 4 & -7 & -6 \end{vmatrix} = 82$$

The determinants of the substitutional matrices are

$$|\mathbf{A}_1| = \begin{vmatrix} 1 & 3 & -4 \\ 4 & -1 & -2 \\ -7 & -7 & -6 \end{vmatrix} = 246$$

$$|\mathbf{A}_2| = \begin{vmatrix} 2 & 1 & -4 \\ 3 & 4 & -2 \\ 4 & -7 & -6 \end{vmatrix} = 82$$

$$|\mathbf{A}_3| = \begin{vmatrix} 2 & 3 & 1 \\ 3 & -1 & 4 \\ 4 & -7 & -7 \end{vmatrix} = 164$$

The values of  $x$ ,  $y$ , and  $z$  that will satisfy the linear equations are

$$x = \frac{246}{82} = 3$$

$$y = \frac{82}{82} = 1$$

$$z = \frac{164}{82} = 2$$

## 15. EIGENVALUES AND EIGENVECTORS

Eigenvalues and eigenvectors (also known as *characteristic values* and *characteristic vectors*) of a square matrix  $\mathbf{A}$  are the scalars  $k$  and matrices  $\mathbf{X}$  such that

$$\mathbf{AX} = k\mathbf{X} \quad 4.26$$

The scalar  $k$  is an eigenvalue of  $\mathbf{A}$  if and only if the matrix  $(k\mathbf{I} - \mathbf{A})$  is singular; that is, if  $|k\mathbf{I} - \mathbf{A}| = 0$ . This equation is called the *characteristic equation* of the matrix  $\mathbf{A}$ . When expanded, the determinant is called the *characteristic polynomial*. The method of using the characteristic polynomial to find eigenvalues and eigenvectors is demonstrated in Ex. 4.10.

If all of the eigenvalues are unique (i.e., nonrepeating), then Eq. 4.27 is valid.

$$[k\mathbf{I} - \mathbf{A}]\mathbf{X} = 0 \quad 4.27$$

### Example 4.10

Find the eigenvalues and nonzero eigenvectors of the matrix  $\mathbf{A}$ .

$$\mathbf{A} = \begin{bmatrix} 2 & 4 \\ 6 & 4 \end{bmatrix}$$

#### *Solution*

$$k\mathbf{I} - \mathbf{A} = \begin{bmatrix} k & 0 \\ 0 & k \end{bmatrix} - \begin{bmatrix} 2 & 4 \\ 6 & 4 \end{bmatrix} = \begin{bmatrix} k-2 & -4 \\ -6 & k-4 \end{bmatrix}$$

The characteristic polynomial is found by setting the determinant  $|k\mathbf{I} - \mathbf{A}|$  equal to zero.

$$(k-2)(k-4) - (-6)(-4) = 0$$

$$k^2 - 6k - 16 = (k-8)(k+2) = 0$$

The roots of the characteristic polynomial are  $k = +8$  and  $k = -2$ . These are the eigenvalues of  $\mathbf{A}$ .

Substituting  $k = 8$ ,

$$k\mathbf{I} - \mathbf{A} = \begin{bmatrix} 8-2 & -4 \\ -6 & 8-4 \end{bmatrix} = \begin{bmatrix} 6 & -4 \\ -6 & 4 \end{bmatrix}$$

The resulting system can be interpreted as the linear equation  $6x_1 - 4x_2 = 0$ . The values of  $x$  that satisfy this equation define the eigenvector. An eigenvector  $\mathbf{X}$  associated with the eigenvalue  $+8$  is

$$\mathbf{X} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} 4 \\ 6 \end{bmatrix}$$

All other eigenvectors for this eigenvalue are multiples of  $\mathbf{X}$ . Normally  $\mathbf{X}$  is reduced to smallest integers.

$$\mathbf{X} = \begin{bmatrix} 2 \\ 3 \end{bmatrix}$$

Similarly, the eigenvector associated with the eigenvalue  $-2$  is

$$\mathbf{X} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} +4 \\ -4 \end{bmatrix}$$

Reducing this to smallest integers gives

$$\mathbf{X} = \begin{bmatrix} +1 \\ -1 \end{bmatrix}$$

## 1. INTRODUCTION

Some characteristics can be described by scalars, vectors, or tensors. A *scalar* has only magnitude. Knowing its value is sufficient to define the characteristic. Mass, enthalpy, density, and speed are examples of scalar characteristics.

Force, momentum, displacement, and velocity are examples of vector characteristics. A *vector* is a directed straight line with a specific magnitude and that is specified completely by its direction (consisting of the vector's *angular orientation* and its *sense*) and magnitude. A vector's *point of application* (*terminal point*) is not needed to define the vector.<sup>1</sup> Two vectors with the same direction and magnitude are said to be *equal vectors* even though their *lines of action* may be different.<sup>2</sup>

A vector can be designated by a boldface variable (as in this book) or as a combination of the variable and some other symbol. For example, the notations  $\mathbf{V}$ ,  $\overline{V}$ ,  $\hat{V}$ ,  $\vec{V}$ , and  $\underline{V}$  are used by different authorities to represent vectors. In this book, the magnitude of a vector can be designated by either  $|\mathbf{V}|$  or  $V$  (italic but not bold).

Stress, dielectric constant, and magnetic susceptibility are examples of tensor characteristics. A *tensor* has magnitude in a specific direction, but the direction is not unique. Tensors are frequently associated with *anisotropic materials* that have different properties in different directions. A tensor in three-dimensional space is defined

<sup>1</sup>A vector that is constrained to act at or through a certain point is a *bound vector* (*fixed vector*). A *sliding vector* (*transmissible vector*) can be applied anywhere along its line of action. A *free vector* is not constrained and can be applied at any point in space.

<sup>2</sup>A distinction is sometimes made between equal vectors and equivalent vectors. *Equivalent vectors* produce the same effect but are not necessarily equal.

by nine components, compared with the three that are required to define vectors. These components are written in matrix form. Stress,  $\sigma$ , at a point, for example, would be defined by the following tensor matrix.

$$\sigma \equiv \begin{bmatrix} \sigma_{xx} & \sigma_{xy} & \sigma_{xz} \\ \sigma_{yx} & \sigma_{yy} & \sigma_{yz} \\ \sigma_{zx} & \sigma_{zy} & \sigma_{zz} \end{bmatrix}$$

## 2. VECTORS IN $n$ -SPACE

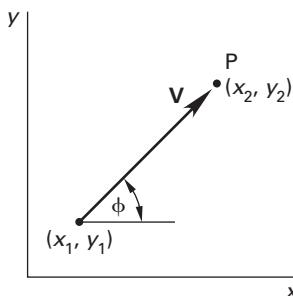

In some cases, a vector,  $\mathbf{V}$ , will be designated by its two endpoints in  $n$ -dimensional vector space. The usual vector space is three-dimensional force-space. Usually, one of the points will be the origin, in which case the vector is said to be "based at the origin," "origin-based," or "zero-based."<sup>3</sup> If one of the endpoints is the origin, specifying a terminal point  $P$  would represent a force directed from the origin to point  $P$ .

If a coordinate system is superimposed on the vector space, a vector can be specified in terms of the  $n$  coordinates of its two endpoints. The magnitude of the vector  $\mathbf{V}$  is the distance in vector space between the two points, as given by Eq. 5.1. Similarly, the direction is defined by the angle the vector makes with one of the axes. Figure 5.1 illustrates a vector in two dimensions.

$$|\mathbf{V}| = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2} \quad 5.1$$

$$\phi = \arctan \frac{y_2 - y_1}{x_2 - x_1} \quad 5.2$$

**Figure 5.1** Vector in Two-Dimensional Space

<sup>3</sup>Any vector directed from  $P_1$  to  $P_2$  can be transformed into a zero-based vector by subtracting the coordinates of point  $P_1$  from the coordinates of terminal point  $P_2$ . The transformed vector will be equivalent to the original vector.

The *components* of a vector are the projections of the vector on the coordinate axes. (For a zero-based vector, the components and the coordinates of the endpoint are the same.) Simple trigonometric principles are used to resolve a vector into its components. A vector reconstructed from its components is known as a *resultant vector*.

$$V_x = |\mathbf{V}| \cos \phi_x \quad 5.3$$

$$V_y = |\mathbf{V}| \cos \phi_y \quad 5.4$$

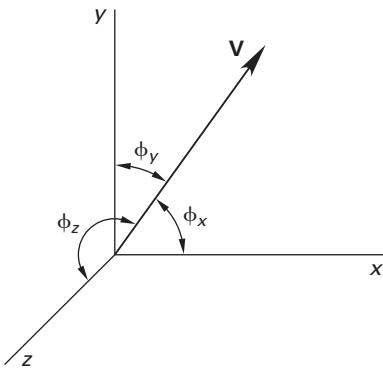

$$V_z = |\mathbf{V}| \cos \phi_z \quad 5.5$$

$$|\mathbf{V}| = \sqrt{V_x^2 + V_y^2 + V_z^2} \quad 5.6$$

In Eq. 5.3 through Eq. 5.5,  $\phi_x$ ,  $\phi_y$ , and  $\phi_z$  are the *direction angles*—the angles between the vector and the  $x$ -,  $y$ -, and  $z$ -axes, respectively. Figure 5.2 shows the location of direction angles. The cosines of these angles are known as *direction cosines*. The sum of the squares of the direction cosines is equal to 1.

$$\cos^2 \phi_x + \cos^2 \phi_y + \cos^2 \phi_z = 1 \quad 5.7$$

**Figure 5.2** Direction Angles of a Vector

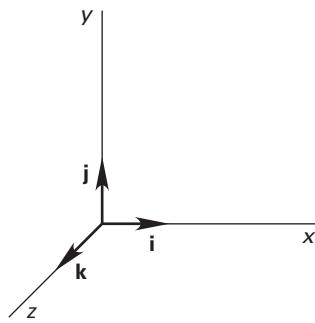

### 3. UNIT VECTORS

*Unit vectors* are vectors with unit magnitudes (i.e., magnitudes of 1). They are represented in the same notation as other vectors. (Unit vectors in this book are written in boldface type.) Although they can have any direction, the standard unit vectors (the *Cartesian unit vectors*  $\mathbf{i}$ ,  $\mathbf{j}$ , and  $\mathbf{k}$ ) have the directions of the  $x$ -,  $y$ -, and  $z$ -coordinate axes and constitute the *Cartesian triad*, as illustrated in Fig. 5.3.

A vector  $\mathbf{V}$  can be written in terms of unit vectors and its components.

$$\mathbf{V} = |\mathbf{V}| \mathbf{a} = V_x \mathbf{i} + V_y \mathbf{j} + V_z \mathbf{k} \quad 5.8$$

**Figure 5.3** Cartesian Unit Vectors

The unit vector,  $\mathbf{a}$ , has the same direction as the vector  $\mathbf{V}$  but has a length of 1. This unit vector is calculated by dividing the original vector,  $\mathbf{V}$ , by its magnitude,  $|\mathbf{V}|$ .

$$\mathbf{a} = \frac{\mathbf{V}}{|\mathbf{V}|} = \frac{V_x \mathbf{i} + V_y \mathbf{j} + V_z \mathbf{k}}{\sqrt{V_x^2 + V_y^2 + V_z^2}} \quad 5.9$$

### 4. VECTOR REPRESENTATION

The most common method of representing a vector is by writing it in *rectangular form*—a vector sum of its orthogonal components. In rectangular form, each of the orthogonal components has the same units as the resultant vector.

$$\mathbf{A} \equiv A_x \mathbf{i} + A_y \mathbf{j} + A_z \mathbf{k} \quad [\text{three dimensions}]$$

However, the vector is also completely defined by its magnitude and associated angle. These two quantities can be written together in *phasor form*, sometimes referred to as *polar form*.

$$\mathbf{A} \equiv |\mathbf{A}| \angle \phi = A \angle \phi$$

### 5. CONVERSION BETWEEN SYSTEMS

The choice of the  $\mathbf{ijk}$  triad may be convenient but is arbitrary. A vector can be expressed in terms of any other set of orthogonal unit vectors,  $\mathbf{uvw}$ .

$$\mathbf{V} = V_x \mathbf{i} + V_y \mathbf{j} + V_z \mathbf{k} = V'_x \mathbf{u} + V'_y \mathbf{v} + V'_z \mathbf{w} \quad 5.10$$

The two representations are related.

$$V'_x = \mathbf{V} \cdot \mathbf{u} = (\mathbf{i} \cdot \mathbf{u}) V_x + (\mathbf{j} \cdot \mathbf{u}) V_y + (\mathbf{k} \cdot \mathbf{u}) V_z \quad 5.11$$

$$V'_y = \mathbf{V} \cdot \mathbf{v} = (\mathbf{i} \cdot \mathbf{v}) V_x + (\mathbf{j} \cdot \mathbf{v}) V_y + (\mathbf{k} \cdot \mathbf{v}) V_z \quad 5.12$$

$$V'_z = \mathbf{V} \cdot \mathbf{w} = (\mathbf{i} \cdot \mathbf{w}) V_x + (\mathbf{j} \cdot \mathbf{w}) V_y + (\mathbf{k} \cdot \mathbf{w}) V_z \quad 5.13$$

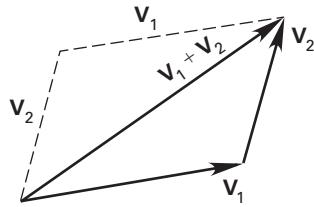

Equation 5.11 through Eq. 5.13 can be expressed in matrix form. The dot products are known as the *coefficients of transformation*, and the matrix containing them is the *transformation matrix*.

$$\begin{pmatrix} V'_x \\ V'_y \\ V'_z \end{pmatrix} = \begin{pmatrix} \mathbf{i} \cdot \mathbf{u} & \mathbf{j} \cdot \mathbf{u} & \mathbf{k} \cdot \mathbf{u} \\ \mathbf{i} \cdot \mathbf{v} & \mathbf{j} \cdot \mathbf{v} & \mathbf{k} \cdot \mathbf{v} \\ \mathbf{i} \cdot \mathbf{w} & \mathbf{j} \cdot \mathbf{w} & \mathbf{k} \cdot \mathbf{w} \end{pmatrix} \begin{pmatrix} V_x \\ V_y \\ V_z \end{pmatrix} \quad 5.14$$

## 6. VECTOR ADDITION

Addition of two vectors by the *polygon method* is accomplished by placing the tail of the second vector at the head (tip) of the first. The sum (i.e., the *resultant vector*) is a vector extending from the tail of the first vector to the head of the second, as shown in Fig. 5.4. Alternatively, the two vectors can be considered as the two sides of a parallelogram, while the sum represents the diagonal. This is known as addition by the *parallelogram method*.

**Figure 5.4** Addition of Two Vectors

The components of the resultant vector are the sums of the components of the added vectors (that is,  $V_{1x} + V_{2x}$ ,  $V_{1y} + V_{2y}$ ,  $V_{1z} + V_{2z}$ ).

Vector addition is both commutative and associative.

$$\mathbf{V}_1 + \mathbf{V}_2 = \mathbf{V}_2 + \mathbf{V}_1 \quad 5.15$$

$$\mathbf{V}_1 + (\mathbf{V}_2 + \mathbf{V}_3) = (\mathbf{V}_1 + \mathbf{V}_2) + \mathbf{V}_3 \quad 5.16$$

## 7. MULTIPLICATION BY A SCALAR

A vector,  $\mathbf{V}$ , can be multiplied by a scalar,  $c$ . If the original vector is represented by its components, each of the components is multiplied by  $c$ .

$$c\mathbf{V} = c|\mathbf{V}|\mathbf{a} = cV_x\mathbf{i} + cV_y\mathbf{j} + cV_z\mathbf{k} \quad 5.17$$

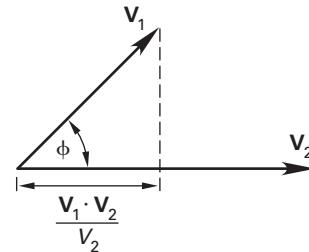

Scalar multiplication is distributive.

$$c(\mathbf{V}_1 + \mathbf{V}_2) = c\mathbf{V}_1 + c\mathbf{V}_2 \quad 5.18$$

## 8. VECTOR DOT PRODUCT

The *dot product (scalar product)*,  $\mathbf{V}_1 \cdot \mathbf{V}_2$ , of two vectors is a scalar that is proportional to the length of the projection of the first vector onto the second vector, as illustrated in Fig. 5.5.<sup>4</sup>

**Figure 5.5** Vector Dot Product

The dot product is commutative and distributive.

$$\mathbf{V}_1 \cdot \mathbf{V}_2 = \mathbf{V}_2 \cdot \mathbf{V}_1 \quad 5.19$$

$$\mathbf{V}_1 \cdot (\mathbf{V}_2 + \mathbf{V}_3) = \mathbf{V}_1 \cdot \mathbf{V}_2 + \mathbf{V}_1 \cdot \mathbf{V}_3 \quad 5.20$$

The dot product can be calculated in two ways, as Eq. 5.21 indicates.  $\phi$  is the acute angle between the two vectors and is less than or equal to 180°.

$$\begin{aligned} \mathbf{V}_1 \cdot \mathbf{V}_2 &= |\mathbf{V}_1| |\mathbf{V}_2| \cos \phi \\ &= V_{1x} V_{2x} + V_{1y} V_{2y} + V_{1z} V_{2z} \end{aligned} \quad 5.21$$

When Eq. 5.21 is solved for the angle between the two vectors,  $\phi$ , it is known as the *Cauchy-Schwartz theorem*.

$$\cos \phi = \frac{V_{1x} V_{2x} + V_{1y} V_{2y} + V_{1z} V_{2z}}{|\mathbf{V}_1| |\mathbf{V}_2|} \quad 5.22$$

The dot product can be used to determine whether a vector is a unit vector and to show that two vectors are orthogonal (perpendicular). For any unit vector,  $\mathbf{u}$ ,

$$\mathbf{u} \cdot \mathbf{u} = 1 \quad 5.23$$

For two non-null orthogonal vectors,

$$\mathbf{V}_1 \cdot \mathbf{V}_2 = 0 \quad 5.24$$

Equation 5.23 and Eq. 5.24 can be extended to the Cartesian unit vectors.

$$\mathbf{i} \cdot \mathbf{i} = 1 \quad 5.25$$

$$\mathbf{j} \cdot \mathbf{j} = 1 \quad 5.26$$

$$\mathbf{k} \cdot \mathbf{k} = 1 \quad 5.27$$

$$\mathbf{i} \cdot \mathbf{j} = 0 \quad 5.28$$

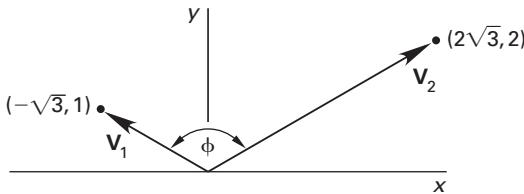

$$\mathbf{i} \cdot \mathbf{k} = 0 \quad 5.29$$

$$\mathbf{j} \cdot \mathbf{k} = 0 \quad 5.30$$

<sup>4</sup>The dot product is also written in parentheses without a dot; that is,  $(\mathbf{V}_1 \mathbf{V}_2)$ .

**Example 5.1**

What is the angle between the zero-based vectors  $\mathbf{V}_1 = (-\sqrt{3}, 1)$  and  $\mathbf{V}_2 = (2\sqrt{3}, 2)$  in an  $x$ - $y$  coordinate system?

*Solution*

From Eq. 5.22,

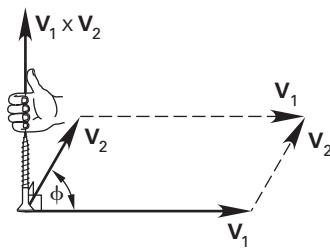

$$\begin{aligned}\cos \phi &= \frac{V_{1x}V_{2x} + V_{1y}V_{2y}}{|\mathbf{V}_1||\mathbf{V}_2|} = \frac{V_{1x}V_{2x} + V_{1y}V_{2y}}{\sqrt{V_{1x}^2 + V_{1y}^2}\sqrt{V_{2x}^2 + V_{2y}^2}} \\ &= \frac{(-\sqrt{3})(2\sqrt{3}) + (1)(2)}{\sqrt{(-\sqrt{3})^2 + (1)^2}\sqrt{(2\sqrt{3})^2 + (2)^2}} \\ &= \frac{-4}{8} \quad \left(-\frac{1}{2}\right) \\ \phi &= \arccos\left(-\frac{1}{2}\right) = 120^\circ\end{aligned}$$

**9. VECTOR CROSS PRODUCT**

The *cross product* (*vector product*),  $\mathbf{V}_1 \times \mathbf{V}_2$ , of two vectors is a vector that is orthogonal (perpendicular) to the plane of the two vectors.<sup>5</sup> The unit vector representation of the cross product can be calculated as a third-order determinant. Figure 5.6 illustrates the vector cross product.

$$\mathbf{V}_1 \times \mathbf{V}_2 = \begin{vmatrix} \mathbf{i} & V_{1x} & V_{2x} \\ \mathbf{j} & V_{1y} & V_{2y} \\ \mathbf{k} & V_{1z} & V_{2z} \end{vmatrix} \quad 5.31$$

Figure 5.6 Vector Cross Product

<sup>5</sup>The cross product is also written in square brackets without a cross, that is,  $[\mathbf{V}_1 \mathbf{V}_2]$ .

The direction of the cross-product vector corresponds to the direction a right-hand screw would progress if vectors  $\mathbf{V}_1$  and  $\mathbf{V}_2$  are placed tail-to-tail in the plane they define and  $\mathbf{V}_1$  is rotated into  $\mathbf{V}_2$ . The direction can also be found from the *right-hand rule*.

The magnitude of the cross product can be determined from Eq. 5.32, in which  $\phi$  is the angle between the two vectors and is limited to  $180^\circ$ . The magnitude corresponds to the area of a parallelogram that has  $\mathbf{V}_1$  and  $\mathbf{V}_2$  as two of its sides.

$$|\mathbf{V}_1 \times \mathbf{V}_2| = |\mathbf{V}_1||\mathbf{V}_2| \sin \phi \quad 5.32$$

Vector cross multiplication is distributive but not commutative.

$$\mathbf{V}_1 \times \mathbf{V}_2 = -(\mathbf{V}_2 \times \mathbf{V}_1) \quad 5.33$$

$$c(\mathbf{V}_1 \times \mathbf{V}_2) = (c\mathbf{V}_1) \times \mathbf{V}_2 = \mathbf{V}_1 \times (c\mathbf{V}_2) \quad 5.34$$

$$\mathbf{V}_1 \times (\mathbf{V}_2 + \mathbf{V}_3) = \mathbf{V}_1 \times \mathbf{V}_2 + \mathbf{V}_1 \times \mathbf{V}_3 \quad 5.35$$

If the two vectors are parallel, their cross product will be zero.

$$\mathbf{i} \times \mathbf{i} = \mathbf{j} \times \mathbf{j} = \mathbf{k} \times \mathbf{k} = 0 \quad 5.36$$

Equation 5.31 and Eq. 5.33 can be extended to the unit vectors.

$$\mathbf{i} \times \mathbf{j} = -\mathbf{j} \times \mathbf{i} = \mathbf{k} \quad 5.37$$

$$\mathbf{j} \times \mathbf{k} = -\mathbf{k} \times \mathbf{j} = \mathbf{i} \quad 5.38$$

$$\mathbf{k} \times \mathbf{i} = -\mathbf{i} \times \mathbf{k} = \mathbf{j} \quad 5.39$$

**Example 5.2**

Find a unit vector orthogonal to  $\mathbf{V}_1 = \mathbf{i} - \mathbf{j} + 2\mathbf{k}$  and  $\mathbf{V}_2 = 3\mathbf{j} - \mathbf{k}$ .

*Solution*

The cross product is a vector orthogonal to  $\mathbf{V}_1$  and  $\mathbf{V}_2$ .

$$\begin{aligned}\mathbf{V}_1 \times \mathbf{V}_2 &= \begin{vmatrix} \mathbf{i} & 1 & 0 \\ \mathbf{j} & -1 & 3 \\ \mathbf{k} & 2 & -1 \end{vmatrix} \\ &= -5\mathbf{i} + \mathbf{j} + 3\mathbf{k}\end{aligned}$$

Check to see whether this is a unit vector.

$$|\mathbf{V}_1 \times \mathbf{V}_2| = \sqrt{(-5)^2 + (1)^2 + (3)^2} = \sqrt{35}$$

Since its length is  $\sqrt{35}$ , the vector must be divided by  $\sqrt{35}$  to obtain a unit vector.

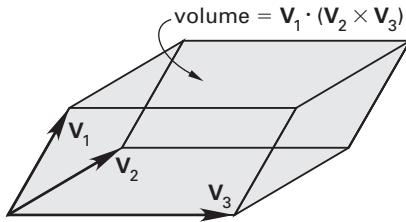

$$\mathbf{a} = \frac{-5\mathbf{i} + \mathbf{j} + 3\mathbf{k}}{\sqrt{35}}$$

## 10. MIXED TRIPLE PRODUCT

The *mixed triple product* (*triple scalar product* or just *triple product*) of three vectors is a scalar quantity representing the volume of a parallelepiped with the three vectors making up the sides. It is calculated as a determinant. Since Eq. 5.40 can be negative, the absolute value must be used to obtain the volume in that case. Figure 5.7 shows a mixed triple product.

$$\mathbf{V}_1 \cdot (\mathbf{V}_2 \times \mathbf{V}_3) = \begin{vmatrix} V_{1x} & V_{1y} & V_{1z} \\ V_{2x} & V_{2y} & V_{2z} \\ V_{3x} & V_{3y} & V_{3z} \end{vmatrix} \quad 5.40$$

**Figure 5.7** Vector Mixed Triple Product

The mixed triple product has the property of *circular permutation*, as defined by Eq. 5.41.

$$\mathbf{V}_1 \cdot (\mathbf{V}_2 \times \mathbf{V}_3) = (\mathbf{V}_1 \times \mathbf{V}_2) \cdot \mathbf{V}_3 \quad 5.41$$

## 11. VECTOR TRIPLE PRODUCT

The *vector triple product* (also known as the *vector triple cross product*, *BAC-CAB identity* (spoken as “BAC minus CAB”), and *Lagrange’s formula*) is a vector defined by Eq. 5.42.<sup>6</sup> The cross products in the parentheses on the right-hand side are scalars, so the vector triple product is the scaled difference between  $\mathbf{V}_2$  and  $\mathbf{V}_3$ . Geometrically, the resultant vector is perpendicular to  $\mathbf{V}_1$  and is in the plane defined by  $\mathbf{V}_2$  and  $\mathbf{V}_3$ .

$$\mathbf{V}_1 \times (\mathbf{V}_2 \times \mathbf{V}_3) = (\mathbf{V}_1 \cdot \mathbf{V}_3)\mathbf{V}_2 - (\mathbf{V}_1 \cdot \mathbf{V}_2)\mathbf{V}_3 \quad 5.42$$

## 12. VECTOR FUNCTIONS

A vector can be a function of another parameter. For example, a vector  $\mathbf{V}$  is a function of variable  $t$  when its  $V_x$ ,  $V_y$ , and  $V_z$  components are functions of  $t$ . For example,

$$\mathbf{V}(t) = (2t - 3)\mathbf{i} + (t^2 + 1)\mathbf{j} + (-7t + 5)\mathbf{k}$$

When the functions of  $t$  are differentiated (or integrated) with respect to  $t$ , the vector itself is differentiated (integrated).<sup>7</sup>

$$\frac{d\mathbf{V}(t)}{dt} = \frac{dV_x}{dt}\mathbf{i} + \frac{dV_y}{dt}\mathbf{j} + \frac{dV_z}{dt}\mathbf{k} \quad 5.43$$

Similarly, the integral of the vector is

$$\int \mathbf{V}(t) dt = \mathbf{i} \int V_x dt + \mathbf{j} \int V_y dt + \mathbf{k} \int V_z dt \quad 5.44$$

<sup>6</sup>This concept is usually encountered only in electrodynamic field theory.

<sup>7</sup>This is particularly valuable when converting among position, velocity, and acceleration vectors.

## 1. DEGREES AND RADIANS

Degrees and radians are two units for measuring angles. One complete circle is divided into 360 degrees (written  $360^\circ$ ) or  $2\pi$  radians (abbreviated *rad*).<sup>1</sup> The conversions between degrees and radians are

multiply	by	to obtain
radians	$\frac{180}{\pi}$	degrees
degrees	$\frac{\pi}{180}$	radians

The number of radians in an angle,  $\theta$ , corresponds to twice the area within a circular sector with arc length  $\theta$  and a radius of one, as shown in Fig. 6.1. Alternatively,

Figure 6.1 Radians and Area of Unit Circle

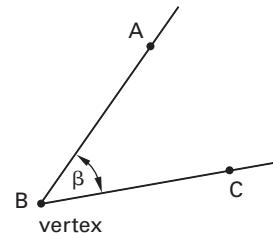

<sup>1</sup>The abbreviation *rad* is also used to represent *radiation absorbed dose*, a measure of radiation exposure.

the area of a sector with central angle  $\theta$  radians is  $\theta/2$  for a *unit circle* (i.e., a circle with a radius of one unit).

## 2. PLANE ANGLES

A *plane angle* (usually referred to as just an *angle*) consists of two intersecting lines and an intersection point known as the *vertex*. The angle can be referred to by a capital letter representing the vertex (e.g., B in Fig. 6.2), a letter representing the angular measure (e.g.,  $B$  or  $\beta$ ), or by three capital letters, where the middle letter is the vertex and the other two letters are two points on different lines, and either the symbol  $\angle$  or  $\measuredangle$  (e.g.,  $\angle ABC$ ).

Figure 6.2 Angle

The angle between two intersecting lines generally is understood to be the smaller angle created.<sup>2</sup> Angles have been classified as follows.

- *acute angle*: an angle less than  $90^\circ$  ( $\pi/2$  rad)
- *obtuse angle*: an angle more than  $90^\circ$  ( $\pi/2$  rad) but less than  $180^\circ$  ( $\pi$  rad)
- *reflex angle*: an angle more than  $180^\circ$  ( $\pi$  rad) but less than  $360^\circ$  ( $2\pi$  rad)
- *related angle*: an angle that differs from another by some multiple of  $90^\circ$  ( $\pi/2$  rad)
- *right angle*: an angle equal to  $90^\circ$  ( $\pi/2$  rad)
- *straight angle*: an angle equal to  $180^\circ$  ( $\pi$  rad); that is, a straight line

*Complementary angles* are two angles whose sum is  $90^\circ$  ( $\pi/2$  rad). *Supplementary angles* are two angles whose sum is  $180^\circ$  ( $\pi$  rad). *Adjacent angles* share a common vertex and one (the interior) side. Adjacent angles are

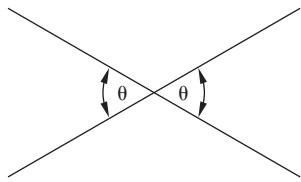

<sup>2</sup>In books on geometry, the term *ray* is used instead of *line*.

supplementary if, and only if, their exterior sides form a straight line.

*Vertical angles* are the two angles with a common vertex and with sides made up by two intersecting straight lines, as shown in Fig. 6.3. Vertical angles are equal.

*Angle of elevation* and *angle of depression* are surveying terms referring to the angle above and below the horizontal plane of the observer, respectively.

Figure 6.3 Vertical Angles

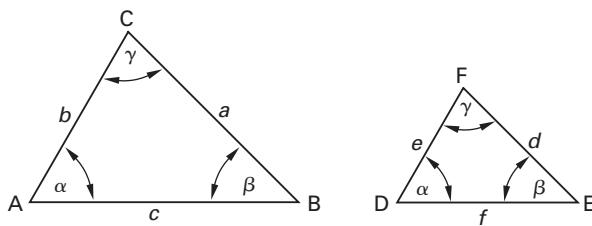

### 3. TRIANGLES

A *triangle* is a three-sided closed polygon with three angles whose sum is  $180^\circ$  ( $\pi$  rad). Triangles are identified by their vertices and the symbol  $\Delta$  (e.g.,  $\Delta ABC$  in Fig. 6.4). A side is designated by its two endpoints (e.g.,  $AB$  in Fig. 6.4) or by a lowercase letter corresponding to the capital letter of the opposite vertex (e.g.,  $c$ ).

In *similar triangles*, the corresponding angles are equal and the corresponding sides are in proportion. (Since there are only two independent angles in a triangle, showing that two angles of one triangle are equal to two angles of the other triangle is sufficient to show similarity.) The symbol for similarity is  $\sim$ . In Fig. 6.4,  $\Delta ABC \sim \Delta DEF$  (i.e.,  $\Delta ABC$  is similar to  $\Delta DEF$ ).

Figure 6.4 Similar Triangles

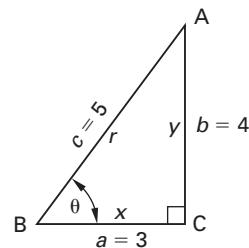

### 4. RIGHT TRIANGLES

A *right triangle* is a triangle in which one of the angles is  $90^\circ$  ( $\pi/2$  rad). The remaining two angles are complementary. If one of the acute angles is chosen as the reference, the sides forming the right angle are known as the *adjacent side*,  $x$ , and the *opposite side*,  $y$ . The longest side is known as the *hypotenuse*,  $r$ . The *Pythagorean theorem* relates the lengths of these sides.

$$x^2 + y^2 = r^2 \quad 6.1$$

In certain cases, the lengths of unknown sides of right triangles can be determined by inspection.<sup>3</sup> This occurs when the lengths of the sides are in the ratios of 3:4:5, 1:1: $\sqrt{2}$ , 1: $\sqrt{3}$ :2, or 5:12:13. Figure 6.5 illustrates a 3:4:5 triangle.

Figure 6.5 3:4:5 Right Triangle

### 5. CIRCULAR TRANSCENDENTAL FUNCTIONS

The *circular transcendental functions* (usually referred to as the *transcendental functions*, *trigonometric functions*, or *functions of an angle*) are calculated from the sides of a right triangle. Equation 6.2 through Eq. 6.7 refer to Fig. 6.5.

$$\text{sine: } \sin \theta = \frac{y}{r} = \frac{\text{opposite}}{\text{hypotenuse}} \quad 6.2$$

$$\text{cosine: } \cos \theta = \frac{x}{r} = \frac{\text{adjacent}}{\text{hypotenuse}} \quad 6.3$$

$$\text{tangent: } \tan \theta = \frac{y}{x} = \frac{\text{opposite}}{\text{adjacent}} \quad 6.4$$

$$\text{cotangent: } \cot \theta = \frac{x}{y} = \frac{\text{adjacent}}{\text{opposite}} \quad 6.5$$

$$\text{secant: } \sec \theta = \frac{r}{x} = \frac{\text{hypotenuse}}{\text{adjacent}} \quad 6.6$$

$$\text{cosecant: } \csc \theta = \frac{r}{y} = \frac{\text{hypotenuse}}{\text{opposite}} \quad 6.7$$

Three of the transcendental functions are reciprocals of the others. However, while the tangent and cotangent functions are reciprocals of each other, the sine and cosine functions are not.

$$\cot \theta = \frac{1}{\tan \theta} \quad 6.8$$

$$\sec \theta = \frac{1}{\cos \theta} \quad 6.9$$

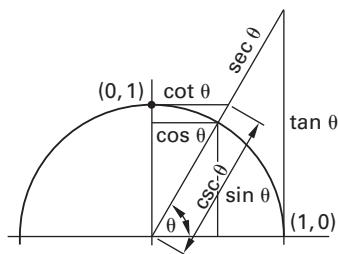

$$\csc \theta = \frac{1}{\sin \theta} \quad 6.10$$

The trigonometric functions correspond to the lengths of various line segments in a right triangle with a unit

<sup>3</sup>These cases are almost always contrived examples. There is nothing intrinsic in nature to cause the formation of triangles with these proportions.

hypotenuse. Figure 6.6 shows such a triangle inscribed in a unit circle.

**Figure 6.6** Trigonometric Functions in a Unit Circle

## 6. SMALL ANGLE APPROXIMATIONS

When an angle is very small, the hypotenuse and adjacent sides are essentially equal in length, and certain approximations can be made. (The angle  $\theta$  must be expressed in radians in Eq. 6.11 and Eq. 6.12.)

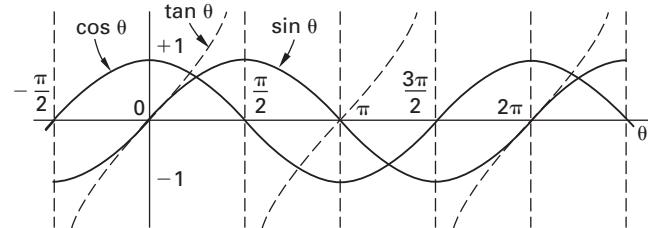

$$\sin \theta \approx \tan \theta \approx \theta \Big|_{\theta < 10^\circ} \quad (0.175 \text{ rad}) \quad 6.11$$

$$\cos \theta \approx 1 \Big|_{\theta < 5^\circ} \quad (0.0873 \text{ rad}) \quad 6.12$$

## 7. GRAPHS OF THE FUNCTIONS

Figure 6.7 illustrates the periodicity of the sine, cosine, and tangent functions.<sup>4</sup>

**Figure 6.7** Graphs of Sine, Cosine, and Tangent Functions

## 8. SIGNS OF THE FUNCTIONS

Table 6.1 shows how the sine, cosine, and tangent functions vary in sign with different values of  $\theta$ . All three functions are positive for angles  $0^\circ \leq \theta \leq 90^\circ$  ( $0 \leq \theta \leq \pi/2$  rad), but only the sine is positive for angles  $90^\circ < \theta \leq 180^\circ$  ( $\pi/2$  rad  $< \theta \leq \pi$  rad). The concept of quadrants is used to summarize the signs of the functions: angles up to  $90^\circ$  ( $\pi/2$  rad) are in quadrant I, angles between  $90^\circ$  and  $180^\circ$  ( $\pi/2$  and  $\pi$  rad) are in quadrant II, and so on.

## 9. FUNCTIONS OF RELATED ANGLES

Figure 6.7 shows that the sine, cosine, and tangent curves are symmetrical with respect to the horizontal

**Table 6.1** Signs of the Functions by Quadrant

function	quadrant			
	I	II	III	IV
sine	+	+	-	-
cosine	+	-	-	+
tangent	+	-	+	-

axis. Furthermore, portions of the curves are symmetrical with respect to a vertical axis. The values of the sine and cosine functions repeat every  $360^\circ$  ( $2\pi$  rad), and the absolute values repeat every  $180^\circ$  ( $\pi$  rad). This can be written as

$$\sin(\theta + 180^\circ) = -\sin \theta \quad 6.13$$

Similarly, the tangent function will repeat every  $180^\circ$  ( $\pi$  rad), and its absolute value will repeat every  $90^\circ$  ( $\pi/2$  rad).

Table 6.2 summarizes the functions of the related angles.

**Table 6.2** Functions of Related Angles

$f(\theta)$	$-\theta$	$90^\circ - \theta$	$90^\circ + \theta$	$180^\circ - \theta$	$180^\circ + \theta$
sin	$-\sin \theta$	$\cos \theta$	$\cos \theta$	$\sin \theta$	$-\sin \theta$
cos	$\cos \theta$	$\sin \theta$	$-\sin \theta$	$-\cos \theta$	$-\cos \theta$
tan	$-\tan \theta$	$\cot \theta$	$-\cot \theta$	$-\tan \theta$	$\tan \theta$

## 10. TRIGONOMETRIC IDENTITIES

There are many relationships between trigonometric functions. For example, Eq. 6.14 through Eq. 6.16 are well known.

$$\sin^2 \theta + \cos^2 \theta = 1 \quad 6.14$$

$$1 + \tan^2 \theta = \sec^2 \theta \quad 6.15$$

$$1 + \cot^2 \theta = \csc^2 \theta \quad 6.16$$

Other relatively common identities are listed as follows.<sup>5</sup>

- double-angle formulas

$$\sin 2\theta = 2 \sin \theta \cos \theta = \frac{2 \tan \theta}{1 + \tan^2 \theta} \quad 6.17$$

$$\cos 2\theta = \cos^2 \theta - \sin^2 \theta = 1 - 2 \sin^2 \theta$$

$$= 2 \cos^2 \theta - 1 = \frac{1 - \tan^2 \theta}{1 + \tan^2 \theta} \quad 6.18$$

$$\tan 2\theta = \frac{2 \tan \theta}{1 - \tan^2 \theta} \quad 6.19$$

$$\cot 2\theta = \frac{\cot^2 \theta - 1}{2 \cot \theta} \quad 6.20$$

<sup>4</sup>The remaining functions, being reciprocals of these three functions, are also periodic.

<sup>5</sup>It is an idiosyncrasy of the subject that these formulas are conventionally referred to as *formulas*, not *identities*.

- two-angle formulas

$$\sin(\theta \pm \phi) = \sin \theta \cos \phi \pm \cos \theta \sin \phi \quad 6.21$$

$$\cos(\theta \pm \phi) = \cos \theta \cos \phi \mp \sin \theta \sin \phi \quad 6.22$$

$$\tan(\theta \pm \phi) = \frac{\tan \theta \pm \tan \phi}{1 \mp \tan \theta \tan \phi} \quad 6.23$$

$$\cot(\theta \pm \phi) = \frac{\cot \phi \cot \theta \mp 1}{\cot \phi \pm \cot \theta} \quad 6.24$$

- half-angle formulas ( $\theta < 180^\circ$ )

$$\sin \frac{\theta}{2} = \sqrt{\frac{1 - \cos \theta}{2}} \quad 6.25$$

$$\cos \frac{\theta}{2} = \sqrt{\frac{1 + \cos \theta}{2}} \quad 6.26$$

$$\tan \frac{\theta}{2} = \sqrt{\frac{1 - \cos \theta}{1 + \cos \theta}} = \frac{\sin \theta}{1 + \cos \theta} = \frac{1 - \cos \theta}{\sin \theta} \quad 6.27$$

- miscellaneous formulas ( $\theta < 90^\circ$ )

$$\sin \theta = 2 \sin \frac{\theta}{2} \cos \frac{\theta}{2} \quad 6.28$$

$$\sin \theta = \sqrt{\frac{1 - \cos 2\theta}{2}} \quad 6.29$$

$$\cos \theta = \cos^2 \frac{\theta}{2} - \sin^2 \frac{\theta}{2} \quad 6.30$$

$$\cos \theta = \sqrt{\frac{1 + \cos 2\theta}{2}} \quad 6.31$$

$$\tan \theta = \frac{2 \tan \frac{\theta}{2}}{1 - \tan^2 \frac{\theta}{2}} = \frac{2 \sin \frac{\theta}{2} \cos \frac{\theta}{2}}{\cos^2 \frac{\theta}{2} - \sin^2 \frac{\theta}{2}} \quad 6.32$$

$$\tan \theta = \sqrt{\frac{1 - \cos 2\theta}{1 + \cos 2\theta}} = \frac{\sin 2\theta}{1 + \cos 2\theta} = \frac{1 - \cos 2\theta}{\sin 2\theta} \quad 6.33$$

$$\begin{aligned} \cot \theta &= \frac{\cot^2 \frac{\theta}{2} - 1}{2 \cot \frac{\theta}{2}} \\ &= \frac{\cos^2 \frac{\theta}{2} - \sin^2 \frac{\theta}{2}}{2 \sin \frac{\theta}{2} \cos \frac{\theta}{2}} \end{aligned} \quad 6.34$$

$$\cot \theta = \sqrt{\frac{1 + \cos 2\theta}{1 - \cos 2\theta}} = \frac{1 + \cos 2\theta}{\sin 2\theta} = \frac{\sin 2\theta}{1 - \cos 2\theta} \quad 6.35$$

## 11. INVERSE TRIGONOMETRIC FUNCTIONS

Finding an angle from a known trigonometric function is a common operation known as an *inverse trigonometric operation*. The inverse function can be designated by adding “inverse,” “arc,” or the superscript  $-1$  to the name of the function. For example,

$$\text{inverse } \sin 0.5 \equiv \arcsin 0.5 \equiv \sin^{-1} 0.5 = 30^\circ$$

## 12. ARCHAIC FUNCTIONS

A few archaic functions are occasionally encountered, primarily in navigation and surveying.<sup>6</sup> The *versine* (*versed sine* or *flipped sine*) is

$$\text{vers } \theta = 1 - \cos \theta = 2 \sin^2 \frac{\theta}{2} \quad 6.36$$

The *coversed sine* (*versed cosine*) is

$$\text{covers } \theta = 1 - \sin \theta \quad 6.37$$

The *haversine* is one-half of the versine.

$$\text{havers } \theta = \frac{1 - \cos \theta}{2} = \sin^2 \frac{\theta}{2} \quad 6.38$$

The *exsecant* is

$$\text{exsec } \theta = \sec \theta - 1 \quad 6.39$$

## 13. HYPERBOLIC TRANSCENDENTAL FUNCTIONS

*Hyperbolic transcendental functions* (normally referred to as *hyperbolic functions*) are specific equations containing combinations of the terms  $e^\theta$  and  $e^{-\theta}$ . These combinations appear regularly in certain types of problems (e.g., analysis of cables and heat transfer through fins) and are given specific names and symbols to simplify presentation.<sup>7</sup>

- hyperbolic sine

$$\sinh \theta = \frac{e^\theta - e^{-\theta}}{2} \quad 6.40$$

- hyperbolic cosine

$$\cosh \theta = \frac{e^\theta + e^{-\theta}}{2} \quad 6.41$$

<sup>6</sup>These functions were useful in eras prior to the widespread use of calculators, because logarithms of their functions eliminated the need for calculating squares and square roots.

<sup>7</sup>The hyperbolic sine and cosine functions are pronounced (by some) as “sinch” and “cosh,” respectively.

- *hyperbolic tangent*

$$\tanh \theta = \frac{e^\theta - e^{-\theta}}{e^\theta + e^{-\theta}} = \frac{\sinh \theta}{\cosh \theta} \quad 6.42$$

- *hyperbolic cotangent*

$$\coth \theta = \frac{e^\theta + e^{-\theta}}{e^\theta - e^{-\theta}} = \frac{\cosh \theta}{\sinh \theta} \quad 6.43$$

- *hyperbolic secant*

$$\operatorname{sech} \theta = \frac{2}{e^\theta + e^{-\theta}} = \frac{1}{\cosh \theta} \quad 6.44$$

- *hyperbolic cosecant*

$$\operatorname{csch} \theta = \frac{2}{e^\theta - e^{-\theta}} = \frac{1}{\sinh \theta} \quad 6.45$$

Hyperbolic functions cannot be related to a right triangle, but they are related to a rectangular (equilateral) hyperbola, as shown in Fig. 6.8. For a *unit hyperbola* ( $a^2=1$ ), the shaded area has a value of  $\theta/2$  and is sometimes given the units of *hyperbolic radians*.

$$\sinh \theta = \frac{y}{a} \quad 6.46$$

$$\cosh \theta = \frac{x}{a} \quad 6.47$$

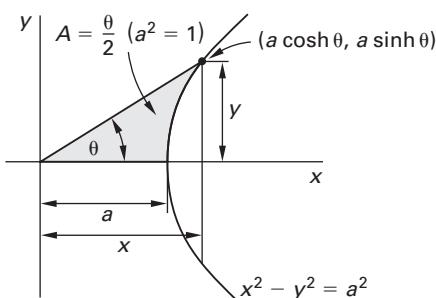

$$\tanh \theta = \frac{y}{x} \quad 6.48$$

$$\coth \theta = \frac{x}{y} \quad 6.49$$

$$\operatorname{sech} \theta = \frac{a}{x} \quad 6.50$$

$$\operatorname{csch} \theta = \frac{a}{y} \quad 6.51$$

**Figure 6.8** Equilateral Hyperbola and Hyperbolic Functions

## 14. HYPERBOLIC IDENTITIES

The hyperbolic identities are different from the standard trigonometric identities. Some of the most important identities are presented as follows.

$$\cosh^2 \theta - \sinh^2 \theta = 1 \quad 6.52$$

$$1 - \tanh^2 \theta = \operatorname{sech}^2 \theta \quad 6.53$$

$$1 - \coth^2 \theta = -\operatorname{csch}^2 \theta \quad 6.54$$

$$\cosh \theta + \sinh \theta = e^\theta \quad 6.55$$

$$\cosh \theta - \sinh \theta = e^{-\theta} \quad 6.56$$

$$\sinh(\theta \pm \phi) = \sinh \theta \cosh \phi \pm \cosh \theta \sinh \phi \quad 6.57$$

$$\cosh(\theta \pm \phi) = \cosh \theta \cosh \phi \pm \sinh \theta \sinh \phi \quad 6.58$$

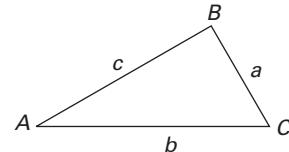

$$\tanh(\theta \pm \phi) = \frac{\tanh \theta \pm \tanh \phi}{1 \pm \tanh \theta \tanh \phi} \quad 6.59$$

## 15. GENERAL TRIANGLES

A *general triangle* (also known as an *oblique triangle*) is one that is not specifically a right triangle, as shown in Fig. 6.9. Equation 6.60 calculates the area of a general triangle.

$$\text{area} = \frac{1}{2}ab \sin C = \frac{1}{2}bc \sin A = \frac{1}{2}ca \sin B \quad 6.60$$

**Figure 6.9** General Triangle

The *law of sines*, as shown in Eq. 6.61, relates the sides and the sines of the angles.

$$\frac{\sin A}{a} = \frac{\sin B}{b} = \frac{\sin C}{c} \quad 6.61$$

The *law of cosines* relates the cosine of an angle to an opposite side. (Equation 6.62 can be extended to the two remaining sides.)

$$a^2 = b^2 + c^2 - 2bc \cos A \quad 6.62$$

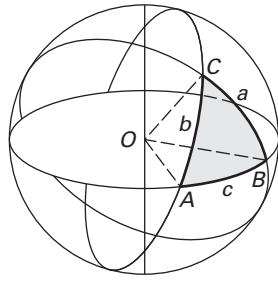

The *law of tangents* relates the sum and difference of two sides. (Equation 6.63 can be extended to the two remaining sides.)

$$\frac{a-b}{a+b} = \frac{\tan\left(\frac{A-B}{2}\right)}{\tan\left(\frac{A+B}{2}\right)} \quad 6.63$$

## 16. SPHERICAL TRIGONOMETRY

A *spherical triangle* is a triangle that has been drawn on the surface of a sphere, as shown in Fig. 6.10. The *trihedral angle*  $O-ABC$  is formed when the vertices  $A$ ,  $B$ , and  $C$  are joined to the center of the sphere. The *face angles* ( $BOC$ ,  $COA$ , and  $AOB$  in Fig. 6.10) are used to measure the sides ( $a$ ,  $b$ , and  $c$  in Fig. 6.10). The *vertex angles* are  $A$ ,  $B$ , and  $C$ . Angles are used to measure both vertex angles and sides.

**Figure 6.10** Spherical Triangle ABC

The following rules are valid for spherical triangles for which each side and angle is less than  $180^\circ$ .

- The sum of the three vertex angles is greater than  $180^\circ$  and less than  $540^\circ$ .

$$180^\circ < A + B + C < 540^\circ \quad 6.64$$

- The sum of any two sides is greater than the third side.
- The sum of the three sides is less than  $360^\circ$ .

$$0^\circ < a + b + c < 360^\circ \quad 6.65$$

- If the two sides are equal, the corresponding angles opposite are equal, and the converse is also true.
- If two sides are unequal, the corresponding angles opposite are unequal. The greater angle is opposite the greater side.

The *spherical excess*,  $\epsilon$ , is the amount by which the sum of the vertex angles exceeds  $180^\circ$ . The *spherical defect*,  $d$ , is the amount by which the sum of the sides differs from  $360^\circ$ .

$$\epsilon = A + B + C - 180^\circ \quad 6.66$$

$$d = 360^\circ - (a + b + c) \quad 6.67$$

There are many trigonometric identities that define the relationships between angles in a spherical triangle. Some of the more common identities are presented as follows.

- *law of sines*

$$\frac{\sin A}{\sin a} = \frac{\sin B}{\sin b} = \frac{\sin C}{\sin c} \quad 6.68$$

- *first law of cosines*

$$\cos a = \cos b \cos c + \sin b \sin c \cos A \quad 6.69$$

- *second law of cosines*

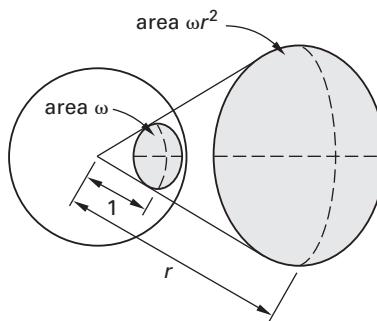

$$\cos A = -\cos B \cos C + \sin B \sin C \cos a \quad 6.70$$

## 17. SOLID ANGLES

A *solid angle*,  $\omega$ , is a measure of the angle subtended at the vertex of a cone, as shown in Fig. 6.11. The solid angle has units of *steradians* (abbreviated *sr*). A steradian is the solid angle subtended at the center of a unit sphere (i.e., a sphere with a radius of one) by a unit area on its surface. Since the surface area of a sphere of radius  $r$  is  $r^2$  times the surface area of a unit sphere, the solid angle is equal to the area cut out by the cone divided by  $r^2$ .

$$\omega = \frac{\text{surface area}}{r^2} \quad 6.71$$

**Figure 6.11** Solid Angle

## 1. MENSURATION OF REGULAR SHAPES

The dimensions, perimeter, area, and other geometric properties constitute the *mensuration* (i.e., the measurements) of a geometric shape. Appendix 7.A and App. 7.B contain formulas and tables used to calculate these properties.

### Example 7.1

In the study of open channel fluid flow, the hydraulic radius is defined as the ratio of flow area to wetted perimeter. What is the hydraulic radius of a 6 in inside diameter pipe filled to a depth of 2 in?

### Solution

Points O, B, and C constitute a circular segment and are used to find the central angle of the circular segment.

$$\frac{1}{2}\angle BOC = \arccos\frac{1}{3} = 70.53^\circ$$

$$\phi = \angle BOC = \frac{(2)(70.53^\circ)(2\pi)}{360^\circ} = 2.462 \text{ rad}$$

From App. 7.A, the area in flow and arc length are

$$\begin{aligned}A &= \frac{1}{2}r^2(\phi - \sin \phi) \\&= (\frac{1}{2})(3 \text{ in})^2(2.462 \text{ rad} - \sin(2.462 \text{ rad})) \\&= 8.251 \text{ in}^2 \\s &= r\phi = (3 \text{ in})(2.462 \text{ rad}) \\&= 7.386 \text{ in}\end{aligned}$$

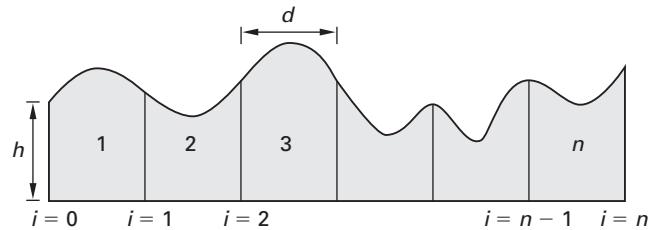

The hydraulic radius is

$$\begin{aligned}r_h &= \frac{A}{s} = \frac{8.251 \text{ in}^2}{7.386 \text{ in}} \\&= 1.12 \text{ in}\end{aligned}$$

## 2. AREAS WITH IRREGULAR BOUNDARIES

Areas of sections with irregular boundaries (such as creek banks) cannot be determined precisely, and approximation methods must be used. If the irregular side can be divided into a series of cells of equal width, either the trapezoidal rule or Simpson's rule can be used. Figure 7.1 shows an example of an irregular area.

Figure 7.1 Irregular Areas

If the irregular side of each cell is fairly straight, the *trapezoidal rule* is appropriate.

$$A = \frac{d}{2} \left( h_0 + h_n + 2 \sum_{i=1}^{n-1} h_i \right) \quad 7.1$$

If the irregular side of each cell is curved (parabolic), *Simpson's rule* should be used. ( $n$  must be even to use Simpson's rule.)

$$A = \frac{d}{3} \left( h_0 + h_n + 4 \sum_{i \text{ odd}}^{n-1} h_i + 2 \sum_{i=2}^{n-2} h_i \right) \quad 7.2$$

### 3. GEOMETRIC DEFINITIONS

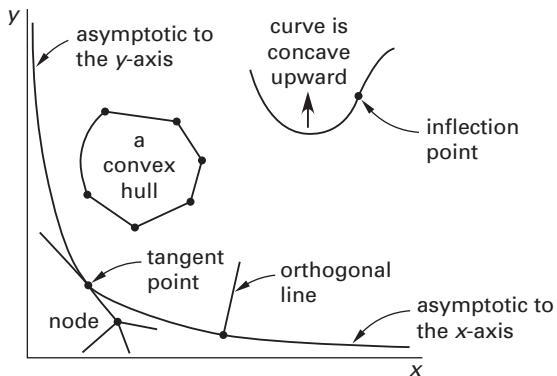

The following terms are used in this book to describe the relationship or orientation of one geometric figure to another. Figure 7.2 illustrates some of the following geometric definitions.

- *abscissa*: the horizontal coordinate, typically designated as  $x$  in a rectangular coordinate system
- *asymptote*: a straight line that is approached but not intersected by a curved line
- *asymptotic*: approaching the slope of another line; attaining the slope of another line in the limit
- *center*: a point equidistant from all other points
- *collinear*: falling on the same line
- *concave*: curved inward (in the direction indicated)<sup>1</sup>
- *convex*: curved outward (in the direction indicated)
- *convex hull*: a closed figure whose surface is convex everywhere
- *coplanar*: falling on the same plane
- *inflection point*: a point where the second derivative changes sign or the curve changes from concave to convex; also known as a *point of contraflexure*
- *locus of points*: a set or collection of points having some common property and being so infinitely close together as to be indistinguishable from a line
- *node*: a point on a line from which other lines enter or leave
- *normal*: rotated 90°; being at right angles
- *ordinate*: the vertical coordinate, typically designated as  $y$  in a rectangular coordinate system
- *orthogonal*: rotated 90°; being at right angles

<sup>1</sup>This is easily remembered since one must go inside to explore a cave.

- *saddle point*: a point on a three-dimensional surface where all adjacent points are higher than the saddle point in one direction (the direction of the saddle) and are lower than the saddle point in an orthogonal direction (the direction of the sides)
- *tangent point*: having equal slopes at a common point

**Figure 7.2** Geometric Definitions

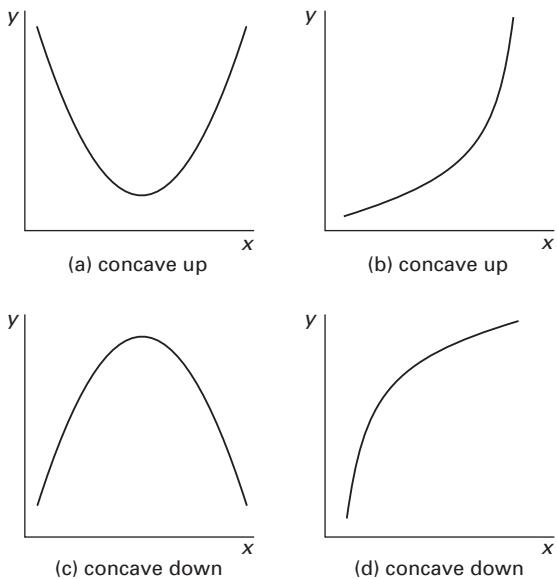

### 4. CONCAVE CURVES

*Concavity* is a term that is applied to curved lines. A *concave up curve* is one whose function's first derivative increases continuously from negative to positive values. Straight lines drawn tangent to concave up curves are all below the curve. The graph of such a function may be thought of as being able to "hold water."

The first derivative of a *concave down curve* decreases continuously from positive to negative. A graph of a concave down function may be thought of as "spilling water." (See Fig. 7.3.)

**Figure 7.3** Concave Curves

## 5. CONVEX REGIONS

*Convexity* is a term that is applied to sets and regions.<sup>2</sup> It plays an important role in many mathematics subjects. A set or multidimensional region is *convex* if it contains the line segment joining any two of its points; that is, if a straight line is drawn connecting any two points in a convex region, that line will lie entirely within the region. For example, the interior of a parabola is a convex region, as is a solid sphere. The *void* or *null region* (i.e., an empty set of points), single points, and straight lines are convex sets. A convex region bounded by separate, connected line segments is known as a *convex hull*. (See Fig. 7.4.)

Figure 7.4 Convexity

Within a convex region, a local maximum is also the global maximum. Similarly, a local minimum is also the global minimum. The intersection of two convex regions is also convex.

## 6. CONGRUENCY

*Congruence* in geometric figures is analogous to *equality* in algebraic expressions. Congruent line segments are segments that have the same length. Congruent angles have the same angular measure. Congruent triangles have the same vertex angles and side lengths.

In general, *congruency*, indicated by the symbol  $\cong$ , means that there is one-to-one correspondence between all points on two objects. This correspondence is defined by the *mapping function* or *isometry*, which can be a translation, rotation, or reflection. Since the identity function is a valid mapping function, every geometric shape is congruent to itself.

Two congruent objects can be in different spaces. For example, a triangular area in three-dimensional space can be mapped into a triangle in two-dimensional space.

## 7. COORDINATE SYSTEMS

The manner in which a geometric figure is described depends on the coordinate system that is used. The three-dimensional system (also known as the *rectangular coordinate system* and *Cartesian coordinate system*)

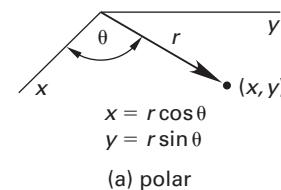

<sup>2</sup>It is tempting to define regions that fail the convexity test as being “concave.” However, it is more proper to define such regions as “nonconvex.” In any case, it is important to recognize that convexity depends on the reference point: An observer within a sphere will see the spherical boundary as convex; an observer outside the sphere may see the boundary as nonconvex.

with its  $x$ -,  $y$ -, and  $z$ -coordinates is the most commonly used in engineering. Table 7.1 summarizes the components needed to specify a point in the various coordinate systems. Figure 7.5 illustrates the use of and conversion between the coordinate systems.

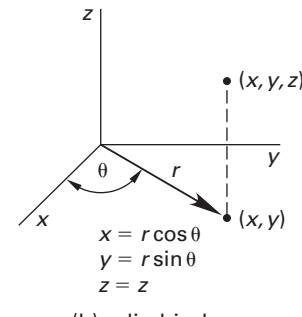

Table 7.1 Components of Coordinate Systems

name	dimensions	components
rectangular	2	$x, y$
rectangular	3	$x, y, z$
polar	2	$r, \theta$
cylindrical	3	$r, \theta, z$
spherical	3	$r, \theta, \phi$

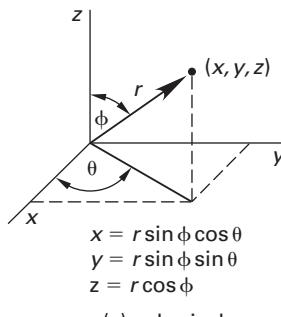

Figure 7.5 Different Coordinate Systems

(b) cylindrical

(c) spherical

## 8. CURVES

A *curve* (commonly called a *line*) is a function over a finite or infinite range of the independent variable. When a curve is drawn in two- or three-dimensional space, it is known as a *graph of the curve*. It may or may not be possible to describe the curve mathematically. The *degree of a curve* is the highest exponent in

the function. For example, Eq. 7.3 is a fourth-degree curve.

$$f(x) = 2x^4 + 7x^3 + 6x^2 + 3x + 9 = 0 \quad 7.3$$

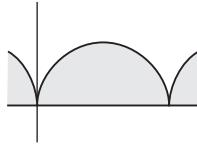

An *ordinary cycloid* ("wheel line") is a curve traced out by a point on the rim of a wheel that rolls without slipping. (See Fig. 7.6.) Cycloids that start with the tracing point down (i.e., on the  $x$ -axis) are described in parametric form by Eq. 7.4 and Eq. 7.5 and in rectangular form by Eq. 7.6. In Eq. 7.4 through Eq. 7.6, using the minus sign results in a bottom (downward) cusp at the origin; using the plus sign results in a vertex (trough) at the origin and a top (upward) cusp.

$$x = r(\theta \pm \sin \theta) \quad 7.4$$

$$y = r(1 \pm \cos \theta) \quad 7.5$$

$$x = r \arccos \frac{r - y}{r} \pm \sqrt{2ry - y^2} \quad 7.6$$

**Figure 7.6** Cycloid (cusp at origin shown)

An *epicycloid* is a curve generated by a point on the rim of a wheel that rolls on the outside of a circle. A *hypocycloid* is a curve generated by a point on the rim of a wheel that rolls on the inside of a circle. The equation of a hypocycloid of four cusps is

$$x^{2/3} + y^{2/3} = r^{2/3} \quad [4 \text{ cusps}] \quad 7.7$$

## 9. SYMMETRY OF CURVES

Two points, P and Q, are symmetrical with respect to a line if the line is a perpendicular bisector of the line segment PQ. If the graph of a curve is unchanged when  $y$  is replaced with  $-y$ , the curve is symmetrical with respect to the  $x$ -axis. If the curve is unchanged when  $x$  is replaced with  $-x$ , the curve is symmetrical with respect to the  $y$ -axis.

Repeating waveforms can be symmetrical with respect to the  $y$ -axis. A curve  $f(x)$  is said to have *even symmetry* if  $f(x) = f(-x)$ . (Alternatively,  $f(x)$  is said to be a *symmetrical function*.) With even symmetry, the function to the left of  $x = 0$  is a reflection of the function to the right of  $x = 0$ . (In effect, the  $y$ -axis is a mirror.) The cosine curve is an example of a curve with even symmetry.

A curve is said to have *odd symmetry* if  $f(x) = -f(-x)$ . (Alternatively,  $f(x)$  is said to be an *asymmetrical function*.<sup>3</sup>) The sine curve is an example of a curve with odd symmetry.

<sup>3</sup>Although they have the same meaning, the semantics of "odd symmetry" and "asymmetrical function" seem contradictory.

A curve is said to have *rotational symmetry (half-wave symmetry)* if  $f(x) = -f(x + \pi)$ .<sup>4</sup> Curves of this type are identical except for a sign reversal on alternate half-cycles. (See Fig. 7.7.)

**Figure 7.7** Waveform Symmetry

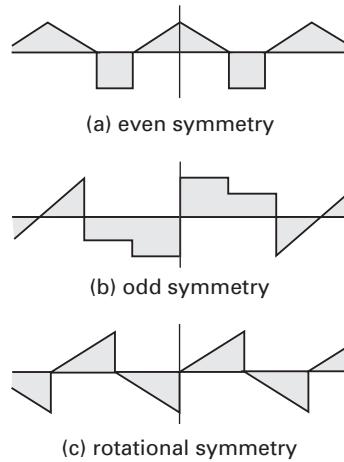

Table 7.2 describes the type of function resulting from the combination of two functions.

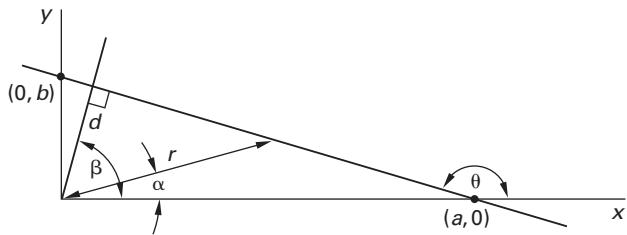

**Table 7.2** Combinations of Functions

	operation			
	+	-	$\times$	$\div$
$f_1(x)$ even, $f_2(x)$ even	even	even	even	even
$f_1(x)$ odd, $f_2(x)$ odd	odd	odd	even	even
$f_1(x)$ even, $f_2(x)$ odd	neither	neither	odd	odd

## 10. STRAIGHT LINES

Figure 7.8 illustrates a straight line in two-dimensional space. The *slope* of the line is  $m$ , the *y-intercept* is  $b$ , and the *x-intercept* is  $a$ . The equation of the line can be represented in several forms. The procedure for finding the equation depends on the form chosen to represent the line. In general, the procedure involves substituting one or more known points on the line into the equation in order to determine the coefficients.

**Figure 7.8** Straight Line

<sup>4</sup>The symbol  $\pi$  represents half of a full cycle of the waveform, not the value 3.141...

- slope-intercept form

$$y = mx + b \quad 7.12$$

$$m = \frac{-A}{B} = \tan \theta = \frac{y_2 - y_1}{x_2 - x_1} \quad 7.13$$

$$b = \frac{-C}{B} \quad 7.14$$

$$a = \frac{-C}{A} \quad 7.15$$

- point-slope form

$$y - y_1 = m(x - x_1) \quad 7.16$$

- intercept form

$$\frac{x}{a} + \frac{y}{b} = 1 \quad 7.17$$

- two-point form

$$\frac{y - y_1}{x - x_1} = \frac{y_2 - y_1}{x_2 - x_1} \quad 7.18$$

- normal form

$$x \cos \beta + y \sin \beta - d = 0 \quad 7.19$$

( $d$  and  $\beta$  are constants;  $x$  and  $y$  are variables.)

- polar form

$$r = \frac{d}{\cos(\beta - \alpha)} \quad 7.20$$

( $d$  and  $\beta$  are constants;  $r$  and  $\alpha$  are variables.)

## 11. DIRECTION NUMBERS, ANGLES, AND COSINES

Given a directed line or vector,  $\mathbf{R}$ , from  $(x_1, y_1, z_1)$  to  $(x_2, y_2, z_2)$ , the *direction numbers* are

$$L = x_2 - x_1 \quad 7.21$$

$$M = y_2 - y_1 \quad 7.22$$

$$N = z_2 - z_1 \quad 7.23$$

The distance between two points is

$$d = \sqrt{L^2 + M^2 + N^2} \quad 7.24$$

The *direction cosines* are

$$\cos \alpha = \frac{L}{d} \quad 7.25$$

$$\cos \beta = \frac{M}{d} \quad 7.26$$

$$\cos \gamma = \frac{N}{d} \quad 7.27$$

The sum of the squares of direction cosines is equal to 1.

$$\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1 \quad 7.28$$

The *direction angles* are the angles between the axes and the lines. They are found from the inverse functions of the direction cosines.

$$\alpha = \arccos \frac{L}{d} \quad 7.29$$

$$\beta = \arccos \frac{M}{d} \quad 7.30$$

$$\gamma = \arccos \frac{N}{d} \quad 7.31$$

The direction cosines can be used to write the equation of the straight line in terms of the unit vectors. The line  $\mathbf{R}$  would be defined as

$$\mathbf{R} = d(\mathbf{i} \cos \alpha + \mathbf{j} \cos \beta + \mathbf{k} \cos \gamma) \quad 7.32$$

Similarly, the line may be written in terms of its direction numbers.

$$\mathbf{R} = L\mathbf{i} + M\mathbf{j} + N\mathbf{k} \quad 7.33$$

### Example 7.2

A directed line,  $\mathbf{R}$ , passes through the points  $(4, 7, 9)$  and  $(0, 1, 6)$ . Write the equation of the line in terms of its (a) direction numbers and (b) direction cosines.

*Solution*

(a) The direction numbers are

$$L = 4 - 0 = 4$$

$$M = 7 - 1 = 6$$

$$N = 9 - 6 = 3$$

Using Eq. 7.33,

$$\mathbf{R} = 4\mathbf{i} + 6\mathbf{j} + 3\mathbf{k}$$

(b) The distance between the two points is

$$d = \sqrt{(4)^2 + (6)^2 + (3)^2} = 7.81$$

From Eq. 7.32, the line in terms of its direction cosines is

$$\begin{aligned}\mathbf{R} &= 7.81 \left( \frac{4\mathbf{i} + 6\mathbf{j} + 3\mathbf{k}}{7.81} \right) \\ &= (7.81)(0.512\mathbf{i} + 0.768\mathbf{j} + 0.384\mathbf{k})\end{aligned}$$

## 12. INTERSECTION OF TWO LINES

The intersection of two lines is a point. The location of the intersection point can be determined by setting the two equations equal and solving them in terms of a common variable. Alternatively, Eq. 7.34 and Eq. 7.35 can be used to calculate the coordinates of the intersection point.

$$x = \frac{B_2 C_1 - B_1 C_2}{A_2 B_1 - A_1 B_2} \quad 7.34$$

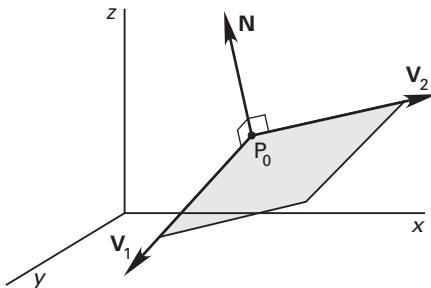

$$y = \frac{A_1 C_2 - A_2 C_1}{A_2 B_1 - A_1 B_2} \quad 7.35$$

## 13. PLANES

A *plane* in three-dimensional space, as shown in Fig. 7.9, is completely determined by one of the following.

- three noncollinear points
- two nonparallel vectors  $\mathbf{V}_1$  and  $\mathbf{V}_2$  and their intersection point  $P_0$
- a point  $P_0$  and a vector,  $\mathbf{N}$ , normal to the plane (i.e., the *normal vector*)

**Figure 7.9** Plane in Three-Dimensional Space

The plane can be specified mathematically in one of two ways: in rectangular form or as a parametric equation. The general form is

$$A(x - x_0) + B(y - y_0) + C(z - z_0) = 0 \quad 7.36$$

$x_0$ ,  $y_0$ , and  $z_0$  are the coordinates of the intersection point of any two vectors in the plane. The coefficients

$A$ ,  $B$ , and  $C$  are the same as the coefficients of the normal vector,  $\mathbf{N}$ .

$$\mathbf{N} = \mathbf{V}_1 \times \mathbf{V}_2 = A\mathbf{i} + B\mathbf{j} + C\mathbf{k} \quad 7.37$$

Equation 7.36 can be simplified as follows.

$$Ax + By + Cz + D = 0 \quad 7.38$$

$$D = -(Ax_0 + By_0 + Cz_0) \quad 7.39$$

The following procedure can be used to determine the equation of a plane from three noncollinear points,  $P_1$ ,  $P_2$ , and  $P_3$ , or from a normal vector and a single point.

*step 1:* (If the normal vector is known, go to step 3.) Determine the equations of the vectors  $\mathbf{V}_1$  and  $\mathbf{V}_2$  from two pairs of the points. For example, determine  $\mathbf{V}_1$  from points  $P_1$  and  $P_2$ , and determine  $\mathbf{V}_2$  from  $P_1$  and  $P_3$ . Express the vectors in the form  $A\mathbf{i} + B\mathbf{j} + C\mathbf{k}$ .

$$\begin{aligned}\mathbf{V}_1 &= (x_2 - x_1)\mathbf{i} + (y_2 - y_1)\mathbf{j} \\ &\quad + (z_2 - z_1)\mathbf{k}\end{aligned} \quad 7.40$$

$$\begin{aligned}\mathbf{V}_2 &= (x_3 - x_1)\mathbf{i} + (y_3 - y_1)\mathbf{j} \\ &\quad + (z_3 - z_1)\mathbf{k}\end{aligned} \quad 7.41$$

*step 2:* Find the normal vector,  $\mathbf{N}$ , as the cross product of the two vectors.

$$\begin{aligned}\mathbf{N} &= \mathbf{V}_1 \times \mathbf{V}_2 \\ &= \begin{vmatrix} \mathbf{i} & (x_2 - x_1) & (x_3 - x_1) \\ \mathbf{j} & (y_2 - y_1) & (y_3 - y_1) \\ \mathbf{k} & (z_2 - z_1) & (z_3 - z_1) \end{vmatrix}\end{aligned} \quad 7.42$$

*step 3:* Write the general equation of the plane in rectangular form using the coefficients  $A$ ,  $B$ , and  $C$  from the normal vector and any one of the three points as  $P_0$ . (See Eq. 7.36.)

The parametric equations of a plane also can be written as a linear combination of the components of two vectors in the plane. Referring to Fig. 7.9, the two known vectors are

$$\mathbf{V}_1 = V_{1x}\mathbf{i} + V_{1y}\mathbf{j} + V_{1z}\mathbf{k} \quad 7.43$$

$$\mathbf{V}_2 = V_{2x}\mathbf{i} + V_{2y}\mathbf{j} + V_{2z}\mathbf{k} \quad 7.44$$

If  $s$  and  $t$  are scalars, the coordinates of each point in the plane can be written as Eq. 7.45 through Eq. 7.47. These are the parametric equations of the plane.

$$x = x_0 + sV_{1x} + tV_{2x} \quad 7.45$$

$$y = y_0 + sV_{1y} + tV_{2y} \quad 7.46$$

$$z = z_0 + sV_{1z} + tV_{2z} \quad 7.47$$

**Example 7.3**

A plane is defined by the following points.

$$P_1 = (2, 1, -4)$$

$$P_2 = (4, -2, -3)$$

$$P_3 = (2, 3, -8)$$

Determine the equation of the plane in (a) general form and (b) parametric form.

*Solution*

(a) Use the first two points to find a vector,  $\mathbf{V}_1$ .

$$\begin{aligned}\mathbf{V}_1 &= (x_2 - x_1)\mathbf{i} + (y_2 - y_1)\mathbf{j} + (z_2 - z_1)\mathbf{k} \\ &= (4 - 2)\mathbf{i} + (-2 - 1)\mathbf{j} + (-3 - (-4))\mathbf{k} \\ &= 2\mathbf{i} - 3\mathbf{j} + 1\mathbf{k}\end{aligned}$$

Similarly, use the first and third points to find  $\mathbf{V}_2$ .

$$\begin{aligned}\mathbf{V}_2 &= (x_3 - x_1)\mathbf{i} + (y_3 - y_1)\mathbf{j} + (z_3 - z_1)\mathbf{k} \\ &= (2 - 2)\mathbf{i} + (3 - 1)\mathbf{j} + (-8 - (-4))\mathbf{k} \\ &= 0\mathbf{i} + 2\mathbf{j} - 4\mathbf{k}\end{aligned}$$

From Eq. 7.42, determine the normal vector as a determinant.

$$\mathbf{N} = \begin{vmatrix} \mathbf{i} & 2 & 0 \\ \mathbf{j} & -3 & 2 \\ \mathbf{k} & 1 & -4 \end{vmatrix}$$

Expand the determinant across the top row.

$$\begin{aligned}\mathbf{N} &= \mathbf{i}(12 - 2) - 2(-4\mathbf{j} - 2\mathbf{k}) \\ &= 10\mathbf{i} + 8\mathbf{j} + 4\mathbf{k}\end{aligned}$$

The rectangular form of the equation of the plane uses the same constants as in the normal vector. Use the first point and write the equation of the plane in the form of Eq. 7.36.

$$(10)(x - 2) + (8)(y - 1) + (4)(z + 4) = 0$$

The three constant terms can be combined by using Eq. 7.39.

$$D = -(10)(2) + (8)(1) + (4)(-4) = -12$$

The equation of the plane is

$$10x + 8y + 4z - 12 = 0$$

(b) The parametric equations based on the first point and for any values of  $s$  and  $t$  are

$$x = 2 + 2s + 0t$$

$$y = 1 - 3s + 2t$$

$$z = -4 + 1s - 4t$$

The scalars  $s$  and  $t$  are not unique. Two of the three coordinates can also be chosen as the parameters. Dividing the rectangular form of the plane's equation by 4 to isolate  $z$  results in an alternate set of parametric equations.

$$x = x$$

$$y = y$$

$$z = 3 - 2.5x - 2y$$

#### 14. DISTANCES BETWEEN GEOMETRIC FIGURES

The smallest distance,  $d$ , between various geometric figures is given by the following equations.

- Between two points in  $(x, y, z)$  format,

$$d = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2} \quad 7.48$$

- Between a point  $(x_0, y_0)$  and a line  $Ax + By + C = 0$ ,

$$d = \frac{|Ax_0 + By_0 + C|}{\sqrt{A^2 + B^2}} \quad 7.49$$

- Between a point  $(x_0, y_0, z_0)$  and a plane  $Ax + By + Cz + D = 0$ ,

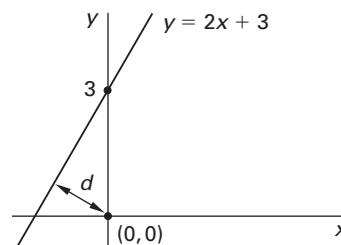

$$d = \frac{|Ax_0 + By_0 + Cz_0 + D|}{\sqrt{A^2 + B^2 + C^2}} \quad 7.50$$

- Between two parallel lines  $Ax + By + C = 0$ ,

$$d = \left| \frac{|C_2|}{\sqrt{A_2^2 + B_2^2}} - \frac{|C_1|}{\sqrt{A_1^2 + B_1^2}} \right| \quad 7.51$$

#### Example 7.4

What is the minimum distance between the line  $y = 2x + 3$  and the origin  $(0, 0)$ ?

**Solution**

Put the equation in general form.

$$Ax + By + C = 2x - y + 3 = 0$$

Use Eq. 7.49 with  $(x, y) = (0, 0)$ .

$$\begin{aligned} d &= \frac{|Ax + By + C|}{\sqrt{A^2 + B^2}} = \frac{(2)(0) + (-1)(0) + 3}{\sqrt{(2)^2 + (-1)^2}} \\ &= \frac{3}{\sqrt{5}} \end{aligned}$$

## 15. ANGLES BETWEEN GEOMETRIC FIGURES

The angle,  $\phi$ , between various geometric figures is given by the following equations.

- Between two lines in  $Ax + By + C = 0$ ,  $y = mx + b$ , or direction angle formats,

$$\phi = \arctan\left(\frac{A_1B_2 - A_2B_1}{A_1A_2 + B_1B_2}\right) \quad 7.52$$

$$\phi = \arctan\left(\frac{m_2 - m_1}{1 + m_1m_2}\right) \quad 7.53$$

$$\phi = |\arctan m_1 - \arctan m_2| \quad 7.54$$

$$\phi = \arccos\left(\frac{L_1L_2 + M_1M_2 + N_1N_2}{d_1d_2}\right) \quad 7.55$$

$$\phi = \arccos\left(\frac{\cos \alpha_1 \cos \alpha_2 + \cos \beta_1 \cos \beta_2}{\cos \gamma_1 \cos \gamma_2}\right) \quad 7.56$$

If the lines are parallel, then  $\phi = 0$ .

$$\frac{A_1}{A_2} = \frac{B_1}{B_2} \quad 7.57$$

$$m_1 = m_2 \quad 7.58$$

$$\alpha_1 = \alpha_2; \beta_1 = \beta_2; \gamma_1 = \gamma_2 \quad 7.59$$

If the lines are perpendicular, then  $\phi = 90^\circ$ .

$$A_1A_2 = -B_1B_2 \quad 7.60$$

$$m_1 = \frac{-1}{m_2} \quad 7.61$$

$$\alpha_1 + \alpha_2 = \beta_1 + \beta_2 = \gamma_1 + \gamma_2 = 90^\circ \quad 7.62$$

- Between two planes in  $A_i\mathbf{i} + B_j\mathbf{j} + C_k\mathbf{k} = 0$  format, the coefficients  $A$ ,  $B$ , and  $C$  are the same as the coefficients for the normal vector. (See Eq. 7.37.)  $\phi$  is equal to the angle between the two normal vectors.

$$\cos \phi = \frac{|A_1A_2 + B_1B_2 + C_1C_2|}{\sqrt{A_1^2 + B_1^2 + C_1^2}\sqrt{A_2^2 + B_2^2 + C_2^2}} \quad 7.63$$

### Example 7.5

Use Eq. 7.52, Eq. 7.53, and Eq. 7.54 to find the angle between the lines.

$$y = -0.577x + 2$$

$$y = +0.577x - 5$$

**Solution**

Write both equations in general form.

$$-0.577x - y + 2 = 0$$

$$0.577x - y - 5 = 0$$

- (a) From Eq. 7.52,

$$\begin{aligned} \phi &= \arctan\left(\frac{A_1B_2 - A_2B_1}{A_1A_2 + B_1B_2}\right) \\ &= \arctan\left(\frac{(-0.577)(-1) - (0.577)(-1)}{(-0.577)(0.577) + (-1)(-1)}\right) \\ &= 60^\circ \end{aligned}$$

- (b) Use Eq. 7.53.

$$\begin{aligned} \phi &= \arctan\left(\frac{m_2 - m_1}{1 + m_1m_2}\right) \\ &= \arctan\left(\frac{0.577 - (-0.577)}{1 + (0.577)(-0.577)}\right) \\ &= 60^\circ \end{aligned}$$

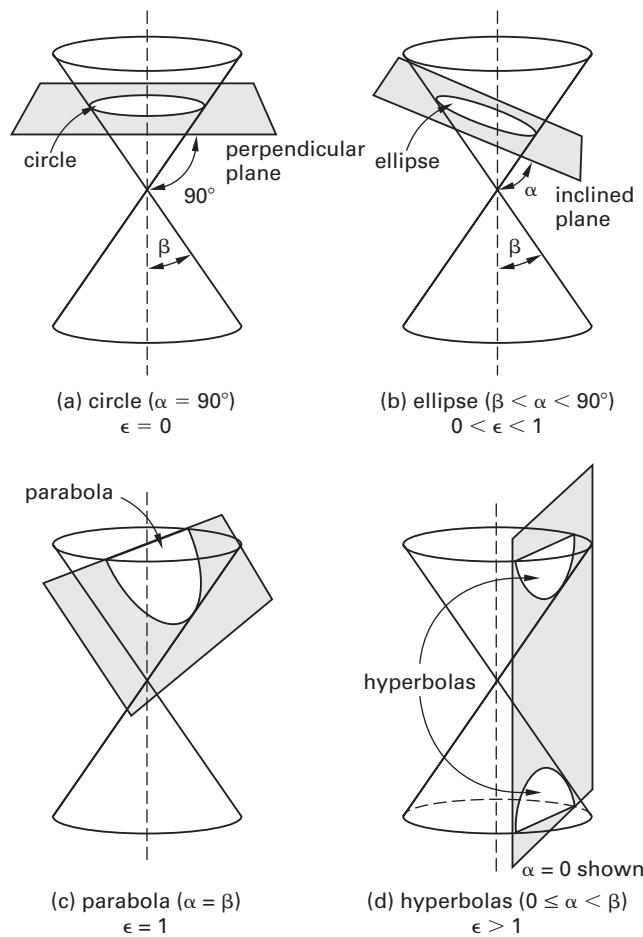

- (c) Use Eq. 7.54.

$$\begin{aligned} \phi &= |\arctan m_1 - \arctan m_2| \\ &= |\arctan(-0.577) - \arctan(0.577)| \\ &= |-30^\circ - 30^\circ| \\ &= 60^\circ \end{aligned}$$

## 16. CONIC SECTIONS

A *conic section* is any one of several curves produced by passing a plane through a cone as shown in Fig. 7.10. If  $\alpha$  is the angle between the vertical axis and the cutting plane and  $\beta$  is the cone generating angle, Eq. 7.64 gives the *eccentricity*,  $\epsilon$ , of the conic section. Values of the eccentricity are given in Fig. 7.10.

$$\epsilon = \frac{\cos \alpha}{\cos \beta} \quad 7.64$$

**Figure 7.10** Conic Sections Produced by Cutting Planes

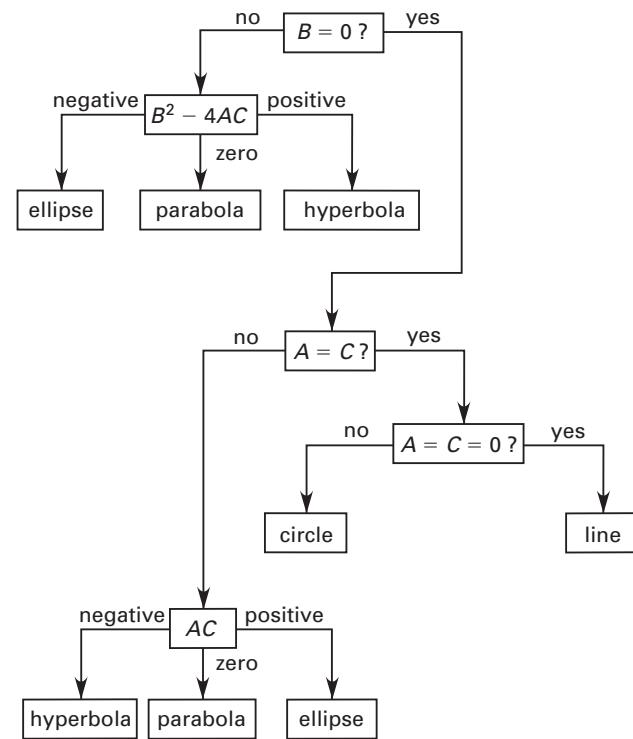

All conic sections are described by second-degree polynomials (i.e., *quadratic equations*) of the following form.<sup>5</sup>

$$Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0 \quad 7.65$$

This is the *general form*, which allows the figure axes to be at any angle relative to the coordinate axes. The *standard forms* presented in the following sections pertain to figures whose axes coincide with the coordinate axes, thereby eliminating certain terms of the general equation.

Figure 7.11 can be used to determine which conic section is described by the quadratic function. The quantity  $B^2 - 4AC$  is known as the *discriminant*. Figure 7.11 determines only the type of conic section; it does not determine whether the conic section is degenerate (e.g., a circle with a negative radius).

<sup>5</sup>One or more straight lines are produced when the cutting plane passes through the cone's vertex. Straight lines can be considered to be quadratic functions without second-degree terms.

**Figure 7.11** Determining Conic Sections from Quadratic Equations

### Example 7.6

What geometric figures are described by the following equations?

- $4y^2 - 12y + 16x + 41 = 0$
- $x^2 - 10xy + y^2 + x + y + 1 = 0$
- $x^2 + 4y^2 + 2x - 8y + 1 = 0$
- $x^2 + y^2 - 6x + 8y + 20 = 0$

### Solution

(a) Referring to Fig. 7.11,  $B = 0$  since there is no  $xy$  term,  $A = 1$  since there is no  $x^2$  term, and  $AC = (1)(4) = 4$ . This is a parabola.

(b)  $B \neq 0$ ;  $B^2 - 4AC = (-10)^2 - (4)(1)(1) = +96$ . This is a hyperbola.

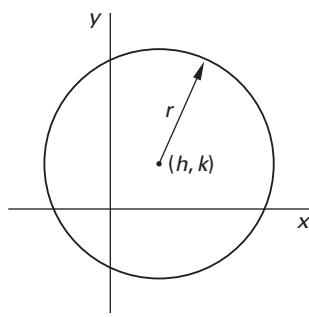

(c)  $B = 0$ ;  $A \neq C$ ;  $AC = (1)(4) = +4$ . This is an ellipse.

(d)  $B = 0$ ;  $A = C$ ;  $A = C = 1 \neq 0$ . This is a circle.

## 17. CIRCLE

The general form of the equation of a circle, as illustrated in Fig. 7.12, is

$$Ax^2 + Ay^2 + Dx + Ey + F = 0 \quad 7.66$$

**Figure 7.12** Circle

The *center-radius form* of the equation of a circle with radius  $r$  and center at  $(h, k)$  is

$$(x - h)^2 + (y - k)^2 = r^2 \quad 7.67$$

The two forms can be converted by use of Eq. 7.68 through Eq. 7.70.

$$h = \frac{-D}{2A} \quad 7.68$$

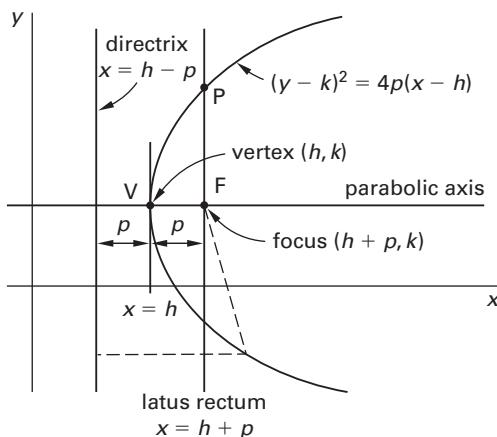

$$k = \frac{-E}{2A} \quad 7.69$$

$$r^2 = \frac{D^2 + E^2 - 4AF}{4A^2} \quad 7.70$$

If the right-hand side of Eq. 7.70 is positive, the figure is a circle. If it is zero, the circle shrinks to a point. If the right-hand side is negative, the figure is imaginary. A *degenerate circle* is one in which the right-hand side is less than or equal to zero.

## 18. PARABOLA

A *parabola* is the locus of points equidistant from the *focus* (point  $F$  in Fig. 7.13) and a line called the *directrix*. A parabola is symmetric with respect to its *parabolic axis*. The line normal to the parabolic axis and passing through the focus is known as the *latus rectum*. The eccentricity of a parabola is 1.

**Figure 7.13** Parabola

There are two common types of parabolas in the Cartesian plane—those that open right and left, and those that open up and down. Equation 7.65 is the general form of the equation of a parabola. With Eq. 7.71, the parabola points horizontally to the right if  $CD > 0$  and to the left if  $CD < 0$ . With Eq. 7.72, the parabola points vertically up if  $AE > 0$  and down if  $AE < 0$ .

$$Cy^2 + Dx + Ey + F = 0 \left| \begin{array}{l} C, D \neq 0 \\ \text{opens horizontally} \end{array} \right. \quad 7.71$$

$$Ax^2 + Dx + Ey + F = 0 \left| \begin{array}{l} A, E \neq 0 \\ \text{opens vertically} \end{array} \right. \quad 7.72$$

The *standard form* of the equation of a parabola with vertex at  $(h, k)$ , focus at  $(h + p, k)$ , and directrix at  $x = h - p$ , and that opens to the right or left is given by Eq. 7.73. The parabola opens to the right (points to the left) if  $p > 0$  and opens to the left (points to the right) if  $p < 0$ .

$$(y - k)^2 = 4p(x - h) \left| \begin{array}{l} \text{opens horizontally} \end{array} \right. \quad 7.73$$

$$y^2 = 4px \left| \begin{array}{l} \text{vertex at origin} \\ h = k = 0 \end{array} \right. \quad 7.74$$

The *standard form* of the equation of a parabola with vertex at  $(h, k)$ , focus at  $(h, k + p)$ , and directrix at  $y = k - p$ , and that opens up or down is given by Eq. 7.75. The parabola opens up (points down) if  $p > 0$  and opens down (points up) if  $p < 0$ .

$$(x - h)^2 = 4p(y - k) \left| \begin{array}{l} \text{opens vertically} \end{array} \right. \quad 7.75$$

$$x^2 = 4py \left| \begin{array}{l} \text{vertex at origin} \end{array} \right. \quad 7.76$$

The general and vertex forms of the equations can be reconciled with Eq. 7.77 through Eq. 7.79. Whether the first or second forms of these equations are used depends on whether the parabola opens horizontally or vertically (i.e., whether  $A = 0$  or  $C = 0$ ), respectively.

$$h = \begin{cases} \frac{E^2 - 4CF}{4CD} & [\text{opens horizontally}] \\ \frac{-D}{2A} & [\text{opens vertically}] \end{cases} \quad 7.77$$

$$k = \begin{cases} \frac{-E}{2C} & [\text{opens horizontally}] \\ \frac{D^2 - 4AF}{4AE} & [\text{opens vertically}] \end{cases} \quad 7.78$$

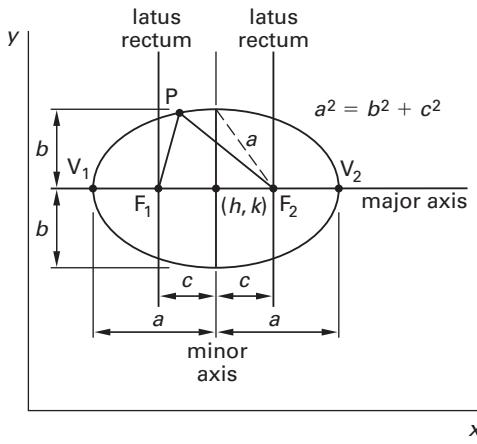

$$p = \begin{cases} \frac{-D}{4C} & [\text{opens horizontally}] \\ \frac{-E}{4A} & [\text{opens vertically}] \end{cases} \quad 7.79$$

## 19. ELLIPSE

An ellipse has two foci separated along its *major axis* by a distance  $2c$ , as shown in Fig. 7.14. The line perpendicular to the major axis passing through the center of the ellipse is the *minor axis*. The two lines passing through the foci perpendicular to the major axis are the *latera recta*. The distance between the two vertices is  $2a$ . The ellipse is the locus of those points whose distances from the two foci add up to  $2a$ . For each point  $P$  on the ellipse,

$$F_1P + PF_2 = 2a \quad 7.80$$

**Figure 7.14** Ellipse

Equation 7.81 is the standard equation used for an ellipse with axes parallel to the coordinate axes, while Eq. 7.65 is the general form.  $F$  is not independent of  $A$ ,  $D$ , and  $E$  for the ellipse.

$$Ax^2 + Cy^2 + Dx + Ey + F = 0 \quad \begin{cases} AC > 0 \\ A \neq C \end{cases} \quad 7.81$$

Equation 7.82 gives the standard form of the equation of an ellipse centered at  $(h, k)$ . Distances  $a$  and  $b$  are known as the *semimajor distance* and *semiminor distance*, respectively.

$$\frac{(x - h)^2}{a^2} + \frac{(y - k)^2}{b^2} = 1 \quad 7.82$$

The distance between the two foci is  $2c$ .

$$2c = 2\sqrt{a^2 - b^2} \quad 7.83$$

The *aspect ratio* of the ellipse is

$$\text{aspect ratio} = \frac{a}{b} \quad 7.84$$

The *eccentricity*,  $\epsilon$ , of the ellipse is always less than 1. If the eccentricity is zero, the figure is a circle (another form of a *degenerative ellipse*).

$$\epsilon = \frac{\sqrt{a^2 - b^2}}{a} < 1 \quad 7.85$$

The standard and center forms of the equations of an ellipse can be reconciled by using Eq. 7.86 through Eq. 7.89.

$$h = \frac{-D}{2A} \quad 7.86$$

$$k = \frac{-E}{2C} \quad 7.87$$

$$a = \sqrt{C} \quad 7.88$$

$$b = \sqrt{A} \quad 7.89$$

## 20. HYPERBOLA

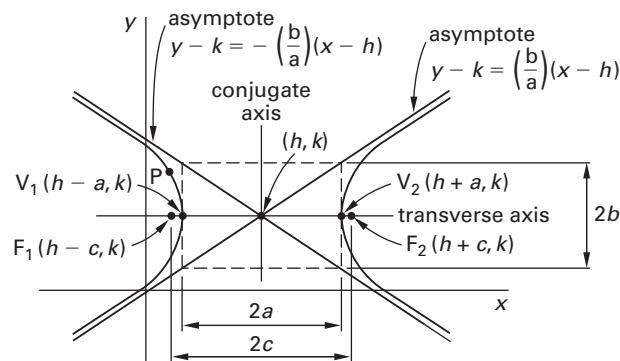

A *hyperbola* has two foci separated along its *transverse axis (major axis)* by a distance  $2c$ , as shown in Fig. 7.15. The line perpendicular to the transverse axis and midway between the foci is the *conjugate axis (minor axis)*. The distance between the two vertices is  $2a$ . If a line is drawn parallel to the conjugate axis through either vertex, the distance between the points where it intersects the asymptotes is  $2b$ . The hyperbola is the locus of those points whose distances from the two foci differ by  $2a$ . For each point  $P$  on the hyperbola,

$$F_2P - PF_1 = 2a \quad 7.90$$

Equation 7.91 is the standard equation of a hyperbola. Coefficients  $A$  and  $C$  have opposite signs.

$$Ax^2 + Cy^2 + Dx + Ey + F = 0 \quad |_{AC < 0} \quad 7.91$$

**Figure 7.15** Hyperbola

Equation 7.92 gives the standard form of the equation of a hyperbola centered at  $(h, k)$  and opening to the left and right.

$$\frac{(x-h)^2}{a^2} - \frac{(y-k)^2}{b^2} = 1 \quad \left| \begin{array}{l} \text{opens horizontally} \\ \text{Eq. 7.92} \end{array} \right.$$

Equation 7.93 gives the standard form of the equation of a hyperbola that is centered at  $(h, k)$  and is opening up and down.

$$\frac{(y-k)^2}{a^2} - \frac{(x-h)^2}{b^2} = 1 \quad \left| \begin{array}{l} \text{opens vertically} \\ \text{Eq. 7.93} \end{array} \right.$$

The distance between the two foci is  $2c$ .

$$2c = 2\sqrt{a^2 + b^2} \quad \text{Eq. 7.94}$$

The eccentricity,  $\epsilon$ , of the hyperbola is calculated from Eq. 7.95 and is always greater than 1.

$$\epsilon = \frac{c}{a} = \frac{\sqrt{a^2 + b^2}}{a} > 1 \quad \text{Eq. 7.95}$$

The hyperbola is asymptotic to the lines given by Eq. 7.96 and Eq. 7.97.

$$y = \pm \frac{b}{a}(x-h) + k \quad \left| \begin{array}{l} \text{opens horizontally} \\ \text{Eq. 7.96} \end{array} \right.$$

$$y = \pm \frac{a}{b}(x-h) + k \quad \left| \begin{array}{l} \text{opens vertically} \\ \text{Eq. 7.97} \end{array} \right.$$

For a *rectangular (equilateral) hyperbola*, the asymptotes are perpendicular,  $a = b$ ,  $c = \sqrt{2}a$ , and the eccentricity is  $\epsilon = \sqrt{2}$ . If the hyperbola is centered at the origin (i.e.,  $h = k = 0$ ), then the equations are  $x^2 - y^2 = a^2$  (opens horizontally) and  $y^2 - x^2 = a^2$  (opens vertically).

If the asymptotes are the  $x$ - and  $y$ -axes, the equation of the hyperbola is simply

$$xy = \pm \frac{a^2}{2} \quad \text{Eq. 7.98}$$

The general and center forms of the equations of a hyperbola can be reconciled by using Eq. 7.99 through Eq. 7.103. Whether the hyperbola opens left and right or up and down depends on whether  $M/A$  or  $M/C$  is positive, respectively, where  $M$  is defined by Eq. 7.99.

$$M = \frac{D^2}{4A} + \frac{E^2}{4C} - F \quad \text{Eq. 7.99}$$

$$h = \frac{-D}{2A} \quad \text{Eq. 7.100}$$

$$k = \frac{-E}{2C} \quad \text{Eq. 7.101}$$

$$a = \begin{cases} \sqrt{-C} & [\text{opens horizontally}] \\ \sqrt{-A} & [\text{opens vertically}] \end{cases} \quad \text{Eq. 7.102}$$

$$b = \begin{cases} \sqrt{A} & [\text{opens horizontally}] \\ \sqrt{C} & [\text{opens vertically}] \end{cases} \quad \text{Eq. 7.103}$$

## 21. SPHERE

Equation 7.104 is the general equation of a sphere. The coefficient  $A$  cannot be zero.

$$Ax^2 + Ay^2 + Az^2 + Bx + Cy + Dz + E = 0 \quad \text{Eq. 7.104}$$

Equation 7.105 gives the standard form of the equation of a sphere centered at  $(h, k, l)$  with radius  $r$ .

$$(x-h)^2 + (y-k)^2 + (z-l)^2 = r^2 \quad \text{Eq. 7.105}$$

The general and center forms of the equations of a sphere can be reconciled by using Eq. 7.106 through Eq. 7.109.

$$h = \frac{-B}{2A} \quad \text{Eq. 7.106}$$

$$k = \frac{-C}{2A} \quad \text{Eq. 7.107}$$

$$l = \frac{-D}{2A} \quad \text{Eq. 7.108}$$

$$r = \sqrt{\frac{B^2 + C^2 + D^2}{4A^2} - \frac{E}{A}} \quad \text{Eq. 7.109}$$

## 22. HELIX

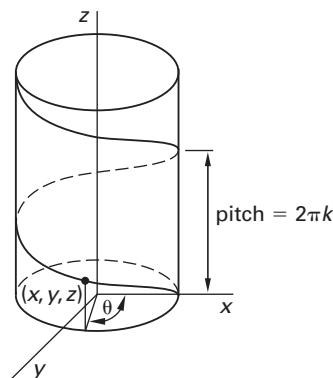

A *helix* is a curve generated by a point moving on, around, and along a cylinder such that the distance the point moves parallel to the cylindrical axis is proportional to the angle of rotation about that axis. (See Fig. 7.16.) For a cylinder of radius  $r$ , Eq. 7.110 through Eq. 7.112 define the three-dimensional positions of points along the helix. The quantity  $2\pi k$  is the *pitch* of the helix.

$$x = r \cos \theta \quad \text{Eq. 7.110}$$

$$y = r \sin \theta \quad \text{Eq. 7.111}$$

$$z = k\theta \quad \text{Eq. 7.112}$$

**Figure 7.16** Helix

## 1. DERIVATIVE OF A FUNCTION

In most cases, it is possible to transform a continuous function,  $f(x_1, x_2, x_3, \dots)$ , of one or more independent variables into a derivative function.<sup>1</sup> In simple cases, the *derivative* can be interpreted as the slope (tangent or rate of change) of the curve described by the original function. Since the slope of the curve depends on  $x$ , the derivative function will also depend on  $x$ . The derivative,  $f'(x)$ , of a function  $f(x)$  is defined mathematically by Eq. 8.1. However, limit theory is seldom needed to actually calculate derivatives.

$$f'(x) = \lim_{\Delta x \rightarrow 0} \frac{\Delta f(x)}{\Delta x} \quad 8.1$$

The derivative of a function  $f(x)$ , also known as the *first derivative*, is written in various ways, including

$$f'(x), \frac{df(x)}{dx}, \frac{df}{dx}, \mathbf{D}f(x), \mathbf{D}_x f(x), f(x), sf(s)$$

A *second derivative* may exist if the derivative operation is performed on the first derivative—that is, a derivative is taken of a derivative function. This is written as

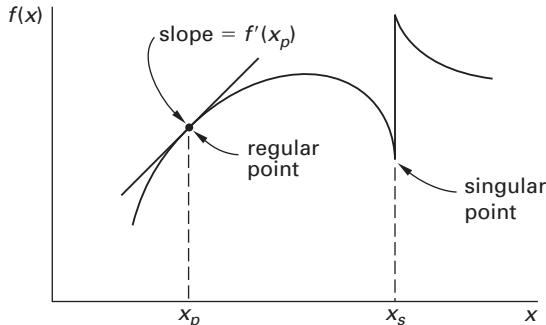

$$f''(x), \frac{d^2f(x)}{dx^2}, \frac{d^2f}{dx^2}, \mathbf{D}^2f(x), \mathbf{D}_x^2f(x), \ddot{f}(x), s^2f(s)$$

<sup>1</sup>A function,  $f(x)$ , of one independent variable,  $x$ , is used in this section to simplify the discussion. Although the derivative is taken with respect to  $x$ , the independent variable can be anything.

*Newton's notation* (e.g.,  $\dot{m}$  and  $\ddot{x}$ ) is generally only used with functions of time.

A *regular (analytic or holomorphic) function* possesses a derivative. A point at which a function's derivative is undefined is called a *singular point*, as Fig. 8.1 illustrates.

**Figure 8.1** Derivatives and Singular Points

## 2. ELEMENTARY DERIVATIVE OPERATIONS

Equation 8.2 through Eq. 8.5 summarize the elementary derivative operations on polynomials and exponentials. Equation 8.2 and Eq. 8.3 are particularly useful. ( $a$ ,  $n$ , and  $k$  represent constants.  $f(x)$  and  $g(x)$  are functions of  $x$ .)

$$\mathbf{D}k = 0 \quad 8.2$$

$$\mathbf{D}x^n = nx^{n-1} \quad 8.3$$

$$\mathbf{D} \ln x = \frac{1}{x} \quad 8.4$$

$$\mathbf{D}e^{ax} = ae^{ax} \quad 8.5$$

Equation 8.6 through Eq. 8.17 summarize the elementary derivative operations on transcendental (trigonometric) functions.

$$\mathbf{D} \sin x = \cos x \quad 8.6$$

$$\mathbf{D} \cos x = -\sin x \quad 8.7$$

$$\mathbf{D} \tan x = \sec^2 x \quad 8.8$$

$$\mathbf{D} \cot x = -\csc^2 x \quad 8.9$$

$$\mathbf{D} \sec x = \sec x \tan x \quad 8.10$$

$$\mathbf{D} \csc x = -\csc x \cot x \quad 8.11$$

$$\mathbf{D} \arcsin x = \frac{1}{\sqrt{1-x^2}} \quad 8.12$$

$$\mathbf{D} \arccos x = -\mathbf{D} \arcsin x \quad 8.13$$

$$\mathbf{D} \arctan x = \frac{1}{1+x^2} \quad 8.14$$

$$\mathbf{D} \text{arccot } x = -\mathbf{D} \arctan x \quad 8.15$$

$$\mathbf{D} \text{arcsec } x = \frac{1}{x\sqrt{x^2-1}} \quad 8.16$$

$$\mathbf{D} \text{arccsc } x = -\mathbf{D} \text{arcsec } x \quad 8.17$$

Equation 8.18 through Eq. 8.23 summarize the elementary derivative operations on hyperbolic transcendental functions. Derivatives of hyperbolic functions are not completely analogous to those of the regular transcendental functions.

$$\mathbf{D} \sinh x = \cosh x \quad 8.18$$

$$\mathbf{D} \cosh x = \sinh x \quad 8.19$$

$$\mathbf{D} \tanh x = \operatorname{sech}^2 x \quad 8.20$$

$$\mathbf{D} \coth x = -\operatorname{csch}^2 x \quad 8.21$$

$$\mathbf{D} \operatorname{sech} x = -\operatorname{sech} x \tanh x \quad 8.22$$

$$\mathbf{D} \operatorname{csch} x = -\operatorname{csch} x \coth x \quad 8.23$$

Equation 8.24 through Eq. 8.29 summarize the elementary derivative operations on functions and combinations of functions.

$$\mathbf{D} kf(x) = k\mathbf{D} f(x) \quad 8.24$$

$$\mathbf{D}(f(x) \pm g(x)) = \mathbf{D}f(x) \pm \mathbf{D}g(x) \quad 8.25$$

$$\mathbf{D}(f(x) \cdot g(x)) = f(x)\mathbf{D}g(x) + g(x)\mathbf{D}f(x) \quad 8.26$$

$$\mathbf{D}\left(\frac{f(x)}{g(x)}\right) = \frac{g(x)\mathbf{D}f(x) - f(x)\mathbf{D}g(x)}{(g(x))^2} \quad 8.27$$

$$\mathbf{D}(f(x))^n = n(f(x))^{n-1}\mathbf{D}f(x) \quad 8.28$$

$$\mathbf{D}f(g(x)) = \mathbf{D}_g f(g)\mathbf{D}_x g(x) \quad 8.29$$

### Example 8.1

What is the slope at  $x = 3$  of the curve  $f(x) = x^3 - 2x^2$ ?

*Solution*

The derivative function found from Eq. 8.3 determines the slope.

$$f'(x) = 3x^2 - 2$$

The slope at  $x = 3$  is

$$f'(3) = (3)(3)^2 - 2 = 25$$

### Example 8.2

What are the derivatives of the following functions?

$$(a) f(x) = 5\sqrt[3]{x^5}$$

$$(b) f(x) = \sin x \cos^2 x$$

$$(c) f(x) = \ln(\cos e^x)$$

*Solution*

(a) Using Eq. 8.3 and Eq. 8.24,

$$\begin{aligned} f'(x) &= 5\mathbf{D}\sqrt[3]{x^5} = 5\mathbf{D}(x^5)^{1/3} \\ &= (5)\left(\frac{1}{3}\right)(x^5)^{-2/3}\mathbf{D}x^5 \\ &= (5)\left(\frac{1}{3}\right)(x^5)^{-2/3}(5)(x^4) \\ &= 25x^{2/3}/3 \end{aligned}$$

(b) Using Eq. 8.26,

$$\begin{aligned} f'(x) &= \sin x \mathbf{D} \cos^2 x + \cos^2 x \mathbf{D} \sin x \\ &= (\sin x)(2 \cos x)(\mathbf{D} \cos x) + \cos^2 x \cos x \\ &= (\sin x)(2 \cos x)(-\sin x) + \cos^2 x \cos x \\ &= -2 \sin^2 x \cos x + \cos^3 x \end{aligned}$$

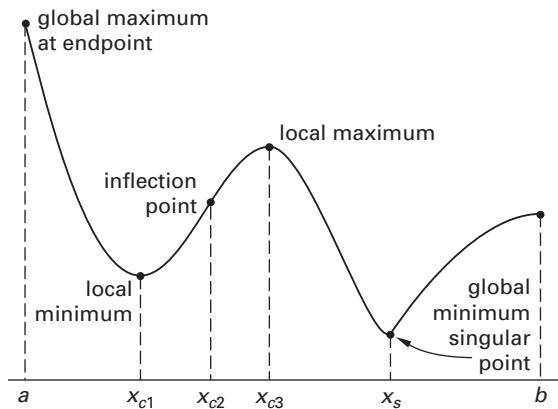

(c) Using Eq. 8.29,

$$\begin{aligned} f'(x) &= \left(\frac{1}{\cos e^x}\right)\mathbf{D} \cos e^x \\ &= \left(\frac{1}{\cos e^x}\right)(-\sin e^x)\mathbf{D}e^x \\ &= \left(\frac{-\sin e^x}{\cos e^x}\right)e^x \\ &= -e^x \tan e^x \end{aligned}$$

### 3. CRITICAL POINTS

Derivatives are used to locate the local *critical points* of functions of one variable—that is, *extreme points* (also known as *maximum* and *minimum* points) as well as the *inflection points* (*points of contraflexure*). The plurals *extrema*, *maxima*, and *minima* are used without the word “points.” These points are illustrated in Fig. 8.2. There is usually an inflection point between two adjacent local extrema.

The first derivative is calculated to determine the locations of possible critical points. The second derivative is calculated to determine whether a particular point is a local maximum, minimum, or inflection point, according to the following conditions. With this method, no distinction is made between local and global extrema. Therefore, the extrema should be compared with the function values at the endpoints of the interval, as

**Figure 8.2** Extreme and Inflection Points

illustrated in Ex. 8.3.<sup>2</sup> Generally,  $f'(x) \neq 0$  at an inflection point.

$$f'(x_c) = 0 \text{ at any extreme point, } x_c \quad 8.30$$

$$f''(x_c) < 0 \text{ at a maximum point} \quad 8.31$$

$$f''(x_c) > 0 \text{ at a minimum point} \quad 8.32$$

$$f''(x_c) = 0 \text{ at an inflection point} \quad 8.33$$

### Example 8.3

Find the global extrema of the function  $f(x)$  on the interval  $[-2, +2]$ .

$$f(x) = x^3 + x^2 - x + 1$$

*Solution*

The first derivative is

$$f'(x) = 3x^2 + 2x - 1$$

Since the first derivative is zero at extreme points, set  $f'(x)$  equal to zero and solve for the roots of the quadratic equation.

$$3x^2 + 2x - 1 = (3x - 1)(x + 1) = 0$$

The roots are  $x_1 = 1/3$ ,  $x_2 = -1$ . These are the locations of the two local extrema.

<sup>2</sup>It is also necessary to check the values of the function at singular points (i.e., points where the derivative does not exist).

The second derivative is

$$f''(x) = 6x + 2$$

Substituting  $x_1$  and  $x_2$  into  $f''(x)$ ,

$$f''(x_1) = (6)\left(\frac{1}{3}\right) + 2 = 4$$

$$f''(x_2) = (6)(-1) + 2 = -4$$

Therefore,  $x_1$  is a local minimum point (because  $f''(x_1)$  is positive), and  $x_2$  is a local maximum point (because  $f''(x_2)$  is negative). The inflection point between these two extrema is found by setting  $f''(x)$  equal to zero.

$$f''(x) = 6x + 2 = 0 \text{ or } x = -\frac{1}{3}$$

Since the question asked for the global extreme points, it is necessary to compare the values of  $f(x)$  at the local extrema with the values at the endpoints.

$$f(-2) = -1$$

$$f(-1) = 2$$

$$f\left(\frac{1}{3}\right) = 22/27$$

$$f(2) = 11$$

Therefore, the actual global extrema are at the endpoints.

## 4. DERIVATIVES OF PARAMETRIC EQUATIONS

The derivative of a function  $f(x_1, x_2, \dots, x_n)$  can be calculated from the derivatives of the parametric equations  $f_1(s), f_2(s), \dots, f_n(s)$ . The derivative will be expressed in terms of the parameter,  $s$ , unless the derivatives of the parametric equations can be expressed explicitly in terms of the independent variables.

### Example 8.4

A circle is expressed parametrically by the equations

$$x = 5 \cos \theta$$

$$y = 5 \sin \theta$$

Express the derivative  $dy/dx$  (a) as a function of the parameter  $\theta$  and (b) as a function of  $x$  and  $y$ .

**Solution**

(a) Taking the derivative of each parametric equation with respect to  $\theta$ ,

$$\frac{dx}{d\theta} = -5 \sin \theta$$

$$\frac{dy}{d\theta} = 5 \cos \theta$$

Then,

$$\frac{dy}{dx} = \frac{\frac{dy}{d\theta}}{\frac{dx}{d\theta}} = \frac{5 \cos \theta}{-5 \sin \theta} = -\cot \theta$$

(b) The derivatives of the parametric equations are closely related to the original parametric equations.

$$\frac{dx}{d\theta} = -5 \sin \theta = -y$$

$$\frac{dy}{d\theta} = 5 \cos \theta = x$$

$$\frac{dy}{dx} = \frac{\frac{dy}{d\theta}}{\frac{dx}{d\theta}} = \frac{-x}{y}$$

**Solution**

The partial derivative with respect to  $x$  is found by considering all variables other than  $x$  to be constants.

$$\frac{\partial z}{\partial x} = 6x - 0 + y + 0 - 0 = 6x + y$$

**Example 8.6**

A surface has the equation  $x^2 + y^2 + z^2 - 9 = 0$ . What is the slope of a line that lies in a plane of constant  $y$  and is tangent to the surface at  $(x, y, z) = (1, 2, 2)$ ?<sup>3</sup>

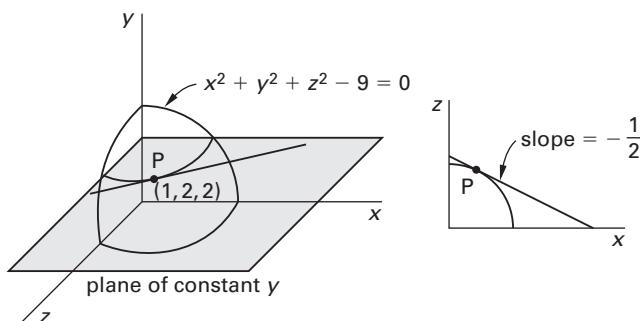

**Solution**

Solve for the dependent variable. Then, consider variable  $y$  to be a constant.

$$\begin{aligned} z &= \sqrt{9 - x^2 - y^2} \\ \frac{\partial z}{\partial x} &= \frac{\partial(9 - x^2 - y^2)^{1/2}}{\partial x} \\ &= (\tfrac{1}{2})(9 - x^2 - y^2)^{-1/2} \left( \frac{\partial(9 - x^2 - y^2)}{\partial x} \right) \\ &= (\tfrac{1}{2})(9 - x^2 - y^2)^{-1/2}(-2x) \\ &= \frac{-x}{\sqrt{9 - x^2 - y^2}} \end{aligned}$$

At the point  $(1, 2, 2)$ ,  $x = 1$  and  $y = 2$ .

$$\left. \frac{\partial z}{\partial x} \right|_{(1, 2, 2)} = \frac{-1}{\sqrt{9 - (1)^2 - (2)^2}} = -\frac{1}{2}$$

**6. IMPLICIT DIFFERENTIATION**

When a relationship between  $n$  variables cannot be manipulated to yield an explicit function of  $n - 1$  independent variables, that relationship implicitly defines the  $n$ th variable. Finding the derivative of the implicit variable with respect to any other independent variable is known as *implicit differentiation*.

<sup>3</sup>Although only implied, it is required that the point actually be on the surface (i.e., it must satisfy the equation  $f(x, y, z) = 0$ ).

$$z = 3x^2 - 6y^2 + xy + 5y - 9$$

An implicit derivative is the quotient of two partial derivatives. The two partial derivatives are chosen so that dividing one by the other eliminates a common differential. For example, if  $z$  cannot be explicitly extracted from  $f(x, y, z) = 0$ , the partial derivatives  $\partial z / \partial x$  and  $\partial z / \partial y$  can still be found as follows.

$$\frac{\partial z}{\partial x} = \frac{\frac{\partial f}{\partial x}}{\frac{\partial f}{\partial z}} \quad 8.34$$

$$\frac{\partial z}{\partial y} = \frac{-\frac{\partial f}{\partial y}}{\frac{\partial f}{\partial z}} \quad 8.35$$

### Example 8.7

Find the derivative  $dy/dx$  of

$$f(x, y) = x^2 + xy + y^3$$

*Solution*

Implicit differentiation is required because  $x$  cannot be extracted from  $f(x, y)$ .

$$\frac{\partial f}{\partial x} = 2x + y$$

$$\frac{\partial f}{\partial y} = x + 3y^2$$

$$\frac{dy}{dx} = \frac{-\frac{\partial f}{\partial x}}{\frac{\partial f}{\partial y}} = \frac{-(2x + y)}{x + 3y^2}$$

### Example 8.8

Solve Ex. 8.6 using implicit differentiation.

*Solution*

$$f(x, y, z) = x^2 + y^2 + z^2 - 9 = 0$$

$$\frac{\partial f}{\partial x} = 2x$$

$$\frac{\partial f}{\partial z} = 2z$$

$$\frac{\partial z}{\partial x} = \frac{-\frac{\partial f}{\partial x}}{\frac{\partial f}{\partial z}} = \frac{-2x}{2z} = -\frac{x}{z}$$

At the point  $(1, 2, 2)$ ,

$$\frac{\partial z}{\partial x} = -\frac{1}{2}$$

### 7. TANGENT PLANE FUNCTION

Partial derivatives can be used to find the equation of a plane tangent to a three-dimensional surface defined by  $f(x, y, z) = 0$  at some point,  $P_0$ .

$$\begin{aligned} T(x_0, y_0, z_0) &= (x - x_0) \frac{\partial f(x, y, z)}{\partial x} \Big|_{P_0} \\ &\quad + (y - y_0) \frac{\partial f(x, y, z)}{\partial y} \Big|_{P_0} \\ &\quad + (z - z_0) \frac{\partial f(x, y, z)}{\partial z} \Big|_{P_0} \\ &= 0 \end{aligned} \quad 8.36$$

The coefficients of  $x$ ,  $y$ , and  $z$  are the same as the coefficients of  $\mathbf{i}$ ,  $\mathbf{j}$ , and  $\mathbf{k}$  of the normal vector at point  $P_0$ . (See Sec. 8.10.)

### Example 8.9

What is the equation of the plane that is tangent to the surface defined by  $f(x, y, z) = 4x^2 + y^2 - 16z = 0$  at the point  $(2, 4, 2)$ ?

*Solution*

Calculate the partial derivatives and substitute the coordinates of the point.

$$\frac{\partial f(x, y, z)}{\partial x} \Big|_{P_0} = 8x|_{(2, 4, 2)} = (8)(2) = 16$$

$$\frac{\partial f(x, y, z)}{\partial y} \Big|_{P_0} = 2y|_{(2, 4, 2)} = (2)(4) = 8$$

$$\frac{\partial f(x, y, z)}{\partial z} \Big|_{P_0} = -16|_{(2, 4, 2)} = -16$$

$$\begin{aligned} T(2, 4, 2) &= (16)(x - 2) + (8)(y - 4) - (16)(z - 2) \\ &= 16x + 8y - 16z - 32 \end{aligned}$$

Substitute into Eq. 8.36, and divide both sides by 8.

$$2x + y - 2z - 4 = 0$$

### 8. GRADIENT VECTOR

The slope of a function is the change in one variable with respect to a distance in a chosen direction. Usually, the direction is parallel to a coordinate axis. However, the maximum slope at a point on a surface may not be in a direction parallel to one of the coordinate axes.

The *gradient vector function*  $\nabla f(x, y, z)$  (pronounced “del f”) gives the maximum rate of change of the function  $f(x, y, z)$ .

$$\nabla f(x, y, z) = \frac{\partial f(x, y, z)}{\partial x} \mathbf{i} + \frac{\partial f(x, y, z)}{\partial y} \mathbf{j} + \frac{\partial f(x, y, z)}{\partial z} \mathbf{k} \quad 8.37$$

### Example 8.10

A two-dimensional function is defined by

$$f(x, y) = 2x^2 - y^2 + 3x - y$$

- (a) What is the gradient vector for this function?
- (b) What is the direction of the line passing through the point  $(1, -2)$  that has a maximum slope? (c) What is the maximum slope at the point  $(1, -2)$ ?

*Solution*

- (a) It is necessary to calculate two partial derivatives in order to use Eq. 8.37.

$$\frac{\partial f(x, y)}{\partial x} = 4x + 3$$

$$\frac{\partial f(x, y)}{\partial y} = -2y - 1$$

$$\nabla f(x, y) = (4x + 3)\mathbf{i} + (-2y - 1)\mathbf{j}$$

- (b) Find the direction of the line passing through  $(1, -2)$  with maximum slope by inserting  $x = 1$  and  $y = -2$  into the gradient vector function.

$$\begin{aligned} \mathbf{V} &= ((4)(1) + 3)\mathbf{i} + ((-2)(-2) - 1)\mathbf{j} \\ &= 7\mathbf{i} + 3\mathbf{j} \end{aligned}$$

- (c) The magnitude of the slope is

$$|\mathbf{V}| = \sqrt{(7)^2 + (3)^2} = 7.62$$

## 9. DIRECTIONAL DERIVATIVE

Unlike the gradient vector (covered in Sec. 8.8), which calculates the maximum rate of change of a function, the *directional derivative*, indicated by  $\nabla_u f(x, y, z)$ ,  $D_u f(x, y, z)$ , or  $f'_u(x, y, z)$ , gives the rate of change in the direction of a given vector,  $\mathbf{u}$  or  $\mathbf{U}$ . The subscript  $u$  implies that the direction vector is a unit vector, but it

does not need to be, as only the direction cosines are calculated from it.

$$\begin{aligned} \nabla_u f(x, y, z) &= \left( \frac{\partial f(x, y, z)}{\partial x} \right) \cos \alpha \\ &\quad + \left( \frac{\partial f(x, y, z)}{\partial y} \right) \cos \beta \\ &\quad + \left( \frac{\partial f(x, y, z)}{\partial z} \right) \cos \gamma \end{aligned} \quad 8.38$$

$$\mathbf{U} = U_x \mathbf{i} + U_y \mathbf{j} + U_z \mathbf{k} \quad 8.39$$

$$\cos \alpha = \frac{U_x}{|\mathbf{U}|} = \frac{U_x}{\sqrt{U_x^2 + U_y^2 + U_z^2}} \quad 8.40$$

$$\cos \beta = \frac{U_y}{|\mathbf{U}|} \quad 8.41$$

$$\cos \gamma = \frac{U_z}{|\mathbf{U}|} \quad 8.42$$

### Example 8.11

What is the rate of change of  $f(x, y) = 3x^2 + xy - 2y^2$  at the point  $(1, -2)$  in the direction  $4\mathbf{i} + 3\mathbf{j}$ ?

*Solution*

The direction cosines are given by Eq. 8.40 and Eq. 8.41.

$$\cos \alpha = \frac{U_x}{|\mathbf{U}|} = \frac{4}{\sqrt{(4)^2 + (3)^2}} = \frac{4}{5}$$

$$\cos \beta = \frac{U_y}{|\mathbf{U}|} = \frac{3}{5}$$

The partial derivatives are

$$\frac{\partial f(x, y)}{\partial x} = 6x + y$$

$$\frac{\partial f(x, y)}{\partial y} = x - 4y$$

The directional derivative is given by Eq. 8.38.

$$\nabla_u f(x, y) = \left( \frac{4}{5} \right) (6x + y) + \left( \frac{3}{5} \right) (x - 4y)$$

Substituting the given values of  $x = 1$  and  $y = -2$ ,

$$\begin{aligned} \nabla_u f(1, -2) &= \left( \frac{4}{5} \right) ((6)(1) - 2) + \left( \frac{3}{5} \right) (1 - (4)(-2)) \\ &= \frac{43}{5} \quad (8.6) \end{aligned}$$

## 10. NORMAL LINE VECTOR

Partial derivatives can be used to find the vector normal to a three-dimensional surface defined by  $f(x, y, z) = 0$

at some point  $P_0$ . The coefficients of  $\mathbf{i}$ ,  $\mathbf{j}$ , and  $\mathbf{k}$  are the same as the coefficients of  $x$ ,  $y$ , and  $z$  calculated for the equation of the tangent plane at point  $P_0$ . (See Sec. 8.7.)

$$\begin{aligned}\mathbf{N} &= \frac{\partial f(x, y, z)}{\partial x} \Big|_{P_0} \mathbf{i} + \frac{\partial f(x, y, z)}{\partial y} \Big|_{P_0} \mathbf{j} \\ &\quad + \frac{\partial f(x, y, z)}{\partial z} \Big|_{P_0} \mathbf{k}\end{aligned}\quad 8.43$$

### Example 8.12

What is the vector normal to the surface of  $f(x, y, z) = 4x^2 + y^2 - 16z = 0$  at the point  $(2, 4, 2)$ ?

*Solution*

The equation of the tangent plane at this point was calculated in Ex. 8.9 to be

$$T(2, 4, 2) = 2x + y - 2z - 4 = 0$$

A vector that is normal to the tangent plane through this point is

$$\mathbf{N} = 2\mathbf{i} + \mathbf{j} - 2\mathbf{k}$$

### 11. DIVERGENCE OF A VECTOR FIELD

The *divergence*,  $\operatorname{div} \mathbf{F}$ , of a vector field  $\mathbf{F}(x, y, z)$  is a scalar function defined by Eq. 8.45 and Eq. 8.46.<sup>4</sup> The divergence of  $\mathbf{F}$  can be interpreted as the *accumulation* of flux (i.e., a flowing substance) in a small region (i.e., at a point). One of the uses of the divergence is to determine whether flow (represented in direction and magnitude by  $\mathbf{F}$ ) is compressible. Flow is incompressible if  $\operatorname{div} \mathbf{F} = 0$ , since the substance is not accumulating.

$$\mathbf{F} = P(x, y, z)\mathbf{i} + Q(x, y, z)\mathbf{j} + R(x, y, z)\mathbf{k}\quad 8.44$$

$$\operatorname{div} \mathbf{F} = \frac{\partial P}{\partial x} + \frac{\partial Q}{\partial y} + \frac{\partial R}{\partial z}\quad 8.45$$

It may be easier to calculate divergence from Eq. 8.46.

$$\operatorname{div} \mathbf{F} = \nabla \cdot \mathbf{F}\quad 8.46$$

The vector del operator,  $\nabla$ , is defined as

$$\nabla = \frac{\partial}{\partial x}\mathbf{i} + \frac{\partial}{\partial y}\mathbf{j} + \frac{\partial}{\partial z}\mathbf{k}\quad 8.47$$

If there is no divergence, then the dot product calculated in Eq. 8.46 is zero.

<sup>4</sup>A bold letter,  $\mathbf{F}$ , is used to indicate that the vector is a function of  $x$ ,  $y$ , and  $z$ .

### Example 8.13

Calculate the divergence of the following vector function.

$$\mathbf{F}(x, y, z) = xz\mathbf{i} + e^x y\mathbf{j} + 7x^3 y\mathbf{k}$$

*Solution*

From Eq. 8.45,

$$\begin{aligned}\operatorname{div} \mathbf{F} &= \frac{\partial}{\partial x} xz + \frac{\partial}{\partial y} e^x y + \frac{\partial}{\partial z} 7x^3 y = z + e^x + 0 \\ &= z + e^x\end{aligned}$$

### 12. CURL OF A VECTOR FIELD

The *curl*,  $\operatorname{curl} \mathbf{F}$ , of a vector field  $\mathbf{F}(x, y, z)$  is a vector field defined by Eq. 8.49 and Eq. 8.50. The curl  $\mathbf{F}$  can be interpreted as the *vorticity* per unit area of flux (i.e., a flowing substance) in a small region (i.e., at a point). One of the uses of the curl is to determine whether flow (represented in direction and magnitude by  $\mathbf{F}$ ) is rotational. Flow is irrotational if  $\operatorname{curl} \mathbf{F} = 0$ .

$$\mathbf{F} = P(x, y, z)\mathbf{i} + Q(x, y, z)\mathbf{j} + R(x, y, z)\mathbf{k}\quad 8.48$$

$$\begin{aligned}\operatorname{curl} \mathbf{F} &= \left( \frac{\partial R}{\partial y} - \frac{\partial Q}{\partial z} \right) \mathbf{i} + \left( \frac{\partial P}{\partial z} - \frac{\partial R}{\partial x} \right) \mathbf{j} \\ &\quad + \left( \frac{\partial Q}{\partial x} - \frac{\partial P}{\partial y} \right) \mathbf{k}\end{aligned}\quad 8.49$$

It may be easier to calculate the curl from Eq. 8.50. (The vector del operator,  $\nabla$ , was defined in Eq. 8.47.)

$$\operatorname{curl} \mathbf{F} = \nabla \times \mathbf{F}$$

$$= \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ P(x, y, z) & Q(x, y, z) & R(x, y, z) \end{vmatrix}\quad 8.50$$

If the velocity vector is  $\mathbf{V}$ , then the vorticity is

$$\omega = \nabla \times \mathbf{V} = \omega_x \mathbf{i} + \omega_y \mathbf{j} + \omega_z \mathbf{k}\quad 8.51$$

The *circulation* is the line integral of the velocity,  $\mathbf{V}$ , along a closed curve.

$$\Gamma = \oint \mathbf{V} \cdot d\mathbf{s} = \oint \omega \cdot dA\quad 8.52$$

### Example 8.14

Calculate the curl of the following vector function.

$$\mathbf{F}(x, y, z) = 3x^2 \mathbf{i} + 7e^x y \mathbf{j}$$

*Solution*

Using Eq. 8.50,

$$\operatorname{curl} \mathbf{F} = \begin{vmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ \frac{\partial}{\partial x} & \frac{\partial}{\partial y} & \frac{\partial}{\partial z} \\ 3x^2 & 7e^x y & 0 \end{vmatrix}$$

Expand the determinant across the top row.

$$\begin{aligned} & \mathbf{i} \left( \frac{\partial}{\partial y}(0) - \frac{\partial}{\partial z}(7e^x y) \right) - \mathbf{j} \left( \frac{\partial}{\partial x}(0) - \frac{\partial}{\partial z}(3x^2) \right) \\ & + \mathbf{k} \left( \frac{\partial}{\partial x}(7e^x y) - \frac{\partial}{\partial y}(3x^2) \right) \\ & = \mathbf{i}(0 - 0) - \mathbf{j}(0 - 0) + \mathbf{k}(7e^x y - 0) \\ & = 7e^x y \mathbf{k} \end{aligned}$$

### 13. TAYLOR'S FORMULA

*Taylor's formula (series)* can be used to expand a function around a point (i.e., approximate the function at one point based on the function's value at another point). The approximation consists of a series, each term composed of a derivative of the original function and a polynomial. Using Taylor's formula requires that the original function be continuous in the interval  $[a, b]$  and have the required number of derivatives. To expand a function,  $f(x)$ , around a point,  $a$ , in order to obtain  $f(b)$ , Taylor's formula is

$$\begin{aligned} f(b) &= f(a) + \frac{f'(a)}{1!}(b-a) + \frac{f''(a)}{2!}(b-a)^2 \\ &+ \cdots + \frac{f^n(a)}{n!}(b-a)^n + R_n(b) \end{aligned} \quad 8.53$$

In Eq. 8.53, the expression  $f^n$  designates the  $n$ th derivative of the function  $f(x)$ . To be a useful approximation, two requirements must be met: (1) point  $a$  must be relatively close to point  $b$ , and (2) the function and its derivatives must be known or easy to calculate. The last term,  $R_n(b)$ , is the uncalculated remainder after  $n$  derivatives. It is the difference between the exact and approximate values. By using enough terms, the remainder can be made arbitrarily small. That is,  $R_n(b)$  approaches zero as  $n$  approaches infinity.

It can be shown that the remainder term can be calculated from Eq. 8.54, where  $c$  is some number in the interval  $[a, b]$ . With certain functions, the constant  $c$  can be completely determined. In most cases, however, it is possible only to calculate an upper bound on the remainder from Eq. 8.55.  $M_n$  is the maximum (positive) value of  $f^{n+1}(x)$  on the interval  $[a, b]$ .

$$R_n(b) = \frac{f^{n+1}(c)}{(n+1)!}(b-a)^{n+1} \quad 8.54$$

$$|R_n(b)| \leq M_n \frac{|(b-a)^{n+1}|}{(n+1)!} \quad 8.55$$

### 14. MACLAURIN POWER APPROXIMATIONS

If  $a = 0$  in the Taylor series, Eq. 8.53 is known as the *Maclaurin series*. The Maclaurin series can be used to approximate functions at some value of  $x$  between 0 and 1. The following common approximations may be referred to as Maclaurin series, Taylor series, or power series approximations.

$$\sin x \approx x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots + (-1)^n \frac{x^{2n+1}}{(2n+1)!} \quad 8.56$$

$$\cos x \approx 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots + (-1)^n \frac{x^{2n}}{(2n)!} \quad 8.57$$

$$\sinh x \approx x + \frac{x^3}{3!} + \frac{x^5}{5!} + \frac{x^7}{7!} + \cdots + \frac{x^{2n+1}}{(2n+1)!} \quad 8.58$$

$$\cosh x \approx 1 + \frac{x^2}{2!} + \frac{x^4}{4!} + \frac{x^6}{6!} + \cdots + \frac{x^{2n}}{(2n)!} \quad 8.59$$

$$e^x \approx 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \cdots + \frac{x^n}{n!} \quad 8.60$$

$$\ln(1+x) \approx x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \cdots + (-1)^{n+1} \frac{x^n}{n} \quad 8.61$$

$$\frac{1}{1-x} \approx 1 + x + x^2 + x^3 + \cdots + x^n \quad 8.62$$

### 1. INTEGRATION

*Integration* is the inverse operation of differentiation. For that reason, *indefinite integrals* are sometimes referred to as *antiderivatives*.<sup>1</sup> Although expressions can be functions of several variables, integrals can only be taken with respect to one variable at a time. The *differential term* ( $dx$  in Eq. 9.1) indicates that variable. In Eq. 9.1, the function  $f'(x)$  is the *integrand*, and  $x$  is the variable of integration.

$$\int f'(x) dx = f(x) + C \quad 9.1$$

While most of a function,  $f(x)$ , can be “recovered” through integration of its derivative,  $f'(x)$ , a constant term will be lost, because the derivative of a constant term vanishes (i.e., is zero), leaving nothing from which to recover. A *constant of integration*,  $C$ , is added to the integral to recognize the possibility of such a constant term.

### 2. ELEMENTARY OPERATIONS

Equation 9.2 through Eq. 9.8 summarize the elementary integration operations on polynomials and exponentials.<sup>2</sup>

<sup>1</sup>The difference between an indefinite and definite integral (covered in Sec. 9.7) is simple: An *indefinite integral* is a function, while a *definite integral* is a number.

<sup>2</sup>More extensive listings, known as *tables of integrals*, are widely available. (See App. 9.A.)

Equation 9.2 and Eq. 9.3 are particularly useful. ( $C$  and  $k$  represent constants.  $f(x)$  and  $g(x)$  are functions of  $x$ .)

$$\int k dx = kx + C \quad 9.2$$

$$\int x^m dx = \frac{x^{m+1}}{m+1} + C \quad [m \neq -1] \quad 9.3$$

$$\int \frac{1}{x} dx = \ln|x| + C \quad 9.4$$

$$\int e^{kx} dx = \frac{e^{kx}}{k} + C \quad 9.5$$

$$\int xe^{kx} dx = \frac{e^{kx}(kx-1)}{k^2} + C \quad 9.6$$

$$\int k^{ax} dx = \frac{k^{ax}}{a \ln k} + C \quad 9.7$$

$$\int \ln x dx = x \ln x - x + C \quad 9.8$$

Equation 9.9 through Eq. 9.20 summarize the elementary integration operations on transcendental functions.

$$\int \sin x dx = -\cos x + C \quad 9.9$$

$$\int \cos x dx = \sin x + C \quad 9.10$$

$$\begin{aligned} \int \tan x dx &= \ln|\sec x| + C \\ &= -\ln|\cos x| + C \end{aligned} \quad 9.11$$

$$\int \cot x dx = \ln|\sin x| + C \quad 9.12$$

$$\begin{aligned} \int \sec x dx &= \ln|\sec x + \tan x| + C \\ &= \ln\left|\tan\left(\frac{x}{2} + \frac{\pi}{4}\right)\right| + C \end{aligned} \quad 9.13$$

$$\begin{aligned} \int \csc x dx &= \ln|\csc x - \cot x| + C \\ &= \ln\left|\tan\frac{x}{2}\right| + C \end{aligned} \quad 9.14$$

$$\int \frac{dx}{k^2 + x^2} = \frac{1}{k} \arctan \frac{x}{k} + C \quad 9.15$$

$$\int \frac{dx}{\sqrt{k^2 - x^2}} = \arcsin \frac{x}{k} + C \quad [k^2 > x^2] \quad 9.16$$

$$\int \frac{dx}{x\sqrt{x^2 - k^2}} = \frac{1}{k} \operatorname{arcsec} \frac{x}{k} + C \quad [x^2 > k^2] \quad 9.17$$

$$\int \sin^2 x \, dx = \frac{1}{2}x - \frac{1}{4}\sin 2x + C \quad 9.18$$

$$\int \cos^2 x \, dx = \frac{1}{2}x + \frac{1}{4}\sin 2x + C \quad 9.19$$

$$\int \tan^2 x \, dx = \tan x - x + C \quad 9.20$$

Equation 9.21 through Eq. 9.26 summarize the elementary integration operations on hyperbolic transcendental functions. Integrals of hyperbolic functions are not completely analogous to those of the regular transcendental functions.

$$\int \sinh x \, dx = \cosh x + C \quad 9.21$$

$$\int \cosh x \, dx = \sinh x + C \quad 9.22$$

$$\int \tanh x \, dx = \ln |\cosh x| + C \quad 9.23$$

$$\int \coth x \, dx = \ln |\sinh x| + C \quad 9.24$$

$$\int \operatorname{sech} x \, dx = \arctan(\sinh x) + C \quad 9.25$$

$$\int \operatorname{csch} x \, dx = \ln \left| \tanh \frac{x}{2} \right| + C \quad 9.26$$

Equation 9.27 through Eq. 9.31 summarize the elementary integration operations on functions and combinations of functions.

$$\int kf(x) \, dx = k \int f(x) \, dx \quad 9.27$$

$$\int (f(x) + g(x)) \, dx = \int f(x) \, dx + \int g(x) \, dx \quad 9.28$$

$$\int \frac{f'(x)}{f(x)} \, dx = \ln |f(x)| + C \quad 9.29$$

$$\begin{aligned} \int f(x) \, dg(x) &= f(x) \int dg(x) - \int g(x) \, df(x) + C \\ &= f(x)g(x) - \int g(x) \, df(x) + C \end{aligned} \quad 9.30$$

### Example 9.1

Find the integral with respect to  $x$  of

$$3x^2 + \frac{1}{3}x - 7 = 0$$

*Solution*

This is a polynomial function, and Eq. 9.3 can be applied to each of the three terms.

$$\int (3x^2 + \frac{1}{3}x - 7) \, dx = x^3 + \frac{1}{6}x^2 - 7x + C$$

### 3. INTEGRATION BY PARTS

Equation 9.30, repeated here as Eq. 9.31, is known as *integration by parts*.  $f(x)$  and  $g(x)$  are functions. The use of this method is demonstrated in Ex. 9.2.

$$\int f(x) \, dg(x) = f(x)g(x) - \int g(x) \, df(x) + C \quad 9.31$$

#### Example 9.2

Find the following integral.

$$\int x^2 e^x \, dx$$

*Solution*

$x^2 e^x$  is factored into two parts so that integration by parts can be used.

$$f(x) = x^2$$

$$dg(x) = e^x \, dx$$

$$df(x) = 2x \, dx$$

$$g(x) = \int dg(x) = \int e^x \, dx = e^x$$

From Eq. 9.31, disregarding the constant of integration (which cannot be evaluated),

$$\int f(x) \, dg(x) = f(x)g(x) - \int g(x) \, df(x)$$

$$\int x^2 e^x \, dx = x^2 e^x - \int e^x (2x) \, dx$$

The second term is also factored into two parts, and integration by parts is used again. This time,

$$f(x) = x$$

$$dg(x) = e^x \, dx$$

$$df(x) = dx$$

$$g(x) = \int dg(x) = \int e^x \, dx = e^x$$

From Eq. 9.31,

$$\begin{aligned}\int 2xe^x dx &= 2 \int xe^x dx \\ &= 2 \left( xe^x - \int e^x dx \right) \\ &= 2(xe^x - e^x)\end{aligned}$$

Then, the complete integral is

$$\begin{aligned}\int x^2 e^x dx &= x^2 e^x - 2(xe^x - e^x) + C \\ &= e^x(x^2 - 2x + 2) + C\end{aligned}$$

#### 4. SEPARATION OF TERMS

Equation 9.28 shows that the integral of a sum of terms is equal to a sum of integrals. This technique is known as *separation of terms*. In many cases, terms are easily separated. In other cases, the technique of *partial fractions* can be used to obtain individual terms. These techniques are used in Ex. 9.3 and Ex. 9.4.

##### Example 9.3

Find the following integral.

$$\int \frac{(2x^2 + 3)^2}{x} dx$$

*Solution*

Expand the numerator to gain access to all of its terms.

$$\begin{aligned}\int \frac{(2x^2 + 3)^2}{x} dx &= \int \frac{4x^4 + 12x^2 + 9}{x} dx \\ &= \int \left( 4x^3 + 12x + \frac{9}{x} \right) dx \\ &= x^4 + 6x^2 + 9 \ln|x| + C\end{aligned}$$

##### Example 9.4

Find the following integral.

$$\int \frac{3x+2}{3x-2} dx$$

*Solution*

The integrand is larger than 1, so use long division to simplify it.

$$\begin{array}{r} 1 \text{ rem } 4 \quad \left( 1 + \frac{4}{3x-2} \right) \\ 3x-2 \overline{)3x+2} \\ \underline{-3x+2} \\ 4 \text{ remainder} \end{array}$$

$$\begin{aligned}\int \frac{3x+2}{3x-2} dx &= \int \left( 1 + \frac{4}{3x-2} \right) dx \\ &= \int dx + \int \frac{4}{3x-2} dx \\ &= x + \frac{4}{3} \ln|(3x-2)| + C\end{aligned}$$

#### 5. DOUBLE AND HIGHER-ORDER INTEGRALS

A function can be successively integrated. (This is analogous to successive differentiation.) A function that is integrated twice is known as a *double integral*; if integrated three times, it is a *triple integral*; and so on. Double and triple integrals are used to calculate areas and volumes, respectively.

The successive integrations do not need to be with respect to the same variable. Variables not included in the integration are treated as constants.

There are several notations used for a multiple integral, particularly when the product of length differentials represents a differential area or volume. A double integral (i.e., two successive integrations) can be represented by one of the following notations.

$$\begin{aligned}&\iint f(x, y) dx dy, \int_{R^2} f(x, y) dx dy, \\ &\text{or } \iint_{R^2} f(x, y) dA\end{aligned}$$

A triple integral can be represented by one of the following notations.

$$\begin{aligned}&\iiint f(x, y, z) dx dy dz, \\ &\int_{R^3} f(x, y, z) dx dy dz, \\ &\text{or } \iiint_{R^3} f(x, y, z) dV\end{aligned}$$

##### Example 9.5

Find the following double integral.

$$\iint (x^2 + y^3 x) dx dy$$

*Solution*

Integrate the function twice, once with respect to  $x$  and once with respect to  $y$ .

$$\begin{aligned}\int (x^2 + y^3 x) dx &= \frac{1}{3}x^3 + \frac{1}{2}y^3 x^2 + C_1 \\ \int \left( \frac{1}{3}x^3 + \frac{1}{2}y^3 x^2 + C_1 \right) dy &= \frac{1}{3}yx^3 + \frac{1}{8}y^4 x^2 + C_1 y + C_2\end{aligned}$$

So,

$$\iint (x^2 + y^3 x) dx dy = \frac{1}{3} y x^3 + \frac{1}{8} y^4 x^2 + C_1 y + C_2$$

## 6. INITIAL VALUES

The constant of integration,  $C$ , can be found only if the value of the function  $f(x)$  is known for some value of  $x_0$ . The value  $f(x_0)$  is known as an *initial value* or *initial condition*. To completely define a function, as many initial values,  $f(x_0)$ ,  $f'(x_0)$ ,  $f''(x_0)$ , and so on, as there are integrations are needed.

### Example 9.6

It is known that  $f(x) = 4$  when  $x = 2$  (i.e., the initial value is  $f(2) = 4$ ). Find the original function.

$$\int (3x^3 - 7x) dx$$

*Solution*

The function is

$$f(x) = \int (3x^3 - 7x) dx = \frac{3}{4}x^4 - \frac{7}{2}x^2 + C$$

Substituting the initial value determines  $C$ .

$$4 = \left(\frac{3}{4}\right)(2)^4 - \left(\frac{7}{2}\right)(2)^2 + C$$

$$4 = 12 - 14 + C$$

$$C = 6$$

The function is

$$f(x) = \frac{3}{4}x^4 - \frac{7}{2}x^2 + 6$$

## 7. DEFINITE INTEGRALS

A *definite integral* is restricted to a specific range of the independent variable. (Unrestricted integrals of the types shown in all preceding examples are known as *indefinite integrals*.) A definite integral restricted to the region bounded by *lower* and *upper limits* (also known as *bounds*),  $x_1$  and  $x_2$ , is written as

$$\int_{x_1}^{x_2} f(x) dx$$

Equation 9.32 indicates how definite integrals are evaluated. It is known as the *fundamental theorem of calculus*.

$$\int_{x_1}^{x_2} f'(x) dx = f(x) \Big|_{x_1}^{x_2} = f(x_2) - f(x_1) \quad 9.32$$

A common use of a definite integral is the calculation of work performed by a force,  $F$ , that moves an object from position  $x_1$  to  $x_2$ .

$$W = \int_{x_1}^{x_2} F dx \quad 9.33$$

### Example 9.7

Evaluate the following definite integral.

$$\int_{\pi/4}^{\pi/3} \sin x dx$$

*Solution*

From Eq. 9.32,

$$\begin{aligned} \int_{\pi/4}^{\pi/3} \sin x dx &= -\cos x \Big|_{\pi/4}^{\pi/3} \\ &= -\cos \frac{\pi}{3} - \left(-\cos \frac{\pi}{4}\right) \\ &= -0.5 - (-0.707) = 0.207 \end{aligned}$$

## 8. AVERAGE VALUE

The average value of a function  $f(x)$  that is integrable over the interval  $[a, b]$  is

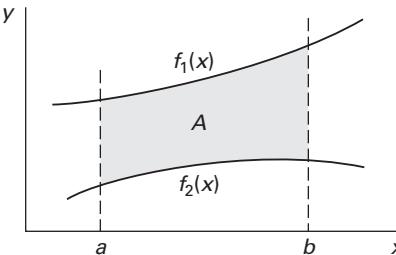

$$\text{average value} = \frac{1}{b-a} \int_a^b f(x) dx \quad 9.34$$

## 9. AREA

Equation 9.35 calculates the area,  $A$ , bounded by  $x = a$ ,  $x = b$ ,  $f_1(x)$  above and  $f_2(x)$  below. ( $f_2(x) = 0$  if the area is bounded by the  $x$ -axis.) The area between two curves is illustrated in Fig. 9.1.

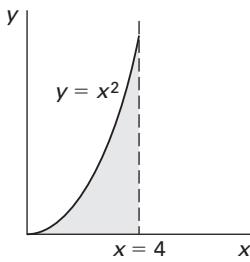

$$A = \int_a^b (f_1(x) - f_2(x)) dx \quad 9.35$$

**Figure 9.1** Area Between Two Curves

**Example 9.8**

Find the area between the  $x$ -axis and the parabola  $y = x^2$  in the interval  $[0, 4]$ .

*Solution*

Referring to Eq. 9.35,

$$\begin{aligned}f_1(x) &= x^2 \\f_2(x) &= 0\end{aligned}$$

$$\begin{aligned}A &= \int_a^b (f_1(x) - f_2(x)) dx = \int_0^4 x^2 dx \\&= \frac{x^3}{3} \Big|_0^4 \\&= 64/3\end{aligned}$$

**10. ARC LENGTH**

Equation 9.36 gives the length of a curve defined by  $f(x)$ , whose derivative exists in the interval  $[a, b]$ .

$$\text{length} = \int_a^b \sqrt{1 + (f'(x))^2} dx \quad 9.36$$

**11. PAPPUS' THEOREMS<sup>3</sup>**

The first and second theorems of Pappus are as follows.<sup>4</sup>

- *First Theorem:* Given a curve,  $C$ , that does not intersect the  $y$ -axis, the area of the *surface of revolution* generated by revolving  $C$  around the  $y$ -axis is equal to the product of the length of the curve and the circumference of the circle traced by the centroid of curve  $C$ .

$$\begin{aligned}A &= \text{length} \times \text{circumference} \\&= \text{length} \times 2\pi \times \text{radius}\end{aligned} \quad 9.37$$

- *Second Theorem:* Given a plane region,  $R$ , that does not intersect the  $y$ -axis, the *volume of revolution* generated by revolving  $R$  around the  $y$ -axis is equal

to the product of the area and the circumference of the circle traced by the centroid of area  $R$ .

$$\begin{aligned}V &= \text{area} \times \text{circumference} \\&= \text{area} \times 2\pi \times \text{radius}\end{aligned} \quad 9.38$$

**12. SURFACE OF REVOLUTION**

The surface area obtained by rotating  $f(x)$  about the  $x$ -axis is

$$A = 2\pi \int_{x=a}^{x=b} f(x) \sqrt{1 + (f'(x))^2} dx \quad 9.39$$

The surface area obtained by rotating  $f(y)$  about the  $y$ -axis is

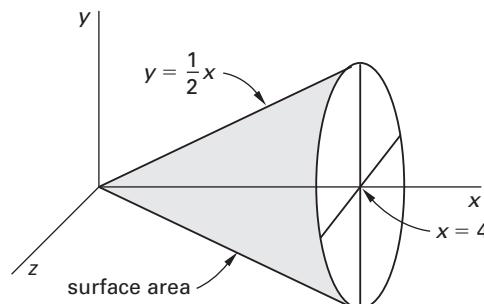

$$A = 2\pi \int_{y=c}^{y=d} f(y) \sqrt{1 + (f'(y))^2} dy \quad 9.40$$

**Example 9.9**

The curve  $f(x) = \frac{1}{2}x$  over the region  $x = [0, 4]$  is rotated about the  $x$ -axis. What is the surface of revolution?

*Solution*

The surface of revolution is

Since  $f(x) = \frac{1}{2}x$ ,  $f'(x) = \frac{1}{2}$ . From Eq. 9.39, the area is

$$\begin{aligned}A &= 2\pi \int_{x=a}^{x=b} f(x) \sqrt{1 + (f'(x))^2} dx \\&= 2\pi \int_0^4 \frac{1}{2}x \sqrt{1 + (\frac{1}{2})^2} dx \\&= \frac{\sqrt{5}}{2}\pi \int_0^4 x dx \\&= \frac{\sqrt{5}}{2}\pi \frac{x^2}{2} \Big|_0^4 \\&= \frac{\sqrt{5}}{2}\pi \left(\frac{(4)^2 - (0)^2}{2}\right) \\&= 4\sqrt{5}\pi\end{aligned}$$

<sup>3</sup>This section is an introduction to surfaces and volumes of revolution. It does not involve integration.

<sup>4</sup>Some authorities call the first theorem the second and vice versa.

### 13. VOLUME OF REVOLUTION

The volume between  $x=a$  and  $x=b$  obtained by rotating  $f(x)$  about the  $x$ -axis can be calculated from the *method of discs*, given by Eq. 9.41 and Eq. 9.43, or the *method of shells*, given by Eq. 9.42 and Eq. 9.44. In Eq. 9.41,  $f^2(x)$  is the square of the function, not the second derivative. In Eq. 9.42,  $h(y)$  is obtained by solving  $f(x)$  for  $x$  (i.e.,  $x = h(y)$ ),  $c = f(a)$ , and  $d = f(b)$ .

$$V = \pi \int_{x=a}^{x=b} f^2(x) dx \quad \begin{bmatrix} \text{rotation about the } x\text{-axis;} \\ \text{volume includes the } x\text{-axis} \end{bmatrix} \quad 9.41$$

$$V = 2\pi \int_{y=c}^{y=d} y(h(b) - h(y)) dy \quad \begin{bmatrix} \text{rotation about the } x\text{-axis;} \\ \text{volume includes the } x\text{-axis} \end{bmatrix} \quad 9.42$$

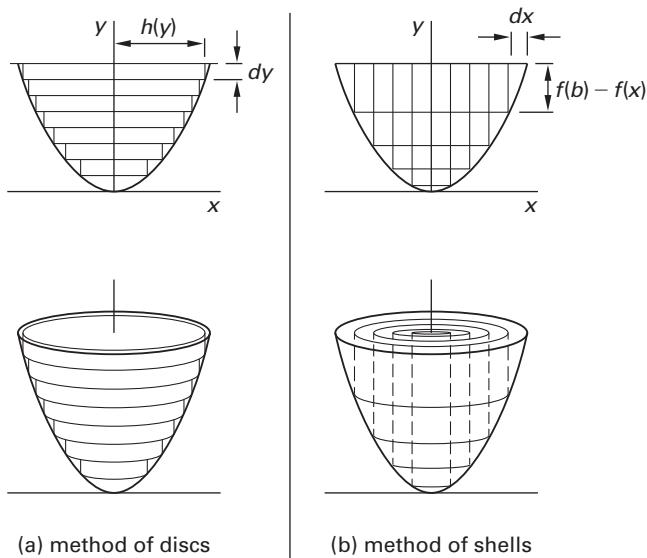

The method of discs and the method of shells can also be used to determine the volume between  $x=a$  and  $x=b$ , which is obtained by rotating  $f(x)$  about the  $y$ -axis.

$$V = \pi \int_{y=c}^{y=d} h^2(y) dy \quad \begin{bmatrix} \text{rotation about the } y\text{-axis;} \\ \text{volume includes the } y\text{-axis} \end{bmatrix} \quad 9.43$$

$$V = 2\pi \int_{x=a}^{x=b} x(f(b) - f(x)) dx \quad \begin{bmatrix} \text{rotation about the } y\text{-axis;} \\ \text{volume includes the } y\text{-axis} \end{bmatrix} \quad 9.44$$

The method of discs is illustrated in Fig. 9.2(a), and the method of shells is illustrated in Fig. 9.2(b).

**Figure 9.2** Volume of a Parabolic Bowl

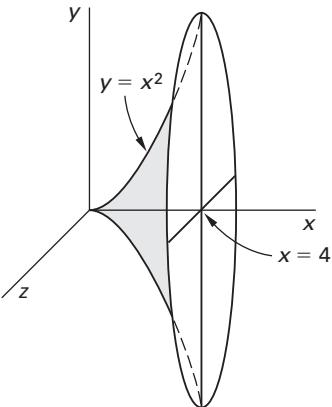

Whether or not a function,  $f(x)$  (or  $h(y)$ ), or its complement,  $f(b) - f(x)$  (or  $h(b) - h(y)$ ), is used for either method depends on whether or not the volume excludes (i.e., merely surrounds or encloses) or includes the axis of rotation. For example, for the volume below (i.e., bounded above by) a function,  $f(x)$ , rotated around the  $y$ -axis, the method of shells would integrate  $xf(x)$  because the  $y$ -axis of rotation does not pass through the volume of rotation. (See Eq. 9.44.)

#### Example 9.10

The curve  $f(x) = x^2$  over the region  $x = [0, 4]$  is rotated about the  $x$ -axis. What is the volume of revolution that includes the  $x$ -axis?

*Solution*

Use the method of discs. The volume of revolution is

$$\begin{aligned} V &= \pi \int_a^b f^2(x) dx = \pi \int_0^4 (x^2)^2 dx \\ &= \pi \frac{x^5}{5} \Big|_0^4 \\ &= \pi \left( \frac{1024}{5} - 0 \right) \\ &= 204.8\pi \end{aligned}$$

### 14. MOMENTS OF A FUNCTION

The *first moment of a function* is a concept used in finding centroids and centers of gravity. Equation 9.45 and Eq. 9.46 are for one- and two-dimensional problems, respectively. It is the exponent of  $x$  (1 in this case) that gives the moment its name.

$$\text{first moment} = \int xf(x) dx \quad 9.45$$

$$\text{first moment} = \iint xf(x, y) dx dy \quad 9.46$$

The *second moment of a function* is a concept used in finding moments of inertia with respect to an axis. Equation 9.47 and Eq. 9.48 are for two- and three-dimensional

problems, respectively. Second moments with respect to other axes are analogous.

$$(\text{second moment})_x = \iint y^2 f(x, y) dy dx \quad 9.47$$

$$(\text{second moment})_x = \iiint (y^2 + z^2) f(x, y, z) dy dz dx \quad 9.48$$

## 15. FOURIER SERIES

Any periodic waveform can be written as the sum of an infinite number of sinusoidal terms, known as *harmonic terms* (i.e., an infinite series). Such a sum of terms is known as a *Fourier series*, and the process of finding the terms is *Fourier analysis*. (Extracting the original waveform from the series is known as *Fourier inversion*.) Since most series converge rapidly, it is possible to obtain a good approximation of the original waveform with a limited number of sinusoidal terms.

*Fourier's theorem* is Eq. 9.49.<sup>5</sup> The object of a Fourier analysis is to determine the coefficients  $a_n$  and  $b_n$ . The constant  $a_0$  can often be determined by inspection since it is the average value of the waveform.<sup>6</sup>

$$\begin{aligned} f(t) &= a_0 + a_1 \cos \omega t + a_2 \cos 2\omega t + \dots \\ &\quad + b_1 \sin \omega t + b_2 \sin 2\omega t + \dots \end{aligned} \quad 9.49$$

$\omega$  is the *natural (fundamental) frequency* of the waveform. It depends on the actual waveform period,  $T$ .

$$\omega = \frac{2\pi}{T} \quad 9.50$$

To simplify the analysis, the time domain can be normalized to the radian scale. The normalized scale is obtained by dividing all frequencies by  $\omega$ . Then the Fourier series becomes

$$\begin{aligned} f(t) &= a_0 + a_1 \cos t + a_2 \cos 2t + \dots \\ &\quad + b_1 \sin t + b_2 \sin 2t + \dots \end{aligned} \quad 9.51$$

The coefficients  $a_n$  and  $b_n$  are found from the following relationships.

$$\begin{aligned} a_0 &= \frac{1}{2\pi} \int_0^{2\pi} f(t) dt \\ &= \frac{1}{T} \int_0^T f(t) dt \end{aligned} \quad 9.52$$

<sup>5</sup>The independent variable used in this section is  $t$ , since Fourier analysis is most frequently used in the time domain.

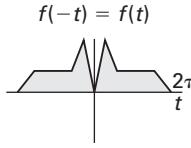

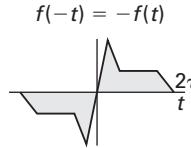

<sup>6</sup>There are different representations of the Fourier series, some with “ $1/2a_0$ ” and some with “ $a_0$ ,” as shown in Eq. 9.49. The latter is used because it is consistent with the form used in NCEES publications. Both are correct, but using “ $1/2a_0$ ” also changes Eq. 9.52. Regardless, the first term in the Fourier series represents the average value.

$$\begin{aligned} a_n &= \frac{1}{\pi} \int_0^{2\pi} f(t) \cos nt dt \\ &= \frac{2}{T} \int_0^T f(t) \cos nt dt \quad [n \geq 1] \end{aligned} \quad 9.53$$

$$\begin{aligned} b_n &= \frac{1}{\pi} \int_0^{2\pi} f(t) \sin nt dt \\ &= \frac{2}{T} \int_0^T f(t) \sin nt dt \quad [n \geq 1] \end{aligned} \quad 9.54$$

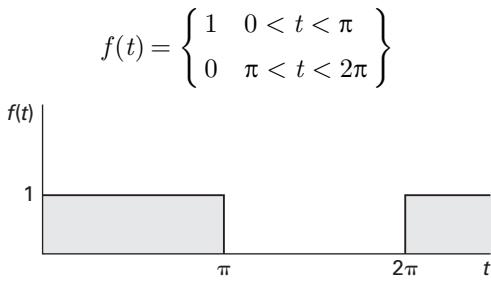

While Eq. 9.53 and Eq. 9.54 are always valid, the work of integrating and finding  $a_n$  and  $b_n$  can be greatly simplified if the waveform is recognized as being symmetrical. Table 9.1 summarizes the simplifications.

**Table 9.1** Fourier Analysis Simplifications for Symmetrical Waveforms

	even symmetry $f(-t) = f(t)$	odd symmetry $f(-t) = -f(t)$
		
full-wave symmetry*	$b_n = 0$ [all $n$ ] $a_n = \frac{1}{\pi} \int_0^{2\pi} f(t) \cos nt dt$ [all $n$ ]	$a_0 = 0$ $a_n = 0$ [all $n$ ] $b_n = \frac{1}{\pi} \int_0^{2\pi} f(t) \sin nt dt$ [all $n$ ]
half-wave symmetry*	$a_n = 0$ [even $n$ ] $b_n = 0$ [all $n$ ] $ A_2  =  A_1 $ $ A_{total}  = 2 A_1 $	$a_0 = 0$ $a_n = 0$ [all $n$ ] $b_n = 0$ [even $n$ ] $ A_2  =  A_1 $ $ A_{total}  = 2 A_1 $
*any repeating waveform		
quarter-wave symmetry	$a_0 = 0$ $a_n = 0$ [even $n$ ] $b_n = 0$ [all $n$ ] $ A_2  =  A_1 $ $ A_{total}  = 4 A_1 $	$a_0 = 0$ $a_n = 0$ [all $n$ ] $b_n = 0$ [even $n$ ] $ A_2  =  A_1 $ $ A_{total}  = 4 A_1 $
*same as rotational symmetry		

**Example 9.11**

Find the first four terms of a Fourier series that approximates the repetitive step function illustrated.

*Solution*

From Eq. 9.52,

$$a_0 = \frac{1}{2\pi} \int_0^\pi (1) dt + \frac{1}{2\pi} \int_\pi^{2\pi} (0) dt = 1/2$$

This value of  $1/2$  corresponds to the average value of  $f(t)$ . It could have been found by observation.

$$\begin{aligned} a_1 &= \frac{1}{\pi} \int_0^\pi (1) \cos t dt + \frac{1}{\pi} \int_\pi^{2\pi} (0) \cos t dt \\ &= \frac{1}{\pi} \sin t \Big|_0^\pi + 0 \\ &= 0 \end{aligned}$$

In general,

$$a_n = \frac{1}{\pi} \frac{\sin nt}{n} \Big|_0^\pi = 0$$

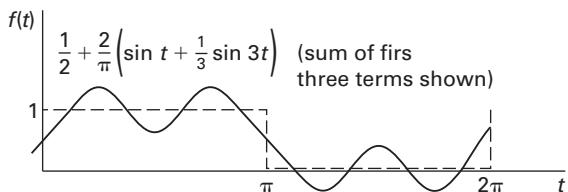

$$\begin{aligned} b_1 &= \frac{1}{\pi} \int_0^\pi (1) \sin t dt + \frac{1}{\pi} \int_\pi^{2\pi} (0) \sin t dt \\ &= \frac{1}{\pi} (-\cos t) \Big|_0^\pi \\ &= \frac{2}{\pi} \end{aligned}$$

In general,

$$b_n = \frac{1}{\pi} \left( \frac{-\cos nt}{n} \right) \Big|_0^\pi = \begin{cases} 0 & \text{for } n \text{ even} \\ \frac{2}{\pi n} & \text{for } n \text{ odd} \end{cases}$$

The series is

$$f(t) = \frac{1}{2} + \frac{2}{\pi} \left( \sin t + \frac{1}{3} \sin 3t + \frac{1}{5} \sin 5t + \dots \right)$$

**16. FAST FOURIER TRANSFORMS**

Many mathematical operations are needed to implement a true Fourier transform. While the terms of a Fourier series might be slowly derived by integration, a faster method is needed to analyze real-time data. The *fast Fourier transform* (FFT) is a computer algorithm implemented in *spectrum analyzers* (*signal analyzers* or *FFT analyzers*) and replaces integration and multiplication operations with table lookups and additions.<sup>7</sup>

Since the complexity of the transform is reduced, the transformation occurs more quickly, enabling efficient analysis of waveforms with little or no periodicity.<sup>8</sup>

Using a spectrum analyzer requires choosing the frequency band (e.g., 0–20 kHz) to be monitored. (This step automatically selects the sampling period. The lower the frequencies sampled, the longer the sampling period.) If they are not fixed by the analyzer, the numbers of time-dependent input variable samples (e.g., 1024) and frequency-dependent output variable values (e.g., 400) are chosen.<sup>9</sup> There are half as many frequency lines as data points because each line contains two pieces of information—real (amplitude) and imaginary (phase). The *resolution* of the resulting frequency analysis is

$$\text{resolution} = \frac{\text{frequency bandwidth}}{\text{no. of output variable values}} \quad 9.55$$

**17. INTEGRAL FUNCTIONS**

Integrals that cannot be evaluated as finite combinations of elementary functions are called *integral functions*. These functions are evaluated by series expansion. Some of the more common functions are listed as follows.<sup>10</sup>

- *integral sine function*

$$\begin{aligned} \text{Si}(x) &= \int_0^x \frac{\sin x}{x} dx \\ &= x - \frac{x^3}{3 \cdot 3!} + \frac{x^5}{5 \cdot 5!} - \frac{x^7}{7 \cdot 7!} + \dots \end{aligned} \quad 9.56$$

<sup>7</sup>*Spectrum analysis*, also known as *frequency analysis*, *signature analysis*, and *time-series analysis*, develops a relationship (usually graphical) between some property (e.g., amplitude or phase shift) versus frequency.

<sup>8</sup>Hours and days of manual computations are compressed into milliseconds.

<sup>9</sup>Two samples per time-dependent cycle (at the maximum frequency) is the lower theoretical limit for sampling, but the practical minimum rate is approximately 2.5 samples per cycle. This will ensure that *alias components* (i.e., low-level frequency signals) do not show up in the frequency band of interest.

<sup>10</sup>Other integral functions include the Fresnel integral, gamma function, and elliptic integral.

- integral cosine function

$$\begin{aligned}\text{Ci}(x) &= \int_{-\infty}^x \frac{\cos x}{x} dx = - \int_x^{\infty} \frac{\cos x}{x} dx \\ &= C_E + \ln x - \frac{x^2}{2 \cdot 2!} + \frac{x^4}{4 \cdot 4!} - \dots\end{aligned}\quad 9.57$$

- integral exponential function

$$\begin{aligned}\text{Ei}(x) &= \int_{-\infty}^x \frac{e^x}{x} dx = - \int_{-x}^{\infty} \frac{e^{-x}}{x} dx \\ &= C_E + \ln x + x + \frac{x^2}{2 \cdot 2!} + \frac{x^3}{3 \cdot 3!} + \dots\end{aligned}\quad 9.58$$

$C_E$  in Eq. 9.57 and Eq. 9.58 is *Euler's constant*.

$$\begin{aligned}C_E &= \int_{+\infty}^0 e^{-x} \ln x dx \\ &= \lim_{m \rightarrow \infty} \left( 1 + \frac{1}{2} + \frac{1}{3} + \dots + \frac{1}{m} - \ln m \right) \\ &= 0.577215665\end{aligned}$$

- error function

$$\begin{aligned}\text{erf}(x) &= \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt \\ &= \left( \frac{2}{\sqrt{\pi}} \right) \left( \frac{x}{1 \cdot 0!} - \frac{x^3}{3 \cdot 1!} + \frac{x^5}{5 \cdot 2!} - \frac{x^7}{7 \cdot 3!} + \dots \right)\end{aligned}\quad 9.59$$

## 1. TYPES OF DIFFERENTIAL EQUATIONS

A *differential equation* is a mathematical expression combining a function (e.g.,  $y = f(x)$ ) and one or more of its derivatives. The *order* of a differential equation is the highest derivative in it. *First-order differential equations* contain only first derivatives of the function, *second-order differential equations* contain second derivatives (and may contain first derivatives as well), and so on.

A *linear differential equation* can be written as a sum of products of multipliers of the function and its derivatives. If the multipliers are scalars, the differential equation is said to have *constant coefficients*. If the function or one of its derivatives is raised to some power (other than one) or is embedded in another function (e.g.,  $y$  embedded in  $\sin y$  or  $e^y$ ), the equation is said to be *nonlinear*.

Each term of a *homogeneous differential equation* contains either the function ( $y$ ) or one of its derivatives; that is, the sum of derivative terms is equal to zero. In a *nonhomogeneous differential equation*, the

sum of derivative terms is equal to a nonzero *forcing function* of the independent variable (e.g.,  $g(x)$ ). In order to solve a nonhomogeneous equation, it is often necessary to solve the homogeneous equation first. The homogeneous equation corresponding to a nonhomogeneous equation is known as a *reduced equation* or *complementary equation*.

The following examples illustrate the types of differential equations.

$$y' - 7y = 0$$

homogeneous, first-order  
linear, with constant  
coefficients

$$y'' - 2y' + 8y = \sin 2x$$

nonhomogeneous, second-order  
linear, with constant  
coefficients

$$y'' - (x^2 - 1)y^2 = \sin 4x$$

nonhomogeneous, second-  
order, nonlinear

An *auxiliary equation* (also called the *characteristic equation*) can be written for a homogeneous linear differential equation with constant coefficients, regardless of order. This auxiliary equation is simply the polynomial formed by replacing all derivatives with variables raised to the power of their respective derivatives.

The purpose of solving a differential equation is to derive an expression for the function in terms of the independent variable. The expression does not need to be explicit in the function, but there can be no derivatives in the expression. Since, in the simplest cases, solving a differential equation is equivalent to finding an indefinite integral, it is not surprising that *constants of integration* must be evaluated from knowledge of how the system behaves. Additional data are known as *initial values*, and any problem that includes them is known as an *initial value problem*.<sup>1</sup>

Most differential equations require lengthy solutions and are not efficiently solved by hand. However, several types are fairly simple and are presented in this chapter.

<sup>1</sup>The term *initial* implies that time is the independent variable. While this may explain the origin of the term, initial value problems are not limited to the time domain. A *boundary value problem* is similar, except that the data come from different points. For example, additional data in the form  $y(x_0)$  and  $y'(x_0)$  or  $y(x_0)$  and  $y'(x_1)$  that need to be simultaneously satisfied constitute an initial value problem. Data of the form  $y(x_0)$  and  $y(x_1)$  constitute a boundary value problem. Until solved, it is difficult to know whether a boundary value problem has zero, one, or more than one solution.

**Example 10.1**

Write the complementary differential equation for the following nonhomogeneous differential equation.

$$y'' + 6y' + 9y = e^{-14x} \sin 5x$$

*Solution*

The complementary equation is found by eliminating the forcing function,  $e^{-14x} \sin 5x$ .

$$y'' + 6y' + 9y = 0$$

**Example 10.2**

Write the auxiliary equation to the following differential equation.

$$y'' + 4y' + y = 0$$

*Solution*

Replacing each derivative with a polynomial term whose degree equals the original order, the auxiliary equation is

$$r^2 + 4r + 1 = 0$$

## 2. HOMOGENEOUS, FIRST-ORDER LINEAR DIFFERENTIAL EQUATIONS WITH CONSTANT COEFFICIENTS

A homogeneous, first-order linear differential equation with constant coefficients will have the general form of Eq. 10.1.

$$y' + ky = 0 \quad 10.1$$

The auxiliary equation is  $r + k = 0$  and it has a root of  $r = -k$ . Equation 10.2 is the solution.

$$y = Ae^{rx} = Ae^{-kx} \quad 10.2$$

If the initial condition is known to be  $y(0) = y_0$ , the solution is

$$y = y_0 e^{-kx} \quad 10.3$$

## 3. FIRST-ORDER LINEAR DIFFERENTIAL EQUATIONS

A first-order linear differential equation has the general form of Eq. 10.4.  $p(x)$  and  $g(x)$  can be constants or any function of  $x$  (but not of  $y$ ). However, if  $p(x)$  is a constant and  $g(x)$  is zero, it is easier to solve the equation as shown in Sec. 10.2.

$$y' + p(x)y = g(x) \quad 10.4$$

The *integrating factor* (which is usually a function) to this differential equation is

$$u(x) = \exp\left(\int p(x)dx\right) \quad 10.5$$

The closed-form solution to Eq. 10.4 is

$$y = \frac{1}{u(x)} \left( \int u(x)g(x)dx + C \right) \quad 10.6$$

For the special case where  $p(x)$  and  $g(x)$  are both constants, Eq. 10.4 becomes

$$y' + ay = b \quad 10.7$$

If the initial condition is  $y(0) = y_0$ , then the solution to Eq. 10.7 is

$$y = \frac{b}{a}(1 - e^{-ax}) + y_0 e^{-ax} \quad 10.8$$

**Example 10.3**

Find a solution to the following differential equation.

$$y' - y = 2xe^{2x} \quad y(0) = 1$$

*Solution*

This is a first-order linear equation with  $p(x) = -1$  and  $g(x) = 2xe^{2x}$ . The integrating factor is

$$u(x) = \exp\left(\int p(x)dx\right) = \exp\left(\int -1dx\right) = e^{-x}$$

The solution is given by Eq. 10.6.

$$\begin{aligned} y &= \frac{1}{u(x)} \left( \int u(x)g(x)dx + C \right) \\ &= \frac{1}{e^{-x}} \left( \int e^{-x} 2xe^{2x} dx + C \right) \\ &= e^x \left( 2 \int xe^x dx + C \right) \\ &= e^x (2xe^x - 2e^x + C) \\ &= e^x (2e^x(x - 1) + C) \end{aligned}$$

From the initial condition,

$$\begin{aligned} y(0) &= 1 \\ e^0((2)(e^0)(0 - 1) + C) &= 1 \\ 1((2)(1)(-1) + C) &= 1 \end{aligned}$$

Therefore,  $C = 3$ . The complete solution is

$$y = e^x (2e^x(x - 1) + 3)$$

## 4. FIRST-ORDER SEPARABLE DIFFERENTIAL EQUATIONS

*First-order separable differential equations* can be placed in the form of Eq. 10.9. For clarity and convenience,  $y'$  is written as  $dy/dx$ .

$$m(x) + n(y) \frac{dy}{dx} = 0 \quad 10.9$$

Equation 10.9 can be placed in the form of Eq. 10.10, both sides of which are easily integrated. An initial value will establish the constant of integration.

$$m(x)dx = -n(y)dy \quad 10.10$$

## 5. FIRST-ORDER EXACT DIFFERENTIAL EQUATIONS

A *first-order exact differential equation* has the form

$$f_x(x, y) + f_y(x, y)y' = 0 \quad 10.11$$

$f_x(x, y)$  is the exact derivative of  $f(x, y)$  with respect to  $x$ , and  $f_y(x, y)$  is the exact derivative of  $f(x, y)$  with respect to  $y$ . The solution is

$$f(x, y) - C = 0 \quad 10.12$$

## 6. HOMOGENEOUS, SECOND-ORDER LINEAR DIFFERENTIAL EQUATIONS WITH CONSTANT COEFFICIENTS

*Homogeneous second-order linear differential equations with constant coefficients* have the form of Eq. 10.13. They are most easily solved by finding the two roots of the auxiliary equation, Eq. 10.14.

$$y'' + k_1 y' + k_2 y = 0 \quad 10.13$$

$$r^2 + k_1 r + k_2 = 0 \quad 10.14$$

There are three cases. If the two roots of Eq. 10.14 are real and different, the solution is

$$y = A_1 e^{r_1 x} + A_2 e^{r_2 x} \quad 10.15$$

If the two roots are real and the same, the solution is

$$y = A_1 e^{rx} + A_2 x e^{rx} \quad 10.16$$

$$r = \frac{-k_1}{2} \quad 10.17$$

If the two roots are imaginary, they will be of the form  $(\alpha + i\omega)$  and  $(\alpha - i\omega)$ , and the solution is

$$y = A_1 e^{\alpha x} \cos \omega x + A_2 e^{\alpha x} \sin \omega x \quad 10.18$$

In all three cases,  $A_1$  and  $A_2$  must be found from the two initial conditions.

## Example 10.4

Solve the following differential equation.

$$y'' + 6y' + 9y = 0$$

$$y(0) = 0 \quad y'(0) = 1$$

*Solution*

The auxiliary equation is

$$r^2 + 6r + 9 = 0$$

$$(r + 3)(r + 3) = 0$$

The roots to the auxiliary equation are  $r_1 = r_2 = -3$ . Therefore, the solution has the form of Eq. 10.16.

$$y = A_1 e^{-3x} + A_2 x e^{-3x}$$

The first initial condition is

$$y(0) = 0$$

$$A_1 e^0 + A_2(0) e^0 = 0$$

$$A_1 + 0 = 0$$

$$A_1 = 0$$

To use the second initial condition, the derivative of the equation is needed. Making use of the known fact that  $A_1 = 0$ ,

$$y' = \frac{d}{dx} A_2 x e^{-3x} = -3A_2 x e^{-3x} + A_2 e^{-3x}$$

Using the second initial condition,

$$y'(0) = 1$$

$$-3A_2(0) e^0 + A_2 e^0 = 1$$

$$0 + A_2 = 1$$

$$A_2 = 1$$

The solution is

$$y = x e^{-3x}$$

## 7. NONHOMOGENEOUS DIFFERENTIAL EQUATIONS

A nonhomogeneous equation has the form of Eq. 10.19.  $f(x)$  is known as the *forcing function*.

$$y'' + p(x)y' + q(x)y = f(x) \quad 10.19$$

The solution to Eq. 10.19 is the sum of two equations. The *complementary solution*,  $y_c$ , solves the complementary (i.e., homogeneous) problem. The *particular solution*,  $y_p$ , is any specific solution to the nonhomogeneous Eq. 10.19 that is known or can be found. Initial values are used to evaluate any unknown coefficients

in the complementary solution  $y_c$  and  $y_p$  have been combined. (The particular solution will not have any unknown coefficients.)

$$y = y_c + y_p \quad 10.20$$

Two methods are available for finding a particular solution. The *method of undetermined coefficients*, as presented here, can be used only when  $p(x)$  and  $q(x)$  are constant coefficients and  $f(x)$  takes on one of the forms in Table 10.1.

The particular solution can be read from Table 10.1 if the forcing function is of one of the forms given. Of course, the coefficients  $A_i$  and  $B_i$  are not known—these are the *undetermined coefficients*. The exponent  $s$  is the smallest nonnegative number (and will be 0, 1, or 2), which ensures that no term in the particular solution,  $y_p$ , is also a solution to the complementary equation,  $y_c$ .  $s$  must be determined prior to proceeding with the solution procedure.

Once  $y_p$  (including  $s$ ) is known, it is differentiated to obtain  $y'_p$  and  $y''_p$ , and all three functions are substituted into the original nonhomogeneous equation. The resulting equation is rearranged to match the forcing function,  $f(x)$ , and the unknown coefficients are determined, usually by solving simultaneous equations.

If the forcing function,  $f(x)$ , is more complex than the forms shown in Table 10.1, or if either  $p(x)$  or  $q(x)$  is a function of  $x$ , the method of *variation of parameters* should be used. This complex and time-consuming method is not covered in this book.

**Table 10.1** Particular Solutions\*

form of $f(x)$	form of $y_p$
$P_n(x) = a_0x^n + a_1x^{n-1} + \dots + a_n$	$x^s \left( A_0x^n + A_1x^{n-1} + \dots + A_n \right)$
$P_n(x)e^{\alpha x}$	$x^s \left( A_0x^n + A_1x^{n-1} + \dots + A_n \right) e^{\alpha x}$
$P_n(x)e^{\alpha x} \left\{ \begin{array}{l} \sin \omega x \\ \cos \omega x \end{array} \right\}$	$\begin{aligned} & x^s \left( \left( A_0x^n + A_1x^{n-1} + \dots + A_n \right) \right. \\ & \quad \times (e^{\alpha x} \cos \omega x) \\ & + \left( B_0x^n + B_1x^{n-1} + \dots + B_n \right) \\ & \quad \times (e^{\alpha x} \sin \omega x) \end{aligned}$

\*  $P_n(x)$  is a polynomial of degree  $n$ .

### Example 10.5

Solve the following nonhomogeneous differential equation.

$$y'' + 2y' + y = e^x \cos x$$

### Solution

**step 1:** Find the solution to the complementary (homogeneous) differential equation.

$$y'' + 2y' + y = 0$$

Since this is a differential equation with constant coefficients, write the auxiliary equation.

$$r^2 + 2r + 1 = 0$$

The auxiliary equation factors in  $(r + 1)^2 = 0$  with two identical roots at  $r = -1$ . Therefore, the solution to the homogeneous differential equation is

$$y_c(x) = C_1 e^{-x} + C_2 x e^{-x}$$

**step 2:** Use Table 10.1 to determine the form of a particular solution. Since the forcing function has the form  $P_n(x)e^{\alpha x} \cos \omega x$  with  $P_n(x) = 1$  (equivalent to  $n = 0$ ),  $\alpha = 1$ , and  $\omega = 1$ , the particular solution has the form

$$y_p(x) = x^s(A e^x \cos x + B e^x \sin x)$$

**step 3:** Determine the value of  $s$ . Check to see if any of the terms in  $y_p(x)$  will themselves solve the homogeneous equation. Try  $A e^x \cos x$  first.

$$\frac{d}{dx}(A e^x \cos x) = A e^x \cos x - A e^x \sin x$$

$$\frac{d^2}{dx^2}(A e^x \cos x) = -2A e^x \sin x$$

Substitute these quantities into the homogeneous equation.

$$\begin{aligned} y'' + 2y' + y &= 0 \\ -2A e^x \sin x + 2A e^x \cos x &= 0 \\ -2A e^x \sin x + A e^x \cos x &= 0 \\ 3A e^x \cos x - 4A e^x \sin x &= 0 \end{aligned}$$

Disregarding the trivial (i.e.,  $A = 0$ ) solution,  $A e^x \cos x$  does not solve the homogeneous equation.

Next, try  $B e^x \sin x$ .

$$\frac{d}{dx}(B e^x \sin x) = B e^x \cos x + B e^x \sin x$$

$$\frac{d^2}{dx^2}(B e^x \sin x) = 2B e^x \cos x$$

Substitute these quantities into the homogeneous equation.

$$\begin{aligned}y'' + 2y' + y &= 0 \\2Be^x \cos x + 2Be^x \cos x \\+ 2Be^x \sin x + Be^x \sin x &= 0 \\3Be^x \sin x + 4Be^x \cos x &= 0\end{aligned}$$

Disregarding the trivial ( $B = 0$ ) case,  $Be^x \sin x$  does not solve the homogeneous equation.

Since none of the terms in  $y_p(x)$  solve the homogeneous equation,  $s = 0$ , and a particular solution has the form

$$y_p(x) = Ae^x \cos x + Be^x \sin x$$

*step 4:* Use the method of unknown coefficients to determine  $A$  and  $B$  in the particular solution. Drawing on the previous steps, substitute the quantities derived from the particular solution into the nonhomogeneous equation.

$$\begin{aligned}y'' + 2y' + y &= e^x \cos x \\-2Ae^x \sin x + 2Be^x \cos x \\+ 2Ae^x \cos x - 2Ae^x \sin x \\+ 2Be^x \cos x + 2Be^x \sin x \\+ Ae^x \cos x + Be^x \sin x &= e^x \cos x\end{aligned}$$

Combining terms,

$$\begin{aligned}(-4A + 3B)e^x \sin x + (3A + 4B)e^x \cos x \\= e^x \cos x\end{aligned}$$

Equating the coefficients of like terms on either side of the equal sign results in the following simultaneous equations.

$$-4A + 3B = 0$$

$$3A + 4B = 1$$

The solution to these equations is

$$A = \frac{3}{25}$$

$$B = \frac{4}{25}$$

A particular solution is

$$y_p(x) = \frac{3}{25}e^x \cos x + \frac{4}{25}e^x \sin x$$

*step 5:* Write the general solution.

$$\begin{aligned}y(x) &= y_c(x) + y_p(x) \\&= C_1 e^{-x} + C_2 x e^{-x} + \frac{3}{25}e^x \cos x \\&\quad + \frac{4}{25}e^x \sin x\end{aligned}$$

The values of  $C_1$  and  $C_2$  would be determined at this time if initial conditions were known.

## 8. NAMED DIFFERENTIAL EQUATIONS

Some differential equations with specific forms are named after the individuals who developed solution techniques for them.

- *Bessel equation of order  $\nu$*

$$x^2 y'' + xy' + (x^2 - \nu^2)y = 0 \quad 10.21$$

- *Cauchy equation*

$$\begin{aligned}a_0 x^n \frac{d^n y}{dx^n} + a_1 x^{n-1} \frac{d^{n-1} y}{dx^{n-1}} + \dots \\+ a_{n-1} x \frac{dy}{dx} + a_n y = f(x) \quad 10.22\end{aligned}$$

- *Euler's equation*

$$x^2 y'' + \alpha xy' + \beta y = 0 \quad 10.23$$

- *Gauss' hypergeometric equation*

$$x(1-x)y'' + (c - (a+b+1)x)y' - aby = 0 \quad 10.24$$

- *Legendre equation of order  $\lambda$*

$$(1-x^2)y'' - 2xy' + \lambda(\lambda+1)y = 0 \quad [-1 < x < 1] \quad 10.25$$

## 9. LAPLACE TRANSFORMS

Traditional methods of solving nonhomogeneous differential equations by hand are usually difficult and/or time consuming. *Laplace transforms* can be used to reduce many solution procedures to simple algebra.

Every mathematical function,  $f(t)$ , for which Eq. 10.26 exists has a Laplace transform, written as  $\mathcal{L}(f)$  or  $F(s)$ . The transform is written in the  $s$ -domain, regardless of the independent variable in the original function.<sup>2</sup> (The variable  $s$  is equivalent to a derivative operator, although it may be handled in the equations as a simple

<sup>2</sup>It is traditional to write the original function as a function of the independent variable  $t$  rather than  $x$ . However, Laplace transforms are not limited to functions of time.

variable.) Equation 10.26 converts a function into a Laplace transform.

$$\mathcal{L}(f(t)) = F(s) = \int_0^\infty e^{-st} f(t) dt \quad 10.26$$

Equation 10.26 is not often needed because tables of transforms are readily available. (Appendix 10.A contains some of the most common transforms.)

Extracting a function from its transform is the *inverse Laplace transform* operation. Although other methods exist, this operation is almost always done by finding the transform in a set of tables.<sup>3</sup>

$$f(t) = \mathcal{L}^{-1}(F(s)) \quad 10.27$$

### Example 10.6

Find the Laplace transform of the following function.

$$f(t) = e^{at} \quad [s > a]$$

*Solution*

Applying Eq. 10.26,

$$\begin{aligned} \mathcal{L}(e^{at}) &= \int_0^\infty e^{-st} e^{at} dt = \int_0^\infty e^{-(s-a)t} dt \\ &= -\frac{e^{-(s-a)t}}{s-a} \Big|_0^\infty \\ &= \frac{1}{s-a} \quad [s > a] \end{aligned}$$

## 10. STEP AND IMPULSE FUNCTIONS

Many forcing functions are sinusoidal or exponential in nature; others, however, can only be represented by a step or impulse function. A *unit step function*,  $u_t$ , is a function describing the disturbance of magnitude 1 that is not present before time  $t$  but is suddenly there after time  $t$ . A step of magnitude 5 at time  $t = 3$  would be represented as  $5u_3$ . (The notation  $5u(t-3)$  is used in some books.)

The *unit impulse function*,  $\delta_t$ , is a function describing a disturbance of magnitude 1 that is applied and removed so quickly as to be instantaneous. An impulse of magnitude 5 at time 3 would be represented by  $5\delta_3$ . (The notation  $5\delta(t-3)$  is used in some books.)

### Example 10.7

What is the notation for a forcing function of magnitude 6 that is applied at  $t = 2$  and that is completely removed at  $t = 7$ ?

*Solution*

The notation is  $f(t) = 6(u_2 - u_7)$ .

<sup>3</sup>Other methods include integration in the complex plane, convolution, and simplification by partial fractions.

### Example 10.8

Find the Laplace transform of  $u_0$ , a unit step at  $t = 0$ .

$$f(t) = 0 \text{ for } t < 0$$

$$f(t) = 1 \text{ for } t \geq 0$$

*Solution*

Since the Laplace transform is an integral that starts at  $t = 0$ , the value of  $f(t)$  prior to  $t = 0$  is irrelevant.

$$\begin{aligned} \mathcal{L}(u_0) &= \int_0^\infty e^{-st}(1) dt = -\frac{e^{-st}}{s} \Big|_0^\infty \\ &= 0 - \frac{-1}{s} \\ &= \frac{1}{s} \end{aligned}$$

## 11. ALGEBRA OF LAPLACE TRANSFORMS

Equations containing Laplace transforms can be simplified by applying the following principles.

- *linearity theorem* ( $c$  is a constant.)

$$\mathcal{L}(cf(t)) = c\mathcal{L}(f(t)) = cF(s) \quad 10.28$$

- *superposition theorem* ( $f(t)$  and  $g(t)$  are different functions.)

$$\begin{aligned} \mathcal{L}(f(t) \pm g(t)) &= \mathcal{L}(f(t)) \pm \mathcal{L}(g(t)) \\ &= F(s) \pm G(s) \end{aligned} \quad 10.29$$

- *time-shifting theorem (delay theorem)*

$$\mathcal{L}(f(t-b)u_b) = e^{-bs}F(s) \quad 10.30$$

- *Laplace transform of a derivative*

$$\begin{aligned} \mathcal{L}(f^n(t)) &= -f^{n-1}(0) - sf^{n-2}(0) - \dots \\ &\quad - s^{n-1}f(0) + s^n F(s) \end{aligned} \quad 10.31$$

- *other properties*

$$\mathcal{L}\left(\int_0^t f(u) du\right) = \frac{1}{s}F(s) \quad 10.32$$

$$\mathcal{L}(tf(t)) = -\frac{dF}{ds} \quad 10.33$$

$$\mathcal{L}\left(\frac{1}{t}f(t)\right) = \int_0^\infty F(u) du \quad 10.34$$

## 12. CONVOLUTION INTEGRAL

A complex Laplace transform,  $F(s)$ , will often be recognized as the product of two other transforms,  $F_1(s)$  and

$F_2(s)$ , whose corresponding functions  $f_1(t)$  and  $f_2(t)$  are known. Unfortunately, Laplace transforms cannot be computed with ordinary multiplication. That is,  $f(t) \neq f_1(t)f_2(t)$  even though  $F(s) = F_1(s)F_2(s)$ .

However, it is possible to extract  $f(t)$  from its *convolution*,  $h(t)$ , as calculated from either of the *convolution integrals* in Eq. 10.35. This process is demonstrated in Ex. 10.9.  $\chi$  is a dummy variable.

$$\begin{aligned} f(t) &= \mathcal{L}^{-1}(F_1(s)F_2(s)) \\ &= \int_0^t f_1(t-\chi)f_2(\chi)d\chi \\ &= \int_0^t f_1(\chi)f_2(t-\chi)d\chi \end{aligned} \quad 10.35$$

### Example 10.9

Use the convolution integral to find the inverse transform of

$$F(s) = \frac{3}{s^2(s^2 + 9)}$$

*Solution*

$F(s)$  can be factored as

$$F_1(s)F_2(s) = \left(\frac{1}{s^2}\right)\left(\frac{3}{s^2 + 9}\right)$$

As the inverse transforms of  $F_1(s)$  and  $F_2(s)$  are  $f_1(t) = t$  and  $f_2(t) = \sin 3t$ , respectively, the convolution integral from Eq. 10.35 is

$$\begin{aligned} f(t) &= \int_0^t (t-\chi)\sin 3\chi d\chi \\ &= \int_0^t (t\sin 3\chi - \chi \sin 3\chi) d\chi \\ &= t \int_0^t \sin 3\chi d\chi - \int_0^t \chi \sin 3\chi d\chi \end{aligned}$$

Expand using integration by parts.

$$\begin{aligned} f(t) &= -\frac{1}{3}t \cos 3\chi + \frac{1}{3}\chi \cos 3\chi - \frac{1}{9}\sin 3\chi \Big|_0^t \\ &= \frac{3t - \sin 3t}{9} \end{aligned}$$

## 13. USING LAPLACE TRANSFORMS

Any nonhomogeneous linear differential equation with constant coefficients can be solved with the following procedure, which reduces the solution to simple algebra. A complete table of transforms simplifies or eliminates step 5.

*step 1:* Put the differential equation in standard form (i.e., isolate the  $y''$  term).

$$y'' + k_1y' + k_2y = f(t) \quad 10.36$$

*step 2:* Take the Laplace transform of both sides. Use the linearity and superposition theorems. (See Eq. 10.28 and Eq. 10.29.)

$$\mathcal{L}(y'') + k_1\mathcal{L}(y') + k_2\mathcal{L}(y) = \mathcal{L}(f(t)) \quad 10.37$$

*step 3:* Use Eq. 10.38 and Eq. 10.39 to expand the equation. (These are specific forms of Eq. 10.31.) Use a table to evaluate the transform of the forcing function.

$$\mathcal{L}(y'') = s^2\mathcal{L}(y) - sy(0) - y'(0) \quad 10.38$$

$$\mathcal{L}(y') = s\mathcal{L}(y) - y(0) \quad 10.39$$

*step 4:* Use algebra to solve for  $\mathcal{L}(y)$ .

*step 5:* If needed, use partial fractions to simplify the expression for  $\mathcal{L}(y)$ .

*step 6:* Take the inverse transform to find  $y(t)$ .

$$y(t) = \mathcal{L}^{-1}(\mathcal{L}(y)) \quad 10.40$$

### Example 10.10

Find  $y(t)$  for the following differential equation.

$$y'' + 2y' + 2y = \cos t$$

$$y(0) = 1 \quad y'(0) = 0$$

*Solution*

*step 1:* The equation is already in standard form.

$$\mathcal{L}(y'') + 2\mathcal{L}(y') + 2\mathcal{L}(y) = \mathcal{L}(\cos t)$$

*step 3:* Use Eq. 10.38 and Eq. 10.39. Use App. 10.A to find the transform of  $\cos t$ .

$$\begin{aligned} s^2\mathcal{L}(y) - sy(0) - y'(0) + 2s\mathcal{L}(y) - 2y(0) + 2\mathcal{L}(y) \\ = \frac{s}{s^2 + 1} \end{aligned}$$

But,  $y(0) = 1$  and  $y'(0) = 0$ .

$$s^2\mathcal{L}(y) - s + 2s\mathcal{L}(y) - 2 + 2\mathcal{L}(y) = \frac{s}{s^2 + 1}$$

*step 4:* Combine terms and solve for  $\mathcal{L}(y)$ .

$$\mathcal{L}(y)(s^2 + 2s + 2) - s - 2 = \frac{s}{s^2 + 1}$$

$$\begin{aligned} \mathcal{L}(y) &= \frac{\frac{s}{s^2 + 1} + s + 2}{s^2 + 2s + 2} \\ &= \frac{s^3 + 2s^2 + 2s + 2}{(s^2 + 1)(s^2 + 2s + 2)} \end{aligned}$$

*step 5:* Expand the expression for  $\mathcal{L}(y)$  by partial fractions.

$$\begin{aligned}\mathcal{L}(y) &= \frac{s^3 + 2s^2 + 2s + 2}{(s^2 + 1)(s^2 + 2s + 2)} \\ &= \frac{A_1 s + B_1}{s^2 + 1} + \frac{A_2 s + B_2}{s^2 + 2s + 2} \\ &\quad s^3(A_1 + A_2) + s^2(2A_1 + B_1 + B_2) \\ &= \frac{+ s(2A_1 + 2B_1 + A_2) + (2B_1 + B_2)}{(s^2 + 1)(s^2 + 2s + 2)}\end{aligned}$$

The following simultaneous equations result.

$$\begin{array}{rcl} A_1 + A_2 & = 1 \\ 2A_1 & + B_1 + B_2 & = 2 \\ 2A_1 + A_2 + 2B_1 & = 2 \\ & 2B_1 + B_2 & = 2 \end{array}$$

These equations have the solutions  $A_1 = 1/5$ ,  $A_2 = 4/5$ ,  $B_1 = 2/5$ , and  $B_2 = 6/5$ .

*step 6:* Refer to App. 10.A and take the inverse transforms. The numerator of the second term is rewritten from  $(4s + 6)$  to  $((4s + 4) + 2)$ .

$$\begin{aligned}y &= \mathcal{L}^{-1}(\mathcal{L}(y)) \\ &= \mathcal{L}^{-1}\left(\frac{\left(\frac{1}{5}\right)(s+2)}{s^2+1} + \frac{\left(\frac{1}{5}\right)(4s+6)}{s^2+2s+2}\right) \\ &= \left(\frac{1}{5}\right)\left(\mathcal{L}^{-1}\left(\frac{s}{s^2+1}\right) + 2\mathcal{L}^{-1}\left(\frac{1}{s^2+1}\right) + 4\mathcal{L}^{-1}\left(\frac{s-(-1)}{\left(s-(-1)\right)^2+1}\right) + 6\mathcal{L}^{-1}\left(\frac{1}{\left(s-(-1)\right)^2+1}\right)\right) \\ &= \left(\frac{1}{5}\right)(\cos t + 2 \sin t + 4e^{-t} \cos t + 6e^{-t} \sin t)\end{aligned}$$

#### 14. THIRD- AND HIGHER-ORDER LINEAR DIFFERENTIAL EQUATIONS WITH CONSTANT COEFFICIENTS

The solutions of third- and higher-order linear differential equations with constant coefficients are extensions of the solutions for second-order equations of this type. Specifically, if an equation is homogeneous, the auxiliary equation is written and its roots are found. If the equation is nonhomogeneous, Laplace transforms can be used to simplify the solution.

Consider the following homogeneous differential equation with constant coefficients.

$$y^n + k_1 y^{n-1} + \cdots + k_{n-1} y' + k_n y = 0 \quad 10.41$$

The auxiliary equation to Eq. 10.41 is

$$r^n + k_1 r^{n-1} + \cdots + k_{n-1} r + k_n = 0 \quad 10.42$$

For each real and distinct root  $r$ , the solution contains the term

$$y = A e^{rx} \quad 10.43$$

For each real root  $r$  that repeats  $m$  times, the solution contains the term

$$y = (A_1 + A_2 x + A_3 x^2 + \cdots + A_m x^{m-1}) e^{rx} \quad 10.44$$

For each pair of complex roots of the form  $r = \alpha \pm i\omega$  the solution contains the terms

$$y = e^{\alpha x} (A_1 \sin \omega x + A_2 \cos \omega x) \quad 10.45$$

#### 15. APPLICATION: ENGINEERING SYSTEMS

There is a wide variety of engineering systems (mechanical, electrical, fluid flow, heat transfer, and so on) whose behavior is described by linear differential equations with constant coefficients.

#### 16. APPLICATION: MIXING

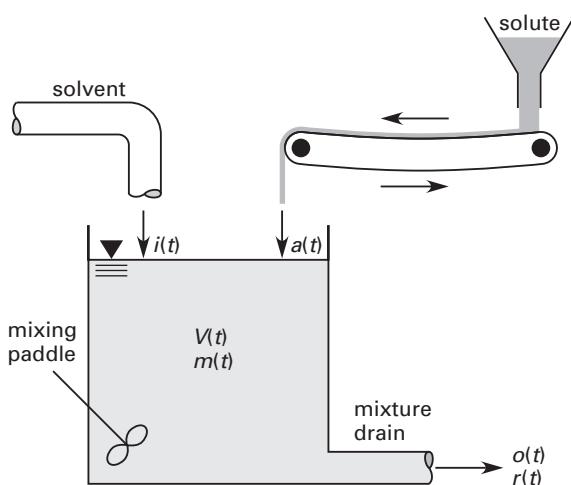

A typical mixing problem involves a liquid-filled tank. The liquid may initially be pure or contain some solute. Liquid (either pure or as a solution) enters the tank at a known rate. A drain may be present to remove thoroughly mixed liquid. The concentration of the solution (or, equivalently, the amount of solute in the tank) at some given time is generally unknown. (See Fig. 10.1.)

If  $m(t)$  is the mass of solute in the tank at time  $t$ , the rate of solute change will be  $m'(t)$ . If the solute is being added at the rate of  $a(t)$  and being removed at the rate of  $r(t)$ , the rate of change is

$$\begin{aligned}m'(t) &= \text{rate of addition} - \text{rate of removal} \\ &= a(t) - r(t) \quad 10.46\end{aligned}$$

The rate of solute addition  $a(t)$  must be known and, in fact, may be constant or zero. However,  $r(t)$  depends on the concentration,  $c(t)$ , of the mixture and volumetric flow rates at time  $t$ . If  $o(t)$  is the volumetric flow rate out of the tank, then

$$r(t) = c(t)o(t) \quad 10.47$$

**Figure 10.1** Fluid Mixture Problem

However, the concentration depends on the mass of solute in the tank at time  $t$ . Recognizing that the volume,  $V(t)$ , of the liquid in the tank may be changing with time,

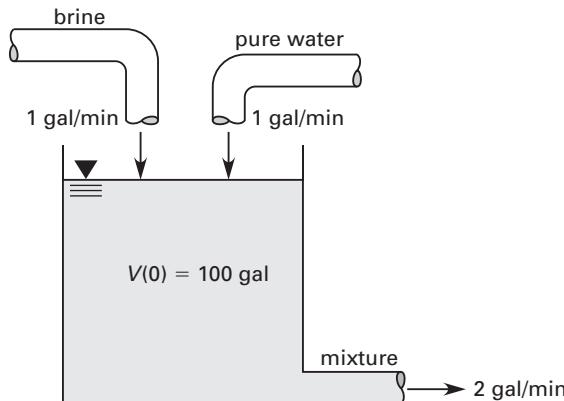

$$c(t) = \frac{m(t)}{V(t)} \quad 10.48$$

The differential equation describing this problem is

$$m'(t) = a(t) - \frac{m(t)o(t)}{V(t)} \quad 10.49$$

### Example 10.11

A tank contains 100 gal of pure water at the beginning of an experiment. Pure water flows into the tank at a rate of 1 gal/min. Brine containing  $\frac{1}{4}$  lbm of salt per gallon enters the tank from a second source at a rate of 1 gal/min. A perfectly mixed solution drains from the tank at a rate of 2 gal/min. How much salt is in the tank 8 min after the experiment begins?

### Solution

Let  $m(t)$  represent the mass of salt in the tank at time  $t$ . 0.25 lbm of salt enters the tank per minute (that is,  $a(t) = 0.25$  lbm/min). The salt removal rate depends on the concentration in the tank. That is,

$$\begin{aligned} r(t) &= o(t)c(t) = \left(2 \frac{\text{gal}}{\text{min}}\right)\left(\frac{m(t)}{100 \text{ gal}}\right) \\ &= \left(0.02 \frac{1}{\text{min}}\right)m(t) \end{aligned}$$

From Eq. 10.46, the rate of change of salt in the tank is

$$\begin{aligned} m'(t) &= a(t) - r(t) \\ &= 0.25 \frac{\text{lbm}}{\text{min}} - \left(0.02 \frac{1}{\text{min}}\right)m(t) \end{aligned}$$

$$m'(t) + \left(0.02 \frac{1}{\text{min}}\right)m(t) = 0.25 \text{ lbm/min}$$

This is a first-order linear differential equation of the form of Eq. 10.7. Since the initial condition is  $m(0) = 0$ , the solution is

$$\begin{aligned} m(t) &= \left(\frac{0.25 \frac{\text{lbm}}{\text{min}}}{0.02 \frac{1}{\text{min}}}\right) \left(1 - e^{-\left(0.02 \frac{1}{\text{min}}\right)t}\right) \\ &= (12.5 \text{ lbm}) \left(1 - e^{-\left(0.02 \frac{1}{\text{min}}\right)t}\right) \end{aligned}$$

At  $t = 8$ ,

$$\begin{aligned} m(t) &= (12.5 \text{ lbm}) \left(1 - e^{-\left(0.02 \frac{1}{\text{min}}\right)(8 \text{ min})}\right) \\ &= (12.5 \text{ lbm})(1 - 0.852) \\ &= 1.85 \text{ lbm} \end{aligned}$$

## 17. APPLICATION: EXPONENTIAL GROWTH AND DECAY

Equation 10.50 describes the behavior of a substance (e.g., radioactive and irradiated molecules) whose quantity,  $m(t)$ , changes at a rate proportional to the quantity present. The constant of proportionality,  $k$ , will be negative for decay (e.g., *radioactive decay*) and positive for growth (e.g., compound interest).

$$m'(t) = km(t) \quad 10.50$$

$$m'(t) - km(t) = 0 \quad 10.51$$

If the initial quantity of substance is  $m(0) = m_0$ , then Eq. 10.51 has the solution

$$m(t) = m_0 e^{kt} \quad 10.52$$

If  $m(t)$  is known for some time  $t$ , the constant of proportionality is

$$k = \frac{1}{t} \ln\left(\frac{m(t)}{m_0}\right) \quad 10.53$$

For the case of a decay, the *half-life*,  $t_{1/2}$ , is the time at which only half of the substance remains. The relationship between  $k$  and  $t_{1/2}$  is

$$kt_{1/2} = \ln\frac{1}{2} = -0.693 \quad 10.54$$

### 18. APPLICATION: EPIDEMICS

During an epidemic in a population of  $n$  people, the density of sick (contaminated, contagious, affected, etc.) individuals is  $\rho_s(t) = s(t)/n$ , where  $s(t)$  is the number of sick individuals at a given time,  $t$ . Similarly, the density of well (uncontaminated, unaffected, susceptible, etc.) individuals is  $\rho_w(t) = w(t)/n$ , where  $w(t)$  is the number of well individuals. Assuming there is no quarantine, the population size is constant, individuals move about freely, and sickness does not limit the activities of individuals, the rate of contagion,  $\rho'_s(t)$ , will be  $k\rho_s(t)\rho_w(t)$ , where  $k$  is a proportionality constant.

$$\rho'_s(t) = k\rho_s(t)\rho_w(t) = k\rho_s(t)(1 - \rho_s(t)) \quad 10.55$$

This is a separable differential equation that has the solution

$$\rho_s(t) = \frac{\rho_s(0)}{\rho_s(0) + (1 - \rho_s(0))e^{-kt}} \quad 10.56$$

### 19. APPLICATION: SURFACE TEMPERATURE

*Newton's law of cooling* states that the surface temperature,  $T$ , of a cooling object changes at a rate proportional to the difference between the surface and ambient temperatures. The constant  $k$  is a positive number.

$$T'(t) = -k(T(t) - T_{\text{ambient}}) \quad [k > 0] \quad 10.57$$

$$T'(t) + kT(t) - kT_{\text{ambient}} = 0 \quad [k > 0] \quad 10.58$$

This first-order linear differential equation with constant coefficients has the following solution (from Eq. 10.8).

$$T(t) = T_{\text{ambient}} + (T(0) - T_{\text{ambient}})e^{-kt} \quad 10.59$$

If the temperature is known at some time  $t$ , the constant  $k$  can be found from Eq. 10.60.

$$k = \frac{-1}{t} \ln\left(\frac{T(t) - T_{\text{ambient}}}{T(0) - T_{\text{ambient}}}\right) \quad 10.60$$

### 20. APPLICATION: EVAPORATION

The mass of liquid evaporated from a liquid surface is proportional to the exposed surface area. Since quantity, mass, and remaining volume are all proportional, the differential equation is

$$\frac{dV}{dt} = -kA \quad 10.61$$

For a spherical drop of radius  $r$ , Eq. 10.61 reduces to

$$\frac{dr}{dt} = -k \quad 10.62$$

$$r(t) = r(0) - kt \quad 10.63$$

For a cube with sides of length  $s$ , Eq. 10.61 reduces to

$$\frac{ds}{dt} = -2k \quad 10.64$$

$$s(t) = s(0) - 2kt \quad 10.65$$

## 1. SET THEORY

A *set* (usually designated by a capital letter) is a population or collection of individual items known as *elements* or *members*. The *null set*,  $\emptyset$ , is empty (i.e., contains no members). If  $A$  and  $B$  are two sets,  $A$  is a *subset* of  $B$  if every member in  $A$  is also in  $B$ .  $A$  is a *proper subset* of  $B$  if  $B$  consists of more than the elements in  $A$ . These relationships are denoted as follows.

$$A \subseteq B \quad [\text{subset}]$$

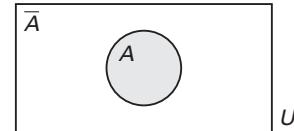

$$A \subset B \quad [\text{proper subset}]$$

The *universal set*,  $U$ , is one from which other sets draw their members. If  $A$  is a subset of  $U$ , then  $A'$  (also

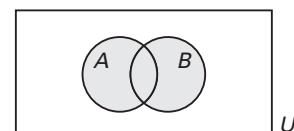

designated as  $A^{-1}$ ,  $\bar{A}$ ,  $-A$ , and  $\overline{A}$ ) is the *complement* of  $A$  and consists of all elements in  $U$  that are not in  $A$ . This is illustrated by the *Venn diagram* in Fig. 11.1(a).

The *union of two sets*, denoted by  $A \cup B$  and shown in Fig. 11.1(b), is the set of all elements that are in either  $A$  or  $B$  or both. The *intersection of two sets*, denoted by  $A \cap B$  and shown in Fig. 11.1(c), is the set of all elements that belong to both  $A$  and  $B$ . If  $A \cap B = \emptyset$ ,  $A$  and  $B$  are said to be *disjoint sets*.

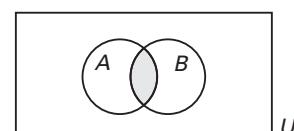

Figure 11.1 Venn Diagrams

(a)  $A \subset U$

(b)  $A \cup B$

(c)  $A \cap B$

If  $A$ ,  $B$ , and  $C$  are subsets of the universal set, the following laws apply.

- *identity laws*

$$A \cup \emptyset = A \quad 11.1$$

$$A \cup U = U \quad 11.2$$

$$A \cap \emptyset = \emptyset \quad 11.3$$

$$A \cap U = A \quad 11.4$$

- *idempotent laws*

$$A \cup A = A \quad 11.5$$

$$A \cap A = A \quad 11.6$$

- complement laws

$$\begin{aligned} A \cup A' &= U & 11.7 \\ (A')' &= A & 11.8 \\ A \cap A' &= \emptyset & 11.9 \\ U' &= \emptyset & 11.10 \end{aligned}$$

- commutative laws

$$\begin{aligned} A \cup B &= B \cup A & 11.11 \\ A \cap B &= B \cap A & 11.12 \end{aligned}$$

- associative laws

$$\begin{aligned} (A \cup B) \cup C &= A \cup (B \cup C) & 11.13 \\ (A \cap B) \cap C &= A \cap (B \cap C) & 11.14 \end{aligned}$$

- distributive laws

$$\begin{aligned} A \cup (B \cap C) &= (A \cup B) \cap (A \cup C) & 11.15 \\ A \cap (B \cup C) &= (A \cap B) \cup (A \cap C) & 11.16 \end{aligned}$$

- de Morgan's laws

$$\begin{aligned} (A \cup B)' &= A' \cap B' & 11.17 \\ (A \cap B)' &= A' \cup B' & 11.18 \end{aligned}$$

## 2. COMBINATIONS OF ELEMENTS

There are a finite number of ways in which  $n$  elements can be combined into distinctly different groups of  $r$  items. For example, suppose a farmer has a hen, a rooster, a duck, and a cage that holds only two birds. The possible *combinations* of three birds taken two at a time are (hen, rooster), (hen, duck), and (rooster, duck). The birds in the cage will not remain stationary, and the combination (rooster, hen) is not distinctly different from (hen, rooster). That is, the groups are not *order conscious*.

The number of combinations of  $n$  items taken  $r$  at a time is written  $C(n, r)$ ,  $C_r^n$ ,  ${}_nC_r$ , or  $\binom{n}{r}$  (pronounced " $n$  choose  $r$ ") and given by Eq. 11.19. It is sometimes referred to as the *binomial coefficient*.

$$\binom{n}{r} = C(n, r) = \frac{n!}{(n - r)!r!} \quad [\text{for } r \leq n] \quad 11.19$$

### Example 11.1

Six people are on a sinking yacht. There are four life jackets. How many combinations of survivors are there?

*Solution*

The groups are not order conscious. From Eq. 11.19,

$$\begin{aligned} C(6, 4) &= \frac{n!}{(n - r)!r!} = \frac{6!}{(6 - 4)!4!} = \frac{6 \cdot 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1}{(2 \cdot 1)(4 \cdot 3 \cdot 2 \cdot 1)} \\ &= 15 \end{aligned}$$

## 3. PERMUTATIONS

An order-conscious subset of  $r$  items taken from a set of  $n$  items is the *permutation*  $P(n, r)$ , also written  $P_r^n$  and  ${}_nP_r$ . The permutation is order conscious because the arrangement of two items (say  $a_i$  and  $b_i$ ) as  $a_i b_i$  is different from the arrangement  $b_i a_i$ . The number of permutations is

$$P(n, r) = \frac{n!}{(n - r)!} \quad [\text{for } r \leq n] \quad 11.20$$

If groups of the entire set of  $n$  items are being enumerated, the number of permutations of  $n$  items taken  $n$  at a time is

$$P(n, n) = \frac{n!}{(n - n)!} = \frac{n!}{0!} = n! \quad 11.21$$

A *ring permutation* is a special case of  $n$  items taken  $n$  at a time. There is no identifiable beginning or end, and the number of permutations is divided by  $n$ .

$$P_{\text{ring}}(n, n) = \frac{P(n, n)}{n} = (n - 1)! \quad 11.22$$

### Example 11.2

A pianist knows four pieces but will have enough stage time to play only three of them. Pieces played in a different order constitute a different program. How many different programs can be arranged?

*Solution*

The groups are order conscious. From Eq. 11.20,

$$P(4, 3) = \frac{n!}{(n - r)!} = \frac{4!}{(4 - 3)!} = \frac{4 \cdot 3 \cdot 2 \cdot 1}{1} = 24$$

### Example 11.3

Seven diplomats from different countries enter a circular room. The only furnishings are seven chairs arranged around a circular table. How many ways are there of arranging the diplomats?

*Solution*

All seven diplomats must be seated, so the groups are permutations of seven objects taken seven at a time. Since there is no head chair, the groups are ring permutations. From Eq. 11.22,

$$\begin{aligned} P_{\text{ring}}(7, 7) &= (7 - 1)! = 6 \cdot 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1 \\ &= 720 \end{aligned}$$

## 4. PROBABILITY THEORY

The act of conducting an experiment (trial) or taking a measurement is known as *sampling*. *Probability theory* determines the relative likelihood that a particular event

will occur. An *event*,  $e$ , is one of the possible outcomes of the *trial*. Taken together, all of the possible events constitute a finite *sample space*,  $E = [e_1, e_2, \dots, e_n]$ . The trial is drawn from the *population* or *universe*. Populations can be finite or infinite in size.

Events can be numerical or nonnumerical, discrete or continuous, and dependent or independent. An example of a nonnumerical event is getting tails on a coin toss. The number from a roll of a die is a discrete numerical event. The measured diameter of a bolt produced from an automatic screw machine is a numerical event. Since the diameter can (within reasonable limits) take on any value, its measured value is a continuous numerical event.

An event is *independent* if its outcome is unaffected by previous outcomes (i.e., previous runs of the experiment) and *dependent* otherwise. Whether or not an event is independent depends on the population size and how the sampling is conducted. Sampling (a trial) from an infinite population is implicitly independent. When the population is finite, *sampling with replacement* produces independent events, while *sampling without replacement* changes the population and produces dependent events.

The terms *success* and *failure* are loosely used in probability theory to designate obtaining and not obtaining, respectively, the tested-for condition. “Failure” is not the same as a *null event* (i.e., one that has a zero probability of occurrence).

The *probability* of event  $e_1$  occurring is designated as  $p\{e_1\}$  and is calculated as the ratio of the total number of ways the event can occur to the total number of outcomes in the sample space.

#### Example 11.4

There are 380 students in a rural school—200 girls and 180 boys. One student is chosen at random and is checked for gender and height. (a) Define and categorize the population. (b) Define and categorize the sample space. (c) Define the trials. (d) Define and categorize the events. (e) In determining the probability that the student chosen is a boy, define success and failure. (f) What is the probability that the student is a boy?

#### Solution

- (a) The population consists of 380 students and is finite.
- (b) In determining the gender of the student, the sample space consists of the two outcomes  $E = [\text{girl}, \text{boy}]$ . This sample space is nonnumerical and discrete. In determining the height, the sample space consists of a range of values and is numerical and continuous.
- (c) The trial is the actual sampling (i.e., the determination of gender and height).
- (d) The events are the outcomes of the trials (i.e., the gender and height of the student). These events are independent if each student returns to the population

prior to the random selection of the next student; otherwise, the events are dependent.

- (e) The event is a success if the student is a boy and is a failure otherwise.

- (f) From the definition of probability,

$$p\{\text{boy}\} = \frac{\text{no. of boys}}{\text{no. of students}} = \frac{180}{380} = \frac{9}{19} \\ = 0.47$$

#### 5. JOINT PROBABILITY

*Joint probability* rules specify the probability of a combination of events. If  $n$  mutually exclusive events from the set  $E$  have probabilities  $p\{e_i\}$ , the probability of any one of these events occurring in a given trial is the sum of the individual probabilities. The events in Eq. 11.23 come from a single sample space and are linked by the word *or*.

$$p\{e_1 \text{ or } e_2 \text{ or } \dots \text{ or } e_k\} = p\{e_1\} + p\{e_2\} + \dots + p\{e_k\} \quad 11.23$$

When given two independent sets of events,  $E$  and  $G$ , Eq. 11.24 will give the probability that events  $e_i$  and  $g_i$  will both occur. The events in Eq. 11.24 are independent and are linked by the word *and*.

$$p\{e_i \text{ and } g_i\} = p\{e_i\}p\{g_i\} \quad 11.24$$

When given two independent sets of events,  $E$  and  $G$ , Eq. 11.25 will give the probability that either event  $e_i$  or  $g_i$  will occur. The events in Eq. 11.25 are mutually exclusive and are linked by the word *or*.

$$p\{e_i \text{ or } g_i\} = p\{e_i\} + p\{g_i\} - p\{e_i\}p\{g_i\} \quad 11.25$$

#### Example 11.5

A bowl contains five white balls, two red balls, and three green balls. What is the probability of getting either a white ball or a red ball in one draw from the bowl?

#### Solution

Since the two possible events are mutually exclusive and come from the same sample space, Eq. 11.23 can be used.

$$p\{\text{white or red}\} = p\{\text{white}\} + p\{\text{red}\} = \frac{5}{10} + \frac{2}{10} \\ = 7/10$$

#### Example 11.6

One bowl contains five white balls, two red balls, and three green balls. Another bowl contains three yellow balls and seven black balls. What is the probability of getting a red ball from the first bowl and a yellow ball from the second bowl in one draw from each bowl?

**Solution**

Equation 11.24 can be used because the two events are independent.

$$\begin{aligned} p\{\text{red and yellow}\} &= p\{\text{red}\}p\{\text{yellow}\} \\ &= \left(\frac{2}{10}\right)\left(\frac{3}{10}\right) \\ &= 6/100 \end{aligned}$$

**6. COMPLEMENTARY PROBABILITIES**

The probability of an event occurring is equal to one minus the probability of the event not occurring. This is known as *complementary probability*.

$$p\{e_i\} = 1 - p\{\text{not } e_i\} \quad 11.26$$

Equation 11.26 can be used to simplify some probability calculations. Specifically, calculation of the probability of numerical events being “greater than” or “less than” or quantities being “at least” a certain number can often be simplified by calculating the probability of the complementary event.

**Example 11.7**

A fair coin is tossed five times.<sup>1</sup> What is the probability of getting at least one tail?

**Solution**

The probability of getting at least one tail in five tosses could be calculated as

$$\begin{aligned} p\{\text{at least 1 tail}\} &= p\{1 \text{ tail}\} + p\{2 \text{ tails}\} \\ &\quad + p\{3 \text{ tails}\} + p\{4 \text{ tails}\} \\ &\quad + p\{5 \text{ tails}\} \end{aligned}$$

However, it is easier to calculate the complementary probability of getting no tails (i.e., getting all heads).

From Eq. 11.24 and Eq. 11.26 (for calculating the probability of getting no tails in five successive tosses),

$$\begin{aligned} p\{\text{at least 1 tail}\} &= 1 - p\{0 \text{ tails}\} \\ &= 1 - (0.5)^5 \\ &= 0.96875 \end{aligned}$$

**7. CONDITIONAL PROBABILITY**

Given two dependent sets of events,  $E$  and  $G$ , the probability that event  $e_k$  will occur given the fact that

<sup>1</sup>It makes no difference whether one coin is tossed five times or five coins are each tossed once.

dependent event  $g$  has already occurred is written as  $p\{e_k|g\}$  and given by *Bayes' theorem*, Eq. 11.27.

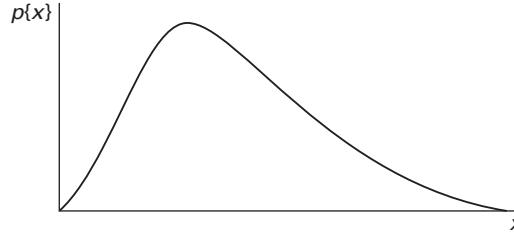

$$p\{e_k|g\} = \frac{p\{\text{e}_k \text{ and } g\}}{p\{g\}} = \frac{p\{g|e_k\}p\{e_k\}}{\sum_{i=1}^n p\{g|e_i\}p\{e_i\}} \quad 11.27$$

**8. PROBABILITY DENSITY FUNCTIONS**

A *density function* is a nonnegative function whose integral taken over the entire range of the independent variable is unity. A *probability density function* is a mathematical formula that gives the probability of a discrete numerical event occurring. A *discrete numerical event* is an occurrence that can be described (usually) by an integer. For example, 27 cars passing through a bridge toll booth in an hour is a discrete numerical event. Figure 11.2 shows a graph of a typical probability density function.

A probability density function,  $f(x)$ , gives the probability that discrete event  $x$  will occur. That is,  $p\{x\} = f(x)$ . Important discrete probability density functions are the binomial, hypergeometric, and Poisson distributions.

**Figure 11.2** Probability Density Function

**9. BINOMIAL DISTRIBUTION**

The *binomial probability density function (binomial distribution)* is used when all outcomes can be categorized as either successes or failures. The probability of success in a single trial is  $\hat{p}$ , and the probability of failure is the complement,  $\hat{q} = 1 - \hat{p}$ . The population is assumed to be infinite in size so that sampling does not change the values of  $\hat{p}$  and  $\hat{q}$ . (The binomial distribution can also be used with finite populations when sampling with replacement.)

Equation 11.28 gives the probability of  $x$  successes in  $n$  independent successive trials. The quantity  $\binom{n}{x}$  is the *binomial coefficient*, identical to the number of combinations of  $n$  items taken  $x$  at a time.

$$p\{x\} = f(x) = \binom{n}{x} \hat{p}^x \hat{q}^{n-x} \quad 11.28$$

$$\binom{n}{x} = \frac{n!}{(n-x)!x!} \quad 11.29$$

Equation 11.28 is a discrete distribution, taking on values only for discrete integer values up to  $n$ . The mean,  $\mu$ , and variance,  $\sigma^2$ , of this distribution are

$$\mu = n\hat{p} \quad 11.30$$

$$\sigma^2 = n\hat{p}\hat{q} \quad 11.31$$

### Example 11.8

Five percent of a large batch of high-strength steel bolts purchased for bridge construction are defective.

- (a) If seven bolts are randomly sampled, what is the probability that exactly three will be defective?
- (b) What is the probability that two or more bolts will be defective?

*Solution*

(a) The bolts are either defective or not, so the binomial distribution can be used.

$$\hat{p} = 0.05 \quad [\text{success} = \text{defective}]$$

$$\hat{q} = 1 - 0.05 = 0.95 \quad [\text{failure} = \text{not defective}]$$

From Eq. 11.28,

$$\begin{aligned} p\{3\} &= f(3) = \binom{n}{x} \hat{p}^x \hat{q}^{n-x} = \binom{7}{3} (0.05)^3 (0.95)^{7-3} \\ &= \left( \frac{7 \cdot 6 \cdot 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1}{4 \cdot 3 \cdot 2 \cdot 1 \cdot 3 \cdot 2 \cdot 1} \right) (0.05)^3 (0.95)^4 \\ &= 0.00356 \end{aligned}$$

(b) The probability that two or more bolts will be defective could be calculated as

$$p\{x \geq 2\} = p\{2\} + p\{3\} + p\{4\} + p\{5\} + p\{6\} + p\{7\}$$

This method would require six probability calculations. It is easier to use the complement of the desired probability.

$$p\{x \geq 2\} = 1 - p\{x \leq 1\} = 1 - (p\{0\} + p\{1\})$$

$$p\{0\} = \binom{n}{x} \hat{p}^x \hat{q}^{n-x} = \binom{7}{0} (0.05)^0 (0.95)^7 = (0.95)^7$$

$$\begin{aligned} p\{1\} &= \binom{n}{x} \hat{p}^x \hat{q}^{n-x} = \binom{7}{1} (0.05)^1 (0.95)^6 \\ &= (7)(0.05)(0.95)^6 \end{aligned}$$

$$\begin{aligned} p\{x \geq 2\} &= 1 - ((0.95)^7 + (7)(0.05)(0.95)^6) \\ &= 1 - (0.6983 + 0.2573) \\ &= 0.0444 \end{aligned}$$

### 10. HYPERGEOMETRIC DISTRIBUTION

Probabilities associated with sampling from a finite population without replacement are calculated from the *hypergeometric distribution*. If a population of finite size  $M$  contains  $K$  items with a given characteristic (e.g., red color, defective construction), then the probability of finding  $x$  items with that characteristic in a sample of  $n$  items is

$$p\{x\} = f(x) = \frac{\binom{K}{x} \binom{M-K}{n-x}}{\binom{M}{n}} \quad [\text{for } x \leq n] \quad 11.32$$

### 11. MULTIPLE HYPERGEOMETRIC DISTRIBUTION

Sampling without replacement from finite populations containing several different types of items is handled by the *multiple hypergeometric distribution*. If a population of finite size  $M$  contains  $K_i$  items of type  $i$  (such that  $\sum K_i = M$ ), the probability of finding  $x_1$  items of type 1,  $x_2$  items of type 2, and so on, in a sample size of  $n$  (such that  $\sum x_i = n$ ) is

$$p\{x_1, x_2, x_3, \dots\} = \frac{\binom{K_1}{x_1} \binom{K_2}{x_2} \binom{K_3}{x_3} \dots}{\binom{M}{n}} \quad 11.33$$

### 12. POISSON DISTRIBUTION

Certain discrete events occur relatively infrequently but at a relatively regular rate. The probability of such an event occurring is given by the *Poisson distribution*. Suppose an event occurs, on the average,  $\lambda$  times per period. The probability that the event will occur  $x$  times per period is

$$p\{x\} = f(x) = \frac{e^{-\lambda} \lambda^x}{x!} \quad [\lambda > 0] \quad 11.34$$

$\lambda$  is both the mean and the variance of the Poisson distribution.

$$\mu = \lambda \quad 11.35$$

$$\sigma^2 = \lambda \quad 11.36$$

### Example 11.9

The number of customers arriving at a hamburger stand in the next period is a Poisson distribution having a mean of eight. What is the probability that exactly six customers will arrive in the next period?

**Solution** $\lambda = 8$ , and  $x = 6$ . From Eq. 11.34,

$$p\{6\} = \frac{e^{-\lambda}\lambda^x}{x!} = \frac{e^{-8}(8)^6}{6!} = 0.122$$

### 13. CONTINUOUS DISTRIBUTION FUNCTIONS

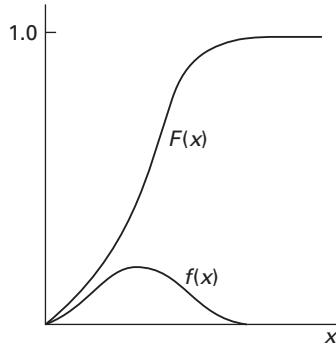

Most numerical events are *continuously distributed* and are not constrained to discrete or integer values. For example, the resistance of a 10% 1  $\Omega$  resistor may be any value between 0.9  $\Omega$  and 1.1  $\Omega$ . The probability of an exact numerical event is zero for continuously distributed variables. That is, there is no chance that a numerical event will be *exactly*  $x$ .<sup>2</sup> It is possible to determine only the probability that a numerical event will be less than  $x$ , greater than  $x$ , or between the values of  $x_1$  and  $x_2$ , but not exactly equal to  $x$ .

Since an expression,  $f(x)$ , for a probability density function cannot always be written, it is more common to specify the *continuous distribution function*,  $F(x_0)$ , which gives the probability of numerical event  $x_0$  or less occurring, as illustrated in Fig. 11.3.

$$p\{X < x_0\} = F(x_0) = \int_0^{x_0} f(x) dx \quad 11.37$$

$$f(x) = \frac{dF(x)}{dx} \quad 11.38$$

**Figure 11.3** Continuous Distribution Function

### 14. EXPONENTIAL DISTRIBUTION

The continuous *exponential distribution* is given by its probability density and continuous distribution functions.

$$f(x) = \lambda e^{-\lambda x} \quad 11.39$$

<sup>2</sup>It is important to understand the rationale behind this statement. Since the variable can take on any value and has an infinite number of significant digits, we can infinitely continue to increase the precision of the value. For example, the probability is zero that a resistance will be exactly 1  $\Omega$  because the resistance is really 1.03 or 1.0260008 or 1.02600080005, and so on.

$$p\{X < x\} = F(x) = 1 - e^{-\lambda x} \quad 11.40$$

The mean and variance of the exponential distribution are

$$\mu = \frac{1}{\lambda} \quad 11.41$$

$$\sigma^2 = \frac{1}{\lambda^2} \quad 11.42$$

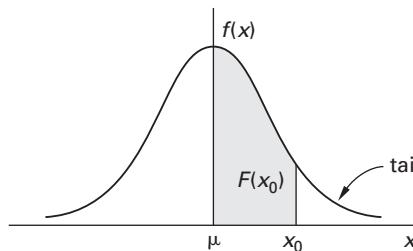

### 15. NORMAL DISTRIBUTION

The *normal distribution (Gaussian distribution)* is a symmetrical distribution commonly referred to as the *bell-shaped curve*, which represents the distribution of outcomes of many experiments, processes, and phenomena. (See Fig. 11.4.) The probability density and continuous distribution functions for the normal distribution with mean  $\mu$  and variance  $\sigma^2$  are

$$f(x) = \frac{e^{-\frac{1}{2}(\frac{x-\mu}{\sigma})^2}}{\sigma\sqrt{2\pi}} \quad [-\infty < x < +\infty] \quad 11.43$$

$$p\{\mu < X < x_0\} = F(x_0) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^{x_0} e^{-\frac{1}{2}(\frac{x-\mu}{\sigma})^2} dx \quad 11.44$$

**Figure 11.4** Normal Distribution

Since  $f(x)$  is difficult to integrate, Eq. 11.43 is seldom used directly, and a *standard normal table* is used instead. (See App. 11.A.) The standard normal table is based on a normal distribution with a mean of zero and a standard deviation of 1. Since the range of values from an experiment or phenomenon will not generally correspond to the standard normal table, a value,  $x_0$ , must be converted to a *standard normal value*,  $z$ . In Eq. 11.45,  $\mu$  and  $\sigma$  are the mean and standard deviation, respectively, of the distribution from which  $x_0$  comes. For all practical purposes, all normal distributions are completely bounded by  $\mu \pm 3\sigma$ .

$$z = \frac{x_0 - \mu}{\sigma} \quad 11.45$$

Numbers in the standard normal table, as given by App. 11.A, are the probabilities of the normalized  $x$  being between zero and  $z$  and represent the areas under the curve up to point  $z$ . When  $x$  is less than  $\mu$ ,  $z$  will be negative. However, the curve is symmetrical, so the table value corresponding to positive  $z$  can be used.

The probability of  $x$  being greater than  $z$  is the complement of the table value. The curve area past point  $z$  is known as the *tail of the curve*.

### Example 11.10

The mass,  $m$ , of a particular hand-laid fiberglass (Fiberglas<sup>TM</sup>) part is normally distributed with a mean of 66 kg and a standard deviation of 5 kg. (a) What percent of the parts will have a mass less than 72 kg? (b) What percent of the parts will have a mass in excess of 72 kg? (c) What percent of the parts will have a mass between 61 kg and 72 kg?

#### Solution

(a) The 72 kg value must be normalized, so use Eq. 11.45. The standard normal variable is

$$z = \frac{x - \mu}{\sigma} = \frac{72 \text{ kg} - 66 \text{ kg}}{5 \text{ kg}} = 1.2$$

Reading from App. 11.A, the area under the normal curve is 0.3849. This represents the probability of the mass,  $m$ , being between 66 kg and 72 kg (i.e.,  $z$  being between 0 and 1.2). However, the probability of the mass being less than 66 kg is also needed. Since the curve is symmetrical, this probability is 0.5. Therefore,

$$p\{m < 72 \text{ kg}\} = p\{z < 1.2\} = 0.5 + 0.3849 = 0.8849$$

(b) The probability of the mass exceeding 72 kg is the area under the tail past point  $z$ .

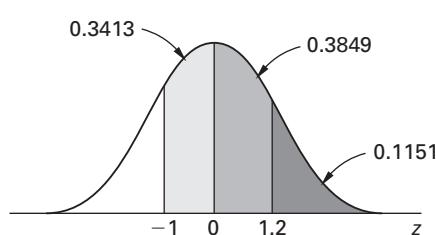

$$p\{m > 72 \text{ kg}\} = p\{z > 1.2\} = 0.5 - 0.3849 = 0.1151$$

(c) The standard normal variable corresponding to  $m = 61$  kg is

$$z = \frac{x - \mu}{\sigma} = \frac{61 \text{ kg} - 66 \text{ kg}}{5 \text{ kg}} = -1$$

Since the two masses are on opposite sides of the mean, the probability will have to be determined in two parts.

$$\begin{aligned} p\{61 < m < 72\} &= p\{61 < m < 66\} + p\{66 < m < 72\} \\ &= p\{-1 < z < 0\} + p\{0 < z < 1.2\} \\ &= 0.3413 + 0.3849 \\ &= 0.7262 \end{aligned}$$

### 16. STUDENT'S *t*-DISTRIBUTION

In many cases requiring statistical analysis, including setting of confidence limits and hypothesis testing, the true population standard deviation,  $\sigma$ , and mean,  $\mu$ , are not known. In such cases, the sample standard deviation,  $s$ , is used as an estimate for the population standard deviation, and the sample mean,  $\bar{x}$ , is used to estimate the population mean,  $\mu$ . To account for the additional uncertainty of not knowing the population parameters exactly, a *t-distribution* is used rather than the normal distribution. The *t*-distribution essentially relaxes or expands the confidence intervals to account for these additional uncertainties.

The *t*-distribution is actually a family of distributions. They are similar in shape (symmetrical and bell-shaped) to the normal distribution, although wider, and flatter in the tails. *t*-distributions are more likely to result in (or, accept) values located farther from the mean than the normal distribution. The specific shape is dependent on the sample size,  $n$ . The smaller the sample size, the wider and flatter the distribution tails. The shape of the distribution approaches the standard normal curve as the sample size increases. Generally, the two distributions have the same shape for  $n > 50$ .

An important parameter needed to define a *t*-distribution is the *degrees of freedom*,  $df$ . (The symbol,  $\nu$ , Greek nu, is also used.) The degrees of freedom is usually 1 less than the sample size.

$$df = n - 1 \quad 11.46$$

*Student's t-distribution* is a standardized *t*-distribution, centered on zero, just like the standard normal variable,  $z$ . With a normal distribution, the population standard deviation would be multiplied by  $z = 1.96$  to get a 95% confidence interval. When using the *t*-distribution, the sample standard deviation,  $s$ , is multiplied by a number,  $t$ , coming from the *t*-distribution.

$$t = \frac{\bar{x} - \mu}{\frac{s}{\sqrt{n}}} \quad 11.47$$

That number is designated as  $t_{\alpha, df}$  or  $t_{\alpha, n-1}$  for a one-tail test/confidence interval, and would be designated as  $t_{\alpha/2, df}$  or  $t_{\alpha/2, n-1}$  for a two-tail test/confidence interval. For example, for a two-tail confidence interval with confidence level  $C = 1 - \alpha$ , the upper and lower confidence limits are

$$\text{UCL, LCL} = \bar{x} \pm t_{\alpha/2, n-1} \frac{s}{\sqrt{n}} \quad 11.48$$

### 17. CHI-SQUARED DISTRIBUTION

The *chi-squared (chi square,  $\chi^2$ ) distribution* is a distribution of the sum of squared standard normal deviates,  $z_i$ . It has numerous useful applications. The

distribution's only parameter, its *degrees of freedom*,  $\nu$  or df, is the number of standard normal deviates being summed. Chi-squared distributions are positively skewed, but the skewness decreases and the distribution approaches a normal distribution as degrees of freedom increases. Appendix 11.B tabulates the distribution. The mean and variance of a chi-squared distribution are related to its degrees of freedom.

$$\mu = \nu \quad 11.49$$

$$\sigma^2 = 2\nu \quad 11.50$$

After taking  $n$  samples from a standard normal distribution, the *chi-squared statistic* is defined as

$$\chi^2 = \frac{(n-1)s^2}{\sigma^2} \quad 11.51$$

The sum of chi-squared variables is itself a chi-squared variable. For example, after taking three measurements from a standard normal distribution, squaring each term, and adding all three squared terms, the sum is a chi-squared variable. A chi-squared distribution with three degrees of freedom can be used to determine the probability of that summation exceeding another number. This characteristic makes the chi-squared distribution useful in determining whether or not a population's variance has shifted, or whether two populations have the same variance. The distribution is also extremely useful in categorical hypothesis testing.

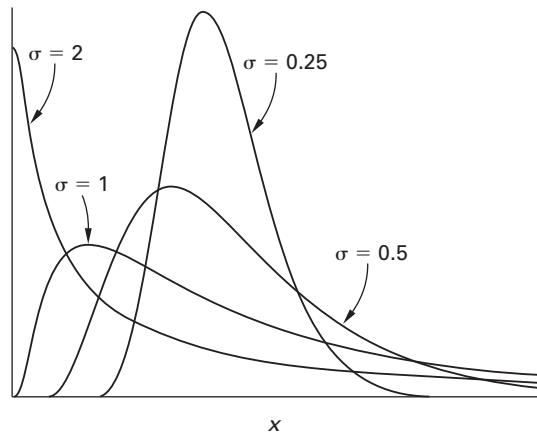

## 18. LOG-NORMAL DISTRIBUTION

With a *log-normal* (*lognormal* or *Galton's*) distribution, the logarithm of the independent variable,  $\ln(x)$  or  $\log(x)$ , is normally distributed, not  $x$ . Log-normal distributions are rare in engineering; they are more common in social, political, financial, biological, and environmental applications.<sup>3</sup> The log-normal distribution may be applicable whenever a normal-appearing distribution is skewed to the left, or when the independent variable is a function (e.g., product) of multiple positive independent variables. Depending on its parameters (i.e., skewness), a log-normal distribution can take on different shapes, as shown in Fig. 11.5.

The symbols  $\mu$  and  $\sigma$  are used to represent the *parameter values* of the transformed (logarithmized) distribution;  $\mu$  is the *location parameter* (*log mean*), the mean of the transformed values; and  $\sigma$  is the *scale parameter* (*log standard deviation*), whose unbiased estimator is the sample standard deviation,  $s$ , of the transformed values. These parameter values are used to calculate the standard normal variable,  $z$ , in order to determine event probabilities (i.e., areas under the normal curve).

<sup>3</sup>Log-normal is a popular reliability distribution. In electrical engineering, some transmission losses are modeled as log-normal. Some geologic mineral concentrations follow the log-normal pattern.

Figure 11.5 Log-Normal Probability Density Function

The *expected value*,  $E\{x\}$ , and standard deviation,  $\sigma_x$ , of the nontransformed distribution,  $x$ , are

$$E\{x\} = e^{\mu + \frac{1}{2}\sigma^2} \quad 11.52$$

$$\sigma_x = \sqrt{(e^{\sigma^2} - 1)e^{2\mu + \sigma^2}} \quad 11.53$$

$$z = \frac{x_0 - \mu}{\sigma} \quad 11.54$$

## 19. ERROR FUNCTION

The *error function*,  $\text{erf}(x)$ , and its complement, the *complementary error function*,  $\text{erfc}(x)$ , are defined by Eq. 11.55 and Eq. 11.56. The functions can be used to determine the probable error of a measurement, but they also appear in many engineering formulas. Values are seldom calculated from Eq. 11.55 or Eq. 11.56. Rather, approximation and tabulations (e.g., App. 11.D) are used.

$$\text{erf}(x_0) = \frac{2}{\sqrt{\pi}} \int_0^{x_0} e^{-u^2} du \quad 11.55$$

$$\text{erfc}(x_0) = 1 - \text{erf}(x_0) \quad 11.56$$

The error function can be used to calculate areas under the normal curve. Combining Eq. 11.44, Eq. 11.45, and Eq. 11.55,

$$\frac{1}{\sqrt{2\pi}} \int_0^z e^{-u^2/2} du = \frac{1}{2} \text{erf}\left(\frac{z}{\sqrt{2}}\right) \quad 11.57$$

The error function has the following properties.

$$\text{erf}(0) = 0$$

$$\text{erf}(+\infty) = 1$$

$$\text{erf}(-\infty) = -1$$

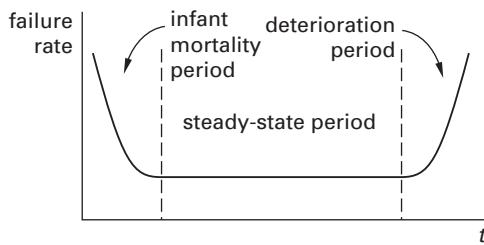

$$\text{erf}(-x_0) = -\text{erf}(x_0)$$

## 20. APPLICATION: RELIABILITY

### Introduction

*Reliability*,  $R\{t\}$ , is the probability that an item will continue to operate satisfactorily up to time  $t$ . The *bath-tub distribution*, Fig. 11.6, is often used to model the probability of failure of an item (or, the number of failures from a large population of items) as a function of time. Items initially fail at a high rate, a phenomenon known as *infant mortality*. For the majority of the operating time, known as the *steady-state operation*, the failure rate is constant (i.e., is due to random causes). After a long period of time, the items begin to deteriorate and the failure rate increases. (No mathematical distribution describes all three of these phases simultaneously.)

Figure 11.6 Bathtub Reliability Curve

The *hazard function*,  $z\{t\}$ , represents the *conditional probability of failure*—the probability of failure in the next time interval, given that no failure has occurred thus far.<sup>4</sup>

$$z\{t\} = \frac{f(t)}{R(t)} = \frac{dF(t)}{dt} \quad 11.58$$

A *proof test* is a comprehensive validation of an item that checks 100% of all failure mechanisms. It tests for faults and degradation so that the item can be certified as being in “as new” condition. The *proof test interval* is the time after initial installation at which an item must be either proof tested or replaced. If the policy is to replace rather than test an item, the item’s lifetime is equal to the proof test interval and is known as *mission time*.

### Exponential Reliability

Steady-state reliability is often described by the *negative exponential distribution*. This assumption is appropriate whenever an item fails only by random causes and does not experience deterioration during its life. The

parameter  $\lambda$  is related to the *mean time to failure* (MTTF) of the item.<sup>5</sup>

$$R\{t\} = e^{-\lambda t} = e^{-t/\text{MTTF}} \quad 11.59$$

$$\lambda = \frac{1}{\text{MTTF}} \quad 11.60$$

Equation 11.59 and the exponential continuous distribution function, Eq. 11.40, are complementary.

$$R\{t\} = 1 - F(t) = 1 - (1 - e^{-\lambda t}) = e^{-\lambda t} \quad 11.61$$

The hazard function for the negative exponential distribution is

$$z\{t\} = \lambda \quad 11.62$$

Therefore, the hazard function for exponential reliability is constant and does not depend on  $t$  (i.e., on the age of the item). In other words, the expected future life of an item is independent of the previous history (length of operation). This lack of memory is consistent with the assumption that only random causes contribute to failure during steady-state operations. And since random causes are unlikely discrete events, their probability of occurrence can be represented by a Poisson distribution with mean  $\lambda$ . That is, the probability of having  $x$  failures in any given period is

$$p\{x\} = \frac{e^{-\lambda} \lambda^x}{x!} \quad 11.63$$

### Serial System Reliability

In the analysis of system reliability, the binary variable  $X_i$  is defined as 1 if item  $i$  operates satisfactorily and 0 if otherwise. Similarly, the binary variable  $\Phi$  is 1 only if the entire system operates satisfactorily. Therefore,  $\Phi$  will depend on a *performance function* containing the  $X_i$ .

A *serial system* is one for which all items must operate correctly for the system to operate. Each item has its own reliability,  $R_i$ . For a serial system of  $n$  items, the performance function is

$$\Phi = X_1 X_2 X_3 \cdots X_n = \min(X_i) \quad 11.64$$

The probability of a serial system operating correctly is

$$p\{\Phi = 1\} = R_{\text{serial system}} = R_1 R_2 R_3 \cdots R_n \quad 11.65$$

### Parallel System Reliability

A *parallel system* with  $n$  items will fail only if all  $n$  items fail. Such a system is said to be *redundant* to the  $n$ th degree. Using redundancy, a highly reliable system can

<sup>4</sup>The symbol  $z\{t\}$  is traditionally used for the hazard function and is not related to the standard normal variable.

<sup>5</sup>The term “mean time between failures” is improper. However, the term *mean time before failure* (MTBF) is acceptable.

be produced from components with relatively low individual reliabilities.

The performance function of a redundant system is

$$\Phi = 1 - (1 - X_1)(1 - X_2)(1 - X_3) \cdots (1 - X_n) \\ = \max(X_i) \quad 11.66$$

The reliability of the parallel system is

$$R = p\{\Phi = 1\} \\ = 1 - (1 - R_1)(1 - R_2)(1 - R_3) \cdots (1 - R_n) \quad 11.67$$

With a fully redundant, parallel  $k$ -out-of- $n$  system of  $n$  independent, identical items, any  $k$  of which maintain system functionality, the ratio of redundant MTTF to single-item MTTF ( $1/\lambda$ ) is given by Table 11.1.

**Table 11.1** MTTF Multipliers for  $k$ -out-of- $n$  Systems

$k$	$n$				
	1	2	3	4	5
1	1	3/2	11/6	25/12	137/60
2		1/2	5/6	13/12	77/60
3			1/3	7/12	47/60
4				1/4	9/20
5					1/5

### Example 11.11

The reliability of an item is exponentially distributed with mean time to failure (MTTF) of 1000 hr. What is the probability that the item will not have failed before 1200 hr of operation?

*Solution*

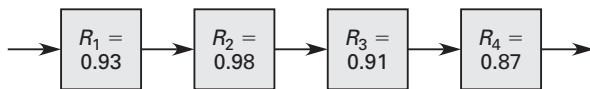

The probability of not having failed before time  $t$  is the reliability. From Eq. 11.60 and Eq. 11.61,

$$\lambda = \frac{1}{\text{MTTF}} = \frac{1}{1000 \text{ hr}} = 0.001 \text{ hr}^{-1} \\ R\{1200\} = e^{-\lambda t} = e^{(-0.001 \text{ hr}^{-1})(1200 \text{ hr})} = 0.3$$

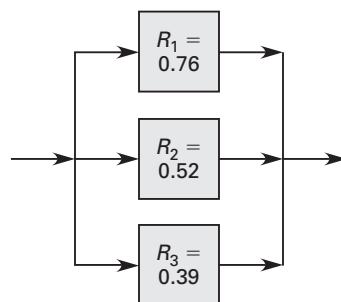

### Example 11.12

What are the reliabilities of the following systems?

(a)

(b)

*Solution*

(a) This is a serial system. From Eq. 11.65,

$$R = R_1 R_2 R_3 R_4 = (0.93)(0.98)(0.91)(0.87) \\ = 0.72$$

(b) This is a parallel system. From Eq. 11.67,

$$R = 1 - (1 - R_1)(1 - R_2)(1 - R_3) \\ = 1 - (1 - 0.76)(1 - 0.52)(1 - 0.39) \\ = 0.93$$

## 21. ANALYSIS OF EXPERIMENTAL DATA

Experiments can take on many forms. An experiment might consist of measuring the mass of one cubic foot of concrete or measuring the speed of a car on a roadway. Generally, such experiments are performed more than once to increase the precision and accuracy of the results.

Both systematic and random variations in the process being measured will cause the observations to vary, and the experiment would not be expected to yield the same result each time it was performed. Eventually, a collection of experimental outcomes (observations) will be available for analysis.

The *frequency distribution* is a systematic method for ordering the observations from small to large, according to some convenient numerical characteristic. The *step interval* should be chosen so that the data are presented in a meaningful manner. If there are too many intervals, many of them will have zero frequencies; if there are too few intervals, the frequency distribution will have little value. Generally, 10 to 15 intervals are used.

Once the frequency distribution is complete, it can be represented graphically as a *histogram*. The procedure in drawing a histogram is to mark off the interval limits (also known as *class limits*) on a number line and then draw contiguous bars with lengths that are proportional to the frequencies in the intervals and that are centered on the midpoints of their respective intervals. The continuous nature of the data can be depicted by a *frequency polygon*. The number or percentage of observations that

occur, up to and including some value, can be shown in a *cumulative frequency table*.

### Example 11.13

The number of cars that travel through an intersection between 12 noon and 1 p.m. is measured for 30 consecutive working days. The results of the 30 observations are

79, 66, 72, 70, 68, 66, 68, 76, 73, 71, 74, 70, 71, 69, 67, 74, 70, 68, 69, 64, 75, 70, 68, 69, 64, 69, 62, 63, 63, 61

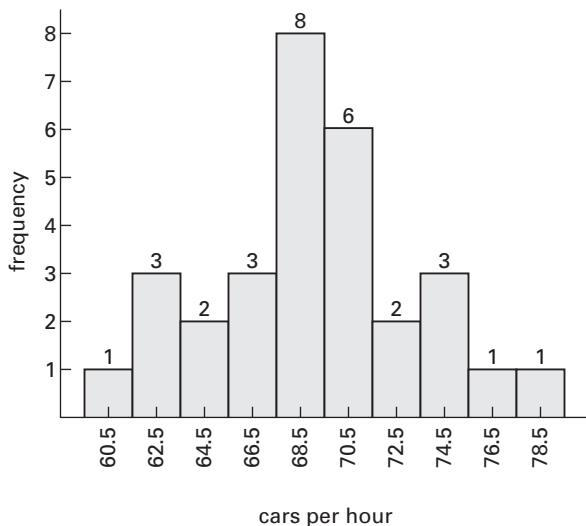

- What are the frequency and cumulative distributions? (Use a distribution interval of two cars per hour.)
- Draw the histogram. (Use a cell size of two cars per hour.)
- Draw the frequency polygon.
- Graph the cumulative frequency distribution.

*Solution*

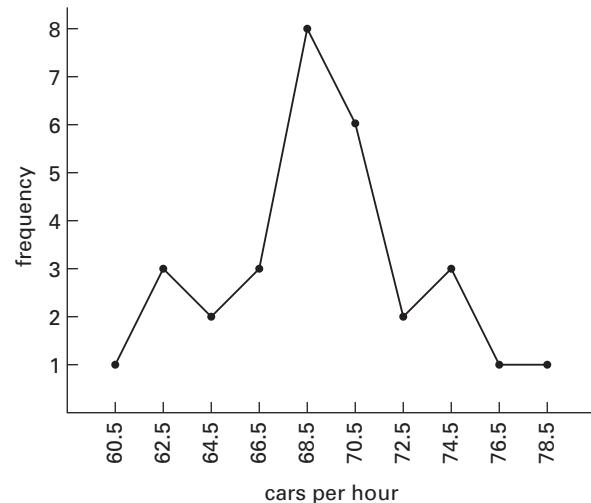

- Tabulate the frequency, cumulative frequency, and cumulative percent distributions.

cars per hour	frequency	cumulative frequency	cumulative percent
60–61	1	1	3
62–63	3	4	13
64–65	2	6	20
66–67	3	9	30
68–69	8	17	57
70–71	6	23	77
72–73	2	25	83
74–75	3	28	93
76–77	1	29	97
78–79	1	30	100

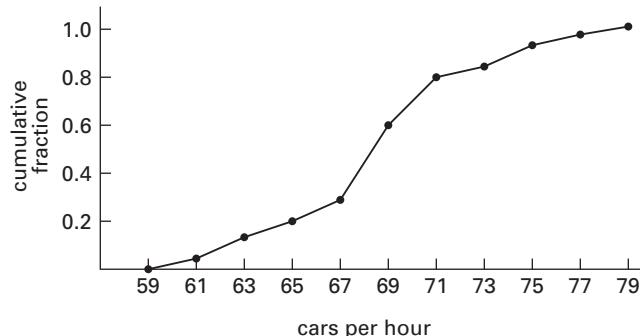

- Draw the histogram.

- Draw the frequency polygon.

- Graph the cumulative frequency distribution.

## 22. MEASURES OF EXPERIMENTAL ADEQUACY

An experiment is said to be *accurate* if it is unaffected by experimental error. In this case, *error* is not synonymous with *mistake*, but rather includes all variations not within the experimenter's control.

For example, suppose a gun is aimed at a point on a target and five shots are fired. The mean distance from the point of impact to the sight in point is a measure of the alignment accuracy between the barrel and sights. The difference between the actual value and the experimental value is known as *bias*.

*Precision* is not synonymous with accuracy. Precision is concerned with the repeatability of the experimental results. If an experiment is repeated with identical results, the experiment is said to be precise.

The average distance of each impact from the centroid of the impact group is a measure of the precision of the experiment. It is possible to have a highly precise experiment with a large bias.

Most of the techniques applied to experiments in order to improve the accuracy (i.e., reduce bias) of the experimental results (e.g., repeating the experiment, refining the experimental methods, or reducing variability) actually increase the precision.

Sometimes the word *reliability* is used with regard to the precision of an experiment. In this case, a “reliable estimate” is used in the same sense as a “precise estimate.”

*Stability* and *insensitivity* are synonymous terms. A stable experiment will be insensitive to minor changes in the experimental parameters. For example, suppose the centroid of a bullet group is 2.1 in from the target point at 65°F and 2.3 in away at 80°F. The sensitivity of the experiment to temperature change would be

$$\text{sensitivity} = \frac{\Delta x}{\Delta T} = \frac{2.3 \text{ in} - 2.1 \text{ in}}{80^\circ\text{F} - 65^\circ\text{F}} = 0.0133 \text{ in}/^\circ\text{F}$$

### 23. MEASURES OF CENTRAL TENDENCY

It is often unnecessary to present the experimental data in their entirety, either in tabular or graphical form. In such cases, the data and distribution can be represented by various parameters. One type of parameter is a measure of *central tendency*. Mode, median, and mean are measures of central tendency.

The *mode* is the observed value that occurs most frequently. The mode may vary greatly between series of observations. Therefore, its main use is as a quick measure of the central value since little or no computation is required to find it. Beyond this, the usefulness of the mode is limited.

The *median* is the point in the distribution that partitions the total set of observations into two parts containing equal numbers of observations. It is not influenced by the extremity of scores on either side of the distribution. The median is found by counting up (from either end of the frequency distribution) until half of the observations have been accounted for.

For even numbers of observations, the median is estimated as some value (i.e., the average) between the two center observations.

Similar in concept to the median are *percentiles* (*percentile ranks*), *quartiles*, and *deciles*. The median could also have been called the *50th percentile* observation. Similarly, the *80th percentile* would be the observed value (e.g., the number of cars per hour) for which the cumulative frequency was 80%. The quartile and decile points on the distribution divide the observations or distribution into segments of 25% and 10%, respectively.

The *arithmetic mean* is the arithmetic average of the observations. The sample mean,  $\bar{x}$ , can be used as an *unbiased estimator* of the population mean,  $\mu$ . The *mean* may be found without ordering the data (as was

necessary to find the mode and median). The mean can be found from the following formula.

$$\bar{x} = \left(\frac{1}{n}\right)(x_1 + x_2 + \cdots + x_n) = \frac{\sum x_i}{n} \quad 11.68$$

The *geometric mean* is used occasionally when it is necessary to average ratios. The geometric mean is calculated as

$$\text{geometric mean} = \sqrt[n]{x_1 x_2 x_3 \cdots x_n} \quad [x_i > 0] \quad 11.69$$

The *harmonic mean* is defined as

$$\text{harmonic mean} = \frac{n}{\frac{1}{x_1} + \frac{1}{x_2} + \cdots + \frac{1}{x_n}} \quad 11.70$$

The *root-mean-squared (rms) value* of a series of observations is defined as

$$x_{\text{rms}} = \sqrt{\frac{\sum x_i^2}{n}} \quad 11.71$$

The *ratio of exceedance* of a single measurement,  $x_i$ , from the mean (or, any other value),  $\mu$ , is

$$\text{ER} = \left| \frac{x_i - \mu}{\mu} \right| \quad 11.72$$

The exceedance of a single measurement from the mean can be expressed in standard deviations. For a normal distribution, this exceedance is usually given the variable  $z$  and is referred to as the *standard normal value*, *variable*, *variate*, or *deviate*.

$$z = \left| \frac{x_i - \mu}{\sigma} \right| \quad 11.73$$

#### Example 11.14

Find the mode, median, and arithmetic mean of the distribution represented by the data given in Ex. 11.13.

*Solution*

First, resequence the observations in increasing order.  
61, 62, 63, 63, 64, 64, 66, 66, 67, 68, 68, 68, 68, 69, 69, 69, 70, 70, 70, 70, 71, 71, 72, 73, 74, 74, 75, 76, 79

The mode is the interval 68–69, since this interval has the highest frequency. If 68.5 is taken as the interval center, then 68.5 would be the mode.

The 15th and 16th observations are both 69, so the median is

$$\frac{69 + 69}{2} = 69$$

The mean can be found from the raw data or from the grouped data using the interval center as the assumed observation value. Using the raw data,

$$\bar{x} = \frac{\sum x_i}{n} = \frac{2069}{30} = 68.97$$

## 24. MEASURES OF DISPERSION

The simplest statistical parameter that describes the variability in observed data is the *range*. The range is found by subtracting the smallest value from the largest. Since the range is influenced by extreme (low probability) observations, its use as a measure of variability is limited.

The *population standard deviation* is a better estimate of variability because it considers every observation. That is, in Eq. 11.74,  $N$  is the total population size, not the sample size,  $n$ .

$$\sigma = \sqrt{\frac{\sum(x_i - \mu)^2}{N}} = \sqrt{\frac{\sum x_i^2}{N} - \mu^2} \quad 11.74$$

The standard deviation of a sample (particularly a small sample) is a biased (i.e., not a good) estimator of the population standard deviation. An *unbiased estimator* of the population standard deviation is the *sample standard deviation*,  $s$ , also known as the *standard error* of a sample.<sup>6</sup>

$$s = \sqrt{\frac{\sum(x_i - \bar{x})^2}{n-1}} = \sqrt{\frac{\sum x_i^2 - \frac{(\sum x_i)^2}{n}}{n-1}} \quad 11.75$$

If the sample standard deviation,  $s$ , is known, the standard deviation of the sample,  $\sigma_{\text{sample}}$ , can be calculated.

$$\sigma_{\text{sample}} = s \sqrt{\frac{n-1}{n}} \quad 11.76$$

The *variance* is the square of the standard deviation. Since there are two standard deviations, there are two variances. The *variance of the sample* is  $\sigma^2$ , and the *sample variance* is  $s^2$ .

The *relative dispersion* is defined as a measure of dispersion divided by a measure of central tendency. The

*coefficient of variation* is a relative dispersion calculated from the sample standard deviation and the mean.

$$\text{coefficient of variation} = \frac{s}{\bar{x}} \quad 11.77$$

### Example 11.15

For the data given in Ex. 11.13, calculate (a) the sample range, (b) the standard deviation of the sample, (c) an unbiased estimator of the population standard deviation, (d) the variance of the sample, and (e) the sample variance.

*Solution*

Calculate the quantities used in Eq. 11.74 and Eq. 11.75.

$$\begin{aligned} \sum x_i &= 2069 \\ (\sum x_i)^2 &= (2069)^2 = 4,280,761 \\ \sum x_i^2 &= 143,225 \\ n &= 30 \\ \bar{x} &= \frac{2069}{30} = 68.967 \end{aligned}$$

(a) The sample range is

$$R = x_{\max} - x_{\min} = 79 - 61 = 18$$

(b) Normally, the standard deviation of the sample would not be calculated. In this case, it was specifically requested. From Eq. 11.74, using  $n$  for  $N$  and  $\bar{x}$  for  $\mu$ ,

$$\begin{aligned} \sigma &= \sqrt{\frac{\sum x_i^2}{n} - (\bar{x})^2} = \sqrt{\frac{143,225}{30} - \left(\frac{2069}{30}\right)^2} \\ &= 4.215 \end{aligned}$$

(c) From Eq. 11.75,

$$\begin{aligned} s &= \sqrt{\frac{\sum x_i^2 - \frac{(\sum x_i)^2}{n}}{n-1}} \\ &= \sqrt{\frac{143,225 - \frac{4,280,761}{30}}{29}} \\ &= 4.287 \end{aligned}$$

(d) The variance of the sample is

$$\sigma^2 = (4.215)^2 = 17.77$$

(e) The sample variance is

$$s^2 = (4.287)^2 = 18.38$$

<sup>6</sup>There is a subtle yet significant difference between *standard deviation of the sample*,  $\sigma$  (obtained from Eq. 11.74 for a finite sample drawn from a larger population), and the *sample standard deviation*,  $s$  (obtained from Eq. 11.75). While  $\sigma$  can be calculated, it has no significance or use as an estimator. It is true that the difference between  $\sigma$  and  $s$  approaches zero when the sample size,  $n$ , is large, but this convergence does nothing to legitimize the use of  $\sigma$  as an estimator of the true standard deviation. (Some people say “large” is 30, others say 50 or 100.)

## 25. SKEWNESS

*Skewness* is a measure of a distribution's lack of symmetry. Distributions that are pushed to the left have negative skewness, while distributions pushed to the right have positive skewness. Various formulas are used to calculate skewness. *Pearson's skewness*,  $sk$ , is a simple normalized difference between the mean and mode. (See Eq. 11.78.) Since the mode is poorly represented when sampling from a distribution, the difference is estimated as three times the deviation from the mean. *Fisher's skewness*,  $\gamma_1$ , and more modern methods are based on the *third moment about the mean*. (See Eq. 11.79.) Normal distributions have zero skewness, although zero skewness is not a sufficient requirement for determining normally distributed data. Square root, log, and reciprocal transformations of a variable can reduce skewness.

$$sk = \frac{\mu - \text{mode}}{\sigma} \approx \frac{3(\bar{x} - \text{median})}{s} \quad 11.78$$

$$\gamma_1 = \frac{\sum_{i=1}^N (x_i - \mu)^3}{N\sigma^3} \approx \frac{n \sum_{i=1}^n (x_i - \bar{x})^3}{(n-1)(n-2)s^3} \quad 11.79$$

## 26. KURTOSIS

While skewness refers to the symmetry of the distribution about the mean, *kurtosis* refers to the contribution of the tails to the distribution, or alternatively, how flat the peak is. A *mesokurtic distribution* ( $\beta_2 = 3$ ) is statistically normal. Compared to a normal curve, a *leptokurtic distribution* ( $\beta_2 < 3$ ) is "fat in the tails," longer-tailed, and more sharp-peaked, while a *platykurtic distribution* ( $\beta_2 > 3$ ) is "thin in the tails," shorter-tailed, and more flat-peaked. Different methods are used to calculate kurtosis. The most common, *Fisher's kurtosis*,  $\beta_2$ , is defined as the *fourth standardized moment* (*fourth moment of the mean*).

$$\beta_2 = \frac{\sum_{i=1}^N (x_i - \mu)^4}{N\sigma^4} \quad 11.80$$

Some statistical analyses, including those in Microsoft Excel, calculate a related statistic, *excess kurtosis* (*kurtosis excess* or *Pearson's kurtosis*), by subtracting 3 from the kurtosis. A normal distribution has zero excess kurtosis; a peaked distribution has positive excess kurtosis; and a flat distribution has negative excess kurtosis.

$$\gamma_2 = \beta_2 - 3$$

$$\approx \frac{n(n+1) \sum_{i=1}^n (x_i - \bar{x})^4}{(n-1)(n-2)(n-3)s^4} - \frac{3(n-1)^2}{(n-2)(n-3)} \quad 11.81$$

## 27. CENTRAL LIMIT THEOREM

Measuring a sample of  $n$  items from a population with mean  $\mu$  and standard deviation  $\sigma$  is the general concept of an experiment. The sample mean,  $\bar{x}$ , is one of the parameters that can be derived from the experiment. This experiment can be repeated  $k$  times, yielding a set of averages ( $\bar{x}_1, \bar{x}_2, \dots, \bar{x}_k$ ). The  $k$  numbers in the set themselves represent samples from distributions of averages. The average of averages,  $\bar{\bar{x}}$ , and sample standard deviation of averages,  $s_{\bar{x}}$  (known as the *standard error of the mean*), can be calculated.

The *central limit theorem* characterizes the distribution of the sample averages. The theorem can be stated in several ways, but the essential elements are the following points.

1. The averages,  $\bar{x}_i$ , are normally distributed variables, even if the original data from which they are calculated are not normally distributed.
2. The grand average,  $\bar{\bar{x}}$  (i.e., the average of the averages), approaches  $\mu$  and is an unbiased estimator of  $\mu$ .

$$\mu \approx \bar{\bar{x}} \quad 11.82$$

The standard deviation of the original distribution,  $\sigma$ , is much larger than the standard error of the mean.

$$\sigma \approx \sqrt{n}s_{\bar{x}} \quad 11.83$$

## 28. CONFIDENCE LEVEL

The results of experiments are seldom correct 100% of the time. Recognizing this, researchers accept a certain probability of being wrong. In order to minimize this probability, experiments are repeated several times. The number of repetitions depends on the desired level of confidence in the results.

If the results have a 5% probability of being wrong, the *confidence level*,  $C$ , is 95% that the results are correct, in which case the results are said to be *significant*. If the results have only a 1% probability of being wrong, the confidence level is 99%, and the results are said to be *highly significant*. Other confidence levels (90%, 99.5%, etc.) are used as appropriate.

The complement of the confidence level is  $\alpha$ , referred to as *alpha*.  $\alpha$  is the *significance level* and may be given as a decimal value or percentage. Alpha is also known as *alpha risk* and *producer risk*, as well as the probability of a type I error. A *type I error*, also known as a *false positive error*, occurs when the null hypothesis is incorrectly rejected, and an action occurs that is not actually required. For a random sample of manufactured products, the null hypothesis would be that the distribution of sample measurements is not different from the historical distribution of those measurements. If the null hypothesis is rejected, all of the products (not just the sample) will be rejected, and the producer will have to

absorb the expense. It is not uncommon to use 5% as the producer risk in noncritical business processes.

$$\alpha = 100\% - C \quad 11.84$$

$\beta$  (*beta* or *beta risk*) is the *consumer risk*, the probability of a type II error. A *type II error* occurs when the null hypothesis (e.g., “everything is fine”) is incorrectly accepted, and no action occurs when action is actually required. If a batch of defective products is accepted, the products are distributed to consumers who then suffer the consequences. Generally, smaller values of  $\alpha$  coincide with larger values of  $\beta$  because requiring overwhelming evidence to reject the null increases the chances of a type II error.  $\beta$  can be minimized while holding  $\alpha$  constant by increasing sample sizes. The *power of the test* is the probability of rejecting the null hypothesis when it is false.

$$\text{power of the test} = 1 - \beta \quad 11.85$$

## 29. NULL AND ALTERNATIVE HYPOTHESES

All statistical conclusions involve constructing two mutually exclusive hypotheses, termed the *null hypothesis* (written as  $H_0$ ) and *alternative hypothesis* (written as  $H_1$ ). Together, the hypotheses describe all possible outcomes of a statistical analysis. The purpose of the analysis is to determine which hypothesis to accept and which to reject.

Usually, when an improvement is made to a program, treatment, or process, the change is expected to make a difference. The null hypothesis is so named because it refers to a case of “no difference” or “no effect.” Typical null hypotheses are:

- $H_0$ : There has been no change in the process.
- $H_0$ : The two distributions are the same.
- $H_0$ : The change has had no effect.
- $H_0$ : The process is in control and has not changed.
- $H_0$ : Everything is fine.

The alternative hypothesis is that there has been an effect, and there is a difference. The null and alternative hypotheses are mutually exclusive.

## 30. APPLICATION: CONFIDENCE LIMITS

As a consequence of the central limit theorem, sample means of  $n$  items taken from a normal distribution with mean  $\mu$  and standard deviation  $\sigma$  will be normally distributed with mean  $\mu$  and variance  $\sigma^2/n$ . The probability that any given average,  $\bar{x}$ , exceeds some value,  $L$ , is given by Eq. 11.86.

$$p\{\bar{x} > L\} = p\left\{ z > \left| \frac{L - \mu}{\frac{\sigma}{\sqrt{n}}} \right| \right\} \quad 11.86$$

$L$  is the *confidence limit* for the confidence level  $1 - p\{\bar{x} > L\}$  (normally expressed as a percent). Values of  $z$  are read directly from the standard normal table. As an example,  $z = 1.645$  for a 95% confidence level since only 5% of the curve is above that value of  $z$  in the upper tail. This is known as a *one-tail confidence limit* because all of the probability is given to one side of the variation. Similar values are given in Table 11.2.

With *two-tail confidence limits*, the probability is split between the two sides of variation. There will be upper and lower confidence limits, UCL and LCL, respectively.

$$p\{\text{LCL} < \bar{x} < \text{UCL}\} = p\left\{ \left| \frac{\text{LCL} - \mu}{\frac{\sigma}{\sqrt{n}}} \right| < z < \left| \frac{\text{UCL} - \mu}{\frac{\sigma}{\sqrt{n}}} \right| \right\} \quad 11.87$$

**Table 11.2** Values of  $z$  for Various Confidence Levels

confidence level, $C$	one-tail limit, $z$	two-tail limit, $z$
90%	1.28	1.645
95%	1.645	1.96
97.5%	1.96	2.24
99%	2.33	2.575
99.5%	2.575	2.81
99.75%	2.81	3.00

## 31. APPLICATION: BASIC HYPOTHESIS TESTING

A *hypothesis test* is a procedure that answers the question, “Did these data come from [a particular type of] distribution?” There are many types of tests, depending on the distribution and parameter being evaluated. The simplest hypothesis test determines whether an average value obtained from  $n$  repetitions of an experiment could have come from a population with known mean,  $\mu$ , and standard deviation,  $\sigma$ . A practical application of this question is whether a manufacturing process has changed from what it used to be or should be. Of course, the answer (i.e., “yes” or “no”) cannot be given with absolute certainty—there will be a confidence level associated with the answer.

The following procedure is used to determine whether the average of  $n$  measurements can be assumed (with a given confidence level) to have come from a known population.

*step 1:* Assume random sampling from a normal population.

*step 2:* Choose the desired confidence level,  $C$ .

*step 3:* Decide on a one-tail or two-tail test. If the hypothesis being tested is that the average has or has not increased or decreased, choose a one-tail test. If the hypothesis being tested is that the average has or has not changed, choose a two-tail test.

*step 4:* Use Table 11.2 or the standard normal table to determine the  $z$ -value corresponding to the confidence level and number of tails.

*step 5:* Calculate the actual standard normal variable,  $z'$ .

$$z' = \left| \frac{\bar{x} - \mu}{\frac{\sigma}{\sqrt{n}}} \right| \quad 11.88$$

*step 6:* If  $z' \geq z$ , the average can be assumed (with confidence level  $C$ ) to have come from a different distribution.

### Example 11.16

When it is operating properly, a cement plant has a daily production rate that is normally distributed with a mean of 880 tons/day and a standard deviation of 21 tons/day. During an analysis period, the output is measured on 50 consecutive days, and the mean output is found to be 871 tons/day. With a 95% confidence level, determine whether the plant is operating properly.

*Solution*

*step 1:* The production rate samples are known to be normally distributed.

*step 2:*  $C = 95\%$  is given.

*step 3:* Since a specific direction in the variation is not given (i.e., the example does not ask whether the average has decreased), use a two-tail hypothesis test.

*step 4:* The population mean and standard deviation are known. The standard normal distribution may be used. From Table 11.2,  $z = 1.96$ .

*step 5:* From Eq. 11.88,

$$z' = \left| \frac{\bar{x} - \mu}{\frac{\sigma}{\sqrt{n}}} \right| = \left| \frac{871 - 880}{\frac{21}{\sqrt{50}}} \right| = 3.03$$

Since  $3.03 > 1.96$ , the distributions are not the same. There is at least a 95% probability that the plant is not operating correctly.

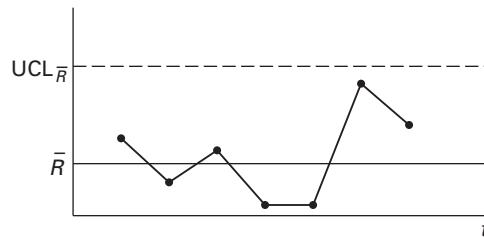

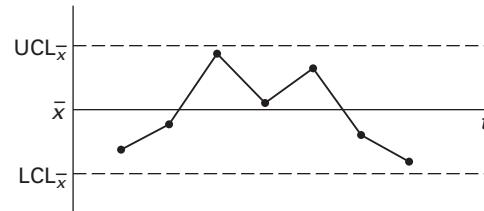

## 32. APPLICATION: STATISTICAL PROCESS CONTROL

All manufacturing processes contain variation due to random and nonrandom causes. Random variation

cannot be eliminated. *Statistical process control* (SPC) is the act of monitoring and adjusting the performance of a process to detect and eliminate nonrandom variation.

Statistical process control is based on taking regular (hourly, daily, etc.) samples of  $n$  items and calculating the mean,  $\bar{x}$ , and range,  $R$ , of the sample. To simplify the calculations, the range is used as a measure of the dispersion. These two parameters are graphed on their respective  $x$ -bar and  $R$ -control charts, as shown in Fig. 11.7.<sup>7</sup> Confidence limits are drawn at  $\pm 3\sigma/\sqrt{n}$ . From a statistical standpoint, the control chart tests a hypothesis each time a point is plotted. When a point falls outside these limits, there is a 99.75% probability that the process is out of control. Until a point exceeds the control limits, no action is taken.<sup>8</sup>

**Figure 11.7** Typical Statistical Process Control Charts

## 33. LINEAR REGRESSION

If it is necessary to draw a straight line ( $y = mx + b$ ) through  $n$  data points  $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$ , the following method based on the *method of least squares* can be used.

*step 1:* Calculate the following nine quantities.

$$\begin{array}{lllll} \sum x_i & \sum x_i^2 & (\sum x_i)^2 & \bar{x} = \frac{\sum x_i}{n} & \sum x_i y_i \\ \sum y_i & \sum y_i^2 & (\sum y_i)^2 & \bar{y} = \frac{\sum y_i}{n} & \end{array}$$

<sup>7</sup>Other charts (e.g., the *sigma chart*, *p-chart*, and *c-chart*) are less common but are used as required.

<sup>8</sup>Other indications that a correction may be required are seven measurements on one side of the average and seven consecutively increasing measurements. Rules such as these detect shifts and trends.

step 2: Calculate the slope,  $m$ , of the line.

$$m = \frac{n \sum x_i y_i - \sum x_i \sum y_i}{n \sum x_i^2 - (\sum x_i)^2} \quad 11.89$$

step 3: Calculate the  $y$ -intercept,  $b$ .

$$b = \bar{y} - m\bar{x} \quad 11.90$$

step 4: To determine the goodness of fit, calculate the *correlation coefficient*,  $r$ .

$$r = \frac{n \sum x_i y_i - \sum x_i \sum y_i}{\sqrt{\left( n \sum x_i^2 - (\sum x_i)^2 \right) \left( n \sum y_i^2 - (\sum y_i)^2 \right)}} \quad 11.91$$

If  $m$  is positive,  $r$  will be positive; if  $m$  is negative,  $r$  will be negative. As a general rule, if the absolute value of  $r$  exceeds 0.85, the fit is good; otherwise, the fit is poor.  $r$  equals 1.0 if the fit is a perfect straight line.

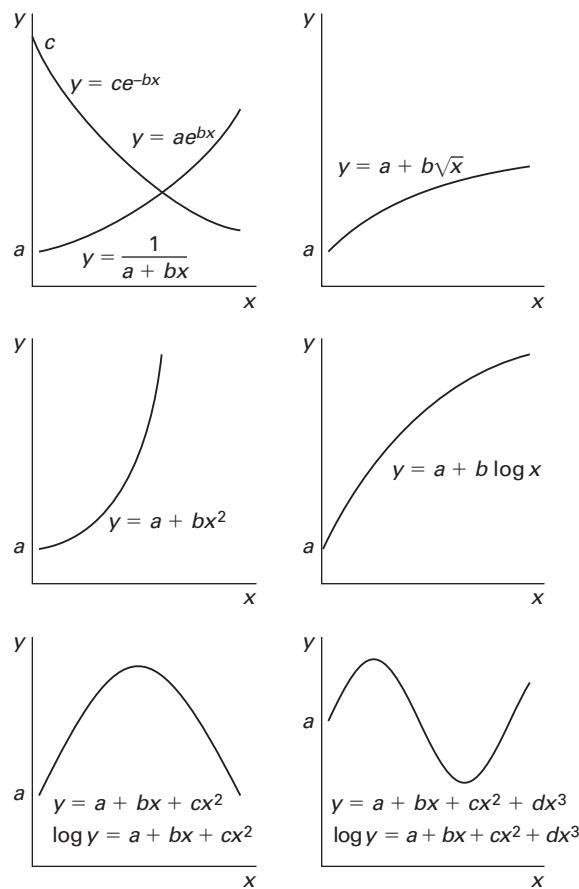

A low value of  $r$  does not eliminate the possibility of a nonlinear relationship existing between  $x$  and  $y$ . It is possible that the data describe a parabolic, logarithmic, or other nonlinear relationship. (Usually this will be apparent if the data are graphed.) It may be necessary to convert one or both variables to new variables by taking squares, square roots, cubes, or logarithms, to name a few of the possibilities, in order to obtain a linear relationship. The apparent shape of the line through the data will give a clue to the type of variable transformation that is required. The curves in Fig. 11.8 may be used as guides to some of the simpler variable transformations.

Figure 11.9 illustrates several common problems encountered in trying to fit and evaluate curves from experimental data. Figure 11.9(a) shows a graph of clustered data with several extreme points. There will be moderate correlation due to the weighting of the extreme points, although there is little actual correlation at low values of the variables. The extreme data should be excluded, or the range should be extended by obtaining more data.

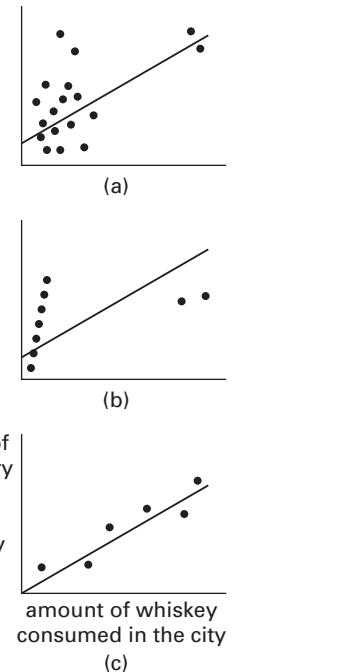

Figure 11.9(b) shows that good correlation exists in general, but extreme points are missed, and the overall correlation is moderate. If the results within the small linear range can be used, the extreme points should be excluded. Otherwise, additional data points are needed, and curvilinear relationships should be investigated.

Figure 11.9(c) illustrates the problem of drawing conclusions of cause and effect. There may be a predictable relationship between variables, but that does not imply a cause and effect relationship. In the case shown, both variables are functions of a third variable, the city population. But there is no direct relationship between the plotted variables.

**Figure 11.8** Nonlinear Data Curves

**Figure 11.9** Common Regression Difficulties

**Example 11.17**

An experiment is performed in which the dependent variable,  $y$ , is measured against the independent variable,  $x$ . The results are as follows.

$x$	$y$
1.2	0.602
4.7	5.107
8.3	6.984
20.9	10.031

- (a) What is the least squares straight line equation that best represents this data? (b) What is the correlation coefficient?

*Solution*

- (a) Calculate the following quantities.

$$\begin{aligned}\sum x_i &= 35.1 \\ \sum y_i &= 22.72 \\ \sum x_i^2 &= 529.23 \\ \sum y_i^2 &= 175.84 \\ (\sum x_i)^2 &= 1232.01 \\ (\sum y_i)^2 &= 516.38 \\ \bar{x} &= 8.775 \\ \bar{y} &= 5.681 \\ \sum x_i y_i &= 292.34 \\ n &= 4\end{aligned}$$

From Eq. 11.89, the slope is

$$\begin{aligned}m &= \frac{n \sum x_i y_i - \sum x_i \sum y_i}{n \sum x_i^2 - (\sum x_i)^2} = \frac{(4)(292.34) - (35.1)(22.72)}{(4)(529.23) - (35.1)^2} \\ &= 0.42\end{aligned}$$

From Eq. 11.90, the  $y$ -intercept is

$$\begin{aligned}b &= \bar{y} - m\bar{x} = 5.681 - (0.42)(8.775) \\ &= 2.0\end{aligned}$$

The equation of the line is

$$y = 0.42x + 2.0$$

- (b) From Eq. 11.91, the correlation coefficient is

$$\begin{aligned}r &= \frac{n \sum x_i y_i - \sum x_i \sum y_i}{\sqrt{\left(n \sum x_i^2 - (\sum x_i)^2\right)\left(n \sum y_i^2 - (\sum y_i)^2\right)}} \\ &= \frac{(4)(292.34) - (35.1)(22.72)}{\sqrt{((4)(529.23) - 1232.01) \times ((4)(175.84) - 516.38)}} \\ &= 0.914\end{aligned}$$

**Example 11.18**

Repeat Ex. 11.17 assuming the relationship between the variables is nonlinear.

*Solution*

The first step is to graph the data. Since the graph has the appearance of the fourth case in Fig. 11.8, it can be assumed that the relationship between the variables has the form of  $y = a + b \log x$ . Therefore, the variable change  $z = \log x$  is made, resulting in the following set of data.

$z$	$y$
0.0792	0.602
0.672	5.107
0.919	6.984
1.32	10.031

If the regression analysis is performed on this set of data, the resulting equation and correlation coefficient are

$$y = 7.599z + 0.000247$$

$$r = 0.999$$

This is a very good fit. The relationship between the variable  $x$  and  $y$  is approximately

$$y = 7.599 \log x + 0.000247$$

## 1. NUMERICAL METHODS

Although the roots of second-degree polynomials are easily found by a variety of methods (by factoring, completing the square, or using the quadratic equation), easy methods of solving cubic and higher-order equations exist only for specialized cases. However, cubic and higher-order equations occur frequently in engineering, and they are difficult to factor. Trial and error solutions, including graphing, are usually satisfactory for finding only the general region in which the root occurs.

*Numerical analysis* is a general subject that covers, among other things, iterative methods for evaluating roots to equations. The most efficient numerical methods are too complex to present and, in any case, work by hand. However, some of the simpler methods are presented here. Except in critical problems that must be solved in real time, a few extra calculator or computer iterations will make no difference.<sup>1</sup>

## 2. FINDING ROOTS: BISECTION METHOD

The *bisection method* is an iterative method that “brackets” (“straddles”) an interval containing the *root* or *zero* of a particular equation.<sup>2</sup> The size of the interval is halved after each iteration. As the method’s name suggests, the best estimate of the root after any iteration is the midpoint of the interval. The maximum error is half the interval length. The procedure continues until the size of the maximum error is “acceptable.”<sup>3</sup>

The disadvantages of the bisection method are (a) the slowness in converging to the root, (b) the need to know

<sup>1</sup>Most advanced hand-held calculators have “root finder” functions that use numerical methods to iteratively solve equations.

<sup>2</sup>The equation does not have to be a pure polynomial. The bisection method requires only that the equation be defined and determinable at all points in the interval.

<sup>3</sup>The bisection method is not a closed method. Unless the root actually falls on the midpoint of one iteration’s interval, the method continues indefinitely. Eventually, the magnitude of the maximum error is small enough not to matter.

the interval containing the root before starting, and (c) the inability to determine the existence of or find other real roots in the starting interval.

The bisection method starts with two values of the independent variable,  $x = L_0$  and  $x = R_0$ , which straddle a root. Since the function passes through zero at a root,  $f(L_0)$  and  $f(R_0)$  will almost always have opposite signs. The following algorithm describes the remainder of the bisection method.

Let  $n$  be the iteration number. Then, for  $n = 0, 1, 2, \dots$ , perform the following steps until sufficient accuracy is attained.

*step 1:* Set  $m = \frac{1}{2}(L_n + R_n)$ .

*step 2:* Calculate  $f(m)$ .

*step 3:* If  $f(L_n)f(m) \leq 0$ , set  $L_{n+1} = L_n$  and  $R_{n+1} = m$ . Otherwise, set  $L_{n+1} = m$  and  $R_{n+1} = R_n$ .

*step 4:*  $f(x)$  has at least one root in the interval  $[L_{n+1}, R_{n+1}]$ . The estimated value of that root,  $x^*$ , is

$$x^* \approx \frac{1}{2}(L_{n+1} + R_{n+1})$$

The maximum error is  $\frac{1}{2}(R_{n+1} - L_{n+1})$ .

### Example 12.1

Use two iterations of the bisection method to find a root of

$$f(x) = x^3 - 2x - 7$$

*Solution*

The first step is to find  $L_0$  and  $R_0$ , which are the values of  $x$  that straddle a root and have opposite signs. A table can be made and values of  $f(x)$  calculated for random values of  $x$ .

$x$	-2	-1	0	+1	+2	+3
$f(x)$	-11	-6	-7	-8	-3	+14

Since  $f(x)$  changes sign between  $x = 2$  and  $x = 3$ ,  $L_0 = 2$  and  $R_0 = 3$ .

First iteration,  $n = 0$ :

$$m = \frac{1}{2}(L_0 + R_0) = \left(\frac{1}{2}\right)(2 + 3) = 2.5$$

$$f(2.5) = x^3 - 2x - 7 = (2.5)^3 - (2)(2.5) - 7 = 3.625$$

Since  $f(2.5)$  is positive, a root must exist in the interval  $[2, 2.5]$ . Therefore,  $L_1 = 2$  and  $R_1 = 2.5$ . Or, using

step 3,  $f(2)f(2.5) = (-3)(3.625) = -10.875 \leq 0$ . So,  $L_1 = 2$ , and  $R_1 = 2.5$ . At this point, the best estimate of the root is

$$x^* \approx \left(\frac{1}{2}\right)(2 + 2.5) = 2.25$$

The maximum error is  $\left(\frac{1}{2}\right)(2.5 - 2) = 0.25$ .

Second iteration,  $n = 1$ :

$$m = \left(\frac{1}{2}\right)(2 + 2.5) = 2.25$$

$$f(2.25) = (2.25)^3 - (2)(2.25) - 7 = -0.1094$$

Since  $f(2.25)$  is negative, a root must exist in the interval  $[2.25, 2.5]$ . Or, using step 3,  $f(2)f(2.25) = (-3)(-0.1096) = 0.3288 > 0$ . Therefore,  $L_2 = 2.25$ , and  $R_2 = 2.5$ . The best estimate of the root is

$$x^* \approx \frac{1}{2}(L_{n+1} + R_{n+1}) \approx \left(\frac{1}{2}\right)(2.25 + 2.5) = 2.375$$

The maximum error is  $\left(\frac{1}{2}\right)(2.5 - 2.25) = 0.125$ .

### 3. FINDING ROOTS: NEWTON'S METHOD

Many other methods have been developed to overcome one or more of the disadvantages of the bisection method. These methods have their own disadvantages.<sup>4</sup>

*Newton's method* is a particular form of *fixed-point iteration*. In this sense, “fixed point” is often used as a synonym for “root” or “zero.” Fixed-point iterations get their name from functions with the characteristic property  $x = g(x)$  such that the limit of  $g(x)$  is the fixed point (i.e., is the root).

All fixed-point techniques require a starting point. Preferably, the starting point will be close to the actual root.<sup>5</sup> And, while Newton's method converges quickly, it requires the function to be continuously differentiable.

Newton's method algorithm is simple. At each iteration ( $n = 0, 1, 2$ , etc.), Eq. 12.1 estimates the root. The maximum error is determined by looking at how much the estimate changes after each iteration. If the change between the previous and current estimates (representing the magnitude of error in the estimate) is too large, the current estimate is used as the independent variable for the subsequent iteration.<sup>6</sup>

$$x_{n+1} = g(x_n) = x_n - \frac{f(x_n)}{f'(x_n)} \quad 12.1$$

<sup>4</sup>The *regula falsi (false position) method* converges faster than the bisection method but is unable to specify a small interval containing the root. The *secant method* is prone to round-off errors and gives no indication of the remaining distance to the root.

<sup>5</sup>Theoretically, the only penalty for choosing a starting point too far away from the root will be a slower convergence to the root.

<sup>6</sup>Actually, the theory defining the maximum error is more definite than this. For example, for a large enough value of  $n$ , the error decreases approximately linearly. Therefore, the consecutive values of  $x_n$  converge linearly to the root as well.

### Example 12.2

Solve Ex. 12.1 using two iterations of Newton's method. Use  $x_0 = 2$ .

*Solution*

The function and its first derivative are

$$f(x) = x^3 - 2x - 7$$

$$f'(x) = 3x^2 - 2$$

First iteration,  $n = 0$ :

$$x_0 = 2$$

$$f(x_0) = f(2) = (2)^3 - (2)(2) - 7 = -3$$

$$f'(x_0) = f'(2) = (3)(2)^2 - 2 = 10$$

$$x_1 = x_0 - \frac{f(x_0)}{f'(x_0)} = 2 - \frac{-3}{10} = 2.3$$

Second iteration,  $n = 1$ :

$$x_1 = 2.3$$

$$f(x_1) = (2.3)^3 - (2)(2.3) - 7 = 0.567$$

$$f'(x_1) = (3)(2.3)^2 - 2 = 13.87$$

$$x_2 = x_1 - \frac{f(x_1)}{f'(x_1)} = 2.3 - \frac{0.567}{13.87} = 2.259$$

### 4. NONLINEAR INTERPOLATION: LAGRANGIAN INTERPOLATING POLYNOMIAL

Interpolating between two points of known data is common in engineering. Primarily due to its simplicity and speed, straight-line interpolation is used most often. Even if more than two points on the curve are explicitly known, they are not used. Since straight-line interpolation ignores all but two of the points on the curve, it ignores the effects of curvature.

A more powerful technique that accounts for the curvature is the *Lagrangian interpolating polynomial*. This method uses an  $n$ th degree parabola (polynomial) as the interpolating curve.<sup>7</sup> This method requires that  $f(x)$  be continuous and real-valued on the interval  $[x_0, x_n]$  and that  $n + 1$  values of  $f(x)$  are known corresponding to  $x_0, x_1, x_2, \dots, x_n$ .

<sup>7</sup>The Lagrangian interpolating polynomial reduces to straight-line interpolation if only two points are used.

The procedure for calculating  $f(x)$  at some intermediate point,  $x$ , starts by calculating the Lagrangian interpolating polynomial for each known point.

$$L_k(x^*) = \prod_{\substack{i=0 \\ i \neq k}}^n \frac{x^* - x_i}{x_k - x_i} \quad 12.2$$

The value of  $f(x)$  at  $x^*$  is calculated from Eq. 12.3.

$$f(x^*) = \sum_{k=0}^n f(x_k) L_k(x^*) \quad 12.3$$

The Lagrangian interpolating polynomial has two primary disadvantages. The first is that a large number of additions and multiplications are needed.<sup>8</sup> The second is that the method does not indicate how many interpolating points should be used. Other interpolating methods have been developed that overcome these disadvantages.<sup>9</sup>

### Example 12.3

A real-valued function has the following values.

$$f(1) = 3.5709$$

$$f(4) = 3.5727$$

$$f(6) = 3.5751$$

Use the Lagrangian interpolating polynomial to estimate the value of the function at 3.5.

*Solution*

The procedure for applying Eq. 12.2, the Lagrangian interpolating polynomial, is illustrated in tabular form. Notice that the term corresponding to  $i = k$  is omitted from the product.

$$\begin{aligned} k = 0: & \quad i = 0 \quad i = 1 \quad i = 2 \\ L_0(3.5) &= \left( \cancel{\frac{3.5-1}{1-1}} \right) \left( \frac{3.5-4}{1-4} \right) \left( \frac{3.5-6}{1-6} \right) \\ &= 0.08333 \end{aligned}$$

$k = 1:$

$$\begin{aligned} L_1(3.5) &= \left( \frac{3.5-1}{4-1} \right) \left( \cancel{\frac{3.5-4}{4-4}} \right) \left( \frac{3.5-6}{4-6} \right) \\ &= 1.04167 \end{aligned}$$

$k = 2:$

$$\begin{aligned} L_2(3.5) &= \left( \frac{3.5-1}{6-1} \right) \left( \frac{3.5-4}{6-4} \right) \left( \cancel{\frac{3.5-6}{6-6}} \right) \\ &= -0.12500 \end{aligned}$$

Equation 12.3 is used to calculate the estimate.

$$\begin{aligned} f(3.5) &= (3.5709)(0.08333) + (3.5727)(1.04167) \\ &\quad + (3.5751)(-0.12500) \\ &= 3.57225 \end{aligned}$$

### 5. NONLINEAR INTERPOLATION: NEWTON'S INTERPOLATING POLYNOMIAL

Newton's form of the interpolating polynomial is more efficient than the Lagrangian method of interpolating between known points.<sup>10</sup> Given  $n + 1$  known points for  $f(x)$ , the *Newton form of the interpolating polynomial* is

$$f(x^*) = \sum_{i=0}^n \left( f[x_0, x_1, \dots, x_i] \prod_{j=0}^{i-1} (x^* - x_j) \right) \quad 12.4$$

$f[x_0, x_1, \dots, x_i]$  is known as the *i*th divided difference.

$$f[x_0, x_1, \dots, x_i] = \sum_{k=0}^i \left( \frac{f(x_k)}{(x_k - x_0) \cdots (x_k - x_{k-1})} \times (x_k - x_{k+1}) \cdots (x_k - x_i) \right) \quad 12.5$$

It is necessary to define the following two terms.

$$f[x_0] = f(x_0) \quad 12.6$$

$$\prod (x^* - x_j) = 1 \quad [i=0] \quad 12.7$$

### Example 12.4

Repeat Ex. 12.3 using Newton's form of the interpolating polynomial.

*Solution*

Since there are  $n + 1 = 3$  data points,  $n = 2$ . Evaluate the terms for  $i = 0, 1$ , and  $2$ .

$i = 0:$

$$f[x_0] \prod_{j=0}^{-1} (x^* - x_j) = f[x_0](1) = f(x_0)$$

<sup>8</sup>As with the numerical methods for finding roots previously discussed, the number of calculations probably will not be an issue if the work is performed by a calculator or computer.

<sup>9</sup>Other common methods for performing interpolation include the *Newton form* and *divided difference table*.

<sup>10</sup>In this case, “efficiency” relates to the ease in adding new known points without having to repeat all previous calculations.

*i* = 1:

$$f[x_0, x_1] \prod_{j=0}^0 (x^* - x_j) = f[x_0, x_1](x^* - x_0)$$

$$f[x_0, x_1] = \frac{f(x_0)}{x_0 - x_1} + \frac{f(x_1)}{x_1 - x_0}$$

*i* = 2:

$$f[x_0, x_1, x_2] \prod_{j=0}^1 (x^* - x_j) = f[x_0, x_1, x_2](x^* - x_0)(x^* - x_1)$$

$$\begin{aligned} f[x_0, x_1, x_2] &= \frac{f(x_0)}{(x_0 - x_1)(x_0 - x_2)} \\ &+ \frac{f(x_1)}{(x_1 - x_0)(x_1 - x_2)} \\ &+ \frac{f(x_2)}{(x_2 - x_0)(x_2 - x_1)} \end{aligned}$$

Use Eq. 12.4. Substitute known values.

$$\begin{aligned} f(3.5) &= \sum_{i=0}^n \left( f[x_0, x_1, \dots, x_i] \prod_{j=0}^{i-1} (x^* - x_j) \right) \\ &= 3.5709 + \left( \frac{3.5709}{1-4} + \frac{3.5727}{4-1} \right) (3.5 - 1) \\ &\quad + \left( \frac{3.5709}{(1-4)(1-6)} + \frac{3.5727}{(4-1)(4-6)} \right. \end{aligned}$$

$$\left. + \frac{3.5751}{(6-1)(6-4)} \right) \times (3.5 - 1)(3.5 - 4)$$

$$= 3.57225$$

This answer is the same as that determined in Ex. 12.3.

<i>v</i>	constant volume

## 1. ENERGY OF A MASS

The *energy* of a mass represents the capacity of the mass to do work. Such energy can be stored and released. There are many forms that it can take, including mechanical, thermal, electrical, and magnetic energies. Energy is a positive, scalar quantity (although the change in energy can be either positive or negative).

The total energy of a body can be calculated from its mass, *m*, and its *specific energy*, *u* (i.e., the energy per unit mass).<sup>1</sup>

$$E = mu \quad 13.1$$

Typical units of mechanical energy are foot-pounds and joules. (A joule is equivalent to the units of N·m and kg·m<sup>2</sup>/s<sup>2</sup>.) In traditional English-unit countries, the *British thermal unit* (Btu) is used for thermal energy, whereas the kilocalorie (kcal) is still used in some applications in SI countries. *Joule's constant*, or the *Joule equivalent* (778.17 ft-lbf/Btu, usually shortened to 778, three significant digits), is used to convert between English mechanical and thermal energy units.

$$\text{energy in Btu} = \frac{\text{energy in ft-lbf}}{J} \quad 13.2$$

Two other units of large amounts of energy are the therm and the quad. A *therm* is 10<sup>5</sup> Btu (1.055 × 10<sup>8</sup> J). A *quad* is equal to a quadrillion (10<sup>15</sup>) Btu. This is 1.055 × 10<sup>18</sup> J, or roughly the energy contained in 200 million barrels of oil.

## 2. LAW OF CONSERVATION OF ENERGY

The *law of conservation of energy* says that energy cannot be created or destroyed. However, energy can be converted into different forms. Therefore, the sum of all energy forms is constant.

$$\sum E = \text{constant} \quad 13.3$$

<sup>1</sup>The use of symbols *E* and *u* for energy is not consistent in the engineering field.

### 3. WORK

*Work*,  $W$ , is the act of changing the energy of a particle, body, or system. For a mechanical system, *external work* is work done by an external force, whereas *internal work* is done by an internal force. Work is a signed, scalar quantity. Typical units are inch-pounds, foot-pounds, and joules. Mechanical work is seldom expressed in British thermal units or kilocalories.

For a mechanical system, work is positive when a force acts in the direction of motion and helps a body move from one location to another. Work is negative when a force acts to oppose motion. (Friction, for example, always opposes the direction of motion and can do only negative work.) The work done on a body by more than one force can be found by superposition.

From a thermodynamic standpoint, work is positive if a particle or body does work on its surroundings. Work is negative if the surroundings do work on the object. (For example, blowing up a balloon represents negative work to the balloon.) This is consistent with the conservation of energy, since the sum of negative work and the positive energy increase is zero (i.e., no net energy change in the system).<sup>2</sup>

The work performed by a variable force and torque are calculated as the dot products of Eq. 13.4 and Eq. 13.5.

$$W_{\text{variable force}} = \int \mathbf{F} \cdot d\mathbf{s} \quad [\text{linear systems}] \quad 13.4$$

$$W_{\text{variable torque}} = \int \mathbf{T} \cdot d\theta \quad [\text{rotational systems}] \quad 13.5$$

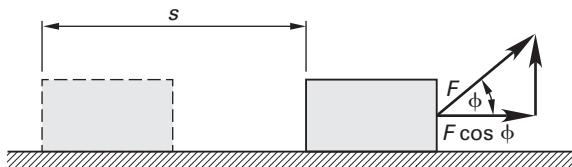

The work done by a force or torque of constant magnitude is

$$W_{\text{constant force}} = \mathbf{F} \cdot \mathbf{s} = F s \cos \phi \quad [\text{linear systems}] \quad 13.6$$

$$\begin{aligned} W_{\text{constant torque}} &= \mathbf{T} \cdot \theta \\ &= Fr\theta \cos \phi \quad [\text{rotational systems}] \end{aligned} \quad 13.7$$

The nonvector forms, Eq. 13.6 and Eq. 13.7, illustrate that only the component of force or torque in the direction of motion contributes to work. (See Fig. 13.1.)

**Figure 13.1** Work of a Constant Force

<sup>2</sup>This is just a partial statement of the *first law of thermodynamics*.

Common applications of the work done by a constant force are frictional work and gravitational work. The work to move an object a distance  $s$  against a frictional force of  $F_f$  is

$$W_{\text{friction}} = F_f s \quad 13.8$$

The work done against gravity when a mass  $m$  changes in elevation from  $h_1$  to  $h_2$  is

$$W_{\text{gravity}} = mg(h_2 - h_1) \quad [\text{SI}] \quad 13.9(a)$$

$$W_{\text{gravity}} = \frac{mg(h_2 - h_1)}{g_c} \quad [\text{U.S.}] \quad 13.9(b)$$

The work done by or on a *linear spring* whose length or deflection changes from  $\delta_1$  to  $\delta_2$  is given by Eq. 13.10.<sup>3</sup> It does not make any difference whether the spring is a compression spring or an extension spring.

$$W_{\text{spring}} = \frac{1}{2}k(\delta_2^2 - \delta_1^2) \quad 13.10$$

#### Example 13.1

A lawn mower engine is started by pulling a cord wrapped around a sheave. The sheave radius is 8.0 cm. The cord is wrapped around the sheave two times. If a constant tension of 90 N is maintained in the cord during starting, what work is done?

*Solution*

The starting torque on the engine is

$$T = Fr = (90 \text{ N}) \left( \frac{8 \text{ cm}}{100 \frac{\text{cm}}{\text{m}}} \right) = 7.2 \text{ N}\cdot\text{m}$$

The cord wraps around the sheave  $(2)(2\pi) = 12.6$  rad. From Eq. 13.7, the work done by a constant torque is

$$\begin{aligned} W &= T\theta = (7.2 \text{ N}\cdot\text{m})(12.6 \text{ rad}) \\ &= 90.7 \text{ J} \end{aligned}$$

#### Example 13.2

A 200 lbm crate is pushed 25 ft at constant velocity across a warehouse floor. There is a frictional force of 60 lbf between the crate and floor. What work is done by the frictional force on the crate?

*Solution*

From Eq. 13.8,

$$\begin{aligned} W_{\text{friction}} &= F_f s = (60 \text{ lbf})(25 \text{ ft}) \\ &= 1500 \text{ ft-lbf} \end{aligned}$$

<sup>3</sup>A *linear spring* is one for which the linear relationship  $F = kx$  is valid.

## 4. POTENTIAL ENERGY OF A MASS

Potential energy (*gravitational energy*) is a form of mechanical energy possessed by a body due to its relative position in a gravitational field. Potential energy is lost when the elevation of a body decreases. The lost potential energy usually is converted to kinetic energy or heat.

$$E_{\text{potential}} = mgh \quad [\text{SI}] \quad 13.11(a)$$

$$E_{\text{potential}} = \frac{mgh}{g_c} \quad [\text{U.S.}] \quad 13.11(b)$$

In the absence of friction and other nonconservative forces, the change in potential energy of a body is equal to the work required to change the elevation of the body.

$$W = \Delta E_{\text{potential}} \quad 13.12$$

## 5. KINETIC ENERGY OF A MASS

Kinetic energy is a form of mechanical energy associated with a moving or rotating body. The kinetic energy of a body moving with instantaneous linear velocity,  $v$ , is

$$E_{\text{kinetic}} = \frac{1}{2}mv^2 \quad [\text{SI}] \quad 13.13(a)$$

$$E_{\text{kinetic}} = \frac{mv^2}{2g_c} \quad [\text{U.S.}] \quad 13.13(b)$$

A body can also have rotational kinetic energy.

$$E_{\text{rotational}} = \frac{1}{2}I\omega^2 \quad [\text{SI}] \quad 13.14(a)$$

$$E_{\text{rotational}} = \frac{I\omega^2}{2g_c} \quad [\text{U.S.}] \quad 13.14(b)$$

According to the *work-energy principle*, the kinetic energy is equal to the work necessary to initially accelerate a stationary body or to bring a moving body to rest. (See Sec. 13.9.)

$$W = \Delta E_{\text{kinetic}} \quad 13.15$$

### Example 13.3

A solid disk flywheel ( $I = 200 \text{ kg}\cdot\text{m}^2$ ) is rotating with a speed of 900 rpm. What is its rotational kinetic energy?

*Solution*

The angular rotational velocity is

$$\omega = \frac{\left(900 \frac{\text{rev}}{\text{min}}\right) \left(2\pi \frac{\text{rad}}{\text{rev}}\right)}{60 \frac{\text{s}}{\text{min}}} = 94.25 \text{ rad/s}$$

From Eq. 13.14, the rotational kinetic energy is

$$\begin{aligned} E &= \frac{1}{2}I\omega^2 = \left(\frac{1}{2}\right)(200 \text{ kg}\cdot\text{m}^2) \left(94.25 \frac{\text{rad}}{\text{s}}\right)^2 \\ &= 888 \times 10^3 \text{ J} \quad (888 \text{ kJ}) \end{aligned}$$

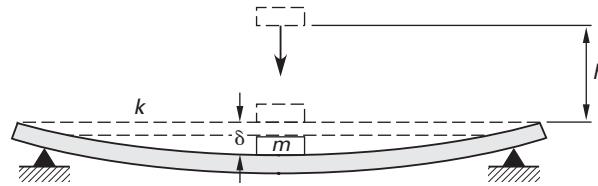

## 6. SPRING ENERGY

A spring is an energy storage device because the spring has the ability to perform work. In a perfect spring, the amount of energy stored is equal to the work required to compress the spring initially. The stored spring energy does not depend on the mass of the spring. Given a spring with spring constant (stiffness)  $k$ , the *spring energy* is

$$E_{\text{spring}} = \frac{1}{2}k\delta^2 \quad 13.16$$

### Example 13.4

A body of mass  $m$  falls from height  $h$  onto a massless, simply supported beam. The mass adheres to the beam. If the beam has a lateral stiffness  $k$ , what will be the deflection,  $\delta$ , of the beam?

*Solution*

The initial energy of the system consists of only the potential energy of the body. Using consistent units, the change in potential energy is

$$E = mg(h + \delta) \quad [\text{consistent units}]$$

All of this energy is stored in the spring. Therefore, from Eq. 13.16,

$$\frac{1}{2}k\delta^2 = mg(h + \delta)$$

Solving for the deflection,

$$\delta = \frac{mg \pm \sqrt{mg(2hk + mg)}}{k}$$

## 7. PRESSURE ENERGY OF A MASS

Since work is done in increasing the pressure of a system (e.g., work is done in blowing up a balloon), mechanical energy can be stored in pressure form. This is known as *pressure energy*, *static energy*, *flow energy*, *flow work*,

and  $p\text{-}V$  work (*energy*). For a system of pressurized mass  $m$ , the pressure energy is

$$E_{\text{flow}} = \frac{mp}{\rho} = mpv \quad [v = \text{specific volume}] \quad 13.17$$

## 8. INTERNAL ENERGY OF A MASS

The property of internal energy is encountered primarily in thermodynamics problems. Typical units are British thermal units, joules, and kilocalories. The total internal energy, usually given the symbol  $U$ , of a body increases when the body's temperature increases.<sup>4</sup> In the absence of any work done on or by the body, the change in internal energy is equal to the heat flow,  $Q$ , into the body.  $Q$  is positive if the heat flow is into the body and negative otherwise.

$$U_2 - U_1 = Q \quad 13.18$$

An increase in internal energy is needed to cause a rise in temperature. Different substances differ in the quantity of heat needed to produce a given temperature increase. The heat,  $Q$ , required to change the temperature of a mass,  $m$ , by an amount,  $\Delta T$ , is called the *specific heat* (*heat capacity*) of the substance,  $c$ .

$$c = \frac{Q}{m\Delta T} \quad 13.19$$

Because specific heats of solids and liquids are slightly temperature dependent, the mean specific heats are used when evaluating processes covering a large temperature range.

The lowercase  $c$  implies that the units are Btu/lbm·°F or J/kg·°C. Typical values of specific heat are given in Table 13.1. The *molar specific heat*, designated by the symbol  $C$ , has units of Btu/lbmol·°F or J/kmol·°C.

$$C = (\text{MW}) \times c \quad 13.20$$

For gases, the specific heat depends on the type of process during which the heat exchange occurs. Specific heats for constant-volume and constant-pressure processes are designated by  $c_v$  and  $c_p$ , respectively.

$$Q = mc_v\Delta T \quad [\text{constant-volume process}] \quad 13.21$$

$$Q = mc_p\Delta T \quad [\text{constant-pressure process}] \quad 13.22$$

Values of  $c_p$  and  $c_v$  for solids and liquids are essentially the same. However, the designation  $c_p$  is often encountered for solids and liquids. Table 13.1 gives values of  $c_p$  for selected liquids and solids.

<sup>4</sup>The *thermal energy*, represented by the body's enthalpy, is the sum of internal and pressure energies.

**Table 13.1** Approximate Specific Heats of Selected Liquids and Solids\*

substance	Btu/lbm·°F	kJ/kg·°C
aluminum, pure	0.23	0.96
aluminum, 2024-T4	0.2	0.84
ammonia	1.16	4.86
asbestos	0.20	0.84
benzene	0.41	1.72
brass, red	0.093	0.39
bronze	0.082	0.34
concrete	0.21	0.88

(Multiply Btu/lbm·°F by 4.1868 to obtain kJ/kg·°C.)

\*Values in Btu/lbm·°F are the same as cal/g·°C. Values in kJ/kg·°C are the same as kJ/kg·K.

## 9. WORK-ENERGY PRINCIPLE

Since energy can neither be created nor destroyed, external work performed on a conservative system goes into changing the system's total energy. This is known as the *work-energy principle* (or *principle of work and energy*).

$$W = \Delta E = E_2 - E_1 \quad 13.23$$

Generally, the term *work-energy principle* is limited to use with mechanical energy problems (i.e., conversion of work into kinetic or potential energies). When energy is limited to kinetic energy, the work-energy principle is a direct consequence of Newton's second law but is valid for only inertial reference systems.

By directly relating forces, displacements, and velocities, the work-energy principle introduces some simplifications into many mechanical problems.

- It is not necessary to calculate or know the acceleration of a body to calculate the work performed on it.
- Forces that do not contribute to work (e.g., are normal to the direction of motion) are irrelevant.

- Only scalar quantities are involved.
- It is not necessary to individually analyze the particles or component parts in a complex system.

**Example 13.5**

A 4000 kg elevator starts from rest, accelerates uniformly to a constant speed of 2.0 m/s, and then decelerates uniformly to a stop 20 m above its initial position. Neglecting friction and other losses, what work was done on the elevator?

*Solution*

By the work-energy principle, the work done on the elevator is equal to the change in the elevator's energy. Since the initial and final kinetic energies are zero, the only mechanical energy change is the potential energy change.

Taking the initial elevation of the elevator as the reference (i.e.,  $h_1 = 0$ ), and combining Eq. 13.9(a) and Eq. 13.23,

$$\begin{aligned} W &= E_{2,\text{potential}} - E_{1,\text{potential}} = mg(h_2 - h_1) \\ &= (4000 \text{ kg})\left(9.81 \frac{\text{m}}{\text{s}^2}\right)(20 \text{ m}) \\ &= 785 \times 10^3 \text{ J} \quad (785 \text{ kJ}) \end{aligned}$$

**10. CONVERSION BETWEEN ENERGY FORMS**

Conversion of one form of energy into another does not violate the conservation of energy law. However, most problems involving conversion of energy are really just special cases of the work-energy principle. For example, consider a falling body that is acted upon by a gravitational force. The conversion of potential energy into kinetic energy can be interpreted as equating the work done by the constant gravitational force to the change in kinetic energy.

In general terms, *Joule's law* states that one energy form can be converted without loss into another. There are two specific formulations of Joule's law. As related to electricity,  $P = I^2R = V^2/R$  is the common formulation of Joule's law. As related to thermodynamics and ideal gases, Joule's law states that "the change in internal energy of an ideal gas is a function of the temperature change, not of the volume." This latter form can also be stated more formally as "at constant temperature, the internal energy of a gas approaches a finite value that is independent of the volume as the pressure goes to zero."

**Example 13.6**

A 2 lbm projectile is launched straight up with an initial velocity of 700 ft/sec. Neglecting air friction, calculate the (a) kinetic energy immediately after launch, (b) kinetic energy at maximum height, (c) potential energy at maximum height, (d) total energy at an elevation where the

velocity has dropped to 300 ft/sec, and (e) maximum height attained.

*Solution*

- (a) From Eq. 13.13, the kinetic energy is

$$\begin{aligned} E_{\text{kinetic}} &= \frac{mv^2}{2g_c} = \frac{(2 \text{ lbm})\left(700 \frac{\text{ft}}{\text{sec}}\right)^2}{(2)\left(32.2 \frac{\text{lbf}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2}\right)} \\ &= 15,217 \text{ ft-lbf} \end{aligned}$$

- (b) The velocity is zero at the maximum height. Therefore, the kinetic energy is zero.

- (c) At the maximum height, all of the kinetic energy has been converted into potential energy. Therefore, the potential energy is 15,217 ft-lbf.

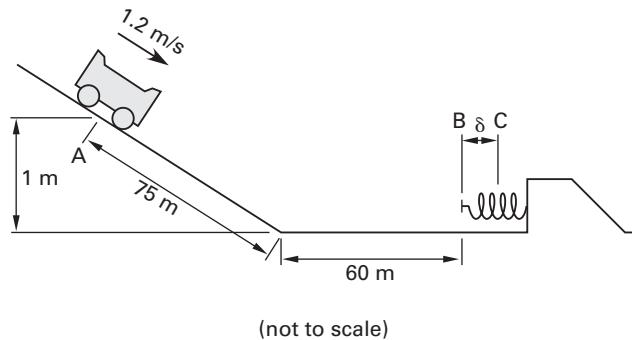

- (d) Although some of the kinetic energy has been transformed into potential energy, the total energy is still 15,217 ft-lbf.

- (e) Since all of the kinetic energy has been converted into potential energy, the maximum height can be found from Eq. 13.11.

$$\begin{aligned} E_{\text{potential}} &= \frac{mgh}{g_c} \\ 15,217 \text{ ft-lbf} &= \frac{(2 \text{ lbm})\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)h}{32.2 \frac{\text{lbf}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2}} \\ h &= 7609 \text{ ft} \end{aligned}$$

**Example 13.7**

A 4500 kg ore car rolls down an incline and passes point A traveling at 1.2 m/s. The ore car is stopped by a spring bumper that compresses 0.6 m. A constant friction force of 220 N acts on the ore car at all times. What is the spring constant?

*Solution*

The car's total energy at point A is the sum of the kinetic and potential energies.

$$\begin{aligned}E_{\text{total,A}} &= E_{\text{kinetic}} + E_{\text{potential}} = \frac{1}{2}mv^2 + mgh \\&= \left(\frac{1}{2}\right)(4500 \text{ kg})\left(1.2 \frac{\text{m}}{\text{s}}\right)^2 \\&\quad + (4500 \text{ kg})\left(9.81 \frac{\text{m}}{\text{s}^2}\right)(1 \text{ m}) \\&= 47385 \text{ J}\end{aligned}$$

At point B, the potential energy has been converted into additional kinetic energy. However, except for friction, the total energy is the same as at point A. Since the frictional force does negative work, the total energy remaining at point B is

$$\begin{aligned}E_{\text{total,B}} &= E_{\text{total,A}} - W_{\text{friction}} \\&= 47385 \text{ J} - (220 \text{ N})(75 \text{ m} + 60 \text{ m}) \\&= 17685 \text{ J}\end{aligned}$$

At point C, the maximum compression point, the remaining energy has gone into compressing the spring a distance  $\delta = 0.6 \text{ m}$  and performing a small amount of frictional work.

$$\begin{aligned}E_{\text{total,C}} &= W_{\text{spring}} + W_{\text{friction}} \\&= \frac{1}{2}k\delta^2 + F_f\delta \\17685 &= \frac{1}{2}k(0.6 \text{ m})^2 + (220 \text{ N})(0.6 \text{ m})\end{aligned}$$

The spring constant can be determined directly.

$$k = 97520 \text{ N/m} \quad (97.5 \text{ kN/m})$$

## 11. POWER

*Power* is the amount of work done per unit time. It is a scalar quantity. (Although power is calculated from two vectors, the vector dot-product operation is seldom needed.) Typical basic units of power are ft-lbf/sec and watts (J/s), although *horsepower* is widely used. Table 13.2 can be used to convert units of power.

$$P = \frac{W}{\Delta t} \quad 13.24$$

For a body acted upon by a force or torque, the instantaneous power can be calculated from the velocity.

$$P = Fv \quad [\text{linear systems}] \quad 13.25$$

$$P = T\omega \quad [\text{rotational systems}] \quad 13.26$$

For a fluid flowing at a rate of  $\dot{m}$ , the unit of time is already incorporated into the flow rate (e.g., lbm/sec). If the fluid experiences a specific energy change of  $\Delta u$ , the power generated or dissipated will be

$$P = \dot{m}\Delta u \quad 13.27$$

**Table 13.2** Useful Power Conversion Formulas

1 hp	= 550 ft-lbf/sec
	= 33,000 ft-lbf/min
	= 0.7457 kW
	= 0.7068 Btu/sec
1 kW	= 737.6 ft-lbf/sec
	= 44,250 ft-lbf/min
	= 1.341 hp
	= 0.9483 Btu/sec
1 Btu/sec	= 778.17 ft-lbf/sec
	= 46,680 ft-lbf/min
	= 1.415 hp

## Example 13.8

When traveling at 100 km/h, a car supplies a constant horizontal force of 50 N to the hitch of a trailer. What tractive power (in horsepower) is required for the trailer alone?

*Solution*

From Eq. 13.25, the power being generated is

$$\begin{aligned}P &= Fv = \frac{(50 \text{ N})\left(100 \frac{\text{km}}{\text{h}}\right)\left(1000 \frac{\text{m}}{\text{km}}\right)}{\left(60 \frac{\text{s}}{\text{min}}\right)\left(60 \frac{\text{min}}{\text{h}}\right)\left(1000 \frac{\text{W}}{\text{kW}}\right)} \\&= 1.389 \text{ kW}\end{aligned}$$

Using a conversion from Table 13.2, the horsepower is

$$P = \left(1.341 \frac{\text{hp}}{\text{kW}}\right)(1.389 \text{ kW}) = 1.86 \text{ hp}$$

## 12. EFFICIENCY

For energy-using systems (such as cars, electrical motors, elevators, etc.), the *energy-use efficiency*,  $\eta$ , of a system is the ratio of an ideal property to an actual property. The property used is commonly work, power, or, for thermodynamics problems, heat. When the rate of work is constant, either work or power can be used to calculate the efficiency. Otherwise, power should be used. Except in rare instances, the numerator and denominator of the ratio must have the same units.<sup>5</sup>

$$\eta = \frac{P_{\text{ideal}}}{P_{\text{actual}}} \quad [P_{\text{actual}} \geq P_{\text{ideal}}] \quad 13.28$$

For energy-producing systems (such as electrical generators, prime movers, and hydroelectric plants), the *energy-production efficiency* is

$$\eta = \frac{P_{\text{actual}}}{P_{\text{ideal}}} \quad [P_{\text{ideal}} \geq P_{\text{actual}}] \quad 13.29$$

The efficiency of an *ideal machine* is 1.0 (100%). However, all *real machines* have efficiencies of less than 1.0.

<sup>5</sup>The *energy-efficiency ratio* used to evaluate refrigerators, air conditioners, and heat pumps, for example, has units of Btu per watt-hour (Btu/W-hr).

## 1. CHARACTERISTICS OF A FLUID

Liquids and gases can both be categorized as fluids, although this chapter is primarily concerned with incompressible liquids. There are certain characteristics shared by all fluids, and these characteristics can be used, if necessary, to distinguish between liquids and gases.<sup>1</sup>

- Compressibility:** Liquids are only slightly compressible and are assumed to be incompressible for most purposes. Gases are highly compressible.
- Shear resistance:** Liquids and gases cannot support shear, and they deform continuously to minimize applied shear forces.
- Shape and volume:** As a consequence of their inability to support shear forces, liquids and gases take on the shapes of their containers. Only liquids have free surfaces. Liquids have fixed volumes, regardless of their container volumes, and these volumes are not significantly affected by temperature and pressure. Unlike liquids, gases take on the volumes of their containers. If allowed to do so, gas densities will change as temperature and pressure are varied.

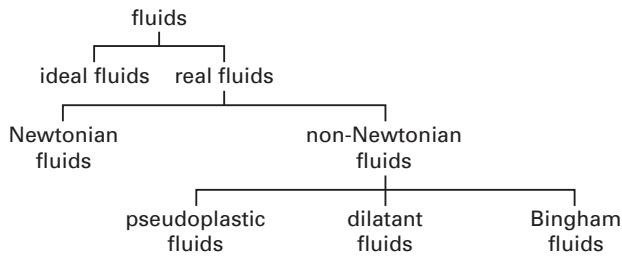

<sup>1</sup>The differences between liquids and gases become smaller as temperature and pressure are increased. Gas and liquid properties become the same at the critical temperature and pressure.

- **Resistance to motion:** Due to viscosity, liquids resist instantaneous changes in velocity, but the resistance stops when liquid motion stops. Gases have very low viscosities.
- **Molecular spacing:** Molecules in liquids are relatively close together and are held together with strong forces of attraction. Liquid molecules have low kinetic energy. The distance each liquid molecule travels between collisions is small. In gases, the molecules are relatively far apart and the attractive forces are weak. Kinetic energy of the molecules is high. Gas molecules travel larger distances between collisions.
- **Pressure:** The pressure at a point in a fluid is the same in all directions. Pressure exerted by a fluid on a solid surface (e.g., container wall) is always normal to that surface.

## 2. TYPES OF FLUIDS

For computational convenience, fluids are generally divided into two categories: **ideal fluids** and **real fluids**. (See Fig. 14.1.) **Ideal fluids** are assumed to have no viscosity (and therefore, no resistance to shear), be incompressible, and have uniform velocity distributions when flowing. In an ideal fluid, there is no friction between moving layers of fluid, and there are no eddy currents or turbulence.

**Figure 14.1** Types of Fluids

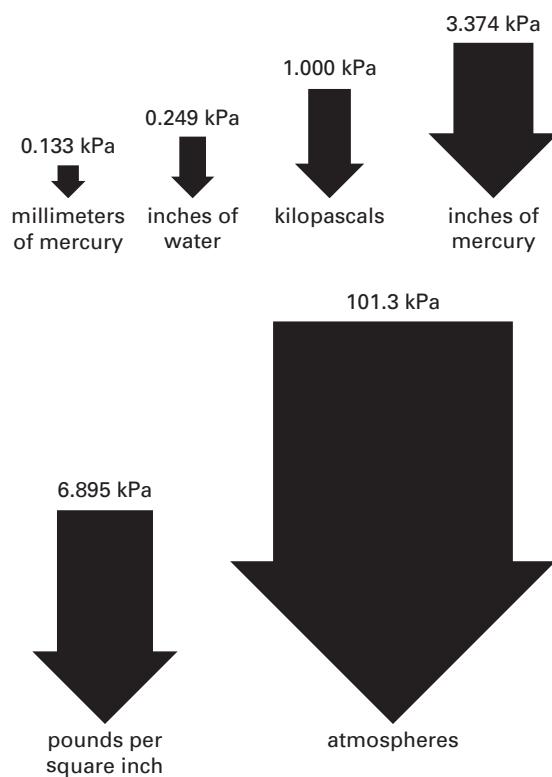

**Real fluids** exhibit finite viscosities and nonuniform velocity distributions, are compressible, and experience friction and turbulence in flow. Real fluids are further divided into *Newtonian fluids* and *non-Newtonian fluids*, depending on their viscous behavior. The differences between Newtonian and the various types of non-Newtonian fluids are described in Sec. 14.9.

For convenience, most fluid problems assume real fluids with Newtonian characteristics. This is an appropriate assumption for water, air, gases, steam, and other simple fluids (alcohol, gasoline, acid solutions, etc.). However, slurries, pastes, gels, suspensions, and polymer/electrolyte solutions may not behave according to simple fluid relationships.

## 3. FLUID PRESSURE AND VACUUM

In the English system, fluid pressure is measured in pounds per square inch ( $\text{lbf/in}^2$  or  $\text{psi}$ ) and pounds per square foot ( $\text{lbf/ft}^2$  or  $\text{psf}$ ), although tons (2000 pounds) per square foot ( $\text{tsf}$ ) are occasionally used. In SI units, pressure is measured in **pascals (Pa)**. Because a pascal is very small, **kilopascals (kPa)** and **megapascals (MPa)** are usually used. Other units of pressure include bars, millibars, atmospheres, inches and feet of water, torrs, and millimeters, centimeters, and inches of mercury. (See Fig. 14.2.)

**Figure 14.2** Relative Sizes of Pressure Units

Fluid pressures are measured with respect to two pressure references: zero pressure and atmospheric pressure. Pressures measured with respect to a true zero pressure reference are known as **absolute pressures**. Pressures measured with respect to atmospheric pressure are known as **gage pressures**.<sup>2</sup> Most pressure gauges read the excess of the test pressure over atmospheric pressure (i.e., the gage pressure). To distinguish between these two pressure measurements, the letters "a" and "g" are traditionally added to the unit symbols in the English unit system (e.g., 14.7 psia and 4015 psfg). For SI units, the actual words "gage" and "absolute" can be added to the measurement (e.g., 25.1 kPa absolute). Alternatively, the pressure is assumed to be absolute unless the "g" is used (e.g., 15 kPag or 98 barg).

<sup>2</sup>The spelling *gage* persists even though pressures are measured with *gauges*. In some countries, the term *meter pressure* is used instead of gage pressure.

Absolute and gage pressures are related by Eq. 14.1. It should be mentioned that  $p_{\text{atmospheric}}$  in Eq. 14.1 is the actual atmospheric pressure existing when the gage measurement is taken. It is not standard atmospheric pressure, unless that pressure is implicitly or explicitly applicable. Also, since a barometer measures atmospheric pressure, *barometric pressure* is synonymous with atmospheric pressure. Table 14.1 lists standard atmospheric pressure in various units.

$$p_{\text{absolute}} = p_{\text{gage}} + p_{\text{atmospheric}} \quad 14.1$$

**Table 14.1** Standard Atmospheric Pressure

1.000 atm	(atmosphere)
14.696 psia	(pounds per square inch absolute)
2116.2 psfa	(pounds per square foot absolute)
407.1 in wg	(inches of water, inches water gage)
33.93 ft wg	(feet of water, feet water gage)
29.921 in Hg	(inches of mercury)
760.0 mm Hg	(millimeters of mercury)
760.0 torr	
1.013 bars	
1013 millibars	
1.013 $\times 10^5$ Pa	(pascals)
101.3 kPa	(kilopascals)

A *vacuum* measurement is implicitly a pressure below atmospheric (i.e., a negative gage pressure). It must be assumed that any measured quantity given as a vacuum is a quantity to be subtracted from the atmospheric pressure. For example, when a condenser is operating with a vacuum of 4.0 in Hg (4 in of mercury), the absolute pressure is 29.92 in Hg – 4.0 in Hg = 25.92 in Hg. Vacuums are generally stated as positive numbers.

$$p_{\text{absolute}} = p_{\text{atmospheric}} - p_{\text{vacuum}} \quad 14.2$$

A difference in two pressures may be reported with units of *psid* (i.e., a *differential* in psi).

#### 4. DENSITY

The *density*,  $\rho$ , of a fluid is its mass per unit volume.<sup>3</sup> In SI units, density is measured in kg/m<sup>3</sup>. In a consistent English system, density would be measured in slugs/ft<sup>3</sup>, even though fluid density is exclusively reported in lbm/ft<sup>3</sup>.

The density of a fluid in a liquid form is usually given, known in advance, or easily obtained from tables in any one of a number of sources. (See Table 14.2.) Most English fluid data are reported on a per pound basis,

and the data included in this book follow that tradition. To convert pounds to slugs, divide by  $g_c$ .

$$\rho_{\text{slugs}} = \frac{\rho_{\text{lbm}}}{g_c} \quad 14.3$$

The density of an ideal gas can be found from the specific gas constant and the ideal gas law.

$$\rho = \frac{p}{R T} \quad 14.4$$

**Table 14.2** Approximate Densities of Common Fluids

fluid	lbm/ft <sup>3</sup>	kg/m <sup>3</sup>
air (STP)	0.0807	1.29
air (70°F, 1 atm)	0.075	1.20
alcohol	49.3	790
ammonia	38	602
gasoline	44.9	720
glycerin	78.8	1260
mercury	848	13 600
water	62.4	1000

(Multiply lbm/ft<sup>3</sup> by 16.01 to obtain kg/m<sup>3</sup>.)

#### Example 14.1

The density of water is typically taken as 62.4 lbm/ft<sup>3</sup> for engineering problems where greater accuracy is not required. What is the value in (a) slugs/ft<sup>3</sup> and (b) kg/m<sup>3</sup>?

*Solution*

(a) Equation 14.3 can be used to calculate the slug-density of water.

$$\rho = \frac{\rho_{\text{lbm}}}{g_c} = \frac{62.4 \frac{\text{lbm}}{\text{ft}^3}}{32.2 \frac{\text{lbm}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2}} = 1.94 \frac{\text{lbf}\cdot\text{sec}^2}{\text{ft}\cdot\text{ft}^3} \\ = 1.94 \text{ slugs/ft}^3$$

(b) The conversion between lbm/ft<sup>3</sup> and kg/m<sup>3</sup> is approximately 16.0, derived as follows.

$$\rho = \left( 62.4 \frac{\text{lbm}}{\text{ft}^3} \right) \left( \frac{35.31 \frac{\text{ft}^3}{\text{m}^3}}{2.205 \frac{\text{lbm}}{\text{kg}}} \right) \\ = \left( 62.4 \frac{\text{lbm}}{\text{ft}^3} \right) \left( 16.01 \frac{\text{kg}\cdot\text{ft}^3}{\text{m}^3\cdot\text{lbm}} \right) \\ = 999 \text{ kg/m}^3$$

In SI problems, it is common to take the density of water as 1000 kg/m<sup>3</sup>.

<sup>3</sup>Mass is an absolute property of a substance. Weight is not absolute, since it depends on the local gravity. The equations using  $\gamma$  that result (such as Bernoulli's equation) cannot be used with SI data, since the equations are not consistent. Thus, engineers end up with two different equations for the same thing.

## 5. SPECIFIC VOLUME

*Specific volume*,  $v$ , is the volume occupied by a unit mass of fluid.<sup>4</sup> Since specific volume is the reciprocal of density, typical units will be  $\text{ft}^3/\text{lbf}$ ,  $\text{ft}^3/\text{lbfmol}$ , or  $\text{m}^3/\text{kg}$ .<sup>5</sup>

$$v = \frac{1}{\rho} \quad 14.5$$

## 6. SPECIFIC GRAVITY

*Specific gravity (SG)* is a dimensionless ratio of a fluid's density to some standard reference density.<sup>6</sup> For liquids and solids, the reference is the density of pure water. There is some variation in this reference density, however, since the temperature at which the water density is evaluated is not standardized. Temperatures of  $39.2^\circ\text{F}$  ( $4^\circ\text{C}$ ),  $60^\circ\text{F}$  ( $16.5^\circ\text{C}$ ), and  $70^\circ\text{F}$  ( $21.1^\circ\text{C}$ ) have been used.<sup>7</sup>

Fortunately, the density of water is the same to three significant digits over the normal ambient temperature range:  $62.4 \text{ lbm}/\text{ft}^3$  or  $1000 \text{ kg}/\text{m}^3$ . However, to be precise, the temperature of both the fluid and water should be specified (e.g., "...the specific gravity of the  $20^\circ\text{C}$  fluid is 1.05 referred to  $4^\circ\text{C}$  water ...").

$$\text{SG}_{\text{liquid}} = \frac{\rho_{\text{liquid}}}{\rho_{\text{water}}} \quad 14.6$$

Since the SI density of water is very nearly  $1.000 \text{ g}/\text{cm}^3$  ( $1000 \text{ kg}/\text{m}^3$ ), the numerical values of density in  $\text{g}/\text{cm}^3$  and specific gravity are the same. Such is not the case with English units.

The standard reference used to calculate the specific gravity of gases is the density of air. Since the density of a gas depends on temperature and pressure, both must be specified for the gas and air (i.e., two temperatures and two pressures must be specified). While STP (standard temperature and pressure) conditions are commonly specified, they are not universal.<sup>8</sup> Table 14.3 lists several common sets of standard conditions.

$$\text{SG}_{\text{gas}} = \frac{\rho_{\text{gas}}}{\rho_{\text{air}}} \quad 14.7$$

<sup>4</sup>Care must be taken to distinguish between the symbol  $\nu$ , used for specific volume, and italic roman "vee,"  $v$ , used for velocity in many engineering textbooks.

<sup>5</sup>Units of  $\text{ft}^3/\text{slug}$  are also possible, but this combination of units is almost never encountered.

<sup>6</sup>The symbols S.G., sp.gr., S, and G are also used. In fact, petroleum engineers in the United States use  $\gamma$ , a symbol that civil engineers use for specific weight. There is no standard engineering symbol for specific gravity.

<sup>7</sup>Density of liquids is sufficiently independent of pressure to make consideration of pressure in specific gravity calculations unnecessary.

<sup>8</sup>The abbreviation "SC" (standard conditions) is interchangeable with "STP."

**Table 14.3** Commonly Quoted Values of Standard Temperature and Pressure

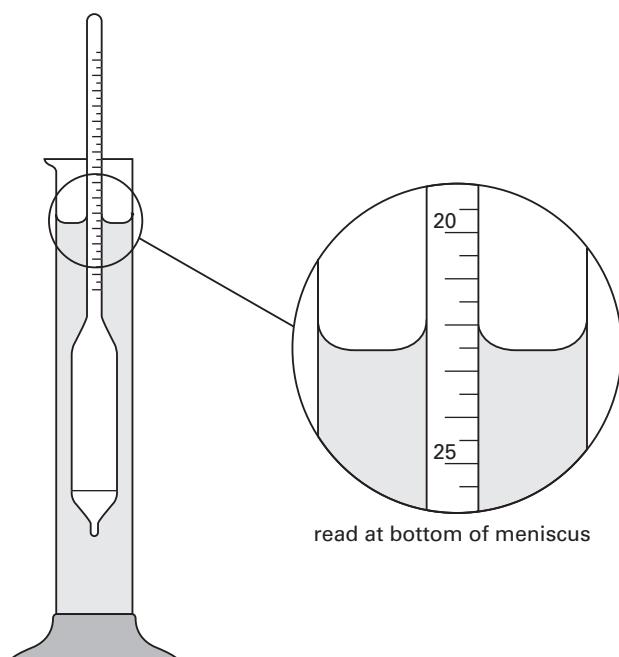

system	temperature	pressure
SI	273.15K	101.325 kPa
scientific	$0^\circ\text{C}$	760 mm Hg
U.S. engineering	$32^\circ\text{F}$	14.696 psia

natural gas industry (Canada)	$60^\circ\text{F}$	14.696 psia

If it is known or implied that the temperature and pressure of the air and gas are the same, the specific gravity of the gas will be equal to the ratio of molecular weights and the inverse ratio of specific gas constants. The density of air evaluated at STP is listed in Table 14.2. At  $70^\circ\text{F}$  ( $21.1^\circ\text{C}$ ) and 1.0 atm, the density is approximately  $0.075 \text{ lbm}/\text{ft}^3$  ( $1.20 \text{ kg}/\text{m}^3$ ).

$$\begin{aligned} \text{SG}_{\text{gas}} &= \frac{\text{MW}_{\text{gas}}}{\text{MW}_{\text{air}}} = \frac{\text{MW}_{\text{gas}}}{29.0} = \frac{R_{\text{air}}}{R_{\text{gas}}} \\ &= \frac{53.3 \frac{\text{ft-lbf}}{\text{lbfm} \cdot ^\circ\text{R}}}{R_{\text{gas}}} \end{aligned} \quad 14.8$$

Specific gravities of petroleum liquids and aqueous solutions (of acid, antifreeze, salts, etc.) can be determined by use of a *hydrometer*. (See Fig. 14.3.) In its simplest form, a hydrometer is constructed as a graduated scale weighted at one end so it will float vertically. The height at which the hydrometer floats depends on the density of the fluid, and the graduated scale can be calibrated directly in specific gravity.<sup>9</sup>

**Figure 14.3** Hydrometer

<sup>9</sup>This is a direct result of the buoyancy principle of Archimedes.

There are two standardized hydrometer scales (i.e., methods for calibrating the hydrometer stem).<sup>10</sup> Both state specific gravity in degrees, although temperature is not being measured. The *American Petroleum Institute* (API) scale ( $^{\circ}$ API) may be used with all liquids, not only with oils or other hydrocarbons. For the specific gravity value, a standard reference temperature of  $60^{\circ}\text{F}$  ( $15.6^{\circ}\text{C}$ ) is implied for both the liquid and the water.

$$^{\circ}\text{API} = \frac{141.5}{\text{SG}} - 131.5 \quad 14.9$$

$$\text{SG} = \frac{141.5}{^{\circ}\text{API} + 131.5} \quad 14.10$$

The *Baumé scale* ( $^{\circ}\text{Be}$ ) is used in the wine, honey, and acid industries. It is somewhat confusing because there are actually two Baumé scales—one for liquids heavier than water and another for liquids lighter than water. (There is also a discontinuity in the scales at SG = 1.00.) As with the API scale, the specific gravity value assumes  $60^{\circ}\text{F}$  ( $15.6^{\circ}\text{C}$ ) is the standard temperature for both scales.

$$\text{SG} = \frac{140.0}{130.0 + ^{\circ}\text{Be}} \quad [\text{SG} < 1.00] \quad 14.11$$

$$\text{SG} = \frac{145.0}{145.0 - ^{\circ}\text{Be}} \quad [\text{SG} > 1.00] \quad 14.12$$

### Example 14.2

Determine the specific gravity of carbon dioxide gas (molecular weight = 44) at  $66^{\circ}\text{C}$  ( $150^{\circ}\text{F}$ ) and 138 kPa (20 psia) using STP air as a reference. The specific gas constant of carbon dioxide is  $35.1 \text{ ft-lbf/lbm}^{\circ}\text{R}$ .

*SI Solution*

Since the specific gas constant for carbon dioxide was not given in SI units, it must be calculated from the universal gas constant.

$$R = \frac{R^*}{\text{MW}} = \frac{8314.47 \frac{\text{J}}{\text{kmol}\cdot\text{K}}}{44 \frac{\text{kg}}{\text{kmol}}} = 189 \text{ J/kg}\cdot\text{K}$$

$$\begin{aligned} \rho &= \frac{p}{RT} = \frac{1.38 \times 10^5 \text{ Pa}}{\left(189 \frac{\text{J}}{\text{kg}\cdot\text{K}}\right)(66^{\circ}\text{C} + 273)} \\ &= 2.15 \text{ kg/m}^3 \end{aligned}$$

<sup>10</sup>In addition to  $^{\circ}\text{Be}$  and  $^{\circ}\text{API}$  mentioned in this chapter, the *Twaddell scale* ( $^{\circ}\text{Tw}$ ) is used in chemical processing, the *Brix* and *Balling scales* are used in the sugar industry, and the *Salometer scale* is used to measure salt ( $\text{NaCl}$  and  $\text{CaCl}_2$ ) solutions.

From Table 14.2, the density of STP air is  $1.29 \text{ kg/m}^3$ . From Eq. 14.7, the specific gravity of carbon dioxide at the conditions given is

$$\text{SG} = \frac{\rho_{\text{gas}}}{\rho_{\text{air}}} = \frac{2.15 \frac{\text{kg}}{\text{m}^3}}{1.29 \frac{\text{kg}}{\text{m}^3}} = 1.67$$

### Customary U.S. Solution

Since the conditions of the carbon dioxide and air are different, Eq. 14.8 cannot be used. Therefore, it is necessary to calculate the density of the carbon dioxide from Eq. 14.4. Absolute temperature (degrees Rankine) must be used. The density is

$$\begin{aligned} \rho &= \frac{p}{RT} = \frac{(20 \frac{\text{lbf}}{\text{in}^2})(12 \frac{\text{in}}{\text{ft}})^2}{\left(35.1 \frac{\text{ft-lbf}}{\text{lbfm}^{\circ}\text{R}}\right)(150^{\circ}\text{F} + 460)} \\ &= 0.135 \text{ lbm/ft}^3 \end{aligned}$$

From Table 14.2, the density of STP air is  $0.0807 \text{ lbm/ft}^3$ . From Eq. 14.7, the specific gravity of carbon dioxide at the conditions given is

$$\text{SG} = \frac{\rho_{\text{gas}}}{\rho_{\text{air}}} = \frac{0.135 \frac{\text{lbm}}{\text{ft}^3}}{0.0807 \frac{\text{lbm}}{\text{ft}^3}} = 1.67$$

## 7. SPECIFIC WEIGHT

*Specific weight (unit weight)*,  $\gamma$ , is the weight of fluid per unit volume. The use of specific weight is most often encountered in civil engineering projects in the United States, where it is commonly called “density.” The usual units of specific weight are  $\text{lbf}/\text{ft}^3$ .<sup>11</sup> Specific weight is not an absolute property of a fluid, since it depends not only on the fluid, but on the local gravitational field as well.

$$\gamma = g\rho \quad [\text{SI}] \quad 14.13(a)$$

$$\gamma = \rho \times \frac{g}{g_c} \quad [\text{U.S.}] \quad 14.13(b)$$

If the gravitational acceleration is  $32.2 \text{ ft/sec}^2$ , as it is almost everywhere on earth, the specific weight in  $\text{lbf}/\text{ft}^3$  will be numerically equal to the density in  $\text{lbm}/\text{ft}^3$ . This concept is demonstrated in Ex. 14.3.

### Example 14.3

What is the sea level ( $g = 32.2 \text{ ft/sec}^2$ ) specific weight (in  $\text{lbf}/\text{ft}^3$ ) of liquids with densities of (a)  $1.95 \text{ slug}/\text{ft}^3$  and (b)  $58.3 \text{ lbm}/\text{ft}^3$ ?

<sup>11</sup>Notice that the units are  $\text{lbf}/\text{ft}^3$ , not  $\text{lbm}/\text{ft}^3$ . Pound-mass (lbm) is a mass unit, not a weight (force) unit.

**Solution**

(a) Equation 14.13(a) can be used with any consistent set of units, including densities involving slugs.

$$\begin{aligned}\gamma &= g\rho = \left(32.2 \frac{\text{ft}}{\text{sec}^2}\right) \left(1.95 \frac{\text{slug}}{\text{ft}^3}\right) \\ &= \left(32.2 \frac{\text{ft}}{\text{sec}^2}\right) \left(1.95 \frac{\text{lbf}\cdot\text{sec}^2}{\text{ft}\cdot\text{ft}^3}\right) \\ &= 62.8 \text{ lbf}/\text{ft}^3\end{aligned}$$

(b) From Eq. 14.13(b),

$$\begin{aligned}\gamma &= \rho \times \frac{g}{g_c} = \left(58.3 \frac{\text{lbm}}{\text{ft}^3}\right) \left(\frac{32.2 \frac{\text{ft}}{\text{sec}^2}}{32.2 \frac{\text{lbm}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2}}\right) \\ &= 58.3 \text{ lbf}/\text{ft}^3\end{aligned}$$

**8. MOLE FRACTION**

*Mole fraction* is an important parameter in many practical engineering problems, particularly in chemistry and chemical engineering. The composition of a fluid consisting of two or more distinctly different substances, *A*, *B*, *C*, and so on, can be described by the mole fractions,  $x_A$ ,  $x_B$ ,  $x_C$ , and so on, of each substance. (There are also other methods of specifying the composition.) The mole fraction of component *A* is the number of moles of that component,  $n_A$ , divided by the total number of moles in the combined fluid mixture.

$$x_A = \frac{n_A}{n_A + n_B + n_C + \dots} \quad 14.14$$

*Mole fraction* is a number between 0 and 1. *Mole percent* is the mole fraction multiplied by 100%, expressed in percent.

**9. VISCOSITY**

The *viscosity* of a fluid is a measure of that fluid's resistance to flow when acted upon by an external force such as a pressure differential or gravity. Some fluids, such as heavy oils, jellies, and syrups, are very viscous. Other fluids, such as water, lighter hydrocarbons, and gases, are not as viscous.

The more viscous the fluid, the more time will be required for the fluid to leak out of a container. *Saybolt Seconds Universal* (SSU) and *Saybolt Seconds Furrol* (SSF) are scales of such viscosity measurement based on the smaller and larger orifices, respectively. Seconds can be converted (empirically) to viscosity in other units. The following relations are approximate conversions between SSU and stokes.

- For  $\text{SSU} < 100$  sec,

$$\nu_{\text{stokes}} = 0.00226(\text{SSU}) - \frac{1.95}{\text{SSU}} \quad 14.15$$

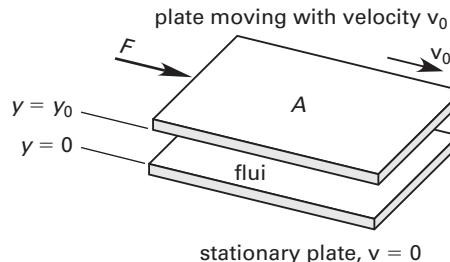

- For  $\text{SSU} > 100$  sec,

$$\nu_{\text{stokes}} = 0.00220(\text{SSU}) - \frac{1.35}{\text{SSU}} \quad 14.16$$

Most common liquids will flow more easily when their temperatures are raised. However, the behavior of a fluid when temperature, pressure, or stress is varied will depend on the type of fluid. The different types of fluids can be determined with a *sliding plate viscometer test*.<sup>12</sup>

Consider two plates of area  $A$  separated by a fluid with thickness  $y_0$ , as shown in Fig. 14.4. The bottom plate is fixed, and the top plate is kept in motion at a constant velocity,  $v_0$ , by a force,  $F$ .

**Figure 14.4 Sliding Plate Viscometer**

Experiments with water and most common fluids have shown that the force,  $F$ , required to maintain the velocity,  $v_0$ , is proportional to the velocity and the area and is inversely proportional to the separation of the plates. That is,

$$\frac{F}{A} \propto \frac{dv}{dy} \quad 14.17$$

The constant of proportionality needed to make Eq. 14.17 an equality is the *absolute viscosity*,  $\mu$ , also known as the *coefficient of viscosity*.<sup>13</sup> The reciprocal of absolute viscosity,  $1/\mu$ , is known as the *fluidity*.

$$\frac{F}{A} = \mu \frac{dv}{dy} \quad 14.18$$

$F/A$  is the *fluid shear stress*,  $\tau$ . The quantity  $dv/dy$  ( $v_0/y_0$ ) is known by various names, including *rate of strain*, *shear rate*, *velocity gradient*, and *rate of shear*.

<sup>12</sup>This test is conceptually simple but is not always practical, since the liquid leaks out between the plates. In research work with liquids, it is common to determine viscosity with a *concentric cylinder viscometer*, also known as a *cup-and-bob viscometer*. Viscosities of perfect gases can be predicted by the kinetic theory of gases. Viscosity can also be measured by a *Saybolt viscometer*, which is essentially a container that allows a given quantity of fluid to leak out through one of two different-sized orifices.

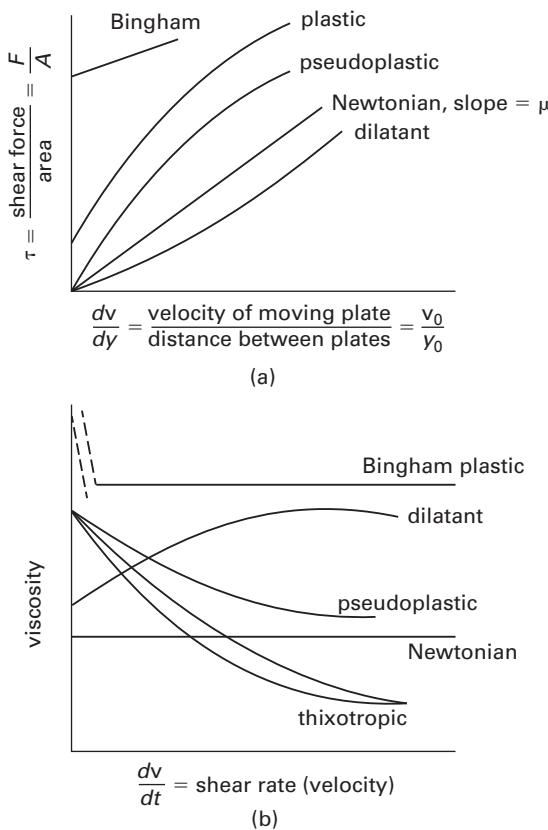

<sup>13</sup>Another name for absolute viscosity is *dynamic viscosity*. The name *absolute viscosity* is preferred, if for no other reason than to avoid confusion with *kinematic viscosity*.

formation. Equation 14.18 is known as *Newton's law of viscosity*, from which *Newtonian fluids* get their name. Sometimes Eq. 14.19 is written with a minus sign to compare viscous behavior with other behavior. However, the direction of positive shear stress is arbitrary. Equation 14.19 is simply the equation of a straight line.

$$\tau = \mu \frac{dv}{dy} \quad 14.19$$

Not all fluids are Newtonian (although most common fluids are), and Eq. 14.19 is not universally applicable. Figure 14.5 (known as a *rheogram*) illustrates how differences in fluid shear stress behavior (at constant temperature and pressure) can be used to define Bingham, pseudoplastic, and dilatant fluids, as well as Newtonian fluids.

**Figure 14.5** Shear Stress Behavior for Different Types of Fluids

Gases, water, alcohol, and benzene are examples of Newtonian fluids. In fact, all liquids with a simple chemical formula are Newtonian. Also, most solutions of simple compounds, such as sugar and salt, are Newtonian. For a more viscous fluid, the straight line will be closer to the  $\tau$  axis (i.e., the slope will be higher). (See Fig. 14.5.) For low-viscosity fluids, the straight line will be closer to the  $dv/dy$  axis (i.e., the slope will be lower).

*Pseudoplastic fluids* (muds, motor oils, polymer solutions, natural gums, and most slurries) exhibit viscosities that decrease with an increasing velocity gradient. Such fluids present no serious pumping problems.

*Plastic materials*, such as tomato catsup, behave similarly to pseudoplastic fluids once movement begins; that is, their viscosities decrease with agitation. However, a finite force must be applied before any fluid movement occurs.

*Bingham fluids* (Bingham plastics), typified by toothpaste, jellies, bread dough, and some slurries, are capable of indefinitely resisting a small shear stress but move easily when the stress becomes large—that is, Bingham fluids become pseudoplastic when the stress increases.

*Dilatant fluids* are rare but include clay slurries, various starches, some paints, milk chocolate with nuts, and other candy compounds. They exhibit viscosities that increase with increasing agitation (i.e., with increasing velocity gradients), but they return rapidly to their normal viscosity after the agitation ceases. Pump selection is critical for dilatant fluids because these fluids can become almost solid if the shear rate is high enough.

Viscosity can also change with time (all other conditions being constant). If viscosity decreases with time during agitation, the fluid is said to be a *thixotropic fluid*. If viscosity increases (usually up to a finite value) with time during agitation, the fluid is a *rheoplectic fluid*. Viscosity does not change in time-independent fluids. *Colloidal materials*, such as gelatinous compounds, lotions, shampoos, and low-temperature solutions of soaps in water and oil, behave like *thixotropic liquids*—their viscosities decrease as the agitation continues. However, viscosity does not return to its original state after the agitation ceases.

Molecular cohesion is the dominating cause of viscosity in liquids. As the temperature of a liquid increases, these cohesive forces decrease, resulting in a decrease in viscosity.

In gases, the dominant cause of viscosity is random collisions between gas molecules. This molecular agitation increases with increases in temperature. Therefore, viscosity in gases increases with temperature.

Although viscosity of liquids increases slightly with pressure, the increase is insignificant over moderate pressure ranges. Therefore, the absolute viscosity of both gases and liquids is usually considered to be essentially independent of pressure.<sup>14</sup>

The units of absolute viscosity, as derived from Eq. 14.19, are lbf·sec/ft<sup>2</sup>. Such units are actually used in the English engineering system.<sup>15</sup> Absolute viscosity is measured in pascal-seconds (Pa·s) in SI units. Another common unit used throughout the world is the *poise* (abbreviated P), equal to a dyne·s/cm<sup>2</sup>. These dimensions are the same primary dimensions as in the English system,  $F\theta/L^2$  or  $M/L\theta$ , and are functionally the same as a g/cm·s. Since the poise is a large unit, the *centipoise* (abbreviated cP) scale is generally used. The viscosity of pure water at room temperature is approximately 1 cP.

<sup>14</sup>This is not true for kinematic viscosity, however.

<sup>15</sup>Units of lbm/ft·sec are also used for absolute viscosity in the English system. These units are obtained by multiplying lbf·sec/ft<sup>2</sup> units by  $g_c$ .

**Example 14.4**

A liquid ( $\mu = 5.2 \times 10^{-5}$  lbf-sec/ft<sup>2</sup>) is flowing in a rectangular duct. The equation of the symmetrical facial velocity distribution (in ft/sec) is approximately  $v = 3y^{0.7}$  ft/sec, where  $y$  is measured in inches from the wall. (a) What is the velocity gradient at  $y = 3.0$  in from the duct wall? (b) What is the shear stress in the fluid at that point?

*Solution*

(a) The velocity is not a linear function of  $y$ , so  $dv/dy$  must be calculated as a derivative.

$$\begin{aligned}\frac{dv}{dy} &= \frac{d}{dy} 3y^{0.7} \\ &= (3)(0.7y^{-0.3}) \\ &= 2.1y^{-0.3}\end{aligned}$$

At  $y = 3$  in,

$$\frac{dv}{dy} = (2.1)(3)^{-0.3} = 1.51 \text{ ft/sec-in}$$

(b) From Eq. 14.19, the shear stress is

$$\begin{aligned}\tau &= \mu \frac{dv}{dy} \\ &= \left(5.2 \times 10^{-5} \frac{\text{lbf-sec}}{\text{ft}^2}\right) \left(1.51 \frac{\text{ft}}{\text{sec-in}}\right) \left(12 \frac{\text{in}}{\text{ft}}\right) \\ &= 9.42 \times 10^{-4} \text{ lbf/ft}^2\end{aligned}$$

**10. KINEMATIC VISCOSITY**

Another quantity with the name *viscosity* is the ratio of absolute viscosity to mass density. This combination of variables, known as *kinematic viscosity*,  $\nu$ , appears sufficiently often in fluids and other problems as to warrant its own symbol and name. Typical units are ft<sup>2</sup>/sec and cm<sup>2</sup>/s (the *stoke*, St). It is also common to give kinematic viscosity in *centistokes*, cSt. The SI units of kinematic viscosity are m<sup>2</sup>/s.

$$\nu = \frac{\mu}{\rho} \quad [\text{SI}] \quad 14.20(a)$$

$$\nu = \frac{\mu g_c}{\rho} = \frac{\mu g}{\gamma} \quad [\text{U.S.}] \quad 14.20(b)$$

It is essential that consistent units be used with Eq. 14.20. The following sets of units are consistent.

$$\text{ft}^2/\text{sec} = \frac{\text{lbf-sec}/\text{ft}^2}{\text{slug}/\text{ft}^3}$$

$$\text{m}^2/\text{s} = \frac{\text{Pa}\cdot\text{s}}{\text{kg}/\text{m}^3}$$

$$\text{St (stoke)} = \frac{\text{P (poise)}}{\text{g}/\text{cm}^3}$$

$$\text{cSt (centistokes)} = \frac{\text{cP (centipoise)}}{\text{g}/\text{cm}^3}$$

Unlike absolute viscosity, kinematic viscosity is greatly dependent on both temperature and pressure, since these variables affect the density of the fluid. Referring to Eq. 14.20, even if absolute viscosity is independent of temperature or pressure, the change in density will change the kinematic viscosity.

**11. VISCOSITY CONVERSIONS**

The most common units of absolute and kinematic viscosity are listed in Table 14.4. Table 14.5 contains conversions between the various viscosity units.

**Table 14.4** Common Viscosity Units

	absolute, $\mu$	kinematic, $\nu$
English	lbf-sec/ft <sup>2</sup> (slug/ft·sec)	ft <sup>2</sup> /sec
conventional metric	dyne·s/cm <sup>2</sup> (poise)	cm <sup>2</sup> /s (stoke)
SI	Pa·s (N·s/m <sup>2</sup> )	m <sup>2</sup> /s

**Example 14.5**

Water at 60°F has a specific gravity of 0.999 and a kinematic viscosity of 1.12 cSt. What is the absolute viscosity in lbf-sec/ft<sup>2</sup>?

*Solution*

The density of a liquid expressed in g/cm<sup>3</sup> is numerically equal to its specific gravity.

$$\rho = 0.999 \text{ g}/\text{cm}^3$$

**Table 14.5** Viscosity Conversions\*

multiply	by	to obtain
<i>absolute viscosity, <math>\mu</math></i>		
dyne-s/cm <sup>2</sup>	0.10	Pa·s

cSt	$1 \times 10^{-6}$	m <sup>2</sup> /s
cSt	$1.0764 \times 10^{-5}$	ft <sup>2</sup> /sec
<i>absolute viscosity to kinematic viscosity</i>		
cP	$1/\rho$ in g/cm <sup>3</sup>	cSt
cP	$6.7195 \times 10^{-4}/\rho$ in lbm/ft <sup>3</sup>	ft <sup>2</sup> /sec
lbf-sec/ft <sup>2</sup>	$32.174/\rho$ in lbm/ft <sup>3</sup>	ft <sup>2</sup> /sec
kgf-s/m <sup>2</sup>	$9.807/\rho$ in kg/m <sup>3</sup>	m <sup>2</sup> /s
Pa·s	$1000/\rho$ in g/cm <sup>3</sup>	cSt
<i>kinematic viscosity to absolute viscosity</i>		
cSt	$\rho$ in g/cm <sup>3</sup>	cP
cSt	$0.001 \times \rho$ in g/cm <sup>3</sup>	Pa·s
cSt	$1.6 \times 10^{-5} \times \rho$ in lbm/ft <sup>3</sup>	Pa·s
m <sup>2</sup> /s	$0.10197 \times \rho$ in kg/m <sup>3</sup>	kgf-s/m <sup>2</sup>
m <sup>2</sup> /s	$1000 \times \rho$ in g/cm <sup>3</sup>	Pa·s
m <sup>2</sup> /s	$\rho$ in kg/m <sup>3</sup>	Pa·s
ft <sup>2</sup> /sec	$0.031081 \times \rho$ in lbm/ft <sup>3</sup>	lbf-sec/ft <sup>2</sup>
ft <sup>2</sup> /sec	$1488.2 \times \rho$ in lbm/ft <sup>3</sup>	cP

\* cP: centipoise; cSt: centistoke; kgf: kilogram-force; P: poise

The centistoke (cSt) is a measure of kinematic viscosity. Kinematic viscosity is converted first to the absolute viscosity units of centipoise. From Table 14.5,

$$\begin{aligned}\mu_{\text{cP}} &= \nu_{\text{cSt}} \rho_{\text{g/cm}^3} \\ &= (1.12 \text{ cSt}) \left( 0.999 \frac{\text{g}}{\text{cm}^3} \right) \\ &= 1.119 \text{ cP}\end{aligned}$$

Next, centipoise is converted to lbf-sec/ft<sup>2</sup>.

$$\begin{aligned}\mu_{\text{lbf-sec/ft}^2} &= \mu_{\text{cP}} (2.0885 \times 10^{-5}) \\ &= (1.119 \text{ cP}) (2.0885 \times 10^{-5}) \\ &= 2.34 \times 10^{-5} \text{ lbf-sec/ft}^2\end{aligned}$$

## 12. VISCOSITY GRADE

The ISO *viscosity grade* (VG) as specified in ISO 3448, is commonly used to classify oils. (See Table 14.6.) Viscosity at 104°F (40°C), the approximate temperature of machinery, in centistokes (same as mm<sup>2</sup>/s), is used as the index. Each subsequent viscosity grade within the classification has approximately a 50% higher viscosity, whereas the minimum and maximum values of each grade range ±10% from the midpoint.

**Table 14.6** ISO Viscosity Grade

ISO 3448 viscosity grade	kinematic viscosity at 40°C (cSt)		
	minimum	midpoint	maximum
ISO VG 2	1.98	2.2	2.42
ISO VG 3	2.88	3.2	3.52
ISO VG 5	4.14	4.6	5.06
ISO VG 7	6.12	6.8	7.48
ISO VG 10	9.0	10	11.0
ISO VG 15	13.5	15	16.5
ISO VG 22	19.8	22	24.2
ISO VG 32	28.8	32	35.2
ISO VG 46	41.4	46	50.6
ISO VG 68	61.2	68	74.8
ISO VG 100	90	100	110
ISO VG 150	135	150	165
ISO VG 220	198	220	242
ISO VG 320	288	320	352
ISO VG 460	414	460	506
ISO VG 680	612	680	748
ISO VG 1000	900	1000	1100
ISO VG 1500	1350	1500	1650

## 13. VISCOSITY INDEX

*Viscosity index* (VI) is a measure of a fluid's viscosity sensitivity to changes in temperature. It has traditionally been applied to crude and refined oils through use of a 100-point scale.<sup>16</sup> The viscosity is measured at two temperatures: 100°F and 210°F (38°C and 99°C). These viscosities are converted into a viscosity index in accordance with standard ASTM D2270. (See App. 14.L.)

## 14. VAPOR PRESSURE

Molecular activity in a liquid will allow some of the molecules to escape the liquid surface. Strictly speaking, a small portion of the liquid vaporizes. Molecules of the vapor also condense back into the liquid. The vaporization and condensation at constant temperature are equilibrium processes. The equilibrium pressure exerted by these free molecules is known as the *vapor pressure* or *saturation pressure*. (Vapor pressure does not include the pressure of other substances in the mixture.) Typical values of vapor pressure are given in Table 14.7.

<sup>16</sup>Use of the *viscosity index* has been adopted by other parts of the chemical process industry (CPI), including in the manufacture of solvents, polymers, and other synthetics. The 100-point scale may be exceeded (on both ends) for these uses. Refer to standard ASTM D2270 for calculating extreme values of the viscosity index.

**Table 14.7** Typical Vapor Pressures

fluid	lbf/ft <sup>2</sup> , 68°F	kPa, 20°C
mercury	0.00362	0.000173
turpentine	1.115	0.0534
water	48.9	2.34
ethyl alcohol	122.4	5.86
ether	1231	58.9
butane	4550	218
Freon-12	12,200	584
propane	17,900	855
ammonia	18,550	888

(Multiply lbf/ft<sup>2</sup> by 0.04788 to obtain kPa.)

Some liquids, such as propane, butane, ammonia, and Freon, have significant vapor pressures at normal temperatures. Liquids near their boiling points or that vaporize easily are said to be *volatile liquids*.<sup>17</sup> Other liquids, such as mercury, have insignificant vapor pressures at normal temperatures. Liquids with low vapor pressures are used in accurate barometers.

The tendency toward vaporization is dependent on the temperature of the liquid. *Boiling* occurs when the liquid temperature is increased to the point that the vapor pressure is equal to the local ambient pressure. Therefore, a liquid's boiling temperature depends on the local ambient pressure as well as on the liquid's tendency to vaporize.

Vapor pressure is usually considered to be a nonlinear function of temperature only. It is possible to derive correlations between vapor pressure and temperature, and such correlations usually involve a logarithmic transformation of vapor pressure.<sup>18</sup> Vapor pressure can also be graphed against temperature in a (logarithmic) *Cox chart* (see App. 14.I) when values are needed over larger temperature extremes. Although there is also some variation with external pressure, the external pressure effect is negligible under normal conditions.

## 15. OSMOTIC PRESSURE

*Osmosis* is a special case of diffusion in which molecules of the *solvent* move under pressure from one fluid to another (i.e., from the *solvent* to the *solution*) in one direction only, usually through a *semipermeable membrane*.<sup>19</sup> Osmosis continues until sufficient solvent has passed through the membrane to make the activity (or solvent pressure) of the solution equal to that of the solvent.<sup>20</sup> The pressure at equilibrium is known as the *osmotic pressure*,  $\pi$ .

<sup>17</sup>Because a liquid that vaporizes easily has an aroma, the term *aromatic liquid* is also occasionally used.

<sup>18</sup>The *Clausius-Clapeyron equation* and *Antoine equation* are two such logarithmic correlations of vapor pressure with temperature.

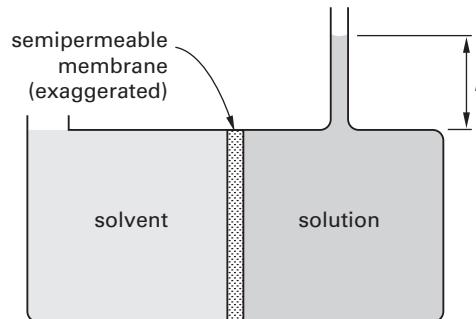

<sup>19</sup>A semipermeable membrane will be impermeable to the solute but permeable for the solvent.

<sup>20</sup>Two solutions in equilibrium (i.e., whose activities are equal) are said to be in *isopiestic equilibrium*.

Figure 14.6 illustrates an *osmotic pressure apparatus*. The fluid column can be interpreted as the result of an osmotic pressure that has developed through diffusion into the solution. The fluid column will continue to increase in height until equilibrium is reached. Alternatively, the fluid column can be adjusted so that the solution pressure just equals the osmotic pressure that would develop otherwise, in order to prevent the flow of solvent. For the arrangement in Fig. 14.6, the osmotic pressure can be calculated from the difference in fluid level heights,  $h$ .

$$\pi = \rho gh \quad [\text{SI}] \quad 14.21(a)$$

$$\pi = \frac{\rho gh}{g_c} \quad [\text{U.S.}] \quad 14.21(b)$$

**Figure 14.6** Osmotic Pressure Apparatus

In dilute solutions, osmotic pressure follows the ideal gas law. The solute acts like a gas in exerting pressure against the membrane. The solvent exerts no pressure since it can pass through. In Eq. 14.22,  $M$  is the molarity (concentration). The value of the *universal gas constant*,  $R^*$ , depends on the units used. Common values include 1545.35 ft-lbf/lbmol·°R, 8314.47 J/kmol·K, and 0.08206 atm·L/mol·K. Consistent units must be used.

$$\pi = MR^*T \quad 14.22$$

### Example 14.6

An aqueous solution is in isopiestic equilibrium with a 0.1 molarity sucrose solution at 22°C. What is the osmotic pressure?

*Solution*

Referring to Eq. 14.22,

$$M = 0.1 \text{ mol/L of solution}$$

$$T = 22^\circ\text{C} + 273^\circ = 295\text{K}$$

$$\begin{aligned} \pi &= MR^*T = \left(0.1 \frac{\text{mol}}{\text{L}}\right) \left(0.08206 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}}\right) (295\text{K}) \\ &= 2.42 \text{ atm} \end{aligned}$$

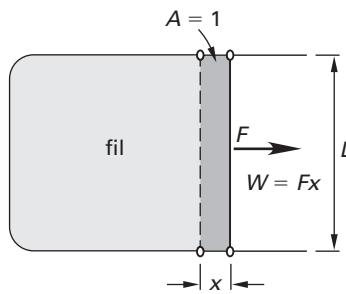

## 16. SURFACE TENSION

The membrane or “skin” that seems to form on the free surface of a fluid is due to the intermolecular cohesive forces and is known as *surface tension*,  $\sigma$ . Surface tension is the reason that insects are able to walk and a needle is able to float on water. Surface tension also causes bubbles and droplets to take on a spherical shape, since any other shape would have more surface area per unit volume.

Data on the surface tension of liquids is important in determining the performance of heat-, mass-, and momentum-transfer equipment, including heat transfer devices.<sup>21</sup> Surface tension data is needed to calculate the nucleate boiling point (i.e., the initiation of boiling) of liquids in a pool (using the *Rohsenow equation*) and the maximum heat flux of boiling liquids in a pool (using the *Zuber equation*).

Surface tension can be interpreted as the tension between two points a unit distance apart on the surface or as the amount of work required to form a new unit of surface area in an apparatus similar to that shown in Fig. 14.7. Typical units of surface tension are lbf/ft (ft-lbf/ft<sup>2</sup>) dyne/cm, and N/m.

**Figure 14.7** Wire Frame for Stretching a Film

The apparatus shown in Fig. 14.7 consists of a wire frame with a sliding side that has been dipped in a liquid to form a film. Surface tension is determined by measuring the force necessary to keep the sliding side stationary against the surface tension pull of the film.<sup>22</sup> (The film does not act like a spring, since the force,  $F$ , does not increase as the film is stretched.) Since the film has two surfaces (i.e., two surface tensions), the surface tension is

$$\sigma = \frac{F}{2L} \quad 14.23$$

Alternatively, surface tension can also be determined by measuring the force required to pull a wire ring out

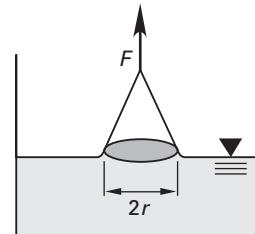

<sup>21</sup>Surface tension plays a role in processes involving dispersion, emulsion, flocculation, foaming, and solubilization. It is not surprising that surface tension data are particularly important in determining the performance of equipment in the chemical process industry (CPI), such as distillation columns, packed towers, wetted-wall columns, strippers, and phase-separation equipment.

<sup>22</sup>The force includes the weight of the sliding side wire if the frame is oriented vertically, with gravity acting on the sliding side wire to stretch the film.

of the liquid, as shown in Fig. 14.8.<sup>23</sup> Since the ring’s inner and outer sides are in contact with the liquid, the wetted perimeter is twice the circumference. The surface tension is

$$\sigma = \frac{F}{4\pi r} \quad 14.24$$

**Figure 14.8** Du Nouy Ring Surface Tension Apparatus

Surface tension depends slightly on the gas in contact with the free surface. Surface tension values are usually quoted for air contact. Typical values of surface tension are listed in Table 14.8.

**Table 14.8** Approximate Values of Surface Tension (air contact)

fluid	lbf/ft, 68°F	N/m, 20°C
n-octane	0.00149	0.0217
ethyl alcohol	0.00156	0.0227
acetone	0.00162	0.0236
kerosene	0.00178	0.0260
carbon tetrachloride	0.00185	0.0270
turpentine	0.00186	0.0271
toluene	0.00195	0.0285
benzene	0.00198	0.0289
olive oil	0.0023	0.034
glycerin	0.00432	0.0631
water	0.00499	0.0728
mercury	0.0356	0.519

(Multiply lbf/ft by 14.59 to obtain N/m.)

(Multiply dyne/cm by 0.001 to obtain N/m.)

At temperatures below freezing, the substance will be a solid, so surface tension is a moot point. As the temperature of a liquid is raised, the surface tension decreases because the cohesive forces decrease. Surface tension is zero at a substance’s critical temperature. If a substance’s critical temperature is known, the *Othmer correlation*, Eq. 14.25, can be used to determine the surface tension at one temperature from the surface tension at another temperature.

$$\sigma_2 = \sigma_1 \left( \frac{T_c - T_2}{T_c - T_1} \right)^{11/9} \quad 14.25$$

Surface tension is the reason that the pressure on the inside of bubbles and droplets is greater than on the

<sup>23</sup>This apparatus is known as a *Du Nouy torsion balance*. The ring is made of platinum with a diameter of 4.00 cm.

outside. Equation 14.26 gives the relationship between the surface tension in a hollow bubble surrounded by a gas and the difference between the inside and outside pressures. For a spherical droplet or a bubble in a liquid, where in both cases there is only one surface in tension, the surface tension is twice as large. ( $r$  is the radius of the bubble or droplet.)

$$\sigma_{\text{bubble}} = \frac{r(p_{\text{inside}} - p_{\text{outside}})}{4} \quad 14.26$$

$$\sigma_{\text{droplet}} = \frac{r(p_{\text{inside}} - p_{\text{outside}})}{2} \quad 14.27$$

## 17. CAPILLARY ACTION

*Capillary action (capillarity)* is the name given to the behavior of a liquid in a thin-bore tube. Capillary action is caused by surface tension between the liquid and a vertical solid surface.<sup>24</sup> In the case of liquid water in a glass tube, the adhesive forces between the liquid molecules and the surface are greater than (i.e., dominate) the cohesive forces between the water molecules themselves.<sup>25</sup> The adhesive forces cause the water to attach itself to and climb a solid vertical surface. It can be said that the water “reaches up and tries to wet as much of the interior surface as it can.” In so doing, the water rises above the general water surface level. The surface is *hydrophilic (lyophilic)*. This is illustrated in Fig. 14.9.

Figure 14.9 Capillarity of Liquids

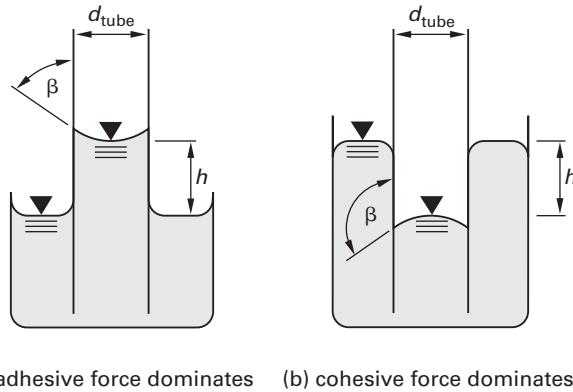

Figure 14.9 also illustrates that the same surface tension forces that keep a droplet spherical are at work on the surface of the liquid in the tube. The curved liquid surface, known as the *meniscus*, can be considered to be an incomplete droplet. If the inside diameter of the tube is less than approximately 0.1 in (2.5 mm), the meniscus is essentially hemispherical, and  $r_{\text{meniscus}} = r_{\text{tube}}$ .

<sup>24</sup>In fact, observing the rise of liquid in a capillary tube is another method of determining the surface tension of a liquid.

<sup>25</sup>*Adhesion* is the attractive force between molecules of different substances. *Cohesion* is the attractive force between molecules of the same substance.

For a few other liquids, such as mercury, the molecules have a strong affinity for each other (i.e., the cohesive forces dominate). The liquid avoids contact with the tube surface. The surface is *hydrophobic (lyophobic)*. In such liquids, the meniscus in the tube will be below the general surface level.

The *angle of contact*,  $\beta$ , is an indication of whether adhesive or cohesive forces dominate. For contact angles less than 90°, adhesive forces dominate. For contact angles greater than 90°, cohesive forces dominate.

Equation 14.28 can be used to predict the capillary rise in a small-bore tube. Surface tension and contact angles can be obtained from Table 14.8 and Table 14.9, respectively.

$$h = \frac{4\sigma \cos \beta}{\rho d_{\text{tube}} g} \quad [\text{SI}] \quad 14.28(a)$$

$$h = \frac{4\sigma \cos \beta}{\rho d_{\text{tube}}} \times \frac{g_c}{g} \quad [\text{U.S.}] \quad 14.28(b)$$

$$\sigma = \frac{h \rho d_{\text{tube}} g}{4 \cos \beta} \quad [\text{SI}] \quad 14.29(a)$$

$$\sigma = \frac{h \rho d_{\text{tube}}}{4 \cos \beta} \times \frac{g}{g_c} \quad [\text{U.S.}] \quad 14.29(b)$$

$$r_{\text{meniscus}} = \frac{d_{\text{tube}}}{2 \cos \beta} \quad 14.30$$

Table 14.9 Contact Angles,  $\beta$

materials	angle
mercury–glass	140°
water–paraffin	107°
water–silver	90°
silicone oil–glass	20°
kerosene–glass	26°
glycerin–glass	19°
water–glass	0°
ethyl alcohol–glass	0°

If it is assumed that the meniscus is hemispherical, then  $r_{\text{meniscus}} = r_{\text{tube}}$ ,  $\beta = 0^\circ$ , and  $\cos \beta = 1.0$ , and the above equations can be simplified. (Such an assumption can only be made when the diameter of the capillary tube is less than 0.1 in.)

### Example 14.7

Ethyl alcohol's density is 49 lbm/ft<sup>3</sup> (790 kg/m<sup>3</sup>). To what height will 68°F (20°C) ethyl alcohol rise in a 0.005 in (0.127 mm) internal diameter glass capillary tube?

**SI Solution**

From Table 14.8 and Table 14.9, respectively, the surface tension and contact angle are

$$\sigma = 0.0227 \text{ N/m}$$

$$\beta = 0^\circ$$

From Eq. 14.28, the height is

$$h = \frac{4\sigma \cos \beta}{\rho d_{\text{tube}} g} = \frac{(4)(0.0227 \frac{\text{N}}{\text{m}})(1.0)(1000 \frac{\text{mm}}{\text{m}})}{\left(790 \frac{\text{kg}}{\text{m}^3}\right)(0.127 \text{ mm})(9.81 \frac{\text{m}}{\text{s}^2})} \\ = 0.0923 \text{ m}$$

**Customary U.S. Solution**

From Table 14.8 and Table 14.9, respectively, the surface tension and contact angle are

$$\sigma = 0.00156 \text{ lbf/ft}$$

$$\beta = 0^\circ$$

From Eq. 14.28, the height is

$$h = \frac{4\sigma \cos \beta g_c}{\rho d_{\text{tube}} g} \\ = \frac{(4)(0.00156 \frac{\text{lbf}}{\text{ft}})(1.0)\left(32.2 \frac{\text{lbf}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2}\right)\left(12 \frac{\text{in}}{\text{ft}}\right)}{\left(49 \frac{\text{lbf}}{\text{ft}^3}\right)(0.005 \text{ in})\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)} \\ = 0.306 \text{ ft}$$

**18. COMPRESSIBILITY<sup>26</sup>**

*Compressibility* (also known as the *coefficient of compressibility*),  $\beta$ , is the fractional change in the volume of a fluid per unit change in pressure in a constant-temperature process.<sup>27</sup> Typical units are  $\text{in}^2/\text{lbf}$ ,  $\text{ft}^2/\text{lbf}$ ,  $1/\text{atm}$ , and  $1/\text{kPa}$ . (See Table 14.10.) It is the reciprocal of the bulk modulus, a quantity that is more commonly tabulated than compressibility. Equation 14.31 is written with a negative sign to show that volume decreases as pressure increases.

$$\beta = -\frac{\Delta V}{V_0} = \frac{1}{E} \quad 14.31$$

<sup>26</sup>Compressibility should not be confused with the *thermal coefficient of expansion*,  $(1/V_0)(\partial V/\partial T)_P$ , which is the fractional change in volume per unit temperature change in a constant-pressure process (with units of  $1/^\circ\text{F}$  or  $1/^\circ\text{C}$ ), or the dimensionless *compressibility factor*,  $Z$ , which is used with the ideal gas law.

<sup>27</sup>Other symbols used for compressibility are  $c$ ,  $C$ , and  $K$ .

**Table 14.10** Approximate Compressibilities of Common Liquids at 1 atm

liquid	temperature	$\beta$ ( $\text{in}^2/\text{lbf}$ )	$\beta$ ( $1/\text{atm}$ )
mercury	32°F	$0.027 \times 10^{-5}$	$0.39 \times 10^{-5}$
glycerin	60°F	$0.16 \times 10^{-5}$	$2.4 \times 10^{-5}$
water	60°F	$0.33 \times 10^{-5}$	$4.9 \times 10^{-5}$
ethyl alcohol	32°F	$0.68 \times 10^{-5}$	$10 \times 10^{-5}$
chloroform	32°F	$0.68 \times 10^{-5}$	$10 \times 10^{-5}$
gasoline	60°F	$1.0 \times 10^{-5}$	$15 \times 10^{-5}$
hydrogen	20K	$11 \times 10^{-5}$	$160 \times 10^{-5}$
helium	2.1K	$48 \times 10^{-5}$	$700 \times 10^{-5}$

(Multiply 1/psi by 14.696 to obtain 1/atm.)

(Multiply  $\text{in}^2/\text{lbf}$  by 0.145 to obtain 1/kPa.)

Compressibility can also be written in terms of partial derivatives.

$$\beta = \left(\frac{-1}{V_0}\right) \left(\frac{\partial V}{\partial p}\right)_T = \left(\frac{1}{\rho_0}\right) \left(\frac{\partial \rho}{\partial p}\right)_T \quad 14.32$$

Compressibility changes only slightly with temperature. The small compressibility of liquids is typically considered to be insignificant, giving rise to the common understanding that liquids are incompressible.

The density of a compressible fluid depends on the fluid's pressure. For small changes in pressure, Eq. 14.33 can be used to calculate the density at one pressure from the density at another pressure.

$$\rho_2 \approx \rho_1 (1 + \beta(p_2 - p_1)) \quad 14.33$$

Gases, of course, are easily compressed. The compressibility of an ideal gas depends on its pressure,  $p$ , its ratio of specific heats,  $k$ , and the nature of the process.<sup>28</sup> Depending on the process, the compressibility may be known as *isothermal compressibility* or *(adiabatic) isentropic compressibility*. Of course, compressibility is zero for constant-volume processes and is infinite (or undefined) for constant-pressure processes.

$$\beta_T = \frac{1}{p} \quad [\text{isothermal ideal gas processes}] \quad 14.34$$

$$\beta_s = \frac{1}{kp} \quad [\text{adiabatic ideal gas processes}] \quad 14.35$$

**Example 14.8**

Water at 68°F (20°C) and 1 atm has a density of 62.3 lbm/ft<sup>3</sup> (997 kg/m<sup>3</sup>). What is the new density if the pressure is isothermally increased from 14.7 lbf/in<sup>2</sup> to 400 lbf/in<sup>2</sup> (100 kPa to 2760 kPa)? The bulk modulus has a constant value of 320,000 lbf/in<sup>2</sup> ( $2.2 \times 10^6$  kPa).

<sup>28</sup>For air,  $k = 1.4$ .

*SI Solution*

Compressibility is the reciprocal of the bulk modulus.

$$\beta = \frac{1}{E} = \frac{1}{2.2 \times 10^6 \text{ kPa}} = 4.55 \times 10^{-7} \text{ 1/kPa}$$

From Eq. 14.33,

$$\begin{aligned}\rho_2 &= \rho_1(1 + \beta(p_2 - p_1)) \\ &= \left(997 \frac{\text{kg}}{\text{m}^3}\right) \left(1 + \left(4.55 \times 10^{-7} \frac{1}{\text{kPa}}\right) \times (2760 \text{ kPa} - 100 \text{ kPa})\right) \\ &= 998.2 \text{ kg/m}^3\end{aligned}$$

*Customary U.S. Solution*

Compressibility is the reciprocal of the bulk modulus.

$$\beta = \frac{1}{E} = \frac{1}{320,000 \frac{\text{lbf}}{\text{in}^2}} = 0.3125 \times 10^{-5} \text{ in}^2/\text{lbf}$$

From Eq. 14.33,

$$\begin{aligned}\rho_2 &= \rho_1(1 + \beta(p_2 - p_1)) \\ &= \left(62.3 \frac{\text{lbm}}{\text{ft}^3}\right) \left(1 + \left(0.3125 \times 10^{-5} \frac{\text{in}^2}{\text{lbf}}\right) \times \left(400 \frac{\text{lbf}}{\text{in}^2} - 14.7 \frac{\text{lbf}}{\text{in}^2}\right)\right) \\ &= 62.38 \text{ lbm/ft}^3\end{aligned}$$

**19. BULK MODULUS**

The *bulk modulus*,  $E$ , of a fluid is analogous to the modulus of elasticity of a solid.<sup>29</sup> Typical units are lbf/in<sup>2</sup>, atm, and kPa. The term  $\Delta p$  in Eq. 14.36 represents an increase in stress. The term  $\Delta V / V_0$  is a *volumetric strain*. Analogous to Hooke's law describing elastic formation, the *bulk modulus* of a fluid (liquid or gas) is given by Eq. 14.36.

$$E = \frac{\text{stress}}{\text{strain}} = \frac{-\Delta p}{\frac{\Delta V}{V_0}} \quad 14.36(a)$$

$$E = -V_0 \left( \frac{\partial p}{\partial V} \right)_T \quad 14.36(b)$$

The term *secant bulk modulus* is associated with Eq. 14.36(a) (the average slope), while the terms *tangent bulk modulus* and *point bulk modulus* are associated with Eq. 14.36(b) (the instantaneous slope).

<sup>29</sup>To distinguish it from the modulus of elasticity, the bulk modulus is represented by the symbol  $B$  when dealing with solids.

The bulk modulus is the reciprocal of compressibility.

$$E = \frac{1}{\beta} \quad 14.37$$

The bulk modulus changes only slightly with temperature. The bulk modulus of water is usually taken as 300,000 lbf/in<sup>2</sup> (2.1 × 10<sup>6</sup> kPa) unless greater accuracy is required, in which case Table 14.11 or App. 14.A can be used.

**Table 14.11 Approximate Bulk Modulus of Water**

pressure (lbf/in <sup>2</sup> )	32°F	68°F	120°F	200°F	300°F
	(thousands of lbf/in <sup>2</sup> )				
15	292	320	332	308	—
1500	300	330	340	319	218
4500	317	348	362	338	271
15,000	380	410	420	405	350

(Multiply lbf/in<sup>2</sup> by 6.8948 to obtain kPa.)

Reprinted with permission from Victor L. Streeter, *Handbook of Fluid Dynamics*, © 1961, by McGraw-Hill Book Company.

**20. SPEED OF SOUND**

The *speed of sound* (*acoustic velocity* or *sonic velocity*),  $a$ , in a fluid is a function of its bulk modulus (or, equivalently, of its compressibility).<sup>30</sup> Equation 14.38 gives the speed of sound through a liquid.

$$a = \sqrt{\frac{E}{\rho}} = \sqrt{\frac{1}{\beta\rho}} \quad [\text{SI}] \quad 14.38(a)$$

$$a = \sqrt{\frac{Eg_c}{\rho}} = \sqrt{\frac{g_c}{\beta\rho}} \quad [\text{U.S.}] \quad 14.38(b)$$

Equation 14.39 gives the speed of sound in an ideal gas. The temperature,  $T$ , must be in degrees absolute (i.e., °R or K). For air, the ratio of specific heats is  $k = 1.4$ , and the molecular weight is 28.967. The universal gas constant is  $R^* = 1545.35 \text{ ft-lbf/lbmol} \cdot ^\circ\text{R}$  (8314.47 J/kmol·K).

$$\begin{aligned}a &= \sqrt{\frac{E}{\rho}} = \sqrt{\frac{kp}{\rho}} \\ &= \sqrt{kRT} = \sqrt{\frac{kR^* T}{\text{MW}}} \quad [\text{SI}] \quad 14.39(a)\end{aligned}$$

$$\begin{aligned}a &= \sqrt{\frac{Eg_c}{\rho}} = \sqrt{\frac{k g_c p}{\rho}} \\ &= \sqrt{kg_c RT} = \sqrt{\frac{kg_c R^* T}{\text{MW}}} \quad [\text{U.S.}] \quad 14.39(b)\end{aligned}$$

Since  $k$  and  $R$  are constant for an ideal gas, the speed of sound is a function of temperature only. Equation 14.40

<sup>30</sup>The symbol  $c$  is also used for the speed of sound.

can be used to calculate the new speed of sound when temperature is varied.

$$\frac{a_1}{a_2} = \sqrt{\frac{T_1}{T_2}} \quad 14.40$$

The *Mach number*,  $M$ , of an object is the ratio of the object's speed to the speed of sound in the medium through which it is traveling. (See Table 14.12.)

$$M = \frac{V}{a} \quad 14.41$$

**Table 14.12** Approximate Speeds of Sound (at one atmospheric pressure)

material	speed of sound	
	(ft/sec)	(m/s)
air	1130 at 70°F	330 at 0°C
aluminum	16,400	4990
carbon dioxide	870 at 70°F	260 at 0°C
hydrogen	3310 at 70°F	1260 at 0°C
steel	16,900	5150
water	4880 at 70°F	1490 at 20°C

(Multiply ft/sec by 0.3048 to obtain m/s.)

The term *subsonic travel* implies  $M < 1$ .<sup>31</sup> Similarly, *supersonic travel* implies  $M > 1$ , but usually  $M < 5$ . Travel above  $M = 5$  is known as *hypersonic travel*. Travel in the transition region between subsonic and supersonic (i.e.,  $0.8 < M < 1.2$ ) is known as *transonic travel*. A *sonic boom* (a shock wave phenomenon) occurs when an object travels at supersonic speed.

### Example 14.9

What is the speed of sound in 150°F (66°C) water? The density is 61.2 lbm/ft<sup>3</sup> (980 kg/m<sup>3</sup>), and the bulk modulus is 328,000 lbf/in<sup>2</sup> ( $2.26 \times 10^6$  kPa).

*SI Solution*

From Eq. 14.38,

$$a = \sqrt{\frac{E}{\rho}} = \sqrt{\frac{(2.26 \times 10^6 \text{ kPa}) \left( 1000 \frac{\text{Pa}}{\text{kPa}} \right)}{980 \frac{\text{kg}}{\text{m}^3}}} = 1519 \text{ m/s}$$

*Customary U.S. Solution*

From Eq. 14.38,

$$a = \sqrt{\frac{Eg_c}{\rho}} = \sqrt{\frac{\left( 328,000 \frac{\text{lbf}}{\text{in}^2} \right) \left( 12 \frac{\text{in}}{\text{ft}} \right)^2 \left( 32.2 \frac{\text{lbf}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2} \right)}{61.2 \frac{\text{lbf}}{\text{ft}^3}}} = 4985 \text{ ft/sec}$$

<sup>31</sup>In the language of compressible fluid flow, this is known as the *subsonic flow regime*.

### Example 14.10

What is the speed of sound in 150°F (66°C) air at standard atmospheric pressure?

*SI Solution*

The specific gas constant,  $R$ , for air is

$$R = \frac{R^*}{MW} = \frac{8314.47 \frac{\text{J}}{\text{kmol}\cdot\text{K}}}{28.967 \frac{\text{kg}}{\text{kmol}}} = 287.03 \text{ J/kg}\cdot\text{K}$$

The absolute temperature is

$$T = 66^\circ\text{C} + 273^\circ = 339\text{K}$$

From Eq. 14.39(a),

$$a = \sqrt{kRT} = \sqrt{(1.4) \left( 287.03 \frac{\text{J}}{\text{kg}\cdot\text{K}} \right) (339\text{K})} = 369 \text{ m/s}$$

*Customary U.S. Solution*

The specific gas constant,  $R$ , for air is

$$R = \frac{R^*}{MW} = \frac{1545.35 \frac{\text{ft-lbf}}{\text{lbfmol}\cdot\text{R}}}{28.967 \frac{\text{lbf}}{\text{lbfmol}}} = 53.35 \text{ ft-lbf/lbm}\cdot\text{R}$$

The absolute temperature is

$$T = 150^\circ\text{F} + 460^\circ = 610^\circ\text{R}$$

From Eq. 14.39(b),

$$a = \sqrt{kg_c RT}$$

$$= \sqrt{(1.4) \left( 32.2 \frac{\text{lbf}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2} \right) \left( 53.35 \frac{\text{ft-lbf}}{\text{lbf}\cdot\text{R}} \right) (610^\circ\text{R})} = 1211 \text{ ft/sec}$$

## 21. PROPERTIES OF MIXTURES OF NONREACTING LIQUIDS

There are very few convenient ways of predicting the properties of nonreacting, nonvolatile organic and aqueous solutions (acids, brines, alcohol mixtures, coolants, etc.) from the individual properties of the components.

Volumes of two nonreacting organic liquids (e.g., acetone and chloroform) in a mixture are essentially additive. The volume change upon mixing will seldom be more than a few tenths of a percent. The volume change

in aqueous solutions is often slightly greater, but is still limited to a few percent (e.g., 3% for some solutions of methanol and water). Therefore, the specific gravity (density, specific weight, etc.) can be considered to be a volumetric weighting of the individual specific gravities.

A rough estimate of the absolute viscosity of a mixture of two or more liquids having different viscosities (at the same temperature) can be found from the mole fractions,  $x_i$ , of the components.

$$\mu_{\text{mixture}} \approx \frac{1}{\sum_i \frac{x_i}{\mu_i}} = \frac{\sum_i \frac{m_i}{\text{MW}_i}}{\sum_i \frac{m_i}{(\text{MW}_i)\mu_i}} \quad 14.42$$

A three-step procedure for calculating a more reliable estimate of the viscosity of a mixture of two or more liquids starts by using the *Refutas equation* to calculate a linearized *viscosity blending index*, VBI, (or, *viscosity blending number*, VBN) for each component.

$$\text{VBI}_i = 10.975 + 14.534 \times \ln(\nu_{i,\text{cSt}} + 0.8) \quad 14.43$$

The second step calculates the average VBI of the mixture from the gravimetrically weighted component VBIs.

$$\text{VBI}_{\text{mixture}} = \sum_i G_i \times \text{VBI}_i \quad 14.44$$

The final step extracts the mixture viscosity from the mixture VBI by inverting the Refutas equation.

$$\nu_{\text{mixture,cSt}} = \exp\left(\exp\left(\frac{\text{VBI}_{\text{mixture}} - 10.975}{14.534}\right)\right) - 0.8 \quad 14.45$$

Components of mixtures of hydrocarbons may be referred to as pseudocomponents.<sup>32</sup> *Raoult's law* can be used to calculate the vapor pressure above a liquid mixture from the vapor pressures of the liquid components.

$$p_{v,\text{mixture}} = \sum_i x_i p_{v,i} \quad 14.46$$

<sup>32</sup>A *pseudocomponent* represents a mixture of components and has the thermodynamic behavior of a mixture, rather than that of a single component. The term can refer to the performance of a blend of known components, or to the performance of a component of a known mixture.

### 1. PRESSURE-MEASURING DEVICES

There are many devices for measuring and indicating fluid pressure. Some devices measure gage pressure; others measure absolute pressure. The effects of nonstandard atmospheric pressure and nonstandard gravitational acceleration must be determined, particularly for devices relying on columns of liquid to indicate pressure. Table 15.1 lists the common types of devices and the ranges of pressure appropriate for each.

**Table 15.1** Common Pressure-Measuring Devices

device	approximate range (in atm)
water manometer	0–0.1
mercury barometer	0–1
mercury manometer	0.001–1
metallic diaphragm	0.01–200
transducer	0.001–15,000
Bourdon pressure gauge	1–3000
Bourdon vacuum gauge	0.1–1

The *Bourdon pressure gauge* is the most common pressure-indicating device. (See Fig. 15.1.) This mechanical device consists of a C-shaped or helical hollow tube that tends to straighten out (i.e., unwind) when the tube is subjected to an internal pressure. The gauge is referred to as a *C-Bourdon gauge* because of the shape of the hollow tube. The degree to which the coiled tube unwinds depends on the difference between the internal and external pressures. A Bourdon gauge directly indicates *gage pressure*. Extreme accuracy is generally not a characteristic of Bourdon gauges.

**Figure 15.1** C-Bourdon Pressure Gauge

In non-SI installations, gauges are always calibrated in psi (or psid). Vacuum pressure is usually calibrated in inches of mercury. SI gauges are marked in kilopascals (kPa) or bars, although kg/cm<sup>2</sup> may be used in older gauges. Negative numbers are used to indicate vacuum. The gauge dial will be clearly marked if other units are indicated.

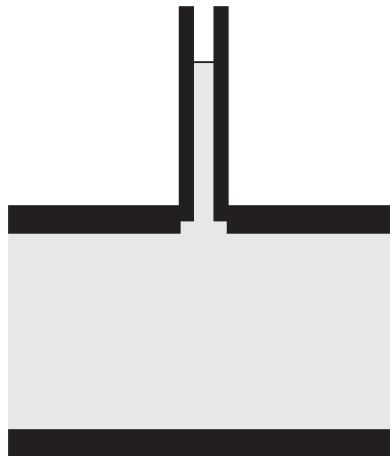

The **barometer** is a common device for measuring the **absolute pressure** of the atmosphere.<sup>1</sup> It is constructed

by filling a long tube open at one end with mercury (or alcohol, or some other liquid) and inverting the tube so that the open end is below the level of a mercury-filled container. If the vapor pressure of the mercury in the tube is neglected, the fluid column will be supported only by the atmospheric pressure transmitted through the container fluid at the lower, open end.

*Strain gauges*, *diaphragm gauges*, *quartz-crystal transducers*, and other devices using the *piezoelectric effect* are also used to measure stress and pressure, particularly when pressure fluctuates quickly (e.g., as in a rocket combustion chamber). With these devices, calibration is required to interpret pressure from voltage generation or changes in resistance, capacitance, or inductance. **These devices are generally unaffected by atmospheric pressure or gravitational acceleration.**

**Manometers (U-tube manometers)** can also be used to indicate small pressure differences, and for this purpose they provide great accuracy. (Manometers are not suitable for measuring pressures much larger than 10 lbf/in<sup>2</sup> (70 kPa), however.) A difference in manometer fluid surface heights is converted into a pressure difference. If one end of a manometer is open to the atmosphere, the manometer indicates gage pressure. It is theoretically possible, but impractical, to have a manometer indicate absolute pressure, since one end of the manometer would have to be exposed to a perfect vacuum.

A **static pressure tube** (*piezometer tube*) is a variation of the manometer. (See Fig. 15.2.) It is a simple method of determining the static pressure in a pipe or other vessel, regardless of fluid motion in the pipe. A vertical transparent tube is connected to a hole in the pipe wall.<sup>2</sup> (None of the tube projects into the pipe.) The static pressure will force the contents of the pipe up into the tube. The height of the contents will be an indication of gage pressure in the pipe.

**Figure 15.2** Static Pressure Tube

<sup>1</sup>A barometer can be used to measure the pressure inside any vessel. However, the barometer must be completely enclosed in the vessel, which may not be possible. Also, it is difficult to read a barometer enclosed within a tank.

<sup>2</sup>Where greater accuracy is required, multiple holes may be drilled around the circumference of the pipe and connected through a manifold (*piezometer ring*) to the pressure-measuring device.

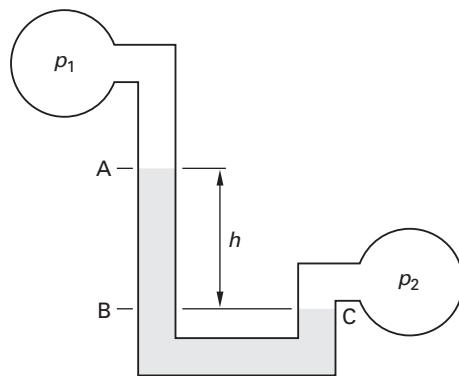

The device used to measure the pressure should not be confused with the method used to obtain exposure to the pressure. For example, a static pressure *tap* in a pipe is merely a hole in the pipe wall. A Bourdon gauge, manometer, or transducer can then be used with the tap to indicate pressure.

Tap holes are generally  $1/8\text{--}1/4$  in (3–6 mm) in diameter, drilled at right angles to the wall, and smooth and flush with the pipe wall. No part of the gauge or connection projects into the pipe. The tap holes should be at least 5 to 10 pipe diameters downstream from any source of turbulence (e.g., a bend, fitting, or valve).

## 2. MANOMETERS

Figure 15.3 illustrates a simple U-tube manometer used to measure the difference in pressure between two vessels. When both ends of the manometer are connected to pressure sources, the name *differential manometer* is used. If one end of the manometer is open to the atmosphere, the name *open manometer* is used.<sup>3</sup> The open manometer implicitly measures gage pressures.

**Figure 15.3** Simple U-Tube Manometer

Since the pressure at point B in Fig. 15.3 is the same as at point C, the pressure differential produces the vertical fluid column of height  $h$ . In Eq. 15.2,  $A$  is the area of the tube. In the absence of any capillary action, the inside diameters of the manometer tubes are irrelevant.

$$F_{\text{net}} = F_C - F_A = \text{weight of fluid column AB} \quad 15.1$$

$$(p_2 - p_1)A = \rho_m ghA \quad 15.2$$

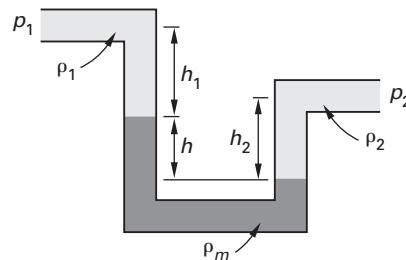

$$p_2 - p_1 = \rho_m gh \quad [\text{SI}] \quad 15.3(a)$$

$$p_2 - p_1 = \rho_m h \times \frac{g}{g_c} = \gamma_m h \quad [\text{U.S.}] \quad 15.3(b)$$

The quantity  $g/g_c$  has a value of 1.0 lbf/lbm in almost all cases, so  $\gamma_m$  is numerically equal to  $\rho_m$ , with units of  $\text{lbf}/\text{ft}^3$ .

Equation 15.3(a) and Eq. 15.3(b) assume that the manometer fluid height is small, or that only low-density gases fill the tubes above the manometer fluid. If a high-density fluid (such as water) is present above the measuring fluid, or if the columns  $h_1$  or  $h_2$  are very long, corrections will be necessary. (See Fig. 15.4.)

**Figure 15.4** Manometer Requiring Corrections

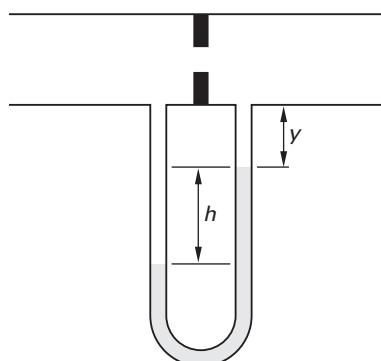

Fluid column  $h_2$  “sits on top” of the manometer fluid, forcing the manometer fluid to the left. This increase must be subtracted out. Similarly, the column  $h_1$  restricts the movement of the manometer fluid. The observed measurement must be increased to correct for this restriction.

$$p_2 - p_1 = g(\rho_m h + \rho_1 h_1 - \rho_2 h_2) \quad [\text{SI}] \quad 15.4(a)$$

$$\begin{aligned} p_2 - p_1 &= (\rho_m h + \rho_1 h_1 - \rho_2 h_2) \times \frac{g}{g_c} \\ &= \gamma_m h + \gamma_1 h_1 - \gamma_2 h_2 \quad [\text{U.S.}] \quad 15.4(b) \end{aligned}$$

When a manometer is used to measure the pressure difference across an orifice or other fitting where the same liquid exists in both manometer sides (shown in Fig. 15.5), it is not necessary to correct the manometer reading for all of the liquid present above the manometer fluid. This is because parts of the correction for both sides of the manometer are the same. Therefore, the distance  $y$  in Fig. 15.5 is an irrelevant distance.

**Figure 15.5** Irrelevant Distance,  $y$

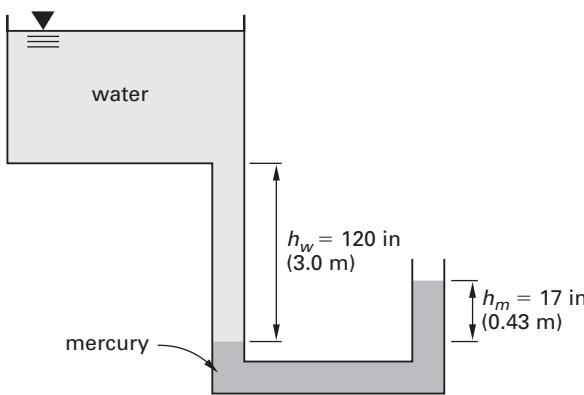

<sup>3</sup>If one of the manometer legs is inclined, the term *inclined manometer* or *draft gauge* is used. Although only the vertical distance between the manometer fluid surfaces should be used to calculate the pressure difference, with small pressure differences it may be more accurate to read the inclined distance (which is larger than the vertical distance) and compute the vertical distance from the angle of inclination.

Manometer tubes are generally large enough in diameter to avoid significant capillary effects. Corrections for capillarity are seldom necessary.

### Example 15.1

The pressure at the bottom of a water tank ( $\rho = 62.4 \text{ lbm/ft}^3$ ;  $\rho = 998 \text{ kg/m}^3$ ) is measured with a mercury manometer located below the tank bottom, as shown. (The density of mercury is  $848 \text{ lbm/ft}^3$ ;  $13575 \text{ kg/m}^3$ .) What is the gage pressure at the bottom of the water tank?

### SI Solution

From Eq. 15.4(a),

$$\begin{aligned}\Delta p &= g(\rho_m h_m - \rho_w h_w) \\ &= (9.81 \frac{\text{m}}{\text{s}^2}) \left( \left( 13575 \frac{\text{kg}}{\text{m}^3} \right) (0.43 \text{ m}) \right. \\ &\quad \left. - \left( 998 \frac{\text{kg}}{\text{m}^3} \right) (3.0 \text{ m}) \right) \\ &= 27892 \text{ Pa} \quad (27.9 \text{ kPa gage})\end{aligned}$$

### Customary U.S. Solution

From Eq. 15.4(b),

$$\begin{aligned}\Delta p &= (\rho_m h_m - \rho_w h_w) \times \frac{g}{g_c} \\ &= \frac{\left( 848 \frac{\text{lbm}}{\text{ft}^3} \right) (17 \text{ in}) - \left( 62.4 \frac{\text{lbm}}{\text{ft}^3} \right) (120 \text{ in})}{\left( 12 \frac{\text{in}}{\text{ft}} \right)^3} \\ &\quad \times \left( \frac{32.2 \frac{\text{ft}}{\text{sec}^2}}{32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2}} \right) \\ &= 4.01 \text{ lbf/in}^2 \quad (4.01 \text{ psig})\end{aligned}$$

### 3. HYDROSTATIC PRESSURE

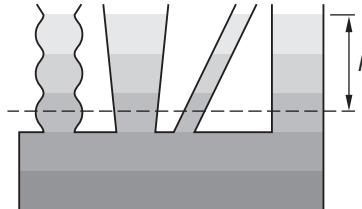

*Hydrostatic pressure* is the pressure a fluid exerts on an immersed object or container walls.<sup>4</sup> Pressure is equal to the force per unit area of surface.

$$p = \frac{F}{A} \quad 15.5$$

Hydrostatic pressure in a stationary, incompressible fluid behaves according to the following characteristics.

- Pressure is a function of vertical depth (and density) only. The pressure will be the same at two points with identical depths.
- Pressure varies linearly with (vertical and inclined) depth.
- Pressure is independent of an object's area and size and the weight (mass) of water above the object. Figure 15.6 illustrates the *hydrostatic paradox*. The pressures at depth  $h$  are the same in all four columns because pressure depends on depth, not volume.

Figure 15.6 Hydrostatic Paradox

- Pressure at a point has the same magnitude in all directions (*Pascal's law*). Therefore, pressure is a scalar quantity.
- Pressure is always normal to a surface, regardless of the surface's shape or orientation. (This is a result of the fluid's inability to support shear stress.)
- The resultant of the pressure distribution acts through the *center of pressure*.
- The center of pressure rarely coincides with the average depth.

### 4. FLUID HEIGHT EQUIVALENT TO PRESSURE

Pressure varies linearly with depth. The relationship between pressure and depth (i.e., the *hydrostatic head*) for an incompressible fluid is given by Eq. 15.6.

$$p = \rho gh \quad [\text{SI}] \quad 15.6(a)$$

$$p = \frac{\rho gh}{g_c} = \gamma h \quad [\text{U.S.}] \quad 15.6(b)$$

<sup>4</sup>The term *hydrostatic* is used with all fluids, not only with water.

Since  $\rho$  and  $g$  are constants, Eq. 15.6 shows that  $p$  and  $h$  are linearly related. Knowing one determines the other.<sup>5</sup> For example, the height of a fluid column needed to produce a pressure is

$$h = \frac{p}{\rho g} \quad [\text{SI}] \quad 15.7(a)$$

$$h = \frac{pg_c}{\rho g} = \frac{p}{\gamma} \quad [\text{U.S.}] \quad 15.7(b)$$

Table 15.2 lists six common fluid height equivalents.<sup>6</sup>

**Table 15.2** Approximate Fluid Height Equivalents at 68°F (20°C)

liquid	height equivalents	
water	0.0361 psi/in	27.70 in/psi
water	62.4 psf/ft	0.01603 ft/psf
water	9.81 kPa/m	0.1019 m/kPa
water	0.4329 psi/ft	2.31 ft/psi
mercury	0.491 psi/in	2.036 in/psi
mercury	133.3 kPa/m	0.00750 m/kPa

A barometer is a device that measures atmospheric pressure by the height of a fluid column. If the vapor pressure of the barometer liquid is neglected, the atmospheric pressure will be given by Eq. 15.8.

$$p_a = \rho gh \quad [\text{SI}] \quad 15.8(a)$$

$$p_a = \frac{\rho gh}{g_c} = \gamma h \quad [\text{U.S.}] \quad 15.8(b)$$

If the vapor pressure of the barometer liquid is significant (as it would be with alcohol or water), the vapor pressure effectively reduces the height of the fluid column, as Eq. 15.9 illustrates.

$$p_a - p_v = \rho gh \quad [\text{SI}] \quad 15.9(a)$$

$$p_a - p_v = \frac{\rho gh}{g_c} = \gamma h \quad [\text{U.S.}] \quad 15.9(b)$$

### Example 15.2

A vacuum pump is used to drain a flooded mine shaft of 68°F (20°C) water.<sup>7</sup> The vapor pressure of water at this temperature is 0.34 lbf/in<sup>2</sup> (2.34 kPa). The pump is incapable of lifting the water higher than 400 in (10.16 m). What is the atmospheric pressure?

<sup>5</sup>In fact, pressure and height of a fluid column can be used interchangeably. The height of a fluid column is known as *head*. For example: "The fan developed a static head of 3 in of water," or "The pressure head at the base of the water tank was 8 m." When the term "head" is used, it is essential to specify the fluid.

<sup>6</sup>Of course, these values are recognized to be the approximate specific weights of the liquids.

<sup>7</sup>A reciprocating or other direct-displacement pump would be a better choice to drain a mine.

### SI Solution

From Eq. 15.9,

$$\begin{aligned} p_a &= p_v + \rho gh \\ &= 2.34 \text{ kPa} + \frac{\left(998 \frac{\text{kg}}{\text{m}^3}\right) \left(9.81 \frac{\text{m}}{\text{s}^2}\right) (10.16 \text{ m})}{1000 \frac{\text{Pa}}{\text{kPa}}} \\ &= 101.8 \text{ kPa} \end{aligned}$$

(Alternate SI solution, using Table 15.2)

$$\begin{aligned} p_a &= p_v + \rho gh = 2.34 \text{ kPa} + \left(9.81 \frac{\text{kPa}}{\text{m}}\right) (10.16 \text{ m}) \\ &= 102 \text{ kPa} \end{aligned}$$

### Customary U.S. Solution

From Table 15.2, the height equivalent of water is approximately 0.0361 psi/in. The unit psi/in is the same as lbf/in<sup>3</sup>, the units of  $\gamma$ . From Eq. 15.9, the atmospheric pressure is

$$\begin{aligned} p_a &= p_v + \rho gh = \rho_v + \gamma h \\ &= 0.34 \frac{\text{lbf}}{\text{in}^2} + \left(0.0361 \frac{\text{lbf}}{\text{in}^3}\right) (400 \text{ in}) \\ &= 14.78 \text{ lbf/in}^2 \quad (14.78 \text{ psia}) \end{aligned}$$

## 5. MULTIFLUID BAROMETERS

It is theoretically possible to fill a barometer tube with several different immiscible fluids.<sup>8</sup> Upon inversion, the fluids will separate, leaving the most dense fluid at the bottom and the least dense fluid at the top. All of the fluids will contribute, by superposition, to the balance between the external atmospheric pressure and the weight of the fluid column.

$$p_a - p_v = g \sum \rho_i h_i \quad [\text{SI}] \quad 15.10(a)$$

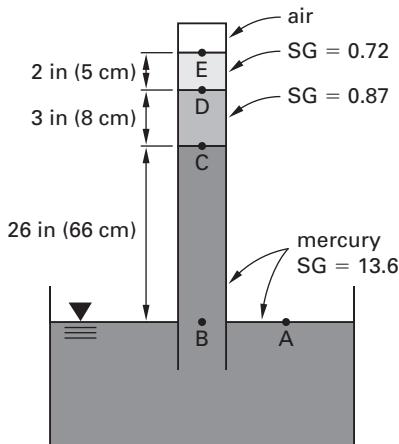

$$p_a - p_v = \frac{g}{g_c} \sum \rho_i h_i = \sum \gamma_i h_i \quad [\text{U.S.}] \quad 15.10(b)$$

The pressure at any intermediate point within the fluid column is found by starting at a location where the pressure is known, and then adding or subtracting  $\rho gh$  terms to get to the point where the pressure is needed. Usually, the known pressure will be the atmospheric pressure located in the barometer barrel at the level (elevation) of the fluid outside of the barometer.

<sup>8</sup>In practice, barometers are never constructed this way. This theory is more applicable to a category of problems dealing with up-ended containers, as illustrated in Ex. 15.3.

**Example 15.3**

Neglecting vapor pressure, what is the pressure of the air at point E in the container shown? The atmospheric pressure is 1.0 atm (14.7 lbf/in<sup>2</sup>, 101 300 Pa).

*SI Solution*

$$\begin{aligned} p_E &= p_a - g\rho_w \sum (\text{SG}_i) h_i \\ &= 101\,300 \text{ Pa} - \left(9.81 \frac{\text{m}}{\text{s}^2}\right) \left(1000 \frac{\text{kg}}{\text{m}^3}\right) \\ &\quad \times \left( (0.66 \text{ m})(13.6) + (0.08 \text{ m})(0.87) \right. \\ &\quad \left. + (0.05 \text{ m})(0.72) \right) \\ &= 12\,210 \text{ Pa} \quad (12.2 \text{ kPa}) \end{aligned}$$

*Customary U.S. Solution*

The pressure at point B is the same as the pressure at point A—1.0 atm. The density of mercury is  $13.6 \times 0.0361 \text{ lbm/in}^3 = 0.491 \text{ lbm/in}^3$ , and the specific weight is  $0.491 \text{ lbf/in}^3$ . Therefore, the pressure at point C is

$$\begin{aligned} p_C &= 14.7 \frac{\text{lbf}}{\text{in}^2} - (26 \text{ in}) \left( 0.491 \frac{\text{lbf}}{\text{in}^3} \right) \\ &= 1.93 \text{ lbf/in}^2 \quad (1.93 \text{ psia}) \end{aligned}$$

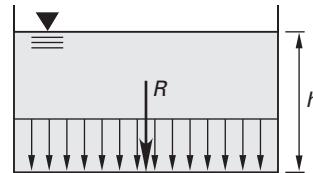

Similarly, the pressure at point E (and anywhere within the captive air space) is

$$\begin{aligned} p_E &= 14.7 \frac{\text{lbf}}{\text{in}^2} - (26 \text{ in}) \left( 0.491 \frac{\text{lbf}}{\text{in}^3} \right) \\ &\quad - (3 \text{ in})(0.87) \left( 0.0361 \frac{\text{lbf}}{\text{in}^3} \right) \\ &\quad - (2 \text{ in})(0.72) \left( 0.0361 \frac{\text{lbf}}{\text{in}^3} \right) \\ &= 1.79 \text{ lbf/in}^2 \quad (1.79 \text{ psia}) \end{aligned}$$

**6. PRESSURE ON A HORIZONTAL PLANE SURFACE**

The pressure on a horizontal plane surface is uniform over the surface because the depth of the fluid is uniform. (See Fig. 15.7.) The resultant of the pressure distribution acts through the center of pressure of the surface, which corresponds to the centroid of the surface.

**Figure 15.7** Hydrostatic Pressure on a Horizontal Plane Surface

The uniform pressure at depth  $h$  is given by Eq. 15.11.<sup>9</sup>

$$p = \rho gh \quad [\text{SI}] \quad 15.11(a)$$

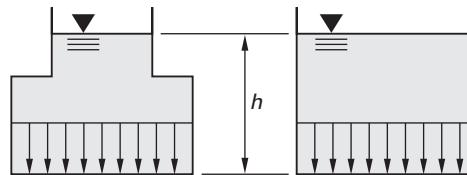

$$p = \frac{\rho gh}{g_c} = \gamma h \quad [\text{U.S.}] \quad 15.11(b)$$

The total vertical force on the horizontal plane of area  $A$  is given by Eq. 15.12.

$$R = pA \quad 15.12$$

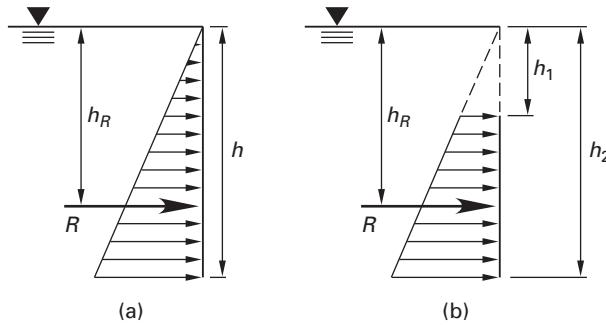

It is tempting, but not always correct, to calculate the vertical force on a submerged surface as the weight of the fluid above it. Such an approach works only when there is no change in the cross-sectional area of the fluid above the surface. This is a direct result of the *hydrostatic paradox*. (See Sec. 15.3.) Figure 15.8 illustrates two containers with the same pressure distribution (force) on their bottom surfaces.

**Figure 15.8** Two Containers with the Same Pressure Distribution

**7. PRESSURE ON A RECTANGULAR VERTICAL PLANE SURFACE**

The pressure on a vertical rectangular plane surface increases linearly with depth. The pressure distribution will be triangular, as in Fig. 15.9(a), if the plane surface extends to the surface; otherwise, the distribution will be trapezoidal, as in Fig. 15.9(b).

<sup>9</sup>The phrase *pressure at a depth* is universally understood to mean the *gauge pressure*, as given by Eq. 15.11.

**Figure 15.9** Hydrostatic Pressure on a Vertical Plane Surface

The resultant force is calculated from the *average pressure*.

$$\bar{p} = \frac{1}{2}(p_1 + p_2) \quad 15.13$$

$$\bar{p} = \frac{1}{2}\rho g(h_1 + h_2) \quad [\text{SI}] \quad 15.14(a)$$

$$\bar{p} = \frac{\frac{1}{2}\rho g(h_1 + h_2)}{g_c} = \frac{1}{2}\gamma(h_1 + h_2) \quad [\text{U.S.}] \quad 15.14(b)$$

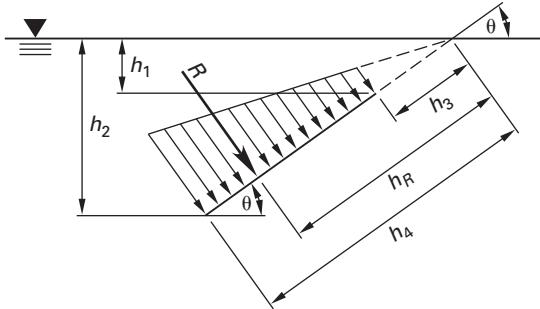

$$R = \bar{p}A \quad 15.15$$

Although the resultant is calculated from the average depth, it does not act at the average depth. The resultant of the pressure distribution passes through the centroid of the pressure distribution. For the triangular distribution of Fig. 15.9(a), the resultant is located at a depth of  $h_R = \frac{2}{3}h$ . For the more general case of Fig. 15.9(b), the resultant is located from Eq. 15.16.

$$h_R = \frac{2}{3} \left( h_1 + h_2 - \frac{h_1 h_2}{h_1 + h_2} \right) \quad 15.16$$

## 8. PRESSURE ON A RECTANGULAR INCLINED PLANE SURFACE

The average pressure and resultant force on an inclined rectangular plane surface are calculated in a similar fashion as that for the vertical plane surface. (See Fig. 15.10.) The pressure varies linearly with depth. The resultant is

**Figure 15.10** Hydrostatic Pressure on an Inclined Rectangular Plane Surface

calculated from the average pressure, which, in turn, depends on the average depth.

The average pressure and resultant are found using Eq. 15.17 through Eq. 15.19.

$$\bar{p} = \frac{1}{2}(p_1 + p_2) \quad 15.17$$

$$\begin{aligned} \bar{p} &= \frac{1}{2}\rho g(h_1 + h_2) \\ &= \frac{1}{2}\rho g(h_3 + h_4)\sin\theta \end{aligned} \quad [\text{SI}] \quad 15.18(a)$$

$$\begin{aligned} \bar{p} &= \frac{\frac{1}{2}\rho g(h_1 + h_2)}{g_c} = \frac{\frac{1}{2}\rho g(h_3 + h_4)\sin\theta}{g_c} \\ &= \frac{1}{2}\gamma(h_1 + h_2) = \frac{1}{2}\gamma(h_3 + h_4)\sin\theta \end{aligned} \quad [\text{U.S.}] \quad 15.18(b)$$

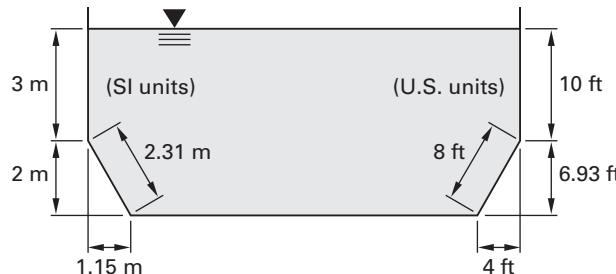

$$R = \bar{p}A \quad 15.19$$

As with the vertical plane surface, the resultant acts at the centroid of the pressure distribution, not at the average depth. Equation 15.16 is rewritten in terms of inclined depths.<sup>10</sup>

$$\begin{aligned} h_R &= \left( \frac{\frac{2}{3}}{\sin\theta} \right) \left( h_1 + h_2 - \frac{h_1 h_2}{h_1 + h_2} \right) \\ &= \frac{2}{3} \left( h_3 + h_4 - \frac{h_3 h_4}{h_3 + h_4} \right) \end{aligned} \quad 15.20$$

### Example 15.4

The tank shown is filled with water ( $\rho = 62.4 \text{ lbm/ft}^3$ ;  $\rho = 1000 \text{ kg/m}^3$ ). (a) What is the total resultant force on a 1 ft (1 m) width of the inclined portion of the wall?<sup>11</sup> (b) At what depth (vertical distance) is the resultant force on the inclined portion of the wall located?

*SI Solution*

(a) The depth of the tank bottom is

$$h_2 = 3 \text{ m} + 2 \text{ m} = 5 \text{ m}$$

<sup>10</sup> $h_R$  is an inclined distance. If a vertical distance is wanted, it must usually be calculated from  $h_R$  and  $\sin\theta$ . Equation 15.20 can be derived simply by dividing Eq. 15.16 by  $\sin\theta$ .

<sup>11</sup>Since the width of the tank (the distance into and out of the illustration) is unknown, it is common to calculate the pressure or force per unit width of tank wall. This is the same as calculating the pressure on a 1 ft (1 m) wide section of wall.

From Eq. 15.18, the average gage pressure on the inclined section is

$$\bar{p} = \left(\frac{1}{2}\right) \left(1000 \frac{\text{kg}}{\text{m}^3}\right) \left(9.81 \frac{\text{m}}{\text{s}^2}\right) (3 \text{ m} + 5 \text{ m}) \\ = 39240 \text{ Pa} \quad (\text{gage})$$

The total resultant force on a 1 m section of the inclined portion of the wall is

$$R = \bar{p}A = (39240 \text{ Pa})(2.31 \text{ m})(1 \text{ m}) \\ = 90644 \text{ N} \quad (90.6 \text{ kN})$$

(b)  $\theta$  must be known to determine  $h_R$ .

$$\theta = \arctan \frac{2 \text{ m}}{1.15 \text{ m}} = 60^\circ$$

From Eq. 15.20, the location of the resultant can be calculated once  $h_3$  and  $h_4$  are known.

$$h_3 = \frac{3 \text{ m}}{\sin 60^\circ} = 3.464 \text{ m}$$

$$h_4 = \frac{5 \text{ m}}{\sin 60^\circ} = 5.774 \text{ m}$$

$$h_R = \left(\frac{2}{3}\right) \left(3.464 \text{ m} + 5.774 \text{ m} - \frac{(3.464 \text{ m})(5.774 \text{ m})}{3.464 \text{ m} + 5.774 \text{ m}}\right) \\ = 4.715 \text{ m} \quad [\text{inclined}]$$

The vertical depth at which the resultant force on the inclined portion of the wall acts is

$$h = h_R \sin \theta = (4.715 \text{ m}) \sin 60^\circ \\ = 4.08 \text{ m} \quad [\text{vertical}]$$

#### Customary U.S. Solution

(a) The water density is given in traditional U.S. mass units. The specific weight,  $\gamma$ , is

$$\gamma = \frac{\rho g}{g_c} = \frac{\left(62.4 \frac{\text{lbfm}}{\text{ft}^3}\right) \left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)}{32.2 \frac{\text{lbfm-ft}}{\text{lbf-sec}^2}} \\ = 62.4 \text{ lbf/ft}^3$$

The depth of the tank bottom is

$$h_2 = 10 \text{ ft} + 6.93 \text{ ft} = 16.93 \text{ ft}$$

From Eq. 15.18, the average gage pressure on the inclined section is

$$\bar{p} = \left(\frac{1}{2}\right) \left(62.4 \frac{\text{lbf}}{\text{ft}^3}\right) (10 \text{ ft} + 16.93 \text{ ft}) \\ = 840.2 \text{ lbf/ft}^2 \quad (\text{gage})$$

The total resultant force on a 1 ft section of the inclined portion of the wall is

$$R = \bar{p}A = \left(840.2 \frac{\text{lbf}}{\text{ft}^2}\right) (8 \text{ ft})(1 \text{ ft}) = 6722 \text{ lbf}$$

(b)  $\theta$  must be known to determine  $h_R$ .

$$\theta = \arctan \frac{6.93 \text{ ft}}{4 \text{ ft}} = 60^\circ$$

From Eq. 15.20, the location of the resultant can be calculated once  $h_3$  and  $h_4$  are known.

$$h_3 = \frac{10 \text{ ft}}{\sin 60^\circ} = 11.55 \text{ ft}$$

$$h_4 = \frac{16.93 \text{ ft}}{\sin 60^\circ} = 19.55 \text{ ft}$$

From Eq. 15.20,

$$h_R = \left(\frac{2}{3}\right) \left(11.55 \text{ ft} + 19.55 \text{ ft} - \frac{(11.55 \text{ ft})(19.55 \text{ ft})}{11.55 \text{ ft} + 19.55 \text{ ft}}\right) \\ = 15.89 \text{ ft} \quad [\text{inclined}]$$

The vertical depth at which the resultant force on the inclined portion of the wall acts is

$$h = h_R \sin \theta = (15.89 \text{ ft}) \sin 60^\circ \\ = 13.76 \text{ ft} \quad [\text{vertical}]$$

## 9. PRESSURE ON A GENERAL PLANE SURFACE

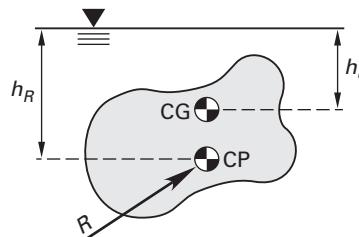

Figure 15.11 illustrates a nonrectangular plane surface that may or may not extend to the liquid surface and that may or may not be inclined, as was shown in Fig. 15.10. As with other regular surfaces, the resultant force depends on the average pressure and acts through the **center of pressure** (CP). The average pressure is calculated from the depth of the surface's centroid (center of gravity, CG).

$$\bar{p} = \rho g h_c \sin \theta \quad [\text{SI}] \quad 15.21(a)$$

$$\bar{p} = \frac{\rho g h_c \sin \theta}{g_c} = \gamma h_c \sin \theta \quad [\text{U.S.}] \quad 15.21(b)$$

$$R = \bar{p}A \quad 15.22$$

**Figure 15.11** General Plane Surface

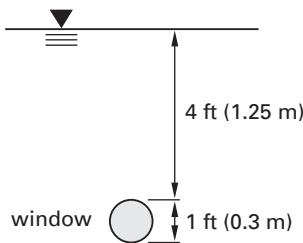

The resultant force acts at depth  $h_R$  normal to the plane surface.  $I_c$  in Eq. 15.23 is the centroidal area moment of inertia about an axis parallel to the surface. Both  $h_c$  and  $h_R$  are measured parallel to the plane surface. That is, if the plane surface is inclined,  $h_c$  and  $h_R$  are inclined distances.

$$h_R = h_c + \frac{I_c}{Ah_c} \quad 15.23$$

### Example 15.5

The top edge of a vertical circular observation window is located 4.0 ft (1.25 m) below the surface of the water. The window is 1.0 ft (0.3 m) in diameter. The water's density is 62.4 lbm/ft<sup>3</sup> (1000 kg/m<sup>3</sup>). Neglect the salinity of the water. (a) What is the resultant force on the window? (b) At what depth does the resultant force act?

#### SI Solution

(a) The radius of the window is

$$r = \frac{0.3 \text{ m}}{2} = 0.15 \text{ m}$$

The depth at which the centroid of the circular window is located is

$$h_c = 1.25 \text{ m} + 0.15 \text{ m} = 1.4 \text{ m}$$

The area of the circular window is

$$A = \pi r^2 = \pi(0.15 \text{ m})^2 = 0.0707 \text{ m}^2$$

The average pressure is

$$\bar{p} = \rho gh_c = \left(1000 \frac{\text{kg}}{\text{m}^3}\right) \left(9.81 \frac{\text{m}}{\text{s}^2}\right) (1.4 \text{ m}) \\ = 13734 \text{ Pa (gage)}$$

The resultant is calculated from Eq. 15.19.

$$R = \bar{p}A = (13734 \text{ Pa})(0.0707 \text{ m}^2) = 971 \text{ N}$$

(b) The centroidal area moment of inertia of a circle is

$$I_c = \frac{\pi}{4} r^4 = \left(\frac{\pi}{4}\right)(0.15 \text{ m})^4 = 3.976 \times 10^{-4} \text{ m}^4$$

<http://wwwbaike.com/wiki/%E6%83%AF%E6%80%A7%E7%9F%A9>  
<https://baike.baidu.com/item/%E6%83%AF%E6%80%A7%E7%9F%A9>

From Eq. 15.23, the depth at which the resultant force acts is

$$h_R = h_c + \frac{I_c}{Ah_c} = 1.4 \text{ m} + \frac{3.976 \times 10^{-4} \text{ m}^4}{(0.0707 \text{ m}^2)(1.4 \text{ m})} \\ = 1.404 \text{ m}$$

#### Customary U.S. Solution

(a) The radius of the window is

$$r = \frac{1 \text{ ft}}{2} = 0.5 \text{ ft}$$

The depth at which the centroid of the circular window is located is

$$h_c = 4.0 \text{ ft} + 0.5 \text{ ft} = 4.5 \text{ ft}$$

The area of the circular window is

$$A = \pi r^2 = \pi(0.5 \text{ ft})^2 = 0.7854 \text{ ft}^2$$

The average pressure is

$$\bar{p} = \gamma h_c = \left(62.4 \frac{\text{lbf}}{\text{ft}^3}\right)(4.5 \text{ ft}) \\ = 280.8 \text{ lbf/ft}^2 \text{ (psfg)}$$

The resultant is calculated from Eq. 15.19.

$$R = \bar{p}A = \left(280.8 \frac{\text{lbf}}{\text{ft}^2}\right)(0.7854 \text{ ft}^2) = 220.5 \text{ lbf}$$

(b) The centroidal area moment of inertia of a circle is

$$I_c = \frac{\pi}{4} r^4 = \left(\frac{\pi}{4}\right)(0.5 \text{ ft})^4 = 0.049 \text{ ft}^4$$

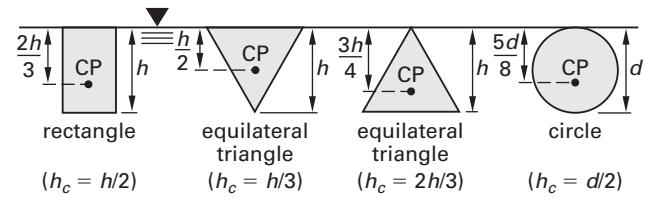

From Eq. 15.23, the depth at which the resultant force acts is

$$h_R = h_c + \frac{I_c}{Ah_c} = 4.5 \text{ ft} + \frac{0.049 \text{ ft}^4}{(0.7854 \text{ ft}^2)(4.5 \text{ ft})} \\ = 4.514 \text{ ft}$$

## 10. SPECIAL CASES: VERTICAL SURFACES

Several simple wall shapes and configurations recur frequently. Figure 15.12 indicates the depths,  $h_R$ , of their hydrostatic pressure resultants (*centers of pressure*). In all cases, the surfaces are vertical and extend to the liquid's surface.

**Figure 15.12** Centers of Pressure for Common Configurations

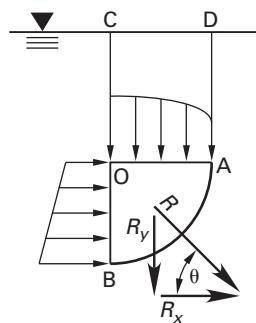

## 11. FORCES ON CURVED AND COMPOUND SURFACES

Figure 15.13 illustrates a curved surface cross section, BA. The resultant force acting on such a curved surface is not difficult to determine, although the  $x$ - and  $y$ -components of the resultant usually must be calculated first. The magnitude and direction of the resultant are found by conventional methods.

$$R = \sqrt{R_x^2 + R_y^2} \quad 15.24$$

$$\theta = \arctan \frac{R_y}{R_x} \quad 15.25$$

**Figure 15.13** Pressure Distributions on a Curved Surface

The horizontal component of the resultant hydrostatic force is found in the same manner as for a vertical plane surface.

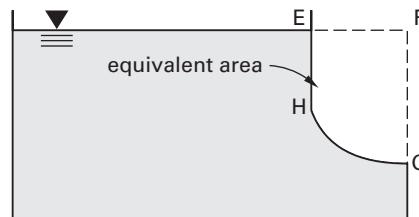

The fact that the surface is curved does not affect the calculation of the horizontal force. In Fig. 15.13, the horizontal pressure distribution on curved surface BA is the same as the horizontal pressure distribution on imaginary projected surface BO.

The vertical component of force on the curved surface is most easily calculated as the weight of the liquid above it.<sup>12</sup> In Fig. 15.13, the vertical component of force on the curved surface BA is the weight of liquid within the area ABCD, with a vertical line of action passing through the centroid of the area ABCD.

Figure 15.14 illustrates a curved surface with no liquid above it. However, it is not difficult to show that the resultant force acting upward on the curved surface HG is equal in magnitude (and opposite in direction) to the force that would be acting downward due to the missing area EFGH. Such an imaginary area used to calculate hydrostatic pressure is known as an *equivalent area*.

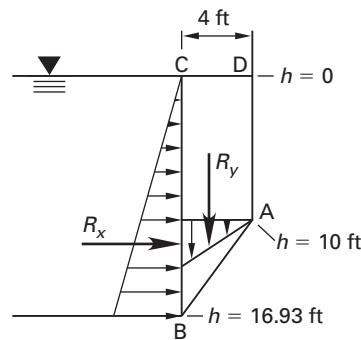

<sup>12</sup>Calculating the vertical force component in this manner is not in conflict with the hydrostatic paradox as long as the cross-sectional area of liquid above the curved surface does not decrease between the curved surface and the liquid's free surface. If there is a change in the cross-sectional area, the vertical component of force is equal to the weight of fluid in an unchanged cross-sectional area (i.e., the equivalent area).

**Figure 15.14** Equivalent Area

### Example 15.6

What is the total resultant force on a 1 ft section of the entire wall in Ex. 15.4?

### Solution

The average depth is

$$\bar{h} = \left(\frac{1}{2}\right)(0 + 16.93 \text{ ft}) = 8.465 \text{ ft}$$

The average pressure and horizontal component of the resultant on a 1 ft section of wall are

$$\begin{aligned} \bar{p} &= \gamma \bar{h} = \left(62.4 \frac{\text{lbf}}{\text{ft}^3}\right)(8.465 \text{ ft}) \\ &= 528.2 \text{ lbf}/\text{ft}^2 \quad (528.2 \text{ psfg}) \end{aligned}$$

$$\begin{aligned} R_x &= \bar{p}A = \left(528.2 \frac{\text{lbf}}{\text{ft}^2}\right)(16.93 \text{ ft})(1 \text{ ft}) \\ &= 8942 \text{ lbf} \end{aligned}$$

The volume of a 1 ft section of area ABCD is

$$\begin{aligned} V_{ABCD} &= (1 \text{ ft})((4 \text{ ft})(10 \text{ ft}) + \left(\frac{1}{2}\right)(4 \text{ ft})(6.93 \text{ ft})) \\ &= 53.86 \text{ ft}^3 \end{aligned}$$

The vertical component is

$$R_y = \gamma V = \left(62.4 \frac{\text{lbf}}{\text{ft}^3}\right)(53.86 \text{ ft}^3) = 3361 \text{ lbf}$$

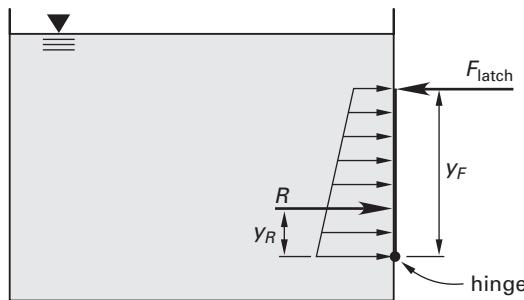

The total resultant force is

$$\begin{aligned} R &= \sqrt{(8942 \text{ lbf})^2 + (3361 \text{ lbf})^2} \\ &= 9553 \text{ lbf} \end{aligned}$$

## 12. TORQUE ON A GATE

When an openable gate or door is submerged in such a manner as to have unequal depths of liquid on its two sides, or when there is no liquid present on one side, the hydrostatic pressure will act to either open or close the door. If the gate does not move, this pressure is resisted, usually by a latching mechanism on the gate itself.<sup>13</sup> The magnitude of the resisting latch force can be determined from the *hydrostatic torque* (*hydrostatic moment*) acting on the gate. (See Fig. 15.15.) The moment is almost always taken with respect to the gate hinges.

**Figure 15.15** Torque on a Hinge (Gate)

The applied moment is calculated as the product of the resultant force on the gate and the distance from the hinge to the resultant on the gate. This applied moment is balanced by the resisting moment, calculated as the latch force times the separation of the latch and hinge.

$$M_{\text{applied}} = M_{\text{resisting}} \quad 15.26$$

$$Ry_R = F_{\text{latch}} y_F \quad 15.27$$

## 13. HYDROSTATIC FORCES ON A DAM

The concepts presented in the preceding sections are applicable to dams. That is, the horizontal force on the dam face can be found as in Ex. 15.6, regardless of inclination or curvature of the dam face. The vertical force on the dam face is calculated as the weight of the water above the dam face. Of course, the vertical force is zero if the dam face is vertical.

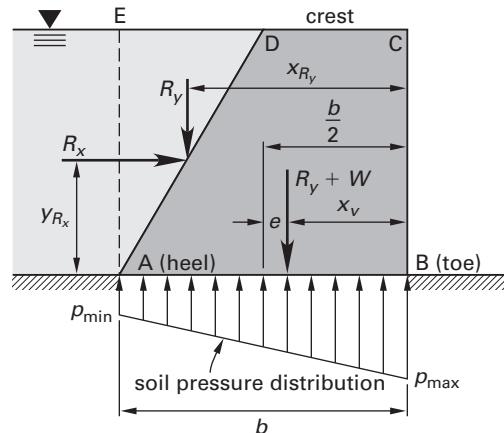

Figure 15.16 illustrates a typical dam, defining its *heel*, *toe*, and *crest*.  $x_{CG}$ , the horizontal distance from the toe to the dam's center of gravity, is not shown.

There are several stability considerations for gravity dams.<sup>14</sup> Most notably, the dam must not tip over or slide away due to the hydrostatic pressure. Furthermore, the pressure distribution within the soil under the dam is not uniform, and soil loading must not be excessive.

<sup>13</sup>Any contribution to resisting force from stiff hinges or other sources of friction is typically neglected.

<sup>14</sup>A *gravity dam* is one that is held in place and orientation by its own mass (weight) and the friction between its base and the ground.

**Figure 15.16** Dam

The *overturning moment* is a measure of the horizontal pressure's tendency to tip the dam over, pivoting it about the toe of the dam (point B in Fig. 15.16). (Usually, moments are calculated with respect to the pivot point.) The overturning moment is calculated as the product of the horizontal component of hydrostatic pressure (i.e., the  $x$ -component of the resultant) and the vertical distance between the toe and the line of action of the force.

$$M_{\text{overturning}} = R_x y_{R_x} \quad 15.28$$

In most configurations, the overturning is resisted jointly by moments from the dam's own weight,  $W$ , and the vertical component of the resultant,  $R_y$  (i.e., the weight of area EAD in Fig. 15.16).<sup>15</sup>

$$M_{\text{resisting}} = R_y x_{R_y} + W x_{CG} \quad 15.29$$

The *factor of safety against overturning* is

$$(FS)_{\text{overturning}} = \frac{M_{\text{resisting}}}{M_{\text{overturning}}} \quad 15.30$$

In addition to causing the dam to tip over, the horizontal component of hydrostatic force will also cause the dam to tend to slide along the ground. This tendency is resisted by the frictional force between the dam bottom and soil. The frictional force,  $F_f$ , is calculated as the product of the *normal force*,  $N$ , and the *coefficient of static friction*,  $\mu$ .

$$F_f = \mu_{\text{static}} N = \mu_{\text{static}} (W + R_y) \quad 15.31$$

The *factor of safety against sliding* is

$$(FS)_{\text{sliding}} = \frac{F_f}{R_x} \quad 15.32$$

The soil pressure distribution beneath the dam is usually assumed to vary linearly from a minimum to a

<sup>15</sup>The density of concrete or masonry with steel reinforcing is usually taken to be approximately 150 lbm/ft<sup>3</sup> (2400 kg/m<sup>3</sup>).

maximum value. (The minimum value must be greater than zero, since soil cannot be in a state of tension. The maximum pressure should not exceed the allowable soil pressure.) Equation 15.33 predicts the minimum and maximum soil pressures.

$$p_{\max}, p_{\min} = \left( \frac{R_y + W}{b} \right) \left( 1 \pm \frac{6e}{b} \right) \quad [\text{per unit width}] \quad 15.33$$

The *eccentricity*,  $e$ , in Eq. 15.33 is the distance between the mid-length of the dam and the line of action of the total vertical force,  $W + R_y$ . (The eccentricity must be less than  $b/6$  for the entire base to be in compression.) Distances  $x_v$  and  $x_{CG}$  are different.

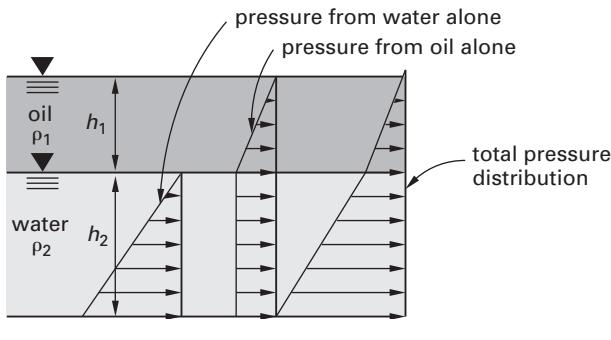

$$e = \frac{b}{2} - x_v \quad 15.34$$

$$x_v = \frac{M_{\text{resisting}} - M_{\text{overturning}}}{R_y + W} \quad 15.35$$

#### 14. PRESSURE DUE TO SEVERAL IMMISCIBLE LIQUIDS

Figure 15.17 illustrates the nonuniform pressure distribution due to two immiscible liquids (e.g., oil on top and water below).

**Figure 15.17** Pressure Distribution from Two Immiscible Liquids

The pressure due to the upper liquid (oil), once calculated, serves as a *surcharge* to the liquid below (water). The pressure at the tank bottom is given by Eq. 15.36. (The principle can be extended to three or more immiscible liquids as well.)

$$p_{\text{bottom}} = \rho_1 gh_1 + \rho_2 gh_2 \quad [\text{SI}] \quad 15.36(a)$$

$$\begin{aligned} p_{\text{bottom}} &= \frac{\rho_1 gh_1}{g_c} + \frac{\rho_2 gh_2}{g_c} \\ &= \gamma_1 h_1 + \gamma_2 h_2 \end{aligned} \quad [\text{U.S.}] \quad 15.36(b)$$

#### 15. PRESSURE FROM COMPRESSIBLE FLUIDS

Fluid density, thus far, has been assumed to be independent of pressure. In reality, even “incompressible” liquids are slightly compressible. Sometimes, the effect of this compressibility cannot be neglected.

The familiar  $p = \rho gh$  equation is a special case of Eq. 15.37. (It is assumed that  $h_2 > h_1$ . The minus sign in Eq. 15.37 indicates that pressure decreases as elevation (height) increases.)

$$\int_{p_1}^{p_2} \frac{dp}{\rho g} = -(h_2 - h_1) \quad [\text{SI}] \quad 15.37(a)$$

$$\int_{p_1}^{p_2} \frac{g_c dp}{\rho g} = -(h_2 - h_1) \quad [\text{U.S.}] \quad 15.37(b)$$

If the fluid is a perfect gas, and if compression is an isothermal (i.e., constant temperature) process, then the relationship between pressure and density is given by Eq. 15.38. The isothermal assumption is appropriate, for example, for the earth’s *stratosphere* (i.e., above 35,000 ft (11 000 m)), where the temperature is assumed to be constant at approximately  $-67^{\circ}\text{F}$  ( $-55^{\circ}\text{C}$ ).

$$pv = \frac{p}{\rho} = RT = \text{constant} \quad 15.38$$

In the isothermal case, Eq. 15.38 can be rewritten as Eq. 15.39. (For air,  $R = 53.35 \text{ ft-lbf/lbm}^{\circ}\text{R}$ ;  $R = 287.03 \text{ J/kg}\cdot\text{K}$ .) Of course, the temperature,  $T$ , must be in degrees absolute (i.e., in  $^{\circ}\text{R}$  or K). Equation 15.39 is known as the *barometric height relationship*<sup>16</sup> because knowledge of atmospheric temperature and the pressures at two points is sufficient to determine the elevation difference between the two points.

$$h_2 - h_1 = \frac{RT}{g} \ln \frac{p_1}{p_2} \quad [\text{SI}] \quad 15.39(a)$$

$$h_2 - h_1 = \frac{g_c RT}{g} \ln \frac{p_1}{p_2} \quad [\text{U.S.}] \quad 15.39(b)$$

The pressure at an elevation (height)  $h_2$  in a layer of perfect gas that has been isothermally compressed is given by Eq. 15.40.

$$p_2 = p_1 e^{g(h_1 - h_2)/RT} \quad [\text{SI}] \quad 15.40(a)$$

$$p_2 = p_1 e^{g(h_1 - h_2)/g_c RT} \quad [\text{U.S.}] \quad 15.40(b)$$

<sup>16</sup>This is equivalent to the work done in an isothermal compression process. The elevation (height) difference,  $h_2 - h_1$  (with units of feet), can be interpreted as the work done per unit mass during compression (with units of ft-lbf/lbm).

If the fluid is a perfect gas, and if compression is an *adiabatic process*, the relationship between pressure and density is given by Eq. 15.41,<sup>17</sup> where  $k$  is the *ratio of specific heats*, a property of the gas. ( $k = 1.4$  for air, hydrogen, oxygen, and carbon monoxide, among others.)

$$pv^k = p\left(\frac{1}{\rho}\right)^k = \text{constant} \quad 15.41$$

The following three equations apply to adiabatic compression of an ideal gas.

$$h_2 - h_1 = \left(\frac{k}{k-1}\right) \left(\frac{RT_1}{g}\right) \left(1 - \left(\frac{p_2}{p_1}\right)^{(k-1)/k}\right) \quad [\text{SI}] \quad 15.42(a)$$

$$h_2 - h_1 = \left(\frac{k}{k-1}\right) \left(\frac{g_c}{g}\right) RT_1 \left(1 - \left(\frac{p_2}{p_1}\right)^{(k-1)/k}\right) \quad [\text{U.S.}] \quad 15.42(b)$$

$$p_2 = p_1 \left(1 - \left(\frac{k-1}{k}\right) \left(\frac{g}{RT_1}\right) (h_2 - h_1)\right)^{k/(k-1)} \quad [\text{SI}] \quad 15.43(a)$$

$$p_2 = p_1 \left(1 - \left(\frac{k-1}{k}\right) \left(\frac{g}{g_c}\right) \left(\frac{h_2 - h_1}{RT_1}\right)\right)^{k/(k-1)} \quad [\text{U.S.}] \quad 15.43(b)$$

$$T_2 = T_1 \left(1 - \left(\frac{k-1}{k}\right) \left(\frac{g}{RT_1}\right) (h_2 - h_1)\right) \quad [\text{SI}] \quad 15.44(a)$$

$$T_2 = T_1 \left(1 - \left(\frac{k-1}{k}\right) \left(\frac{g}{g_c}\right) \left(\frac{h_2 - h_1}{RT_1}\right)\right) \quad [\text{U.S.}] \quad 15.44(b)$$

The three adiabatic compression equations can be used for the more general *polytropic compression* case simply by substituting the *polytropic exponent*,  $n$ , for  $k$ .<sup>18</sup> Unlike the ratio of specific heats, the polytropic exponent is a function of the process, not of the gas. The polytropic compression assumption is appropriate for the earth's *troposphere*.<sup>19</sup> Assuming a linear decrease in temperature along with an altitude of  $-0.00356^\circ\text{F}/\text{ft}$  ( $-0.00649^\circ\text{C}/\text{m}$ ), the polytropic exponent is  $n = 1.235$ .

<sup>17</sup>There is no heat or energy transfer to or from the ideal gas in an adiabatic process. However, this is not the same as an isothermal process.

<sup>18</sup>Actually, polytropic compression is the general process. Isothermal compression is a special case ( $n = 1$ ) of the polytropic process, as is adiabatic compression ( $n = k$ ).

<sup>19</sup>The *troposphere* is the part of the earth's atmosphere we live in and where most atmospheric disturbances occur. The *stratosphere*, starting at approximately 35,000 ft (11,000 m), is cold, clear, dry, and still. Between the troposphere and the stratosphere is the *tropopause*, a transition layer that contains most of the atmosphere's dust and moisture. Temperature actually increases with altitude in the stratosphere and decreases with altitude in the troposphere, but is constant in the tropopause.

### Example 15.7

The air pressure and temperature at sea level are 1.0 standard atmosphere and  $68^\circ\text{F}$  ( $20^\circ\text{C}$ ), respectively. Assume polytropic compression with  $n = 1.235$ . What is the pressure at an altitude of 5000 ft (1525 m)?

*SI Solution*

The absolute temperature of the air is  $20^\circ\text{C} + 273^\circ = 293\text{K}$ . From Eq. 15.43 (substituting  $k = n = 1.235$  for polytropic compression), the pressure at 1525 m altitude is

$$p_2 = (1.0 \text{ atm})$$

$$\times \left(1 - \left(\frac{1.235 - 1}{1.235}\right) \left(9.81 \frac{\text{m}}{\text{s}^2}\right)\right)^{1.235/(1.235-1)} \\ \times \left(\frac{1525 \text{ m}}{\left(287.03 \frac{\text{J}}{\text{kg}\cdot\text{K}}\right)(293\text{K})}\right) \\ = 0.834 \text{ atm}$$

*Customary U.S. Solution*

The absolute temperature of the air is  $68^\circ\text{F} + 460^\circ = 528^\circ\text{R}$ . From Eq. 15.43 (substituting  $k = n = 1.235$  for polytropic compression), the pressure at an altitude of 5000 ft is

$$p_2 = (1.0 \text{ atm})$$

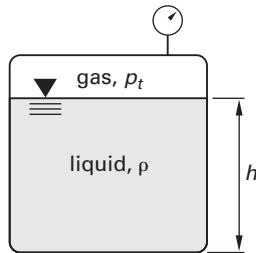

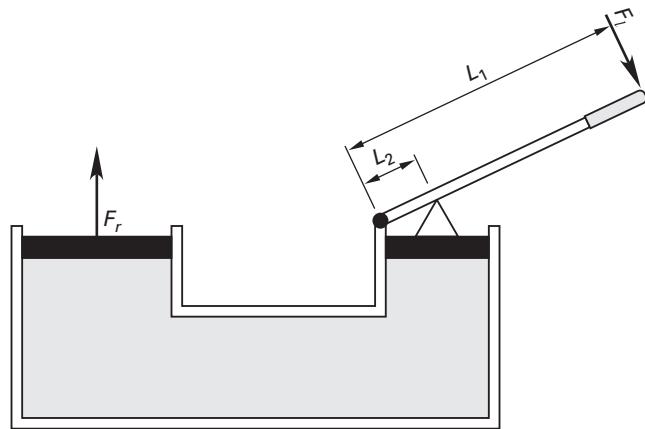

$$\times \left(1 - \left(\frac{1.235 - 1}{1.235}\right) \left(\frac{32.2 \frac{\text{ft}}{\text{sec}^2}}{32.2 \frac{\text{lbf}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2}}\right)\right)^{1.235/(1.235-1)} \\ \times \left(\frac{5000 \text{ ft}}{\left(53.35 \frac{\text{ft-lbf}}{\text{lbf}\cdot\text{ft}^\circ\text{R}}\right)(528^\circ\text{R})}\right) \\ = 0.835 \text{ atm}$$

## 16. EXTERNALLY PRESSURIZED LIQUIDS

If the gas above a liquid in a closed tank is pressurized to a gage pressure of  $p_t$ , this pressure will add to the hydrostatic pressure anywhere in the fluid. The pressure at the tank bottom illustrated in Fig. 15.18 is given by Eq. 15.45.

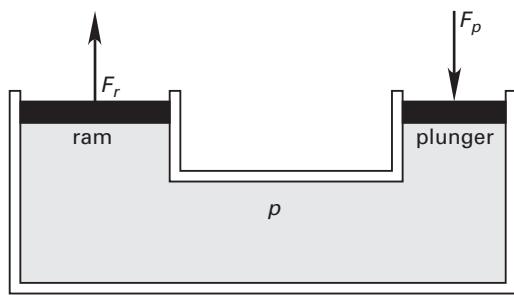

$$p_{\text{bottom}} = p_t + \rho gh \quad [\text{SI}] \quad 15.45(a)$$

$$p_{\text{bottom}} = p_t + \frac{\rho gh}{g_c} = p_t + \gamma h \quad [\text{U.S.}] \quad 15.45(b)$$

**Figure 15.18** Externally Pressurized Liquid**Figure 15.20** Hydraulic Ram with Mechanical Advantage

## 17. HYDRAULIC RAM

A *hydraulic ram* (*hydraulic jack*, *hydraulic press*, *fluid press*, etc.) is illustrated in Fig. 15.19. This is a force-multiplying device. A force,  $F_p$ , is applied to the *plunger*, and a useful force,  $F_r$ , appears at the *ram*. Even though the pressure in the hydraulic fluid is the same on the ram and plunger, the forces on them will be proportional to their respective cross-sectional areas.

**Figure 15.19** Hydraulic Ram

Since the pressure,  $p$ , is the same on both the plunger and ram, Eq. 15.46 can be solved for it.

$$F = pA = p\pi\left(\frac{d^2}{4}\right) \quad 15.46$$

$$p_p = p_r \quad 15.47$$

$$\frac{F_p}{A_p} = \frac{F_r}{A_r} \quad 15.48$$

$$\frac{F_p}{d_p^2} = \frac{F_r}{d_r^2} \quad 15.49$$

A small, manually actuated hydraulic ram will have a lever handle to increase the *mechanical advantage* of the ram from 1.0 to  $M$ , as illustrated in Fig. 15.20. In most cases, the pivot and connection mechanism will not be frictionless, and some of the applied force will be used to overcome the friction. This friction loss is accounted for by a *lever efficiency* or *lever effectiveness*,  $\eta$ .

$$M = \frac{L_1}{L_2} \quad 15.50$$

$$F_p = \eta M F_l \quad 15.51$$

## 18. BUOYANCY

The *buoyant force* is an upward force that acts on all objects that are partially or completely submerged in a fluid. The fluid can be a liquid, as in the case of a ship floating at sea, or the fluid can be a gas, as in a balloon floating in the atmosphere.

There is a buoyant force on all submerged objects, not just those that are stationary or ascending. There will be, for example, a buoyant force on a rock sitting at the bottom of a pond. There will also be a buoyant force on a rock sitting exposed on the ground, since the rock is “submerged” in air. For partially submerged objects floating in liquids, such as icebergs, a buoyant force due to displaced air also exists, although it may be insignificant.

Buoyant force always acts to counteract an object’s weight (i.e., buoyancy acts against gravity). The magnitude of the buoyant force is predicted from *Archimedes’ principle* (*the buoyancy theorem*): The buoyant force on a submerged object is equal to the weight of the displaced fluid.<sup>20</sup> An equivalent statement of Archimedes’ principle is: A floating object displaces liquid equal in weight to its own weight.

$$F_{\text{buoyant}} = \rho g V_{\text{displaced}} \quad [\text{SI}] \quad 15.53(a)$$

$$F_{\text{buoyant}} = \frac{\rho g V_{\text{displaced}}}{g_c} = \gamma V_{\text{displaced}} \quad [\text{U.S.}] \quad 15.53(b)$$

In the case of stationary (i.e., not moving vertically) objects, the buoyant force and object weight are in equilibrium. If the forces are not in equilibrium, the

<sup>20</sup>The volume term in Eq. 15.53 is the total volume of the object only in the case of complete submergence.

object will rise or fall until equilibrium is reached. That is, the object will sink until its remaining weight is supported by the bottom, or it will rise until the weight of displaced liquid is reduced by breaking the surface.<sup>21</sup>

The specific gravity (SG) of an object submerged in water can be determined from its dry and submerged weights. Neglecting the buoyancy of any surrounding gases,

$$\text{SG} = \frac{W_{\text{dry}}}{W_{\text{dry}} - W_{\text{submerged}}} \quad 15.54$$

Figure 15.21 illustrates an object floating partially exposed in a liquid. Neglecting the insignificant buoyant force from the displaced air (or other gas), the fractions,  $x$ , of volume exposed and submerged are easily determined.

$$x_{\text{submerged}} = \frac{\rho_{\text{object}}}{\rho_{\text{liquid}}} = \frac{(\text{SG})_{\text{object}}}{(\text{SG})_{\text{liquid}}} \quad 15.55$$

$$x_{\text{exposed}} = 1 - x_{\text{submerged}} \quad 15.56$$

**Figure 15.21** Partially Submerged Object

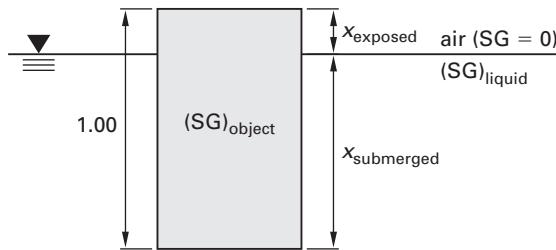

Figure 15.22 illustrates a somewhat more complicated situation—that of an object floating at the interface between two liquids of different densities. The fractions of immersion in each liquid are given by the following equations.

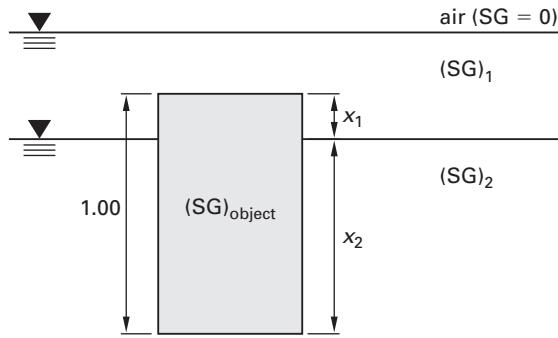

$$x_1 = \frac{(\text{SG})_2 - (\text{SG})_{\text{object}}}{(\text{SG})_2 - (\text{SG})_1} \quad 15.57$$

$$x_2 = 1 - x_1 = \frac{(\text{SG})_{\text{object}} - (\text{SG})_1}{(\text{SG})_2 - (\text{SG})_1} \quad 15.58$$

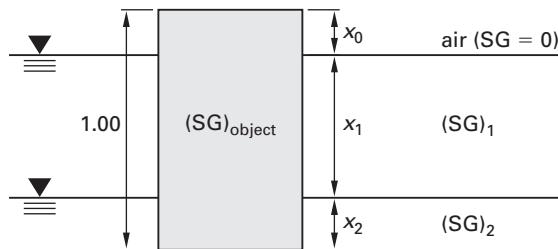

A more general case of a floating object is shown in Fig. 15.23. Situations of this type are easily evaluated by equating the object's weight with the sum of the buoyant forces.

<sup>21</sup>An object can also stop rising or falling due to a change in the fluid's density. The buoyant force will increase with increasing depth in the ocean due to an increase in density at great depths. The buoyant force will decrease with increasing altitude in the atmosphere due to a decrease in density at great heights.

**Figure 15.22** Object Floating in Two Liquids

**Figure 15.23** General Two-Liquid Buoyancy Problem

In the case of Fig. 15.23 (with two liquids), the following relationships apply, where  $x_0$  is the fraction, if any, extending into the air above.

$$(\text{SG})_{\text{object}} = x_1(\text{SG})_1 + x_2(\text{SG})_2 \quad 15.59$$

$$(\text{SG})_{\text{object}} = (1 - x_0 - x_2)(\text{SG})_1 + x_2(\text{SG})_2 \quad 15.60$$

$$(\text{SG})_{\text{object}} = x_1(\text{SG})_1 + (1 - x_0 - x_1)(\text{SG})_2 \quad 15.61$$

### Example 15.8

An empty polyethylene telemetry balloon and payload have a mass of 500 lbm (225 kg). The balloon is filled with helium when the atmospheric conditions are 60°F (15.6°C) and 14.8 psia (102 kPa). The specific gas constant of helium is 2079 J/kg·K (386.3 ft-lbf/lbm·°R). What minimum volume of helium is required for lift-off from a sea-level platform?

*SI Solution*

$$\rho_{\text{air}} = \frac{p}{RT} = \frac{1.02 \times 10^5 \text{ Pa}}{\left(287.03 \frac{\text{J}}{\text{kg}\cdot\text{K}}\right)(15.6^\circ\text{C} + 273^\circ)} \\ = 1.231 \text{ kg/m}^3$$

$$\rho_{\text{helium}} = \frac{1.02 \times 10^5 \text{ Pa}}{\left(2079 \frac{\text{J}}{\text{kg}\cdot\text{K}}\right)(288.6\text{K})} = 0.17 \text{ kg/m}^3$$

$$m = 225 \text{ kg} + \left( 0.17 \frac{\text{kg}}{\text{m}^3} \right) V_{\text{He}}$$

$$m_b = \left( 1.231 \frac{\text{kg}}{\text{m}^3} \right) V_{\text{He}}$$

$$225 \text{ kg} + \left( 0.17 \frac{\text{kg}}{\text{m}^3} \right) V_{\text{He}} = \left( 1.231 \frac{\text{kg}}{\text{m}^3} \right) V_{\text{He}}$$

$$V_{\text{He}} = 212.1 \text{ m}^3$$

### Customary U.S. Solution

The gas densities are

$$\rho_{\text{air}} = \frac{p}{RT} = \frac{\left( 14.8 \frac{\text{lbf}}{\text{in}^2} \right) \left( 12 \frac{\text{in}}{\text{ft}} \right)^2}{\left( 53.35 \frac{\text{ft-lbf}}{\text{lbfm} \cdot ^\circ\text{R}} \right) (60^\circ\text{F} + 460^\circ)} \\ = 0.07682 \text{ lbm/ft}^3$$

$$\gamma_{\text{air}} = \rho \times \frac{g}{g_c} = 0.07682 \text{ lbf/ft}^3$$

$$\rho_{\text{helium}} = \frac{\left( 14.8 \frac{\text{lbf}}{\text{in}^2} \right) \left( 12 \frac{\text{in}}{\text{ft}} \right)^2}{\left( 386.3 \frac{\text{ft-lbf}}{\text{lbfm} \cdot ^\circ\text{R}} \right) (520^\circ\text{R})} \\ = 0.01061 \text{ lbm/ft}^3$$

$$\gamma_{\text{helium}} = 0.01061 \text{ lbf/ft}^3$$

The total weight of the balloon, payload, and helium is

$$W = 500 \text{ lbf} + \left( 0.01061 \frac{\text{lbf}}{\text{ft}^3} \right) V_{\text{He}}$$

The buoyant force is the weight of the displaced air. Neglecting the payload volume, the displaced air volume is the same as the helium volume.

$$F_b = \left( 0.07682 \frac{\text{lbf}}{\text{ft}^3} \right) V_{\text{He}}$$

At lift-off, the weight of the balloon is just equal to the buoyant force.

$$W = F_b$$

$$500 \text{ lbf} + \left( 0.01061 \frac{\text{lbf}}{\text{ft}^3} \right) V_{\text{He}} = \left( 0.07682 \frac{\text{lbf}}{\text{ft}^3} \right) V_{\text{He}} \\ V_{\text{He}} = 7552 \text{ ft}^3$$

### 19. BUOYANCY OF SUBMERGED PIPELINES

Whenever possible, submerged pipelines for river crossings should be completely buried at a level below river scour. This will reduce or eliminate loads and movement due to flutter, scour and fill, drag, collisions, and buoyancy. Submerged pipelines should cross at right angles to the river. For maximum flexibility and ductility, pipelines should be made of thick-walled mild steel.

Submerged pipelines should be weighted to achieve a minimum of 20% negative buoyancy (i.e., an average density of 1.2 times the environment, approximately 72 lbm/ft<sup>3</sup> or 1200 kg/m<sup>3</sup>). Metal or concrete clamps can be used for this purpose, as well as concrete coatings. Thick steel clamps have the advantage of a smaller lateral exposed area (resulting in less drag from river flow), while brittle concrete coatings are sensitive to pipeline flutter and temperature fluctuations.

Due to the critical nature of many pipelines and the difficulty in accessing submerged portions for repair, it is common to provide a parallel auxiliary line. The auxiliary and main lines are provided with crossover and mainline valves, respectively, on high ground at both sides of the river to permit either or both lines to be used.

### 20. INTACT STABILITY: STABILITY OF FLOATING OBJECTS

A stationary object is said to be in *static equilibrium*. However, an object in static equilibrium is not necessarily stable. For example, a coin balanced on edge is in static equilibrium, but it will not return to the balanced position if it is disturbed. An object is said to be *stable* (i.e., in *stable equilibrium*) if it tends to return to the equilibrium position when slightly displaced.

Stability of floating and submerged objects is known as *intact stability*.<sup>22</sup> There are two forces acting on a stationary floating object: the buoyant force and the object's weight. The buoyant force acts upward through the centroid of the displaced volume. This centroid is known as the *center of buoyancy*. The gravitational force on the object (i.e., the object's weight) acts downward through the object's center of gravity.

For a totally submerged object (as in the balloon and submarine shown in Fig. 15.24) to be stable, the center of buoyancy must be above the center of gravity. The object will be stable because a righting moment will be created if the object tips over, since the center of buoyancy will move outward from the center of gravity.

The stability criterion is different for partially submerged objects (e.g., surface ships). If the vessel shown in

<sup>22</sup>The subject of intact stability, being a part of naval architecture curriculum, is not covered extensively in most fluids books. However, it is covered extensively in basic ship design and naval architecture books.

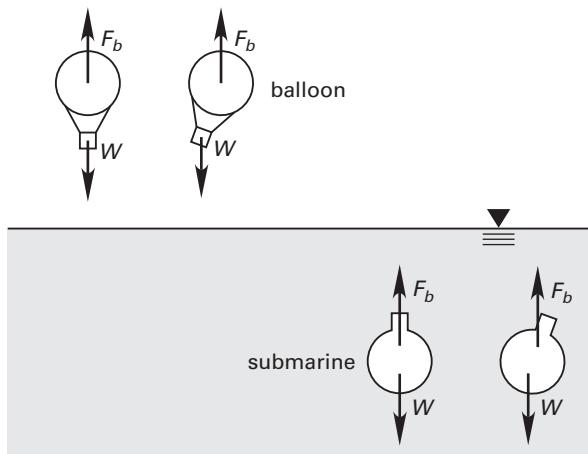

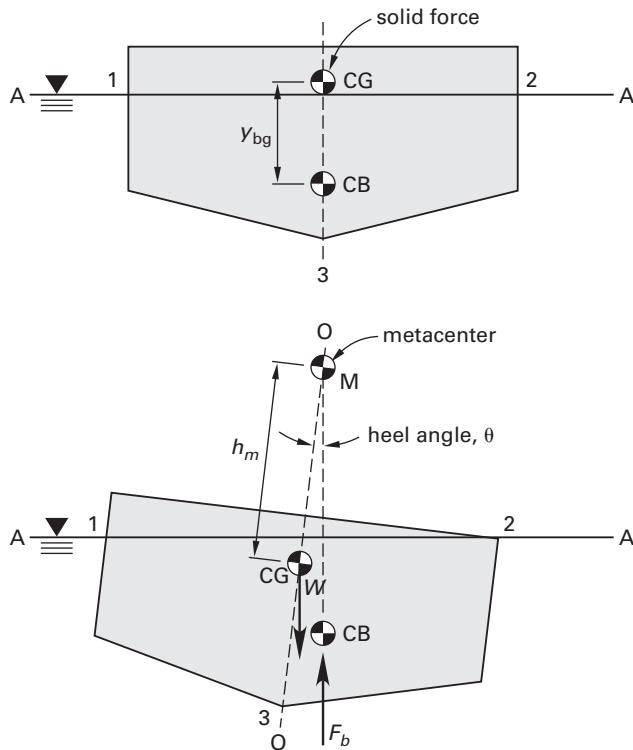

**Figure 15.24** Stability of a Submerged Object

Fig. 15.25 heels (i.e., lists or rolls), the location of the center of gravity of the object does not change.<sup>23</sup> However, the center of buoyancy shifts to the centroid of the new submerged section 123. The centers of buoyancy and gravity are no longer in line.

**Figure 15.25** Stability of a Partially Submerged Floating Object

This righting couple exists when the extension of the buoyant force,  $F_b$ , intersects line O–O above the center of gravity at M, the *metacenter*. For partially submerged objects to be stable, the metacenter must be above the center of gravity. If M lies below the center

<sup>23</sup>The verbs *roll*, *list*, and *heel* are synonymous.

of gravity, an overturning couple will exist. The distance between the center of gravity and the metacenter is called the *metacentric height*, and it is reasonably constant for heel angles less than 10°. Also, for angles less than 10°, the center of buoyancy follows a locus for which the metacenter is the instantaneous center.

The metacentric height is one of the most important and basic parameters in ship design. It determines the ship's ability to remain upright as well as the ship's roll and pitch characteristics.

"Acceptable" minimum values of the metacentric height have been established from experience, and these depend on the ship type and class. For example, many submarines are required to have a metacentric height of 1 ft (0.3 m) when surfaced. This will increase to approximately 3.5 ft (1.2 m) for some of the largest surface ships. If an acceptable metacentric height is not achieved initially, the center of gravity must be lowered or the keel depth increased. The beam width can also be increased slightly to increase the waterplane moment of inertia.

For a surface vessel rolling through an angle less than approximately 10°, the distance between the vertical center of gravity and the metacenter can be found from Eq. 15.62. Variable  $I$  is the centroidal area moment of inertia of the original waterline (free surface) cross section about a longitudinal (fore and aft) waterline axis;  $V$  is the displaced volume.

If the distance,  $y_{bg}$ , separating the centers of buoyancy and gravity is known, Eq. 15.62 can be solved for the metacentric height.  $y_{bg}$  is positive when the center of gravity is above the center of buoyancy. This is the normal case. Otherwise,  $y_{bg}$  is negative.

$$y_{bg} + h_m = \frac{I}{V} \quad 15.62$$

The *righting moment* (also known as the *restoring moment*) is the stabilizing moment exerted when the ship rolls. Values of the righting moment are typically specified with units of foot-tonnes (MN·m).

$$M_{\text{righting}} = h_m \gamma_w V_{\text{displaced}} \sin \theta \quad 15.63$$

The transverse (roll) and longitudinal (pitch) periods also depend on the metacentric height. The roll characteristics are found from the differential equation formed by equating the righting moment to the product of the ship's transverse mass moment of inertia and the angular acceleration. Larger metacentric heights result in lower roll periods. If  $k$  is the radius of gyration about the roll axis, the roll period is

$$T_{\text{roll}} = \frac{2\pi k}{\sqrt{gh_m}} \quad 15.64$$

The roll and pitch periods must be adjusted for the appropriate level of crew and passenger comfort. A "beamy" ice-breaking ship will have a metacentric

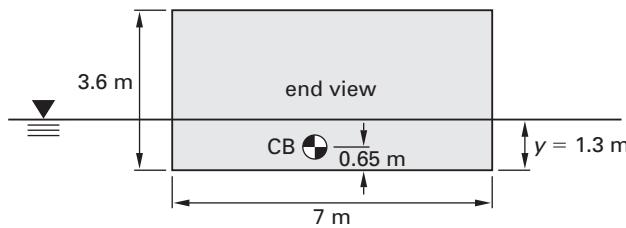

height much larger than normally required for intact stability, resulting in a short, nauseating roll period. The designer of a passenger ship, however, would have to decrease the intact stability (i.e., decrease the metacentric height) in order to achieve an acceptable ride characteristic. This requires a moderate metacentric height that is less than approximately 6% of the beam length.

### Example 15.9

A 600,000 lbm (280 000 kg) rectangular barge has external dimensions of 24 ft width, 98 ft length, and 12 ft height (7 m × 30 m × 3.6 m). It floats in seawater ( $\gamma_w = 64.0 \text{ lbf/ft}^3$ ;  $\rho_w = 1024 \text{ kg/m}^3$ ). The center of gravity is 7.8 ft (2.4 m) from the top of the barge as loaded. Find (a) the location of the center of buoyancy when the barge is floating on an even keel, and (b) the approximate location of the metacenter when the barge experiences a 5° heel.

*SI Solution*

(a) Refer to the following diagram. Let dimension  $y$  represent the depth of the submerged barge.

From Archimedes' principle, the buoyant force equals the weight of the barge. This, in turn, equals the weight of the displaced seawater.

$$F_b = W = V\rho_w g$$

$$(280\,000 \text{ kg}) \left( 9.81 \frac{\text{m}}{\text{s}^2} \right) = y \left( (7 \text{ m})(30 \text{ m}) \right) \left( 1024 \frac{\text{kg}}{\text{m}^3} \right)$$

$$\times \left( 9.81 \frac{\text{m}}{\text{s}^2} \right)$$

$$y = 1.3 \text{ m}$$

The center of buoyancy is located at the centroid of the submerged cross section. When floating on an even keel, the submerged cross section is rectangular with a height of 1.3 m. The height of the center of buoyancy above the keel is

$$\frac{1.3 \text{ m}}{2} = 0.65 \text{ m}$$

(b) While the location of the new center of buoyancy can be determined, the location of the metacenter does not change significantly for small angles of heel. For approximate calculations, the angle of heel is not significant.

The area moment of inertia of the longitudinal waterline cross section is

$$I = \frac{Lw^3}{12} = \frac{(30 \text{ m})(7 \text{ m})^3}{12} = 858 \text{ m}^4$$

The submerged volume is

$$V = (1.3 \text{ m})(7 \text{ m})(30 \text{ m}) = 273 \text{ m}^3$$

The distance between the center of gravity and the center of buoyancy is

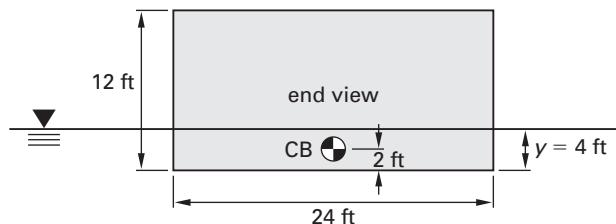

$$y_{bg} = 3.6 \text{ m} - 2.4 \text{ m} - 0.65 \text{ m} = 0.55 \text{ m}$$

The metacentric height measured above the center of gravity is

$$h_m = \frac{I}{V} - y_{bg} = \frac{858 \text{ m}^4}{273 \text{ m}^3} - 0.55 \text{ m} = 2.6 \text{ m}$$

*Customary U.S. Solution*

(a) Refer to the following diagram. Let dimension  $y$  represent the depth of the submerged barge.

From Archimedes' principle, the buoyant force equals the weight of the barge. This, in turn, equals the weight of the displaced seawater.

$$F_b = W = V\gamma_w g$$

$$600,000 \text{ lbf} = y \left( (24 \text{ ft})(98 \text{ ft}) \right) \left( 64 \frac{\text{lbf}}{\text{ft}^3} \right)$$

$$y = 4 \text{ ft}$$

The center of buoyancy is located at the centroid of the submerged cross section. When floating on an even keel, the submerged cross section is rectangular with a height of 4 ft. The height of the center of buoyancy above the keel is

$$\frac{4 \text{ ft}}{2} = 2 \text{ ft}$$

(b) While the location of the new center of buoyancy can be determined, the location of the metacenter does not change significantly for small angles of heel. Therefore, for approximate calculations, the angle of heel is not significant.

The area moment of inertia of the longitudinal waterline cross section is

$$I = \frac{Lw^3}{12} = \frac{(98 \text{ ft})(24 \text{ ft})^3}{12} = 112,900 \text{ ft}^4$$

The submerged volume is

$$V = (4 \text{ ft})(24 \text{ ft})(98 \text{ ft}) = 9408 \text{ ft}^3$$

The distance between the center of gravity and the center of buoyancy is

$$y_{bg} = 12 \text{ ft} - 7.8 \text{ ft} - 2 \text{ ft} = 2.2 \text{ ft}$$

The metacentric height measured above the center of gravity is

$$\begin{aligned} h_m &= \frac{I}{V} - y_{bg} = \frac{112,900 \text{ ft}^4}{9408 \text{ ft}^3} - 2.2 \text{ ft} \\ &= 9.8 \text{ ft} \end{aligned}$$

## 21. FLUID MASSES UNDER EXTERNAL ACCELERATION

If a fluid mass is subjected to an external acceleration (moved sideways, rotated, etc.), an additional force will be introduced. This force will change the equilibrium position of the fluid surface as well as the hydrostatic pressure distribution.

Figure 15.26 illustrates a liquid mass subjected to constant accelerations in the vertical and/or horizontal directions. ( $a_y$  is negative if the acceleration is downward.) The surface is inclined at the angle predicted by Eq. 15.65. The planes of equal hydrostatic pressure beneath the surface are also inclined at the same angle.<sup>24</sup>

$$\theta = \arctan \frac{a_x}{a_y + g} \quad 15.65$$

$$p = \rho(g + a_y)h \quad [\text{SI}] \quad 15.66(a)$$

$$p = \frac{\rho(g + a_y)h}{g_c} = \gamma h \left(1 + \frac{a_y}{g}\right) \quad [\text{U.S.}] \quad 15.66(b)$$

**Figure 15.26** Fluid Mass Under Constant Linear Acceleration

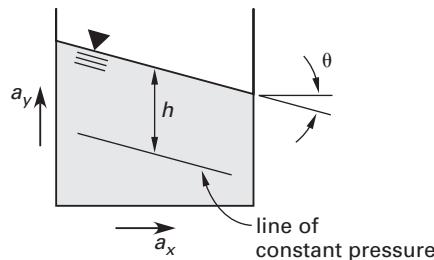

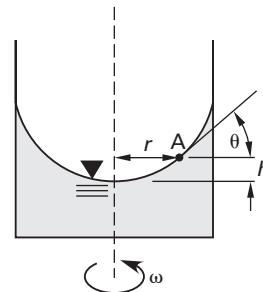

Figure 15.27 illustrates a fluid mass rotating about a vertical axis at constant angular velocity,  $\omega$ , in rad/sec.<sup>25</sup> The resulting surface is parabolic in shape. The elevation of the fluid surface at point A at distance  $r$  from the axis of rotation is given by Eq. 15.68. The distance  $h$  in Fig. 15.27 is measured from the lowest fluid elevation during rotation.  $h$  is not measured from the original elevation of the stationary fluid.

$$\theta = \arctan \frac{\omega^2 r}{g} \quad 15.67$$

$$h = \frac{(\omega r)^2}{2g} = \frac{v^2}{2g} \quad 15.68$$

**Figure 15.27** Rotating Fluid Mass

<sup>24</sup>Once the orientation of the surface is known, the pressure distribution can be determined without considering the acceleration. The hydrostatic pressure at a point depends only on the height of the liquid above that point. The acceleration affects that height but does not change the  $p = \rho gh$  relationship.

<sup>25</sup>Even though the rotational speed is not increasing, the fluid mass experiences a constant *centripetal acceleration* radially outward from the axis of rotation.

## 1. INTRODUCTION TO FLUID ENERGY UNITS

Several important fluids and thermodynamics equations, such as Bernoulli's equation and the steady-flow energy equation, are special applications of the *conservation of energy* concept. However, it is not always obvious how some formulations of these equations can be termed "energy." For example, elevation, *z*, with units of feet, is often called *gravitational energy*.

Fluid energy is expressed per unit mass, as indicated by the name, *specific energy*. Units of fluid specific energy are commonly ft-lbf/lbm and J/kg.<sup>1</sup>

## 2. KINETIC ENERGY

Energy is needed to accelerate a stationary body. Therefore, a moving mass of fluid possesses more energy than an identical, stationary mass. The energy difference is the *kinetic energy* of the fluid.<sup>2</sup> If the kinetic energy is

<sup>1</sup>The ft-lbf/lbm unit may be thought of as just "ft," although lbf and lbm do not really cancel out. The combination of variables  $E \times (g_d/g)$  is required in order for the units to resolve into "ft."

<sup>2</sup>The terms *velocity energy* and *dynamic energy* are used less often.

evaluated per unit mass, the term *specific kinetic energy* is used. Equation 16.1 gives the specific kinetic energy corresponding to a fluid flow with average velocity,  $v$ .

$$E_v = \frac{v^2}{2} \quad [\text{SI}] \quad 16.1(a)$$

$$E_v = \frac{v^2}{2g_c} \quad [\text{U.S.}] \quad 16.1(b)$$

### 3. POTENTIAL ENERGY

Work is performed in elevating a body. Therefore, a mass of fluid at a high elevation will have more energy than an identical mass of fluid at a lower elevation. The energy difference is the *potential energy* of the fluid.<sup>3</sup> Like kinetic energy, potential energy is usually expressed per unit mass. Equation 16.2 gives the potential energy of fluid at an elevation  $z$ .<sup>4</sup>

$$E_z = zg \quad [\text{SI}] \quad 16.2(a)$$

$$E_z = \frac{zg}{g_c} \quad [\text{U.S.}] \quad 16.2(b)$$

The units of potential energy in a consistent system are again  $\text{m}^2/\text{s}^2$  or  $\text{ft}^2/\text{sec}^2$ . The units in a traditional English system are  $\text{ft-lbf/lbm}$ .

$z$  is the elevation of the fluid. The reference point (i.e., zero elevation point) is entirely arbitrary and can be chosen for convenience. This is because potential energy always appears in a difference equation (i.e.,  $\Delta E_z$ ), and the reference point cancels out.

### 4. PRESSURE ENERGY

Work is performed and energy is added when a substance is compressed. Therefore, a mass of fluid at a high pressure will have more energy than an identical mass of fluid at a lower pressure. The energy difference is the *pressure energy* of the fluid.<sup>5</sup> Pressure energy is usually found in equations along with kinetic and potential energies and is expressed as energy per unit mass. Equation 16.3 gives the pressure energy of fluid at pressure  $p$ .

$$E_p = \frac{p}{\rho} \quad 16.3$$

<sup>3</sup>The term *gravitational energy* is also used.

<sup>4</sup>Since  $g = g_c$  (numerically), it is tempting to write  $E_z = z$ . In fact, many engineers in the United States do just that.

<sup>5</sup>The terms *static energy* and *flow energy* are also used. The name *flow energy* results from the need to push (pressurize) a fluid to get it to flow through a pipe. However, flow energy and kinetic energy are not the same.

### 5. BERNOULLI EQUATION

The *Bernoulli equation* is an ideal energy conservation equation based on several reasonable assumptions. The equation assumes the following.

- The fluid is incompressible.
- There is no fluid friction.
- Changes in thermal energy are negligible.<sup>6</sup>

The Bernoulli equation states that the *total energy* of a fluid flowing without friction losses in a pipe is constant.<sup>7</sup> The total energy possessed by the fluid is the sum of its pressure, kinetic, and potential energies. Drawing on Eq. 16.1, Eq. 16.2, and Eq. 16.3, the Bernoulli equation is written as

$$E_t = E_p + E_v + E_z \quad 16.4$$

$$E_t = \frac{p}{\rho} + \frac{v^2}{2} + zg \quad [\text{SI}] \quad 16.5(a)$$

$$E_t = \frac{p}{\rho} + \frac{v^2}{2g_c} + \frac{zg}{g_c} \quad [\text{U.S.}] \quad 16.5(b)$$

Equation 16.5 is valid for both laminar and turbulent flows. Since the original research by Bernoulli assumed laminar flow, when Eq. 16.5 is used for turbulent flow, it may be referred to as the “steady-flow energy equation” instead of the “Bernoulli equation.” It can also be used for gases and vapors if the incompressibility assumption is valid.<sup>8</sup>

The quantities known as *total head*,  $h_t$ , and *total pressure*,  $p_t$ , can be calculated from total energy.

$$h_t = \frac{E_t}{g} \quad [\text{SI}] \quad 16.6(a)$$

$$h_t = E_t \times \frac{g_c}{g} \quad [\text{U.S.}] \quad 16.6(b)$$

$$p_t = \rho gh_t \quad [\text{SI}] \quad 16.7(a)$$

$$p_t = \rho h_t \times \frac{g}{g_c} \quad [\text{U.S.}] \quad 16.7(b)$$

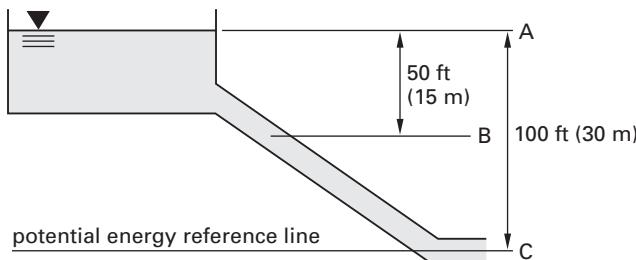

#### Example 16.1

A pipe draws water from the bottom of a reservoir and discharges it freely at point C, 100 ft (30 m) below the surface. The flow is frictionless. (a) What is the total specific energy at an elevation 50 ft (15 m) below the water surface (i.e., point B)? (b) What is the velocity at point C?

<sup>6</sup>In thermodynamics, the fluid flow is said to be *adiabatic*.

<sup>7</sup>Strictly speaking, this is the *total specific energy*, since the energy is per unit mass. However, the word “specific,” being understood, is seldom used. Of course, “the total energy of the system” means something else and requires knowing the fluid mass in the system.

<sup>8</sup>A gas or vapor can be considered to be incompressible as long as its pressure does not change by more than 10% between the entrance and exit, and its velocity is less than Mach 0.3 everywhere.

**SI Solution**

(a) At point A, the velocity and gage pressure are both zero. Therefore, the total energy consists only of potential energy. Choose point C as the reference ( $z = 0$ ) elevation.

$$\begin{aligned} E_A &= z_A g = (30 \text{ m}) \left( 9.81 \frac{\text{m}}{\text{s}^2} \right) \\ &= 294.3 \text{ m}^2/\text{s}^2 \quad (\text{J/kg}) \end{aligned}$$

At point B, the fluid is moving and possesses kinetic energy. The fluid is also under hydrostatic pressure and possesses pressure energy. These energy forms have come at the expense of potential energy. (This is a direct result of the Bernoulli equation.) Also, the flow is frictionless. Therefore, there is no net change in the total energy between points A and B.

$$E_B = E_A = 294.3 \text{ m}^2/\text{s}^2 \quad (\text{J/kg})$$

(b) At point C, the gage pressure and pressure energy are again zero, since the discharge is at atmospheric pressure. The potential energy is zero, since  $z = 0$ . The total energy of the system has been converted to kinetic energy. From Eq. 16.5,

$$\begin{aligned} E_t &= 294.3 \frac{\text{m}^2}{\text{s}^2} = 0 + \frac{v^2}{2} + 0 \\ v &= 24.3 \text{ m/s} \end{aligned}$$

**Customary U.S. Solution**

$$\begin{aligned} (a) \quad E_A &= \frac{z_A g}{g_c} = \frac{(100 \text{ ft}) \left( 32.2 \frac{\text{ft}}{\text{sec}^2} \right)}{32.2 \frac{\text{lbf-ft}}{\text{lbf-sec}^2}} \\ &= 100 \text{ ft-lbf/lbm} \\ E_t &= E_B = E_A = 100 \text{ ft-lbf/lbm} \end{aligned}$$

$$\begin{aligned} (b) \quad E_t &= E_C = 100 \frac{\text{ft-lbf}}{\text{lbf}} = 0 + \frac{v^2}{2g_c} + 0 \\ v^2 &= 2g_c E_t = (2) \left( 32.2 \frac{\text{lbf-ft}}{\text{lbf-sec}^2} \right) \left( 100 \frac{\text{ft-lbf}}{\text{lbf}} \right) \\ &= 6440 \text{ ft}^2/\text{sec}^2 \\ v &= \sqrt{6440 \frac{\text{ft}^2}{\text{sec}^2}} = 80.2 \text{ ft/sec} \end{aligned}$$

**Example 16.2**

Water (62.4 lbm/ft<sup>3</sup>; 1000 kg/m<sup>3</sup>) is pumped up a hillside into a reservoir. The pump discharges water with a velocity of 6 ft/sec (2 m/s) and a pressure of 150 psig (1000 kPa). Disregarding friction, what is the maximum elevation (above the centerline of the pump's discharge) of the reservoir's water surface?

**SI Solution**

At the centerline of the pump's discharge, the potential energy is zero. The atmospheric pressure at the pump inlet is the same as (and counteracts) the atmospheric pressure at the reservoir surface, so gage pressures may be used. The pressure and velocity energies are

$$E_p = \frac{p}{\rho} = \frac{(1000 \text{ kPa}) \left( 1000 \frac{\text{Pa}}{\text{kPa}} \right)}{1000 \frac{\text{kg}}{\text{m}^3}} = 1000 \text{ J/kg}$$

$$E_v = \frac{v^2}{2} = \frac{\left( 2 \frac{\text{m}}{\text{s}} \right)^2}{2} = 2 \text{ J/kg}$$

The total energy at the pump's discharge is

$$\begin{aligned} E_{t,1} &= E_p + E_v = 1000 \frac{\text{J}}{\text{kg}} + 2 \frac{\text{J}}{\text{kg}} \\ &= 1002 \text{ J/kg} \end{aligned}$$

Since the flow is frictionless, the same energy is possessed by the water at the reservoir's surface. Since the velocity and gage pressure at the surface are zero, all of the available energy has been converted to potential energy.

$$E_{t,2} = E_{t,1}$$

$$z_2 g = 1002 \text{ J/kg}$$

$$z_2 = \frac{E_{t,2}}{g} = \frac{1002 \frac{\text{J}}{\text{kg}}}{9.81 \frac{\text{m}}{\text{s}^2}} = 102.1 \text{ m}$$

The volumetric flow rate of the water is not relevant since the water velocity was known. Similarly, the pipe size is not needed.

**Customary U.S. Solution**

The atmospheric pressure at the pump inlet is the same as (and counteracts) the atmospheric pressure at the reservoir surface, so gage pressures may be used.

$$\begin{aligned} E_p &= \frac{p}{\rho} = \frac{\left( 150 \frac{\text{lbf}}{\text{in}^2} \right) \left( 12 \frac{\text{in}}{\text{ft}} \right)^2}{62.4 \frac{\text{lbf}}{\text{ft}^3}} \\ &= 346.15 \text{ ft-lbf/lbm} \end{aligned}$$

$$E_v = \frac{v^2}{2g_c} = \frac{\left(6 \frac{\text{ft}}{\text{sec}}\right)^2}{(2)(32.2 \frac{\text{lbf-ft}}{\text{lbf-sec}^2})} = 0.56 \text{ ft-lbf/lbm}$$

$$E_{t,1} = E_p + E_v = 346.15 \frac{\text{ft-lbf}}{\text{lbm}} + 0.56 \frac{\text{ft-lbf}}{\text{lbm}} = 346.71 \text{ ft-lbf/lbm}$$

$$E_{t,2} = E_{t,1}$$

$$\frac{z_2 g}{g_c} = 346.71 \text{ ft-lbf/lbm}$$

$$z_2 = \frac{E_{t,2} g_c}{g} = \frac{(346.71 \frac{\text{ft-lbf}}{\text{lbm}})(32.2 \frac{\text{lbf-ft}}{\text{lbf-sec}^2})}{32.2 \frac{\text{ft}}{\text{sec}^2}} = 346.71 \text{ ft}$$

## 6. IMPACT ENERGY

*Impact energy*,  $E_i$ , (also known as *stagnation energy* and *total energy*), is the sum of the kinetic and pressure energy terms.<sup>9</sup> Equation 16.9 is applicable to liquids and gases flowing with velocities less than approximately Mach 0.3.

$$E_i = E_p + E_v \quad 16.8$$

$$E_i = \frac{p}{\rho} + \frac{v^2}{2} \quad [\text{SI}] \quad 16.9(a)$$

$$E_i = \frac{p}{\rho} + \frac{v^2}{2g_c} \quad [\text{U.S.}] \quad 16.9(b)$$

*Impact head*,  $h_i$ , is calculated from the impact energy in a manner analogous to Eq. 16.6. Impact head represents the height the liquid will rise in a piezometer-pitot tube when the liquid has been brought to rest (i.e., stagnated) in an adiabatic manner. Such a case is illustrated in Fig. 16.1. If a gas or high-velocity, high-pressure liquid is flowing, it will be necessary to use a mercury manometer or pressure gauge to measure stagnation head.

## 7. PITOT TUBE

A *pitot tube* (also known as an *impact tube* or *stagnation tube*) is simply a hollow tube that is placed longitudinally in the direction of fluid flow, allowing the flow to enter one end at the fluid's *velocity of approach*. (See Fig. 16.2.)

<sup>9</sup>It is confusing to label Eq. 16.8 *total* when the gravitational energy term has been omitted. However, the reference point for gravitational energy is arbitrary, and in this application the reference coincides with the centerline of the fluid flow. In truth, the effective pressure developed in a fluid which has been brought to rest adiabatically does not depend on the elevation or altitude of the fluid. This situation is seldom ambiguous. The application will determine which definition of total head or total energy is intended.

Figure 16.1 Pitot Tube-Piezometer Apparatus

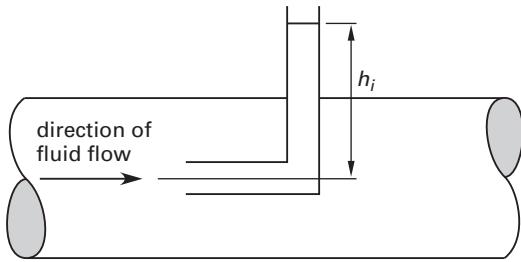

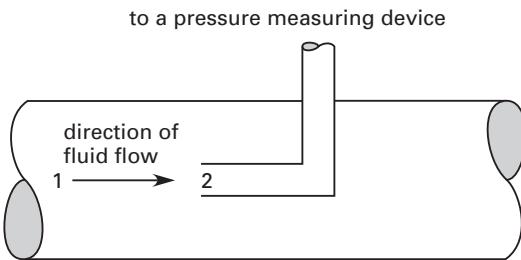

Figure 16.2 Pitot Tube

It is used to measure velocity of flow and finds uses in both subsonic and supersonic applications.

When the fluid enters the pitot tube, it is forced to come to a stop (at the *stagnation point*), and the velocity energy is transformed into pressure energy. If the fluid is a low-velocity gas, the stagnation is assumed to occur without compression heating of the gas. If there is no friction (the common assumption), the process is said to be adiabatic.

Bernoulli's equation can be used to predict the static pressure at the stagnation point. Since the velocity of the fluid within the pitot tube is zero, the upstream velocity can be calculated if the static and stagnation pressures are known.

$$\frac{p_1}{\rho} + \frac{v_1^2}{2} = \frac{p_2}{\rho} \quad 16.10$$

$$v_1 = \sqrt{\frac{2(p_2 - p_1)}{\rho}} \quad [\text{SI}] \quad 16.11(a)$$

$$v_1 = \sqrt{\frac{2g_c(p_2 - p_1)}{\rho}} \quad [\text{U.S.}] \quad 16.11(b)$$

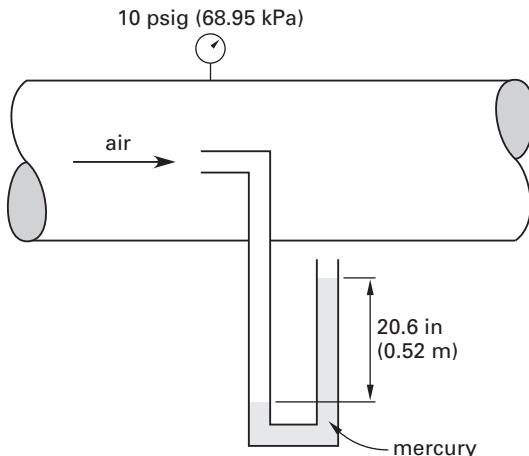

In reality, both friction and heating occur, and the fluid may be compressible. These errors are taken care of by a correction factor known as the *impact factor*,  $C_i$ , which is applied to the derived velocity.  $C_i$  is usually very close to 1.00 (e.g., 0.99 or 0.995).

$$V_{\text{actual}} = C_i V_{\text{indicated}}$$

Since accurate measurements of fluid velocity are dependent on one-dimensional fluid flow, it is essential that any obstructions or pipe bends be more than 10 pipe diameters upstream from the pitot tube.

**Example 16.3**

The static pressure of air ( $0.075 \text{ lbm/ft}^3$ ;  $1.20 \text{ kg/m}^3$ ) flowing in a pipe is measured by a precision gauge to be 10.00 psig (68.95 kPa). A pitot tube-manometer indicates 20.6 in (0.523 m) of mercury. The density of mercury is  $0.491 \text{ lbm/in}^3$  ( $13\,600 \text{ kg/m}^3$ ). Losses are insignificant. What is the velocity of the air in the pipe?

*SI Solution*

The impact pressure is

$$\begin{aligned} p_i &= \rho gh \\ &= \frac{\left(13\,600 \frac{\text{kg}}{\text{m}^3}\right)\left(9.81 \frac{\text{m}}{\text{s}^2}\right)(0.523 \text{ m})}{1000 \frac{\text{Pa}}{\text{kPa}}} \\ &= 69.78 \text{ kPa} \end{aligned}$$

From Eq. 16.11, the velocity is

$$\begin{aligned} v &= \sqrt{\frac{2(p_i - p_s)}{\rho}} \\ &= \sqrt{\frac{(2)(69.78 \text{ kPa} - 68.95 \text{ kPa})(1000 \frac{\text{Pa}}{\text{kPa}})}{1.20 \frac{\text{kg}}{\text{m}^3}}} \\ &= 37.2 \text{ m/s} \end{aligned}$$

*Customary U.S. Solution*

The impact pressure is

$$\begin{aligned} p_i &= \frac{\rho gh}{g_c} = \frac{\left(0.491 \frac{\text{lbm}}{\text{in}^3}\right)\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)(20.6 \text{ in})}{32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2}} \\ &= 10.11 \text{ lbf/in}^2 \quad (10.11 \text{ psig}) \end{aligned}$$

Since impact pressure is the sum of the static and kinetic (velocity) pressures, the kinetic pressure is

$$\begin{aligned} p_v &= p_i - p_s \\ &= 10.11 \text{ psig} - 10.00 \text{ psig} \\ &= 0.11 \text{ psi} \end{aligned}$$

From Eq. 16.11, the velocity is

$$\begin{aligned} v &= \sqrt{\frac{2g_c(p_i - p_s)}{\rho}} \\ &= \sqrt{\frac{(2)\left(32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2}\right)\left(0.11 \frac{\text{lbf}}{\text{in}^2}\right)\left(12 \frac{\text{in}}{\text{ft}}\right)^2}{0.075 \frac{\text{lbm}}{\text{ft}^3}}} \\ &= 116.6 \text{ ft/sec} \end{aligned}$$

## 8. HYDRAULIC RADIUS

The *hydraulic radius* is defined as the area in flow divided by the *wetted perimeter*.<sup>10</sup> (The hydraulic radius is not the same as the radius of a pipe.) The area in flow is the cross-sectional area of the fluid flowing. When a fluid is flowing under pressure in a pipe (i.e., *pressure flow* in a *pressure conduit*), the area in flow will be the internal area of the pipe. However, the fluid may not completely fill the pipe and may flow simply because of a sloped surface (i.e., *gravity flow* or *open channel flow*).

The wetted perimeter is the length of the line representing the interface between the fluid and the pipe or channel. It does not include the *free surface* length (i.e., the interface between fluid and atmosphere).

$$r_h = \frac{\text{area in flow}}{\text{wetted perimeter}} = \frac{A}{s} \quad 16.12$$

Consider a circular pipe flowing completely full. The area in flow is  $\pi r^2$ . The wetted perimeter is the entire circumference,  $2\pi r$ . The hydraulic radius is

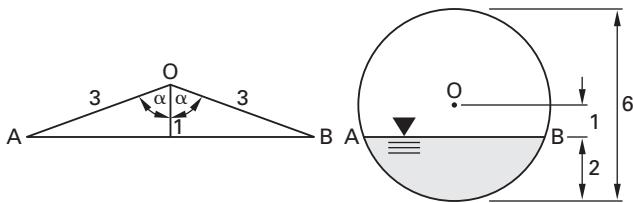

$$r_{h,\text{pipe}} = \frac{\pi r^2}{2\pi r} = \frac{r}{2} = \frac{D}{4} \quad 16.13$$

The hydraulic radius of a pipe flowing half full is also  $r/2$ , since the flow area and wetted perimeter are both halved. However, it is time-consuming to calculate the hydraulic radius for pipe flow at any intermediate depth, due to the difficulty in evaluating the flow area and wetted perimeter. Appendix 16.A greatly simplifies such calculations.

<sup>10</sup>The hydraulic radius can also be calculated as one-fourth of the hydraulic diameter of the pipe or channel, as will be subsequently shown. That is,  $r_h = \frac{1}{4}D_h$ .

**Example 16.4**

A pipe (internal diameter = 6) carries water with a depth of 2 flowing under the influence of gravity. (a) Calculate the hydraulic radius analytically. (b) Verify the result by using App. 16.A.

**Solution**

(a) Use App. 7.A. The equations for a circular segment must be used. The radius is  $6/2 = 3$ .

Points A, O, and B are used to find the central angle of the circular segment.

$$\begin{aligned}\phi &= 2\alpha = 2 \arccos \frac{1}{3} = (2)(70.53^\circ) \\ &= 141.06^\circ\end{aligned}$$

$\phi$  must be expressed in radians.

$$\phi = 2\pi \left( \frac{141.06^\circ}{360^\circ} \right) = 2.46 \text{ rad}$$

The area of the circular segment (i.e., the area in flow) is

$$\begin{aligned}A &= \frac{1}{2}r^2(\phi - \sin \phi) \quad [\phi \text{ in radians}] \\ &= \left(\frac{1}{2}\right)(3)^2(2.46 \text{ rad} - \sin(2.46 \text{ rad})) \\ &= 8.235\end{aligned}$$

The arc length (i.e., the wetted perimeter) is

$$s = r\phi = (3)(2.46 \text{ rad}) = 7.38$$

The hydraulic radius is

$$r_h = \frac{A}{s} = \frac{8.235}{7.38} = 1.12$$

(b) The ratio  $d/D$  is needed to use App. 16.A.

$$\frac{d}{D} = \frac{2}{6} = 0.333$$

From App. 16.A,

$$\frac{r_h}{D} \approx 0.186$$

$$r_h = (0.186)(6) = 1.12$$

**9. HYDRAULIC DIAMETER**

Many fluid, thermodynamic, and heat transfer processes are dependent on the physical length of an object. This controlling variable is generally known as the *characteristic dimension*. The characteristic

dimension in evaluating fluid flow is the *hydraulic diameter* (also known as the *equivalent hydraulic diameter*).<sup>11</sup> The hydraulic diameter for a full-flowing pipe is simply its inside diameter. The hydraulic diameters of other cross sections in flow are given in Table 16.1. If the hydraulic radius is known, it can be used to calculate the hydraulic diameter.

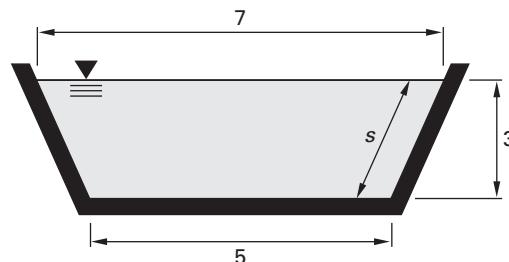

$$D_h = 4r_h \quad 16.14$$

**Table 16.1** Hydraulic Diameters for Common Conduit Shapes

conduit cross section	$D_h$
flowing full	
circle	$D$
annulus (outer diameter $D_o$ , inner diameter $D_i$ )	$D_o - D_i$
square (side $L$ )	$L$
rectangle (sides $L_1$ and $L_2$ )	$\frac{2L_1 L_2}{L_1 + L_2}$
flowing partially full	
half-filled circle (diameter $D$ )	$D$
rectangle ( $h$ deep, $L$ wide)	$\frac{4hL}{L + 2h}$
wide, shallow stream ( $h$ deep)	$4h$
triangle, vertex down ( $h$ deep, $L$ broad, $s$ side)	$\frac{hL}{s}$
trapezoid ( $h$ deep, $a$ wide at top, $b$ wide at bottom, $s$ side)	$\frac{2h(a + b)}{b + 2s}$

**Example 16.5**

Determine the hydraulic diameter and hydraulic radius for the open trapezoidal channel shown.

<sup>11</sup>The engineering community is very inconsistent, but the three terms *hydraulic depth*, *hydraulic diameter*, and *equivalent diameter* do not have the same meanings. Hydraulic depth (flow area divided by exposed surface width) is a characteristic length used in Froude number and other open channel flow calculations. Hydraulic diameter (four times the area in flow divided by the wetted surface) is a characteristic length used in Reynolds number and friction loss calculations. Equivalent diameter  $(1.3(ab)^{0.625}/(a + b)^{0.25})$  is the diameter of a round duct or pipe that will have the same friction loss per unit length as a noncircular duct. Unfortunately, these terms are often used interchangeably.

**Solution**

The batter of the inclined walls is  $(7 - 5)/2$  walls = 1.

$$s = \sqrt{(3)^2 + (1)^2} = 3.16$$

Using Table 16.1,

$$D_h = \frac{2h(a+b)}{b+2s} = \frac{(2)(3)(7+5)}{5+(2)(3.16)} = 6.36$$

From Eq. 16.14,

$$r_h = \frac{D_h}{4} = \frac{6.36}{4} = 1.59$$

**10. REYNOLDS NUMBER**

The *Reynolds number*,  $Re$ , is a dimensionless number interpreted as the ratio of inertial forces to viscous forces in the fluid.<sup>12</sup>

$$Re = \frac{\text{inertial forces}}{\text{viscous forces}} \quad 16.15$$

The inertial forces are proportional to the flow diameter, velocity, and fluid density. (Increasing these variables will increase the momentum of the fluid in flow.) The viscous force is represented by the fluid's absolute viscosity,  $\mu$ . Thus, the Reynolds number is calculated as

$$Re = \frac{D_h v \rho}{\mu} \quad [\text{SI}] \quad 16.16(a)$$

$$Re = \frac{D_h v \rho}{g_c \mu} \quad [\text{U.S.}] \quad 16.16(b)$$

Since  $\mu/\rho$  is defined as the *kinematic viscosity*,  $\nu$ , Eq. 16.16 can be simplified.

$$Re = \frac{D_h v}{\nu} \quad 16.17$$

Occasionally, the *mass flow rate per unit area*,  $G = \rho v$ , will be known. This variable expresses the quantity of fluid flowing in  $\text{kg}/\text{m}^2 \cdot \text{s}$  or  $\text{lbm}/\text{ft}^2 \cdot \text{sec}$ .

$$G = \frac{\dot{m}}{A} \quad 16.18$$

$$Re = \frac{D_h G}{\mu} \quad [\text{SI}] \quad 16.19(a)$$

$$Re = \frac{D_h G}{g_c \mu} \quad [\text{U.S.}] \quad 16.19(b)$$

<sup>12</sup>Engineering authors are not in agreement about the symbol for the Reynolds number. In addition to  $Re$  (used in this book), engineers commonly use  $\mathbf{Re}$ ,  $R$ ,  $\mathfrak{R}$ ,  $N_{Re}$ , and  $N_R$ .

**11. LAMINAR FLOW**

Laminar flow gets its name from the word *laminae* (layers). If all of the fluid particles move in paths parallel to the overall flow direction (i.e., in layers), the flow is said to be *laminar*. (The terms *viscous flow* and *streamline flow* are also used.) This occurs in pipeline flow when the Reynolds number is less than (approximately) 2100. Laminar flow is typical when the flow channel is small, the velocity is low, and the fluid is viscous. Viscous forces are dominant in laminar flow.

In laminar flow, a stream of dye inserted in the flow will continue from the source in a continuous, unbroken line with very little mixing of the dye and surrounding liquid. The fluid particle paths coincide with imaginary *streamlines*. (Streamlines and velocity vectors are always tangent to each other.) A "bundle" of these streamlines (i.e., a *streamtube*) constitutes a complete fluid flow.

**12. TURBULENT FLOW**

A fluid is said to be in *turbulent flow* if the Reynolds number is greater than (approximately) 4000. Turbulent flow is characterized by a three-dimensional movement of the fluid particles superimposed on the overall direction of motion. A stream of dye injected into a turbulent flow will quickly disperse and uniformly mix with the surrounding flow. Inertial forces dominate in turbulent flow. At very high Reynolds numbers, the flow is said to be *fully turbulent*.

**13. CRITICAL FLOW**

The flow is said to be in a *critical zone* or *transition region* when the Reynolds number is between 2100 and 4000. These numbers are known as the lower and upper *critical Reynolds numbers* for fluid flow, respectively. (Critical Reynolds numbers for other processes are different.) It is difficult to design for the transition region, since fluid behavior is not consistent and few processes operate in the critical zone. In the event a critical zone design is required, the conservative assumption of turbulent flow will result in the greatest value of friction loss.

**14. FLUID VELOCITY DISTRIBUTION IN PIPES**

With laminar flow, the viscosity makes some fluid particles adhere to the pipe wall. The closer a particle is to the pipe wall, the greater the tendency will be for the fluid to adhere to the pipe wall. The following statements characterize laminar flow.

- The velocity distribution is parabolic.
- The velocity is zero at the pipe wall.

- The velocity is maximum at the center and equal to twice the average velocity.

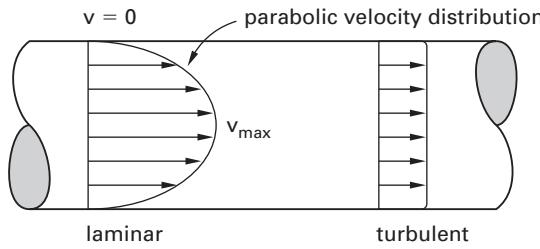

$$v_{ave} = \frac{\dot{V}}{A} = \frac{v_{max}}{2} \quad [\text{laminar}] \quad 16.20$$

With turbulent flow, there is generally no distinction made between the velocities of particles near the pipe wall and particles at the pipe centerline.<sup>13</sup> All of the fluid particles are assumed to have the same velocity. This velocity is known as the *average* or *bulk velocity*. It can be calculated from the volume flowing.

$$v_{ave} = \frac{\dot{V}}{A} \quad [\text{turbulent}] \quad 16.21$$

Laminar and turbulent velocity distributions are shown in Fig. 16.3. In actuality, no flow is completely turbulent, and there is a difference between the *centerline velocity* and the average velocity. The error decreases as the Reynolds number increases. The ratio  $v_{ave}/v_{max}$  starts at approximately 0.75 for  $Re = 4000$  and increases to approximately 0.86 at  $Re = 10^6$ . Most problems ignore the difference between  $v_{ave}$  and  $v_{max}$ , but care should be taken when a centerline measurement (as from a pitot tube) is used to evaluate the average velocity.

**Figure 16.3** Laminar and Turbulent Velocity Distributions

The ratio of the average velocity to maximum velocity is known as the *pipe coefficient* or *pipe factor*. Considering all the other coefficients used in pipe flow, these names are somewhat vague and ambiguous. Therefore, they are not in widespread use.

For turbulent flow ( $Re \approx 10^5$ ) in a smooth, circular pipe of radius  $r_o$ , the velocity at a radial distance  $r$  from the centerline is given by the *1/7-power law*.

$$v_r = v_{max} \left( \frac{r_o - r}{r_o} \right)^{1/7} \quad [\text{turbulent flow}] \quad 16.22$$

The fluid's *velocity profile*, given by Eq. 16.22, is valid in smooth pipes up to a Reynolds number of approximately 100,000. Above that, up to a Reynolds number of approximately 400,000, an exponent of  $1/8$  fits experimental data better. For rough pipes, the exponent is larger (e.g.,  $1/5$ ).

<sup>13</sup>This disregards the *boundary layer*, a thin layer near the pipe wall, where the velocity goes from zero to  $v_{ave}$ .

Equation 16.22 can be integrated to determine the average velocity.

$$v_{ave} = \left( \frac{49}{60} \right) v_{max} = 0.817 v_{max} \quad [\text{turbulent flow}] \quad 16.23$$

When the flow is laminar, the velocity profile within a pipe will be parabolic and of the form of Eq. 16.24. (Equation 16.22 is for turbulent flow and does not describe a parabolic velocity profile.) The velocity at a radial distance  $r$  from the centerline in a pipe of radius  $r_o$  is

$$v_r = v_{max} \left( \frac{r_o^2 - r^2}{r_o^2} \right) \quad [\text{laminar flow}] \quad 16.24$$

When the velocity profile is parabolic, the flow rate and pressure drop can easily be determined. The average velocity is half of the maximum velocity given in the velocity profile equation.

$$v_{ave} = \frac{1}{2} v_{max} \quad [\text{laminar flow}] \quad 16.25$$

The average velocity is used to determine the flow quantity and friction loss. The friction loss is determined by traditional means.

$$\dot{V} = A v_{ave} \quad 16.26$$

The kinetic energy of laminar flow can be found by integrating the velocity profile equation, resulting in Eq. 16.27.

$$E_v = v_{ave}^2 \quad [\text{laminar flow}] \quad [\text{SI}] \quad 16.27(a)$$

$$E_v = \frac{v_{ave}^2}{g_c} \quad [\text{laminar flow}] \quad [\text{U.S.}] \quad 16.27(b)$$

## 15. ENERGY GRADE LINE

The *energy grade line* (EGL) is a graph of the total energy (total specific energy) along a length of pipe.<sup>14</sup> In a frictionless pipe without pumps or turbines, the total specific energy is constant, and the EGL will be horizontal. (This is a restatement of the Bernoulli equation.)

$$\text{elevation of EGL} = h_p + h_v + h_z \quad 16.28$$

The *hydraulic grade line* (HGL) is the graph of the sum of the pressure and gravitational heads, plotted as a position along the pipeline. Since the pressure head can increase at the expense of the velocity head, the HGL can increase in elevation if the flow area is increased.

$$\text{elevation of HGL} = h_p + h_z \quad 16.29$$

<sup>14</sup>The term *energy line* (EL) is also used.

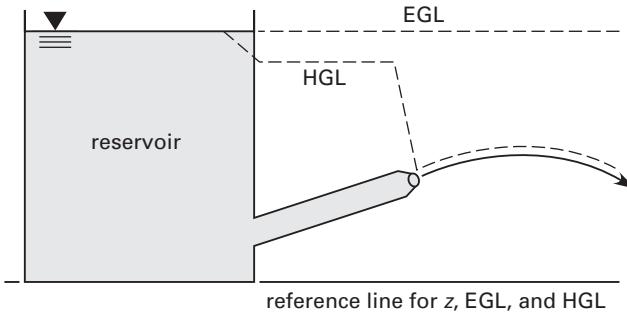

The difference between the EGL and the HGL is the velocity head,  $h_v$ , of the fluid.

$$h_v = \text{elevation of EGL} - \text{elevation of HGL} \quad 16.30$$

The following rules apply to these grade lines in a frictionless environment, in a pipe flowing full (i.e., under pressure), without pumps or turbines. (See Fig. 16.4.)

- The EGL is always horizontal.
- The HGL is always equal to or below the EGL.
- For still ( $v = 0$ ) fluid at a free surface, EGL = HGL (i.e., the EGL coincides with the fluid surface in a reservoir).
- If flow velocity is constant (i.e., flow in a constant-area pipe), the HGL will be horizontal and parallel to the EGL, regardless of pipe orientation or elevation.
- When the flow area decreases, the HGL decreases.
- When the flow area increases, the HGL increases.
- In a free jet (i.e., a stream of water from a hose), the HGL coincides with the jet elevation, following a parabolic path.

**Figure 16.4** Energy and Hydraulic Grade Lines Without Friction

## 16. SPECIFIC ENERGY

*Specific energy* is a term that is used primarily with open channel flow. It is the total energy with respect to the channel bottom, consisting of pressure and velocity energy contributions only.

$$E_{\text{specific}} = E_p + E_v \quad 16.31$$

Since the channel bottom is chosen as the reference elevation ( $z = 0$ ) for gravitational energy, there is no contribution by gravitational energy to specific energy.

$$E_{\text{specific}} = \frac{p}{\rho} + \frac{v^2}{2} \quad [\text{SI}] \quad 16.32(a)$$

$$E_{\text{specific}} = \frac{p}{\rho} + \frac{v^2}{2g_c} \quad [\text{U.S.}] \quad 16.32(b)$$

However, since  $p$  is the hydrostatic pressure at the channel bottom due to a fluid depth, the  $p/\rho$  term can be interpreted as the depth of the fluid,  $d$ .

$$E_{\text{specific}} = d + \frac{v^2}{2g} \quad [\text{open channel}] \quad 16.33$$

Specific energy is constant when the flow depth and width are constant (i.e., *uniform flow*). A change in channel width will cause a change in flow depth, and since width is not part of the equation for specific energy, there will be a corresponding change in specific energy. There are other ways that specific energy can decrease, also.<sup>15</sup>

## 17. PIPE MATERIALS AND SIZES

Many materials are used for pipes. The material used depends on the application. Water supply distribution, wastewater collection, and air conditioning refrigerant lines place different demands on pipe material performance. Pipe materials are chosen on the basis of tensile strength to withstand internal pressures, compressive strength to withstand external loads from backfill and traffic, smoothness, corrosion resistance, chemical inertness, cost, and other factors.

The following are characteristics of the major types of legacy and new installation commercial pipe materials that are in use.

- *asbestos cement*: immune to electrolysis and corrosion, light in weight but weak structurally; environmentally limited
- *concrete*: durable, watertight, low maintenance, smooth interior
- *copper and brass*: used primarily for water, condensate, and refrigerant lines; in some cases, easily bent by hand, good thermal conductivity
- *ductile cast iron*: long lived, strong, impervious, heavy, scour resistant, but costly
- *plastic* (PVC, CPVC, HDPE, and ABS):<sup>16</sup> chemically inert, resistant to corrosion, very smooth, lightweight, low cost
- *steel*: high strength, ductile, resistant to shock, very smooth interior, but susceptible to corrosion
- *vitrified clay*: resistant to corrosion, acids (e.g., hydrogen sulfide from septic sewage), scour, and erosion

The required wall thickness of a pipe is proportional to the pressure the pipe must carry. However, not all pipes operate at high pressures. Therefore, pipes and tubing

<sup>15</sup>Specific energy changes dramatically in a *hydraulic jump* or *hydraulic drop*.

<sup>16</sup>PVC: polyvinyl chloride; CPVC: chlorinated polyvinyl chloride; HDPE: high-density polyethylene; ABS: acrylonitrile-butadiene-styrene.

may be available in different wall thicknesses (*schedules*, *series*, or *types*). Steel pipe, for example, is available in schedules 40, 80, and others.<sup>17</sup>

For initial estimates, the approximate schedule of steel pipe can be calculated from Eq. 16.34.  $p$  is the operating pressure in psig;  $S$  is the allowable stress in the pipe material; and,  $E$  is the *joint efficiency*, also known as the *joint quality factor* (typically 1.00 for seamless pipe, 0.85 for electric resistance-welded pipe, 0.80 for electric fusion-welded pipe, and 0.60 for furnace butt-welded pipe). For seamless carbon steel (A53) pipe used below 650°F (340°C), the allowable stress is approximately between 12,000 psi and 15,000 psi. So, with butt-welded joints, a value of 6500 psi is often used for the product  $SE$ .

$$\text{schedule} \approx \frac{1000p}{SE} \quad 16.34$$

Steel pipe is available in black (i.e., plain *black pipe*) and galvanized (inside, outside, or both) varieties. Steel pipe is manufactured in plain-carbon and stainless varieties. AISI 316 stainless steel pipe is particularly corrosion resistant.

The actual dimensions of some pipes (concrete, clay, some cast iron, etc.) coincide with their *nominal dimensions*. For example, a 12 in concrete pipe has an inside diameter of 12 in, and no further refinement is needed. However, some pipes and tubing (e.g., steel pipe, copper and brass tubing, and some cast iron) are called out by a nominal diameter that has nothing to do with the internal diameter of the pipe. For example, a 16 in schedule-40 steel pipe has an actual inside diameter of 15 in. In some cases, the nominal size does not coincide with the external diameter, either.

PVC (polyvinyl chloride) pipe is used extensively as water and sewer pipe due to its combination of strength, ductility, and corrosion resistance. Manufactured lengths range approximately 10–13 ft (3–3.9 m) for sewer pipe and 20 ft (6 m) for water pipe, with integral gasketed joints or solvent-weld bells. Infiltration is very low (less than 50 gal/in-mile-day), even in the wettest environments. The low Manning's roughness constant (0.009 typical) allows PVC sewer pipe to be used with flatter grades or smaller diameters. PVC pipe is resistant to corrosive soils and sewerage gases and is generally resistant to abrasion from pipe-cleaning tools.

*Truss pipe* is a double-walled PVC or ABS pipe with radial or zigzag (diagonal) reinforcing ribs between the thin walls and with lightweight concrete filling all voids. It is used primarily for underground sewer service because

<sup>17</sup>Other schedules of steel pipe, such as 30, 60, 120, and so on, also exist, but in limited sizes, as App. 16.B indicates. Schedule-40 pipe roughly corresponds to the standard weight (S) designation used in the past. Schedule-80 roughly corresponds to the extra-strong (X) designation. There is no uniform replacement designation for double-extra-strong (XX) pipe.

of its smooth interior surface ( $n = 0.009$ ), infiltration-resistant, impervious exterior, and resistance to bending.

*Prestressed concrete pipe* (PSC) or *reinforced concrete pipe* (RCP) consists of a concrete core that is compressed by a circumferential wrap of high-tensile strength wire and covered with an exterior mortar coating. *Prestressed concrete cylinder pipe* (PCCP), or *lined concrete pipe* (LCP), is constructed with a concrete core, a thin steel cylinder, prestressing wires, and an exterior mortar coating. The concrete core is the primary structural, load-bearing component. The prestressing wires induce a uniform compressive stress in the core that offsets tensile stresses in the pipe. If present, the steel cylinder acts as a water barrier between concrete layers. The mortar coating protects the prestressing wires from physical damage and external corrosion. PSC and PCCP are ideal for large-diameter pressurized service and are used primarily for water supply systems. PSC is commonly available in diameters from 16 in to 60 in (400 mm to 1500 mm), while PCCP diameters as large as 144 in (3600 mm) are available.

It is essential that tables of pipe sizes, such as App. 16.B, be used when working problems involving steel and copper pipes, since there is no other way to obtain the inside diameters of such pipes.<sup>18</sup>

## 18. MANUFACTURED PIPE STANDARDS

There are many different standards governing pipe diameters and wall thicknesses. A pipe's nominal outside diameter is rarely sufficient to determine the internal dimensions of the pipe. A manufacturing specification and class or category are usually needed to completely specify pipe dimensions.

Cast-iron pressure pipe was formerly produced to ANSI/AWWA C106/A21.6 standards but is now obsolete. Modern cast-iron soil (i.e., sanitary) pipe is produced according to ASTM A74. Ductile iron (CI/DI) pipe is produced to ANSI/AWWA C150/A21.50 and C151/A21.51 standards. Gasketed PVC sewer pipe up to 15 in inside diameter is produced to ASTM D3034 standards. Gasketed sewer PVC pipe from 18 in to 48 in is produced to ASTM F679 standards. PVC pressure pipe for water distribution is manufactured to ANSI/AWWA C900 standards. Reinforced concrete pipe (RCP) for culvert, storm drain, and sewer applications is manufactured to ASTM/AASHTO C76/M170 standards.

## 19. PIPE CLASS

The term *pipe class* has several valid meanings that can be distinguished by designation and context. For plastic and metallic (i.e., steel, cast and ductile iron, cast bronze, and wrought copper) pipe and fittings, pressure class

<sup>18</sup>It is a characteristic of standard steel pipes that the schedule number does not affect the outside diameter of the pipe. An 8 in schedule-40 pipe has the same exterior dimensions as an 8 in schedule-80 pipe. However, the interior flow area will be less for the schedule-80 pipe.

designations such as 25, 150, and 300 refer to the pressure ratings and dimensional design systems as defined in the appropriate ASME, ANSI, AWWA, and other standards. Generally, the class corresponds roughly to a maximum operating pressure category in psig.

ASME *Code* pipe classes 1, 2, and 3 refer to the maximum stress categories allowed in pipes, piping systems, components, and supports, as defined in the ASME *Boiler and Pressure Vessel Code* (BPVC), Sec. III, Div. 1, "Rules for Construction of Nuclear Facility Components."

For precast concrete pipe manufactured according to ASTM C76, the pipe classes 1, 2, 3, 4, and 5 correspond to the minimum vertical loading (D-load) capacity as determined in a *three-edge bearing test* (ASTM C497), according to Table 16.2.<sup>19</sup> Each pipe has two D-load ratings: the pressure that induces a crack 0.01 in (0.25 mm) wide at least 1 ft (100 mm) long ( $D_{0.01}$ ), and the pressure that results in structural collapse ( $D_{ult}$ ).<sup>20</sup>

$$D\text{-load} = \frac{F_{lb}}{D_{ft} L_{ft}} \quad [\text{ASTM C76 pipe}] \quad 16.35$$

**Table 16.2** ASTM C76 Concrete Pipe D-Load Equivalent Pipe Class\*

ASTM C76 pipe class	D <sub>0.01</sub> -load rating (lbf/ft <sup>2</sup> )	D <sub>ult</sub> -load rating (lbf/ft <sup>2</sup> )
class 1 (I)	800	1200
class 2 (II)	1000	1500
class 3 (III)	1350	2000
class 4 (IV)	2000	3000
class 5 (V)	3000	3750

(Multiply lbf/ft<sup>2</sup> by 0.04788 to obtain kPa.)

\* As defined in ASTM C76 and AASHTO M170.

## 20. PAINTS, COATINGS, AND LININGS

Various materials have been used to protect steel and ductile iron pipes against rust and other forms of corrosion. *Red primer* is a shop-applied, rust-inhibiting primer applied to prevent short-term rust prior to shipment and the application of subsequent coatings. *Asphaltic coating* ("tar" coating) is applied to the exterior of underground pipes. *Bituminous coating* refers to a similar coating made from tar pitch. Both asphaltic and bituminous coatings should be completely removed or sealed with a synthetic resin prior to the pipe being finish-coated, since their oils may bleed through otherwise.

Though bituminous materials (i.e., asphaltic materials) continue to be cost effective, epoxy-based products are

<sup>19</sup>The D-load rating for ASTM C14 concrete pipe is D-load =  $F/L$  in lbf/ft.

<sup>20</sup>This D-load rating for concrete pipe is analogous to the *pipe stiffness* (PS) rating (also known as *ring stiffness*) for PVC and other plastic pipe, although the units are different. The PS rating is stated in lbf/in<sup>2</sup> (pounds per inch of pipe length per inch of pipe diameter).

now extensively used. Epoxy products are delivered as a two-part formulation (a polyamide resin and liquid chemical hardener) that is mixed together prior to application. *Coal tar epoxy*, also referred to as *epoxy coal tar*, a generic name, sees frequent use in pipes exposed to high humidity, seawater, other salt solutions, and crude oil. Though suitable for coating steel penstocks of hydroelectric installations, coal tar epoxy is generally not suitable for potable water delivery systems. Though it is self-priming, appropriate surface preparation is required for adequate adhesion. Coal tar epoxy has a density range of 1.9–2.3 lbm/gal (230–280 g/L).

## 21. CORRUGATED METAL PIPE

*Corrugated metal pipe* (CMP, also known as *corrugated steel pipe*) is frequently used for culverts. Pipe is made from corrugated sheets of galvanized steel that are rolled and riveted together along a longitudinal seam. Aluminized steel may also be used in certain ranges of soil pH. Standard round pipe diameters range from 8 in to 96 in (200 mm to 2450 mm). Metric dimensions of standard diameters are usually rounded to the nearest 25 mm or 50 mm (e.g., a 42 in culvert would be specified as a 1050 mm culvert, not 1067 mm).

Larger and noncircular culverts can be created out of curved steel plate. Standard section lengths are 10–20 ft (3–6 m). Though most corrugations are transverse (i.e., annular), helical corrugations are also used. Metal gauges of 8, 10, 12, 14, and 16 are commonly used, depending on the depth of burial.

The most common corrugated steel pipe has transverse corrugations that are  $\frac{1}{2}$  in (13 mm) deep and  $2\frac{2}{3}$  in (68 mm) from crest to crest. These are referred to as "2 $\frac{1}{2}$  inch" or "68 × 13" corrugations. For larger culverts, corrugations with a 2 in (25 mm) depth and 3 in, 5 in, or 6 in (76 mm, 125 mm, or 152 mm) pitches are used. Plate-based products using 6 in × 2 in (152 mm × 51 mm) corrugations are known as *structural plate corrugated steel pipe* (SPCSP) and *multiplate* after the trade-named product "Multi-Plate™."

The flow area for circular culverts is based on the nominal culvert diameter, regardless of the gage of the plate metal used to construct the pipe. Flow area is calculated to (at most) three significant digits.

A Hazen-Williams coefficient,  $C$ , of 60 is typically used with all sizes of corrugated pipe. Values of  $C$  and Manning's coefficient,  $n$ , for corrugated pipe are generally not affected by age. *Design Charts for Open Channel Flow* (U.S. Department of Transportation, 1979) recommends a Manning constant of  $n = 0.024$  for all cases. The U.S. Department of the Interior recommends the following values.

For standard ( $2\frac{2}{3}$  in ×  $\frac{1}{2}$  in or 68 mm × 13 mm) corrugated pipe with the diameter ranges given: 12 in (457 mm), 0.027; 24 in (610 mm), 0.025; 36–48 in

(914–1219 mm), 0.024; 60–84 in (1524–2134 mm), 0.023; 96 in (2438 mm), 0.022.

For (6 in  $\times$  2 in or 152 mm  $\times$  51 mm) multiplate construction with the diameter ranges given: 5–6 ft (1.5–1.8 m), 0.034; 7–8 ft (2.1–2.4 m), 0.033; 9–11 ft (2.7–3.3 m), 0.032; 12–13 ft (3.6–3.9 m), 0.031; 14–15 ft (4.2–4.5 m), 0.030; 16–18 ft (4.8–5.4 m), 0.029; 19–20 ft (5.8–6.0 m), 0.028; 21–22 ft (6.3–6.6 m), 0.027.

If the inside of the corrugated pipe has been asphalted completely smooth 360° circumferentially, Manning's  $n$  ranges from 0.009 to 0.011. For culverts with 40% asphalted invert,  $n = 0.019$ . For other percentages of paved invert, the resulting value is proportional to the percentage and the values normally corresponding to that diameter pipe. For field-bolted corrugated metal pipe arches,  $n = 0.025$ .

It is also possible to calculate the Darcy friction loss if the corrugation depth, 0.5 in (13 mm) for standard corrugations and 2.0 in (51 mm) for multiplate, is taken as the specific roughness.

## 22. TYPES OF VALVES

Valves used for *shutoff service* (e.g., gate, plug, ball, and some butterfly valves) are used fully open or fully closed. *Gate valves* offer minimum resistance to flow. They are used in clean fluid and slurry services when valve operation is infrequent. Many turns of the handwheels are required to raise or lower their gates. *Plug valves* provide for tight shutoff. A 90° turn of their handles is sufficient to rotate the plugs fully open or closed. *Eccentric plug valves*, in which the plug rotates out of the fluid path when open, are among the most common wastewater valves. *Plug cock valves* have a hollow passageway in their plugs through which fluid can flow. Both eccentric plug valves and plug cock valves are referred to as "plug valves." *Ball valves* offer an unobstructed flow path and tight shutoff. They are often used with slurries and viscous fluids, as well as with cryogenic fluids. A 90° turn of their handles rotates the balls fully open or closed. *Butterfly valves* (when specially designed with appropriate seats) can be used for shutoff operation. They are particularly applicable to large flows of low-pressure (vacuum up to 200 psig (1.4 MPa)) gases or liquids, although high-performance butterfly valves can operate as high as 600 psig (4.1 MPa). Their straight-through, open-disk design results in minimal solids build-up and low pressure drops.

Other valve types (e.g., globe, needle, Y-, angle, and some butterfly valves) are more suitable for *throttling service*. *Globe valves* provide positive shutoff and precise metering on clean fluids. However, since the seat is parallel to the direction of flow and the fluid makes two right-angle turns, there is substantial resistance and pressure drop through them, as well as relatively fast erosion of the seat. *Globe valves* are intended for frequent operation. *Needle valves* are similar to globe valves, except that the plug is a tapered, needlelike cone.

Needle valves provide accurate metering of small flows of clean fluids. Needle valves are applicable to cryogenic fluids. *Y-valves* are similar to globe valves in operation, but their seats are inclined to the direction of flow, offering more of a straight-through passage and unobstructed flow than the globe valve. *Angle valves* are essentially globe valves where the fluid makes a 90° turn. They can be used for throttling and shutoff of clean or viscous fluids and slurries. *Butterfly valves* are often used for throttling services with the same limitations and benefits as those listed for shutoff use.

Other valves are of the *check (nonreverse-flow, anti-reversal)* variety. These react automatically to changes in pressure to prevent reversals of flow. Special check valves can also prevent excess flow. Figure 16.5 illustrates *swing*, *lift*, and *angle lift check valves*, and Table 16.3 gives typical characteristics of common valve types.

## 23. SAFETY AND PRESSURE RELIEF VALVES

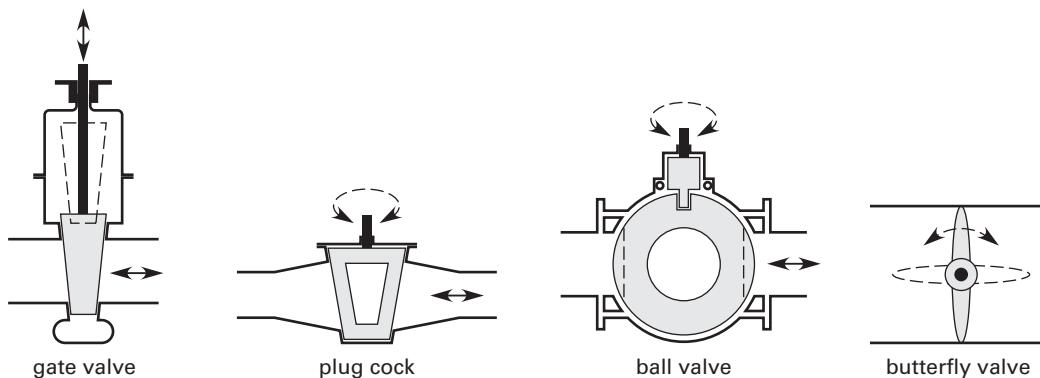

A *pressure relief device* typically incorporates a disk or needle that is held in place by spring force, and that is lifted off its seat (i.e., opens) when the static pressure at the valve inlet exceeds the opening pressure. A *relief valve* is a pressure relief device used primarily for liquid service. It has a gradual lift that is approximately proportional (though not necessarily linear) to the increase in pressure over opening pressure. A *safety valve* is used for compressible steam, air, and gas services. Its performance is characterized by rapid opening ("pop action"). In a *low-lift safety valve*, the discharge area depends on the disc position and is limited by the lift amount. In a *full-lift (high-lift) safety valve*, the discharge area is not determined by the position of the disc. Since discs in low-lift valves have lift distances of only approximately 1/24th of the bore diameter, the discharge capacities tend to be much lower than those of high-lift valves.

A *safety relief valve* is a dual-function valve that can be used for either a liquid or a compressible fluid. Its operation is characterized by rapid opening (for gases) and by slower opening in proportion to the increase in inlet pressure over the opening pressure (for liquids), depending on the application.

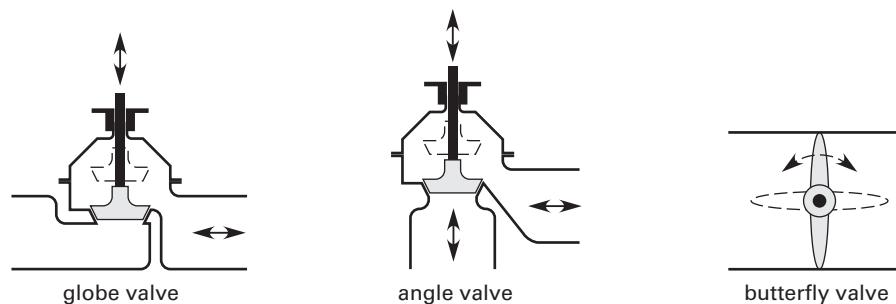

## 24. AIR RELEASE AND VACUUM VALVES

Small amounts of air in fluid flows tend to accumulate at high points in the line. These air pockets reduce flow capacities, increase pumping power, and contribute to pressure surges and water hammer. *Air release valves* should be installed at high points in the line, particularly with line diameters greater than 12 in (3000 mm).<sup>21</sup> They are float operated and open against the line's internal pressure to release accumulated air and gases. Air release valves are essential when lines are being filled. Valves for

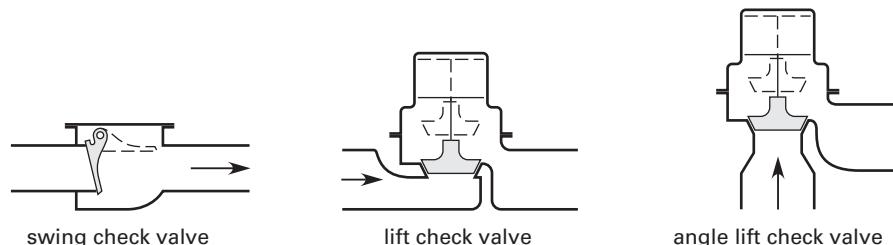

<sup>21</sup>Smaller diameter lines may develop flow velocities sufficiently high (e.g., greater than 5 ft/sec (1.5 m/s)) to flush gas accumulations.

**Figure 16.5** Types of Valves

(a) valves for shutoff service

(b) valves for throttle service

(c) valves for antireversal service

**Table 16.3** Typical Characteristics of Common Valve Types

valve type	fluid condition	switching frequency	pressure drop (fully open)	typical control response	typical maximum pressure (atm)	typical maximum temperature (°C)
ball	clean	low	low	very poor	160	300
butterfly	clean	low	low	poor	200	400
diaphragm*	clean to slurred	very high	low to medium	very good	16	150

globe	clean	high	medium to high	very good	80	300
plug	clean	low	low	very poor	160	300

(Multiply atm by 101.33 to obtain kPa.)

\*Diaphragm valves use a flexible diaphragm to block the flow path. The diaphragm may be manually or pneumatically actuated. Such valves are suitable for both throttling and shutoff service.

sewage lines prevent buildups of sewage gases (e.g., hydrogen sulfide) and are similar in functionality, though they contain features to prevent clogging and fouling.

*Vacuum valves* are similar in design, except that they permit air to enter a line when the line is drained, preventing pipeline collapse. *Combination air valves* (CAV), also known as *double orifice air valves*, combine the functions of both air release valves and vacuum valves. Vacuum valves should not be used in drinking water supply distribution systems due to the potential for contamination.

If unrestricted, air moving through a valve orifice will reach a maximum velocity of approximately 300 ft/sec (91 m/s) at 6.7 lbf/in<sup>2</sup> (46 kPa) differential pressure. It is good practice to limit the flow to 10 ft/sec (3 m/s) (occurring at about 1 lbf/in<sup>2</sup> (7 kPa)), and this can be accomplished with slow-closing units.

*Siphon air valves (make-or-break valves)* are a type of air vacuum valve that includes a paddle which hangs down in the flow. As long as the flow exists, the valve remains closed. When the flow stops or reverses, the valve opens. In a typical application, a pump is used to initiate siphon flow, and once flow is started, the pump is removed.

## 25. STEAM TRAPS

*Steam traps* are installed in steam lines. Since the heat content of condensate is significantly less than that of the steam, condensate is not as useful in downstream applications. Traps collect and automatically release condensed water while permitting vapor to pass through. They may also release accumulated noncondensing gases (e.g., air).

*Inverted bucket steam traps* are simple, mechanically robust, and reliable. They are best for applications with water hammer. *Thermostatic steam traps* operate with either a bimetallic or a balanced pressure design to detect the difference in temperature between live steam and condensate or air. They are suitable for cold start-up conditions, but less desirable with variable loadings. The *float steam trap* is the best choice for variable loadings, but it is less robust due to its mechanical complexity and is less resistant to water hammer. A *thermodynamic disc steam trap* uses flash steam as the stream passes through the trap and is both simple and robust. It is suitable for intermittent, not continuous, operation only.

**1. HYDRAULICS AND HYDRODYNAMICS**

This chapter covers fluid moving through pipes, measurements with venturis and orifices, and other motion-related topics such as model theory, lift and drag, and pumps. In a strict interpretation, any fluid-related phenomenon that is not hydrostatics should be hydrodynamics. However, tradition has separated the study of moving fluids into the fields of hydraulics and hydrodynamics.

In a general sense, *hydraulics* is the study of the practical laws of fluid flow and resistance in pipes and open channels. Hydraulic formulas are often developed from experimentation, empirical factors, and curve fitting, without an attempt to justify why the fluid behaves the way it does.

On the other hand, *hydrodynamics* is the study of fluid behavior based on theoretical considerations. Hydrodynamicists start with Newton's laws of motion and try to develop models of fluid behavior. Models developed in this manner are complicated greatly by the inclusion of viscous friction and compressibility. Therefore, hydrodynamic models assume a perfect fluid with constant density and zero viscosity. The conclusions reached by hydrodynamicists can differ greatly from those reached by hydraulicians.<sup>1</sup>

**2. CONSERVATION OF MASS**

Fluid mass is always conserved in fluid systems, regardless of the pipeline complexity, orientation of the flow, and fluid. This single concept is often sufficient to solve simple fluid problems.

$$\dot{m}_1 = \dot{m}_2$$

17.1

<sup>1</sup>Perhaps the most disparate conclusion is *D'Alembert's paradox*. In 1744, D'Alembert derived theoretical results "proving" that there is no resistance to bodies moving through an ideal (nonviscous) fluid.

When applied to fluid flow, the conservation of mass law is known as the *continuity equation*.

$$\rho_1 A_1 v_1 = \rho_2 A_2 v_2 \quad 17.2$$

If the fluid is incompressible, then  $\rho_1 = \rho_2$ .

$$A_1 v_1 = A_2 v_2 \quad 17.3$$

$$\dot{V}_1 = \dot{V}_2 \quad 17.4$$

Various units and symbols are used for *volumetric flow rate*. (Though this book uses  $\dot{V}$ , the symbol  $Q$  is commonly used when the flow rate is expressed in gallons.) MGD (millions of gallons per day) and MGPCD (millions of gallons per capita day) are units commonly used in municipal water works problems. MMSCFD (millions of standard cubic feet per day) may be used to express gas flows.

Calculation of flow rates is often complicated by the interdependence between flow rate and friction loss. Each affects the other, so many pipe flow problems must be solved iteratively. Usually, a reasonable friction factor is assumed and used to calculate an initial flow rate. The flow rate establishes the flow velocity, from which a revised friction factor can be determined.

### 3. TYPICAL VELOCITIES IN PIPES

Fluid friction in pipes is kept at acceptable levels by maintaining reasonable fluid velocities. Table 17.1 lists typical maximum fluid velocities. Higher velocities may be observed in practice, but only with a corresponding increase in friction and pumping power.

### 4. STREAM POTENTIAL AND STREAM FUNCTION

An application of hydrodynamic theory is the derivation of the stream function from stream potential. The *stream potential function* (*velocity potential function*),  $\Phi$ , is the algebraic sum of the component velocity potential functions.<sup>2</sup>

$$\Phi = \Phi_x(x, y) + \Phi_y(x, y) \quad 17.5$$

The velocity component of the resultant in the  $x$ -direction is

$$u = \frac{\partial \Phi}{\partial x} \quad 17.6$$

The velocity component of the resultant in the  $y$ -direction is

$$v = \frac{\partial \Phi}{\partial y} \quad 17.7$$

<sup>2</sup>The two-dimensional derivation of the stream function can be extended to three dimensions, if necessary. The stream function can also be expressed in the cylindrical coordinate system.

**Table 17.1** Typical Full-Pipe Bulk Fluid Velocities

fluid and application	ft/sec	m/s
water: city service	2–10	0.6–2.1
3 in diameter	4	1.2
6 in diameter	5	1.5
12 in diameter	9	2.7
water: boiler feed	8–15	2.4–4.5
water: pump suction	4	1.2
water: pump discharge	4–8.5	1.2–2.5
water, sewage: partially filled sewer	2.5 (min)	0.75 (min)
brine, water: chillers and coolers	6–8 typ (3–10)	1.8–2.4 typ (0.9–3)
air: compressor suction	75–200	23–60
air: compressor discharge	100–250	30–75
air: HVAC forced air	15–25	5–8
natural gas: overland pipeline	< 150 (60 typ)	< 45 (18 typ)
steam, saturated: heating	65–100	20–30
steam, saturated:	100–200	30–60
miscellaneous		
50–100 psia	< 150	< 45
150–400 psia	< 130	< 39
400–600 psia	< 100	< 30
steam, superheated: turbine feed	160–250	50–75
hydraulic fluid: fluid power	7–15	2.1–4.6
liquid sodium	10 typ (T > 525°C): heat transfer	3 typ (0.3–40) (0.1–12)
ammonia: compressor suction	85 (max)	25 (max)
ammonia: compressor discharge	100 (max)	30 (max)
oil, crude: overland pipeline	4–12	1.2–3.6
oil, lubrication: pump suction	< 2	< 0.6
oil, lubrication: pump discharge	3–7	0.9–2.1

(Multiply ft/sec by 0.3048 to obtain m/s.)

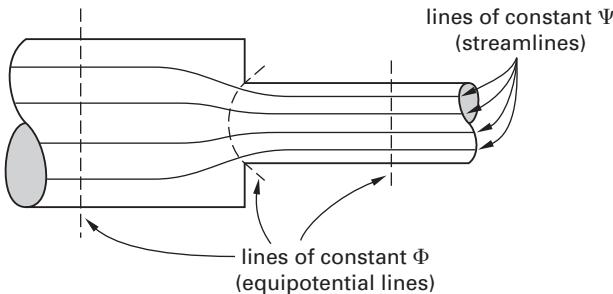

The total derivative of the stream potential function is

$$d\Phi = \frac{\partial \Phi}{\partial x} dx + \frac{\partial \Phi}{\partial y} dy = u dx + v dy \quad 17.8$$

An *equipotential line* is a line along which the function  $\Phi$  is constant (i.e.,  $d\Phi = 0$ ). The slope of the equipotential line is derived from Eq. 17.8.

$$\left. \frac{dy}{dx} \right|_{\text{equipotential}} = -\frac{u}{v} \quad 17.9$$

For flow through a porous, permeable medium, pressure will be constant along equipotential lines (i.e., along lines of constant  $\Phi$ ). (See Fig. 17.1.) However, for an ideal, nonviscous fluid flowing in a frictionless environment,  $\Phi$  has no physical significance.

**Figure 17.1** Equipotential Lines and Streamlines

The *stream function* (*Lagrange stream function*),  $\Psi(x, y)$ , defines the direction of flow at a point.

$$u = \frac{\partial \Psi}{\partial y} \quad 17.10$$

$$v = -\frac{\partial \Psi}{\partial x} \quad 17.11$$

The stream function can also be written in total derivative form.

$$\begin{aligned} d\Psi &= \frac{\partial \Psi}{\partial x} dx + \frac{\partial \Psi}{\partial y} dy \\ &= -v dx + u dy \end{aligned} \quad 17.12$$

The stream function,  $\Psi(x, y)$ , satisfies Eq. 17.12. For a given streamline,  $d\Psi = 0$ , and each streamline is a line representing a constant value of  $\Psi$ . A streamline is perpendicular to an equipotential line.

$$\left. \frac{dy}{dx} \right|_{\text{streamline}} = \frac{v}{u} \quad 17.13$$

### Example 17.1

The stream potential function for water flowing through a particular valve is  $\Phi = 3xy - 2y$ . What is the stream function,  $\Psi$ ?

*Solution*

First, work with  $\Phi$  to obtain  $u$  and  $v$ .

$$u = \frac{\partial \Phi}{\partial x} = \frac{\partial(3xy - 2y)}{\partial x} = 3y$$

$$v = \frac{\partial \Phi}{\partial y} = 3x - 2$$

$u$  and  $v$  are also related to the stream function,  $\Psi$ . From Eq. 17.10,

$$u = \frac{\partial \Psi}{\partial y}$$

$$\partial \Psi = u \partial y$$

$$\Psi = \int 3y dy = \frac{3}{2}y^2 + \text{some function of } x + C_1$$

Similarly, from Eq. 17.11,

$$v = -\frac{\partial \Psi}{\partial x}$$

$$\partial \Psi = -v \partial x$$

$$\begin{aligned} \Psi &= - \int (3x - 2) dx \\ &= 2x - \frac{3}{2}x^2 + \text{some function of } y + C_2 \end{aligned}$$

The entire stream function is found by superposition of these two results.

$$\Psi = \frac{3}{2}y^2 + 2x - \frac{3}{2}x^2 + C$$

## 5. HEAD LOSS DUE TO FRICTION

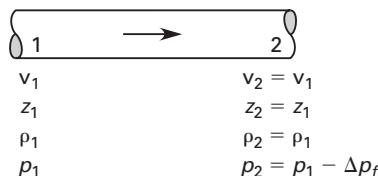

The original Bernoulli equation was based on an assumption of frictionless flow. In actual practice, friction occurs during fluid flow. This friction “robs” the fluid of energy,  $E$ , so that the fluid at the end of a pipe section has less energy than it does at the beginning.<sup>3</sup>

$$E_1 > E_2 \quad 17.14$$

Most formulas for calculating friction loss use the symbol  $h_f$  to represent the *head loss due to friction*.<sup>4</sup> This loss is added into the original Bernoulli equation to restore the equality. Of course, the units of  $h_f$  must be the same as the units for the other terms in the Bernoulli equation. (See Eq. 17.23.) If the Bernoulli equation is written in terms of energy, the units will be ft-lbf/lbm or J/kg.

$$E_1 = E_2 + E_f \quad 17.15$$

Consider the constant-diameter, horizontal pipe in Fig. 17.2. An incompressible fluid is flowing at a steady rate. Since the elevation of the pipe,  $z$ , does not change, the potential energy is constant. Since the pipe has a constant area, the kinetic energy (velocity) is constant. Therefore, the friction energy loss must show up as a decrease in pressure energy. Since the fluid is incompressible, this can only occur if the pressure,  $p$ , decreases in the direction of flow.

**Figure 17.2** Pressure Drop in a Pipe

<sup>3</sup>The friction generates minute amounts of heat. The heat is lost to the surroundings.

<sup>4</sup>Other names and symbols for this friction loss are *friction head loss* ( $h_L$ ), *lost work* (LW), *friction heating* ( $\mathcal{F}$ ), *skin friction loss* ( $F_f$ ), and *pressure drop due to friction* ( $\Delta p_f$ ). All terms and symbols essentially mean the same thing, although the units may be different.

## 6. RELATIVE ROUGHNESS

It is intuitive that pipes with rough inside surfaces will experience greater friction losses than smooth pipes.<sup>5</sup> Specific roughness,  $\epsilon$ , is a parameter that measures the average size of imperfections inside the pipe. Table 17.2 lists values of  $\epsilon$  for common pipe materials. (Also, see App. 17.A.)

**Table 17.2** Values of Specific Roughness,  $\epsilon$ , for Common Pipe Materials

material	$\epsilon$	
	ft	m
plastic (PVC, ABS)	0.000005	$1.5 \times 10^{-6}$
copper and brass	0.000005	$1.5 \times 10^{-6}$
steel	0.0002	$6.0 \times 10^{-5}$
plain cast iron	0.0008	$2.4 \times 10^{-4}$
concrete	0.004	$1.2 \times 10^{-3}$

(Multiply ft by 0.3048 to obtain m.)

However, an imperfection the size of a sand grain will have much more effect in a small-diameter hydraulic line than in a large-diameter sewer. Therefore, the *relative roughness*,  $\epsilon/D$ , is a better indicator of pipe roughness. Both  $\epsilon$  and  $D$  have units of length (e.g., feet or meters), and the relative roughness is dimensionless.

## 7. FRICTION FACTOR

The *Darcy friction factor*,  $f$ , is one of the parameters used to calculate friction loss.<sup>6</sup> The friction factor is not constant but decreases as the Reynolds number (fluid velocity) increases, up to a certain point known as *fully turbulent flow* (or *rough-pipe flow*). Once the flow is fully turbulent, the friction factor remains constant and depends only on the relative roughness and not on the Reynolds number. (See Fig. 17.3.) For very smooth pipes, fully turbulent flow is achieved only at very high Reynolds numbers.

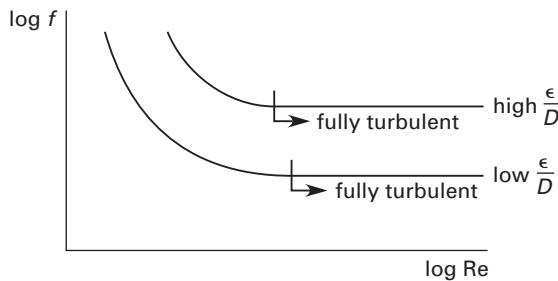

The friction factor is not dependent on the material of the pipe but is affected by the roughness. For example, for a given Reynolds number, the friction factor will be the same for any smooth pipe material (glass, plastic, smooth brass and copper, etc.).

The friction factor is determined from the relative roughness,  $\epsilon/D$ , and the Reynolds number,  $Re$ , by various methods. These methods include explicit and implicit

<sup>5</sup>Surprisingly, this intuitive statement is valid only for turbulent flow. The roughness does not (ideally) affect the friction loss for laminar flow.

<sup>6</sup>There are actually two friction factors: the Darcy friction factor and the *Fanning friction factor*,  $f_{\text{Fanning}}$ , also known as the *skin friction coefficient* and *wall shear stress factor*. Both factors are in widespread use, sharing the same symbol,  $f$ . Civil and (most) mechanical engineers use the Darcy friction factor. The Fanning friction factor is encountered more often by chemical engineers. One can be derived from the other:  $f_{\text{Darcy}} = 4f_{\text{Fanning}}$ .

**Figure 17.3** Friction Factor as a Function of Reynolds Number

equations, the Moody diagram, and tables. The values obtained are based on experimentation, primarily the work of J. Nikuradse in the early 1930s.

When a moving fluid initially encounters a parallel surface (as when a moving gas encounters a flat plate or when a fluid first enters the mouth of a pipe), the flow will generally not be turbulent, even for very rough surfaces. The flow will be laminar for a certain *critical distance* before becoming turbulent.

### Friction Factors for Laminar Flow

The easiest method of obtaining the friction factor for laminar flow ( $Re < 2100$ ) is to calculate it. Equation 17.16 illustrates that roughness is not a factor in determining the frictional loss in ideal laminar flow.

$$f = \frac{64}{Re} \quad [\text{circular pipe}] \quad 17.16$$

Table 17.3 gives friction factors for laminar flow in various cross sections.

### Friction Factors for Turbulent Flow: by Formula

One of the earliest attempts to predict the friction factor for turbulent flow in smooth pipes resulted in the *Blasius equation* (claimed “valid” for  $3000 < Re < 100,000$ ).

$$f = \frac{0.316}{Re^{0.25}} \quad 17.17$$

The *Nikuradse equation* can also be used to determine the friction factor for smooth pipes (i.e., when  $\epsilon/D = 0$ ). Unfortunately, this equation is implicit in  $f$  and must be solved iteratively.

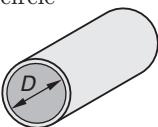

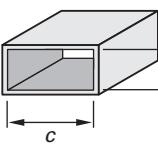

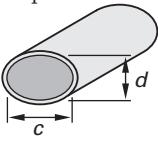

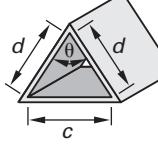

$$\frac{1}{\sqrt{f}} = 2.0 \log_{10}(Re\sqrt{f}) - 0.80 \quad 17.18$$

The *Karman-Nikuradse equation* predicts the fully turbulent friction factor (i.e., when  $Re$  is very large).

$$\frac{1}{\sqrt{f}} = 1.74 - 2 \log_{10} \frac{2\epsilon}{D} \quad 17.19$$

The most widely known method of calculating the friction factor for any pipe roughness and Reynolds number

**Table 17.3** Friction Factors for Laminar Flow in Various Cross Sections\*

\* $\text{Re} = v_{\text{bulk}} D_h / v$ , and  $D_h = 4A/P$ .

is another implicit formula, the *Colebrook equation*. Most other equations are variations of this equation. (Notice that the relative roughness,  $\epsilon/D$ , is used to calculate  $f$ .)

$$\frac{1}{\sqrt{f}} = -2 \log_{10} \left( \frac{\epsilon}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}} \right) \quad 17.20$$

A suitable approximation would appear to be the *Swamee-Jain equation*, which claims to have less than 1% error (as measured against the Colebrook equation) for relative roughnesses between 0.000001 and 0.01, and for Reynolds numbers between 5000 and 100,000,000.<sup>7</sup> Even with a 1% error, this equation produces more accurate results than can be read from the Moody friction factor chart.

$$f = \frac{0.25}{\left( \log_{10} \left( \frac{\epsilon}{3.7} + \frac{5.74}{\text{Re}^{0.9}} \right) \right)^2} \quad 17.21$$

<sup>7</sup>American Society of Civil Engineers. *Journal of Hydraulic Engineering* 102 (May 1976): 657. This is not the only explicit approximation to the Colebrook equation in existence.

### Friction Factors for Turbulent Flow: by Moody Chart

The *Moody friction factor chart*, shown in Fig. 17.4, presents the friction factor graphically as a function of Reynolds number and relative roughness. There are different lines for selected discrete values of relative roughness. Due to the complexity of this graph, it is easy to mislocate the Reynolds number or use the wrong curve. Nevertheless, the Moody chart remains the most common method of obtaining the friction factor.

### Friction Factors for Turbulent Flow: by Table

Appendix 17.B (based on the Colebrook equation), or a similar table, will usually be the most convenient method of obtaining friction factors for turbulent flow.

#### Example 17.2

Determine the friction factor for a Reynolds number of  $\text{Re} = 400,000$  and a relative roughness of  $\epsilon/D = 0.004$  using (a) the Moody diagram, (b) Appendix 17.B, and (c) the Swamee-Jain approximation. (d) Check the table value of  $f$  with the Colebrook equation.

*Solution*

(a) From Fig. 17.4, the friction factor is approximately 0.028.

(b) Appendix 17.B lists the friction factor as 0.0287.

(c) From Eq. 17.21,

$$\begin{aligned} f &= \frac{0.25}{\left( \log_{10} \left( \frac{\epsilon}{3.7} + \frac{5.74}{\text{Re}^{0.9}} \right) \right)^2} \\ &= \frac{0.25}{\left( \log_{10} \left( \frac{0.004}{3.7} + \frac{5.74}{(400,000)^{0.9}} \right) \right)^2} \\ &= 0.0288 \end{aligned}$$

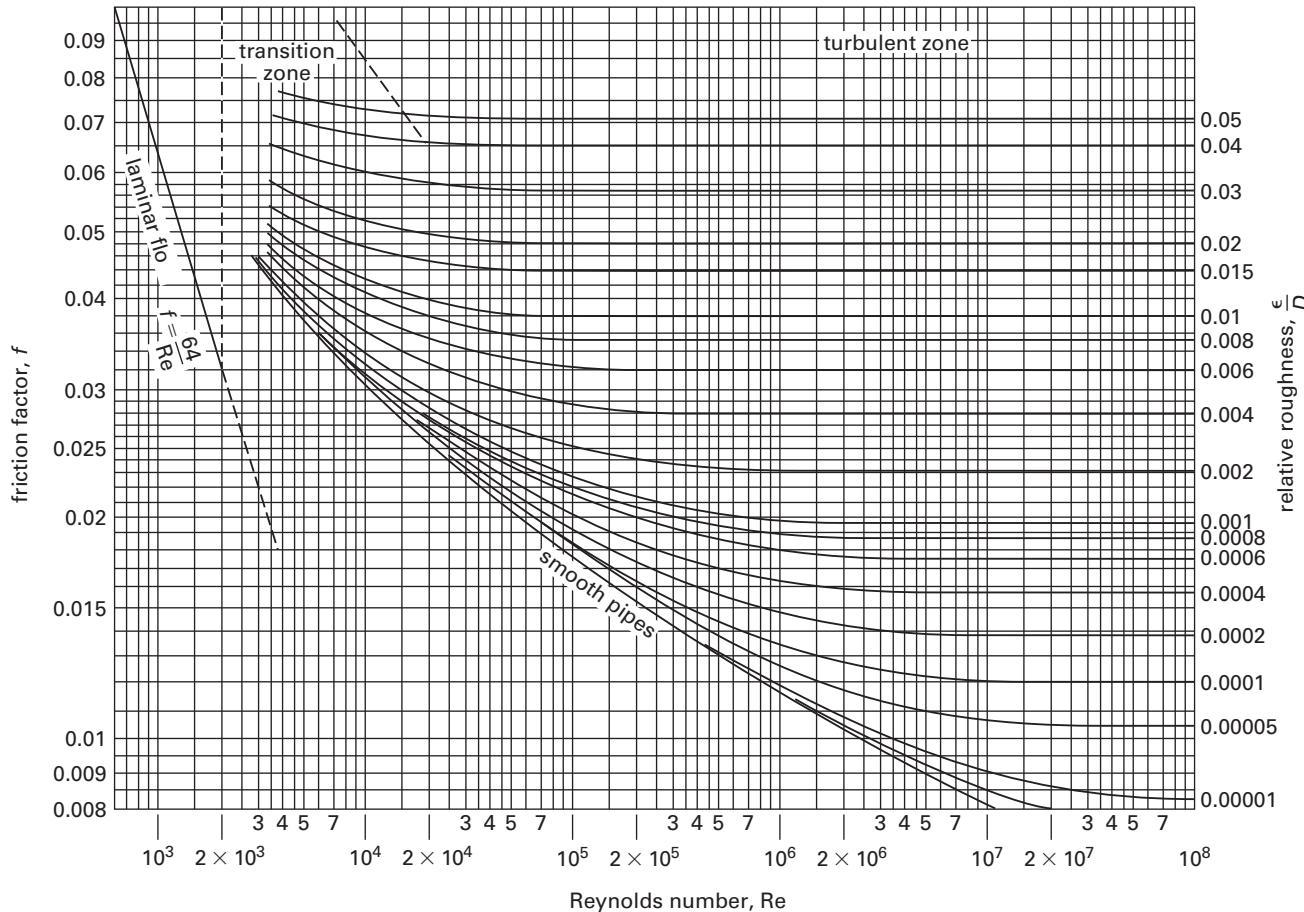

(d) From Eq. 17.20,

$$\begin{aligned} \frac{1}{\sqrt{f}} &= -2 \log_{10} \left( \frac{\epsilon}{3.7} + \frac{2.51}{\text{Re}\sqrt{f}} \right) \\ \frac{1}{\sqrt{0.0287}} &= -2 \log_{10} \left( \frac{0.004}{3.7} + \frac{2.51}{400,000\sqrt{0.0287}} \right) \\ 5.903 &= 5.903 \end{aligned}$$

### 8. ENERGY LOSS DUE TO FRICTION: LAMINAR FLOW

Two methods are available for calculating the frictional energy loss for fluids experiencing laminar flow. The most common is the *Darcy equation* (which is also

**Figure 17.4** Moody Friction Factor Chart

Reprinted with permission from L. F. Moody, "Friction Factor for Pipe Flow," *ASME Transactions*, Vol. 66, published by the American Society of Mechanical Engineers, copyright © 1944.

known as the *Weisbach equation* or the *Darcy-Weisbach equation*), which can be used for both laminar and turbulent flow.<sup>8</sup> One of the advantages of using the Darcy equation is that the assumption of laminar flow does not need to be confirmed if  $f$  is known.

$$h_f = \frac{fLv^2}{2Dg} \quad 17.22$$

$$E_f = h_f g = \frac{fLv^2}{2D} \quad [\text{SI}] \quad 17.23(a)$$

$$E_f = h_f \times \frac{g}{g_c} = \frac{fLv^2}{2Dg_c} \quad [\text{U.S.}] \quad 17.23(b)$$

If the flow is truly laminar and the fluid is flowing in a circular pipe, then the *Hagen-Poiseuille equation* can be used.

$$E_f = \frac{32\mu vL}{D^2\rho} = \frac{128\mu \dot{V}L}{\pi D^4\rho} \quad 17.24$$

If necessary,  $h_f$  can be converted to an actual pressure drop in  $\text{lbf}/\text{ft}^2$  or  $\text{Pa}$  by multiplying by the fluid density.

$$\Delta p = h_f \times \rho g \quad [\text{SI}] \quad 17.25(a)$$

$$\Delta p = h_f \times \rho \left( \frac{g}{g_c} \right) = h_f \gamma \quad [\text{U.S.}] \quad 17.25(b)$$

Values of the Darcy friction factor,  $f$ , are often quoted for new, clean pipe. The friction head losses and pumping power requirements calculated from these values are minimum values. Depending on the nature of the service, scale and impurity buildup within pipes may decrease the pipe diameters over time. Since the frictional loss is proportional to the fifth power of the diameter, such diameter decreases can produce dramatic increases in the friction loss.

$$\frac{h_{f,\text{scaled}}}{h_{f,\text{new}}} = \left( \frac{D_{\text{new}}}{D_{\text{scaled}}} \right)^5 \quad 17.26$$

<sup>8</sup>The difference is that the friction factor can be derived by hydrodynamics:  $f = 64/\text{Re}$ . For turbulent flow,  $f$  is empirical.

Equation 17.26 accounts for only the decrease in diameter. Any increase in roughness (i.e., friction factor) will produce a proportional increase in friction loss.

Because the “new, clean” condition is transitory in most applications, an uprating factor of 10–30% is often applied to either the friction factor,  $f$ , or the head loss,  $h_f$ . Of course, even larger increases should be considered when extreme fouling is expected.

Another approach eliminates the need to estimate the scaled pipe diameter. This simplistic approach multiplies the initial friction loss by a factor based on the age of the pipe. For example, for schedule-40 pipe between 4 in and 10 in (10 cm and 25 cm) in diameter, the multipliers of 1.4, 2.2, and 5.0 have been proposed for pipe ages of 5, 10, and 20 years, respectively. For larger pipes, the corresponding multipliers are 1.3, 1.6, and 2.0. Obviously, use of these values should be based on a clear understanding of the method’s limitations.

## 9. ENERGY LOSS DUE TO FRICTION: TURBULENT FLOW

The *Darcy equation* is used almost exclusively to calculate the head loss due to friction for turbulent flow.

$$h_f = \frac{fLv^2}{2Dg} \quad 17.27$$

The head loss can be converted to pressure drop.

$$\Delta p = h_f \times \rho g \quad [\text{SI}] \quad 17.28(a)$$

$$\Delta p = h_f \times \rho \left( \frac{g}{g_c} \right) = h_f \gamma \quad [\text{U.S.}] \quad 17.28(b)$$

In problems where the pipe size is unknown, it will be impossible to obtain an accurate initial value of the friction factor,  $f$  (since  $f$  depends on velocity). In such problems, an iterative solution will be necessary.

Civil engineers commonly use the *Hazen-Williams equation* to calculate head loss. This method requires knowing the Hazen-Williams *roughness coefficient*,  $C$ , values of which are widely tabulated.<sup>9</sup> (See App. 17.A.) The advantage of using this equation is that  $C$  does not depend on the Reynolds number. The Hazen-Williams equation is empirical and is not dimensionally homogeneous. It is taken as a matter of faith that the units of  $h_f$  are feet.

$$h_{f,ft} = \frac{3.022v_{ft/sec}^{1.85} L_{ft}}{C^{1.85} D_{ft}^{1.17}} = \frac{10.44L_{ft} Q_{gpm}^{1.85}}{C^{1.85} d_{in}^{4.87}} \quad [\text{U.S.}] \quad 17.29$$

<sup>9</sup>An approximate value of  $C = 140$  is often chosen for initial calculations for new water pipe.  $C = 100$  is more appropriate for water pipe that has been in service for some time. For sludge,  $C$  values are 20–40% lower than the equivalent water pipe values.

The Hazen-Williams equation should be used only for turbulent flow. It gives good results for liquids that have kinematic viscosities around  $1.2 \times 10^{-5}$  ft<sup>2</sup>/sec ( $1.1 \times 10^{-6}$  m<sup>2</sup>/s), which corresponds to the viscosity of 60°F (16°C) water. At extremely high and low temperatures, the Hazen-Williams equation can be 20% or more in error for water.

### Example 17.3

50°F water is pumped through 1000 ft of 4 in, schedule-40 welded steel pipe at the rate of 300 gpm. What friction loss (in ft-lbf/lbm) is predicted by the Darcy equation?

*Solution*

The fluid viscosity, pipe dimensions, and other parameters can be found from the appendices.

From App. 14.A,  $\nu = 1.41 \times 10^{-5}$  ft<sup>2</sup>/sec.

From App. 17.A,  $\epsilon = 0.0002$  ft.

From App. 16.B,

$$D = 0.3355 \text{ ft}$$

$$A = 0.0884 \text{ ft}^2$$

The flow quantity is converted from gallons per minute to cubic feet per second.

$$\dot{V} = \frac{300 \frac{\text{gal}}{\text{min}}}{\left( 7.4805 \frac{\text{gal}}{\text{ft}^3} \right) \left( 60 \frac{\text{sec}}{\text{min}} \right)} = 0.6684 \text{ ft}^3/\text{sec}$$

The velocity is

$$v = \frac{\dot{V}}{A} = \frac{0.6684 \frac{\text{ft}^3}{\text{sec}}}{0.0884 \text{ ft}^2} = 7.56 \text{ ft/sec}$$

The Reynolds number is

$$\text{Re} = \frac{Dv}{\nu} = \frac{(0.3355 \text{ ft}) (7.56 \frac{\text{ft}}{\text{sec}})}{1.41 \times 10^{-5} \frac{\text{ft}^2}{\text{sec}}} = 1.8 \times 10^5$$

The relative roughness is

$$\frac{\epsilon}{D} = \frac{0.0002 \text{ ft}}{0.3355 \text{ ft}} = 0.0006$$

From the friction factor table, App. 17.B (or the Moody friction factor chart),  $f = 0.0195$ . Equation 17.23(b) is used to calculate the friction loss.

$$\begin{aligned}
 E_f &= h_f \times \frac{g}{g_c} = \frac{f L v^2}{2 D g_c} \\
 &= \frac{(0.0195)(1000 \text{ ft}) \left( 7.56 \frac{\text{ft}}{\text{sec}} \right)^2}{(2)(0.3355 \text{ ft}) \left( 32.2 \frac{\text{lbf}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2} \right)} \\
 &= 51.6 \text{ ft-lbf/lbm}
 \end{aligned}$$

**Example 17.4**

Calculate the head loss due to friction for the pipe in Ex. 17.3 using the Hazen-Williams formula. Assume  $C = 100$ .

*Solution*

Substituting the parameters derived in Ex. 17.3 into Eq. 17.29,

$$\begin{aligned}
 h_f &= \frac{3.022 v_{\text{ft/sec}}^{1.85} L_{\text{ft}}}{C^{1.85} D_{\text{ft}}^{1.17}} = \frac{(3.022) \left( 7.56 \frac{\text{ft}}{\text{sec}} \right)^{1.85} (1000 \text{ ft})}{(100)^{1.85} (0.3355 \text{ ft})^{1.17}} \\
 &= 91.3 \text{ ft}
 \end{aligned}$$

Alternatively, the given data can be substituted directly into Eq. 17.29.

$$\begin{aligned}
 h_f &= \frac{10.44 L_{\text{ft}} Q_{\text{gpm}}^{1.85}}{C^{1.85} d_{\text{in}}^{4.87}} = \frac{(10.44)(1000 \text{ ft})(300 \text{ gpm})^{1.85}}{(100)^{1.85} (4.026 \text{ in})^{4.87}} \\
 &= 90.4 \text{ ft}
 \end{aligned}$$

**10. FRICTION LOSS FOR WATER FLOW IN STEEL PIPES**

Since water's specific volume is essentially constant within the normal temperature range, tables and charts can be used to determine water velocity. Friction loss and velocity for water flowing through steel pipe (as well as for other liquids and other pipe materials) in table and chart form are widely available. (Appendix 17.C is an example of such a table.) Tables and charts almost always give the friction loss per 100 ft or 10 m of pipe. The pressure drop is proportional to the length, so the value read can be scaled for other pipe lengths. Flow velocity is independent of pipe length.

These tables and charts are unable to compensate for the effects of fluid temperature and different pipe roughness. Unfortunately, the assumptions made in developing the tables and charts are seldom listed. Another disadvantage is that the values can be read to only a few significant figures. Friction loss data should be considered accurate to only  $\pm 20\%$ . Alternatively, a 20% safety margin should be established in choosing pumps and motors.

**11. FRICTION LOSS IN NONCIRCULAR DUCTS**

The frictional energy loss by a fluid flowing in a rectangular, annular, or other noncircular duct can be calculated from the Darcy equation by using the *hydraulic diameter*,  $D_h$ , in place of the diameter,  $D$ .<sup>10</sup> The friction factor,  $f$ , is determined in any of the conventional manners.

**12. FRICTION LOSS FOR OTHER LIQUIDS, STEAM, AND GASES**

The Darcy equation can be used to calculate the frictional energy loss for all incompressible liquids, not just for water. Alcohol, gasoline, fuel oil, and refrigerants, for example, are all handled well, since the effect of viscosity is considered in determining the friction factor,  $f$ .<sup>11</sup>

In fact, the Darcy equation is commonly used with noncondensing vapors and compressed gases, such as air, nitrogen, and steam.<sup>12</sup> In such cases, reasonable accuracy will be achieved as long as the fluid is not moving too fast (i.e., less than Mach 0.3) and is incompressible. The fluid is assumed to be incompressible if the pressure (or density) change along the section of interest is less than 10% of the starting pressure.

If possible, it is preferred to base all calculations on the average properties of the fluid as determined at the midpoint of a pipe.<sup>13</sup> Specifically, the fluid velocity would normally be calculated as

$$v = \frac{\dot{m}}{\rho_{\text{ave}} A} \quad 17.30$$

However, the average density of a gas depends on the average pressure, which is unknown at the start of a problem. The solution is to write the Reynolds number and Darcy equation in terms of the constant mass flow rate per unit area,  $G$ , instead of velocity,  $v$ , which varies.

$$G = v_{\text{ave}} \rho_{\text{ave}} \quad 17.31$$

$$\text{Re} = \frac{DG}{\mu} \quad [\text{SI}] \quad 17.32(a)$$

$$\text{Re} = \frac{DG}{g_c \mu} \quad [\text{U.S.}] \quad 17.32(b)$$

<sup>10</sup>Although it is used for both, this approach is better suited for turbulent flow than for laminar flow. Also, the accuracy of this method decreases as the flow area becomes more noncircular. The friction drop in long, narrow slit passageways is poorly predicted, for example. However, there is no other convenient method of predicting friction drop. Experimentation should be used with a particular flow geometry if extreme accuracy is required.

<sup>11</sup>Since viscosity is not an explicit factor in the formula, it should be obvious that the Hazen-Williams equation is primarily used for water.

<sup>12</sup>Use of the Darcy equation is limited only by the availability of the viscosity data needed to calculate the Reynolds number.

<sup>13</sup>Of course, the entrance (or exit) conditions can be used if great accuracy is not needed.

$$\Delta p_f = p_1 - p_2 = \rho_{ave} h_f g = \frac{f L G^2}{2 D \rho_{ave}} \quad [SI] \quad 17.33(a)$$

$$\begin{aligned} \Delta p_f &= p_1 - p_2 = \gamma_{ave} h_f = \rho_{ave} h_f \times \frac{g}{g_c} \\ &= \frac{f L G^2}{2 D \rho_{ave} g_c} \end{aligned} \quad [U.S.] \quad 17.33(b)$$

Assuming a perfect gas with a molecular weight of MW, the ideal gas law can be used to calculate  $\rho_{ave}$  from the absolute temperature,  $T$ , and  $p_{ave} = (p_1 + p_2)/2$ .

$$p_1^2 - p_2^2 = \frac{f L G^2 R^* T}{D(MW)} \quad [SI] \quad 17.34(a)$$

$$p_1^2 - p_2^2 = \frac{f L G^2 R^* T}{D g_c(MW)} \quad [U.S.] \quad 17.34(b)$$

To summarize, use the following guidelines when working with compressible gases or vapors flowing in a pipe or duct. (a) If the pressure drop, based on the entrance pressure, is less than 10%, the fluid can be assumed to be incompressible, and the gas properties can be evaluated at any point known along the pipe. (b) If the pressure drop is between 10% and 40%, use of the midpoint properties will yield reasonably accurate friction losses. (c) If the pressure drop is greater than 40%, the pipe can be divided into shorter sections and the losses calculated for each section, or exact calculations based on compressible flow theory must be made.

Calculating a friction loss for steam flow using the Darcy equation can be frustrating if steam viscosity data are unavailable. Generally, the steam viscosities listed in compilations of heat transfer data are sufficiently accurate. Various empirical methods are also in use. For example, the *Babcock formula*, given by Eq. 17.35, for pressure drop when steam with a specific volume,  $v$ , flows in a pipe of diameter  $d$  is

$$\Delta p_{psi} = 0.470 \left( \frac{d_{in} + 3.6}{d_{in}^6} \right) \dot{m}_{lbm/sec}^2 L_{ft} v_{ft^3/lbm} \quad 17.35$$

Use of empirical formulas is not limited to steam. Theoretical formulas (e.g., the *complete isothermal flow equation*) and specialized empirical formulas (e.g., the *Weymouth*, *Panhandle*, and *Spitzglass formulas*) have been developed, particularly by the gas pipeline industry. Each of these provides reasonable accuracy within their operating limits. However, none should be used without knowing the assumptions and operational limitations that were used in their derivations.

### Example 17.5

0.0011 kg/s of 25°C nitrogen gas flows isothermally through a 175 m section of smooth tubing (inside diameter = 0.012 m). The viscosity of the nitrogen is

$1.8 \times 10^{-5}$  Pa·s. The pressure of the nitrogen is 200 kPa originally. At what pressure is the nitrogen delivered?

#### SI Solution

The flow area of the pipe is

$$A = \frac{\pi D^2}{4} = \frac{\pi (0.012 \text{ m})^2}{4} = 1.131 \times 10^{-4} \text{ m}^2$$

The mass flow rate per unit area is

$$G = \frac{\dot{m}}{A} = \frac{0.0011 \frac{\text{kg}}{\text{s}}}{1.131 \times 10^{-4} \text{ m}^2} = 9.73 \text{ kg/m}^2 \cdot \text{s}$$

The Reynolds number is

$$Re = \frac{DG}{\mu} = \frac{(0.012 \text{ m})(9.73 \frac{\text{kg}}{\text{m}^2 \cdot \text{s}})}{1.8 \times 10^{-5} \text{ Pa} \cdot \text{s}} = 6487$$

The flow is turbulent, and the pipe is said to be smooth. Therefore, the friction factor is interpolated (from App. 17.B) as 0.0347.

Since two atoms of nitrogen form a molecule of nitrogen gas, the molecular weight of nitrogen is twice the atomic weight, or 28.0 kg/kmol. The temperature must be in degrees absolute:  $T = 25^\circ\text{C} + 273^\circ = 298\text{K}$ . The universal gas constant is 8314.47 J/kmol·K.

From Eq. 17.34, the final pressure is

$$\begin{aligned} p_2^2 &= p_1^2 - \frac{f L G^2 R^* T}{D(MW)} \\ &= (200 \text{ kPa})^2 - \frac{(0.0347)(175 \text{ m}) \left( 9.73 \frac{\text{kg}}{\text{m}^2 \cdot \text{s}} \right)^2 \times \left( 8314.47 \frac{\text{J}}{\text{kmol} \cdot \text{K}} \right) (298\text{K})}{(0.012 \text{ m}) \left( 28 \frac{\text{kg}}{\text{kmol}} \right)} \\ &= 3.576 \times 10^{10} \text{ Pa}^2 \end{aligned}$$

$$p_2 = \sqrt{3.576 \times 10^{10} \text{ Pa}^2} = 1.89 \times 10^5 \text{ Pa} \quad (189 \text{ kPa})$$

The percentage drop in pressure should not be more than 10%.

$$\frac{200 \text{ kPa} - 189 \text{ kPa}}{200 \text{ kPa}} = 0.055 \quad (5.5\%) \quad [\text{OK}]$$

### Example 17.6

Superheated steam at 140 psi and 500°F enters a 200 ft long steel pipe (Darcy friction factor of 0.02) with an internal diameter of 3.826 in. The pipe is insulated so that there is no heat loss. (a) Use the Babcock formula

to determine the maximum velocity and mass flow rate such that the steam does not experience more than a 10% drop in pressure. (b) Verify the velocity by calculating the pressure drop with the Darcy equation.

*Solution*

(a) From the superheated steam table (see App. 18.C), the interpolated specific volume of the steam is

$$\begin{aligned} v &= 5.588 \frac{\text{ft}^3}{\text{lbfm}} - \left( \frac{140 \text{ psia} - 100 \text{ psia}}{150 \text{ psia} - 100 \text{ psia}} \right) \\ &\quad \times \left( 5.588 \frac{\text{ft}^3}{\text{lbfm}} - 3.680 \frac{\text{ft}^3}{\text{lbfm}} \right) \\ &= 4.062 \text{ ft}^3/\text{lbfm} \end{aligned}$$

The maximum pressure drop is 10% of 140 psi or 14 psi.

From Eq. 17.35,

$$\begin{aligned} \Delta p_{\text{psi}} &= 0.470 \left( \frac{d_{\text{in}} + 3.6}{d_{\text{in}}^6} \right) \dot{m}_{\text{lbfm/sec}}^2 L_{\text{ft}} v_{\text{ft}^3/\text{lbfm}} \\ 14 \text{ psi} &= (0.470) \left( \frac{3.826 \text{ in} + 3.6}{(3.826 \text{ in})^6} \right) \dot{m}^2 \\ &\quad \times (200 \text{ ft}) \left( 4.062 \frac{\text{ft}^3}{\text{lbfm}} \right) \\ \dot{m} &= 3.935 \text{ lbm/sec} \end{aligned}$$

The steam velocity is

$$\begin{aligned} v &= \frac{\dot{V}}{A} = \frac{\dot{m}}{\rho A} = \frac{\dot{m}v}{A} \\ &= \frac{\left( 3.935 \frac{\text{lbm}}{\text{sec}} \right) \left( 4.062 \frac{\text{ft}^3}{\text{lbfm}} \right)}{\left( \frac{\pi}{4} \right) \left( \frac{3.826 \text{ in}}{12 \frac{\text{in}}{\text{ft}}} \right)^2} \\ &= 200.2 \text{ ft/sec} \end{aligned}$$

(b) The steam friction head is

$$\begin{aligned} h_f &= \frac{fLv^2}{2Dg} = \frac{(0.02)(200 \text{ ft}) \left( 200.2 \frac{\text{ft}}{\text{sec}} \right)^2}{(2) \left( \frac{3.826 \text{ in}}{12 \frac{\text{in}}{\text{ft}}} \right) \left( 32.2 \frac{\text{ft}}{\text{sec}^2} \right)} \\ &= 7808 \text{ ft of steam} \end{aligned}$$

From Eq. 17.33,

$$\begin{aligned} \Delta p &= \rho h_f \times \frac{g}{g_c} = \frac{h_f}{v} \times \frac{g}{g_c} \\ &= \frac{7808 \text{ ft}}{\left( 4.062 \frac{\text{ft}^3}{\text{lbfm}} \right) \left( 12 \frac{\text{in}}{\text{ft}} \right)^2} \times \left( \frac{32.2 \frac{\text{ft}}{\text{sec}^2}}{32.2 \frac{\text{lbf}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2}} \right) \\ &= 13.3 \text{ lbf/in}^2 \quad (13.3 \text{ psi}) \end{aligned}$$

### 13. EFFECT OF VISCOSITY ON HEAD LOSS

Friction loss in a pipe is affected by the fluid viscosity. For both laminar and turbulent flow, viscosity is considered when the Reynolds number is calculated. When viscosities substantially increase without a corresponding decrease in flow rate, two things usually happen: (a) the friction loss greatly increases, and (b) the flow becomes laminar.

It is sometimes necessary to estimate head loss for a new fluid viscosity based on head loss at an old fluid viscosity. The estimation procedure used depends on the flow regimes for the new and old fluids.

For laminar flow, the friction factor is directly proportional to the viscosity. If the flow is laminar for both fluids, the ratio of new-to-old head losses will be equal to the ratio of new-to-old viscosities. Therefore, if a flow is already known to be laminar at one viscosity and the fluid viscosity increases, a simple ratio will define the new friction loss.

If both flows are fully turbulent, the friction factor will not change. If flow is fully turbulent and the viscosity decreases, the Reynolds number will increase. Theoretically, this will have no effect on the friction loss.

There are no analytical ways of estimating the change in friction loss when the flow regime changes between laminar and turbulent or between semiturbulent and fully turbulent. Various graphical methods are used, particularly by the pump industry, for calculating power requirements.

### 14. FRICTION LOSS WITH SLURRIES AND NON-NEWTONIAN FLUIDS

A *slurry* is a mixture of a liquid (usually water) and a solid (e.g., coal, paper pulp, foodstuff). The liquid is generally used as the transport mechanism (i.e., the *carrier*) for the solid.

Friction loss calculations for slurries vary in sophistication depending on what information is available. In many cases, only the slurry's specific gravity is known. In that case, use is made of the fact that friction loss can be reasonably predicted by multiplying the friction loss based on the pure carrier (e.g., water) by the specific gravity of the slurry.

Another approach is possible if the density and viscosity in the operating range are known. The traditional Darcy equation and Reynolds number can be used for thin slurries as long as the flow velocity is high enough to keep solids from settling. (See Eq. 17.27.) (Settling is more of a concern for laminar flow. With turbulent flow, the direction of velocity components fluctuates, assisting the solids to remain in suspension.)

The most analytical approach to slurries or other non-Newtonian fluids requires laboratory-derived rheological data. *Non-Newtonian viscosity* ( $\eta$ , in Pa·s) is fitted to data of the shear rate ( $dv/dy$ , in  $s^{-1}$ ) according to two common models: the power-law model and the Bingham-plastic model. These two models are applicable to both laminar and turbulent flow, although each has its advantages and disadvantages.

The *power-law model* has two empirical constants,  $m$  and  $n$ , that must be determined.

$$\eta = m \left( \frac{dv}{dy} \right)^{n-1} \quad 17.36$$

The *Bingham-plastic model* also requires finding two empirical constants: the *yield* (or *critical*) *stress*,  $\tau_0$  (in units of Pa) below which the fluid is immobile, and the *Bingham-plastic limiting viscosity*,  $\mu_\infty$  (in units of Pa·s).

$$\eta = \frac{\tau_0}{\frac{dv}{dy} + \mu_\infty} \quad 17.37$$

Once  $m$  and  $n$  (or  $\tau_0$  and  $\mu_\infty$ ) have been determined, the friction factor is determined from one of various models (e.g., Buckingham-Reiner, Dodge-Metzner, Metzner-Reed, Hanks-Ricks, Darby, or Hanks-Dadia). Specialized texts and articles cover these models in greater detail. The friction loss is calculated from the traditional Darcy equation.

## 15. MINOR LOSSES

In addition to the frictional energy lost due to viscous effects, friction losses also result from fittings in the line, changes in direction, and changes in flow area. These losses are known as *minor losses* or *local losses*, since they are usually much smaller in magnitude than the pipe wall frictional loss.<sup>14</sup> Two methods are used to calculate minor losses: equivalent lengths and loss coefficients.

With the *method of equivalent lengths*, each fitting or other flow variation is assumed to produce friction equal to the pipe wall friction from an *equivalent length* of pipe. For example, a 2 in globe valve may produce the

<sup>14</sup>Example and practice problems often include the instruction to “ignore minor losses.” In some industries, valves are considered to be “components,” not fittings. In such cases, instructions to “ignore minor losses in fittings” would be ambiguous, since minor losses in valves would be included in the calculations. However, this interpretation is rare in examples and practice problems.

same amount of friction as 54 ft (its equivalent length) of 2 in pipe. The equivalent lengths for all minor losses are added to the pipe length term,  $L$ , in the Darcy equation. The method of equivalent lengths can be used with all liquids, but it is usually limited to turbulent flow by the unavailability of laminar equivalent lengths, which are significantly larger than turbulent equivalent lengths.

$$L_t = L + \sum L_e \quad 17.38$$

Equivalent lengths are simple to use, but the method depends on having a table of equivalent length values. The actual value for a fitting will depend on the fitting manufacturer, as well as the fitting material (e.g., brass, cast iron, or steel) and the method of attachment (e.g., weld, thread, or flange).<sup>15</sup> Because of these many variations, it may be necessary to use a “generic table” of equivalent lengths during the initial design stages. (See App. 17.D.)

An alternative method of calculating the minor loss for a fitting is to use the *method of loss coefficients*. Each fitting has a *loss coefficient*,  $K$ , associated with it, which, when multiplied by the kinetic energy, gives the loss. (See Table 17.4.) Therefore, a loss coefficient is the minor loss expressed in fractions (or multiples) of the velocity head.

$$h_m = K h_v \quad 17.39$$

The loss coefficient for any minor loss can be calculated if the equivalent length is known. However, there is no advantage to using one method over the other, other than convention and for consistency in calculations.

$$K = \frac{f L_e}{D} \quad 17.40$$

Exact friction loss coefficients for bends, fittings, and valves are unique to each manufacturer. Furthermore, except for contractions, enlargements, exits, and entrances, the coefficients decrease fairly significantly (according to the fourth power of the diameter ratio) with increases in valve size. Therefore, a single  $K$  value is seldom applicable to an entire family of valves. Nevertheless, generic tables and charts have been developed. These compilations can be used for initial estimates as long as the general nature of the data is recognized.

Loss coefficients for specific fittings and valves must be known in order to be used. They cannot be derived theoretically. However, the loss coefficients for certain changes in flow area can be calculated from the following equations.<sup>16</sup>

<sup>15</sup>In the language of pipe fittings, a *threaded fitting* is known as a *screwed fitting*, even though no screws are used.

<sup>16</sup>No attempt is made to imply great accuracy with these equations. Correlation between actual and theoretical losses is fair.

**Table 17.4** Typical Loss Coefficients,  $K^a$ 

device	$K$
angle valve	5
bend, close return	2.2
butterfly valve, <sup>b</sup> 2–8 in	$45f_t$
butterfly valve, 10–14 in	$35f_t$
butterfly valve, 16–24 in	$25f_t$
check valve, swing, fully open	2.3
corrugated bends	1.3–1.6 times value for smooth bend
standard 90° elbow	0.9
long radius 90° elbow	0.6
45° elbow	0.42
gate valve, fully open	0.19
gate valve, 1/4 closed	1.15
gate valve, 1/2 closed	5.6
gate valve, 3/4 closed	24
globe valve	10
meter disk or wobble	3.4–10
meter, rotary (star or cog-wheel piston)	10
meter, reciprocating piston	15
meter, turbine wheel (double flow)	5–7.5
tee, standard	1.8

<sup>a</sup>The actual loss coefficient will usually depend on the size of the valve.  
Average values are given.

<sup>b</sup>Loss coefficients for butterfly valves are calculated from the friction factors for the pipes with complete turbulent flow.

- *sudden enlargements* ( $D_1$  is the smaller of the two diameters)

$$K = \left(1 - \left(\frac{D_1}{D_2}\right)^2\right)^2 \quad 17.41$$

- *sudden contractions* ( $D_1$  is the smaller of the two diameters)

$$K = \frac{1}{2} \left(1 - \left(\frac{D_1}{D_2}\right)^2\right) \quad 17.42$$

- *pipe exit* (projecting exit, sharp-edged, or rounded)

$$K = 1.0 \quad 17.43$$

- *pipe entrance*

reentrant:  $K = 0.78$

sharp-edged:  $K = 0.50$

rounded:

<u>bend radius</u>	<u><math>D</math></u>	$K$
0.02	0.28	
0.04	0.24	
0.06	0.15	
0.10	0.09	
0.15	0.04	

- *tapered diameter changes*

$$\beta = \frac{\text{small diameter}}{\text{large diameter}} = \frac{D_1}{D_2}$$

$\phi$  = wall-to-horizontal angle

For enlargement,  $\phi \leq 22^\circ$ :

$$K = 2.6 \sin \phi (1 - \beta^2)^2 \quad 17.44$$

For enlargement,  $\phi > 22^\circ$ :

$$K = (1 - \beta^2)^2 \quad 17.45$$

For contraction,  $\phi \leq 22^\circ$ :

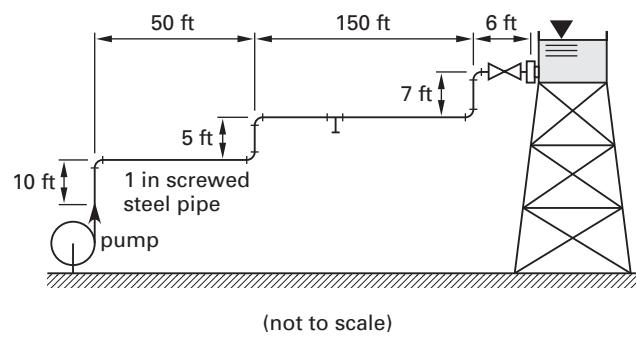

$$K = 0.8 \sin \phi (1 - \beta^2) \quad 17.46$$

For contraction,  $\phi > 22^\circ$ :

$$K = 0.5 \sqrt{\sin \phi} (1 - \beta^2) \quad 17.47$$

### Example 17.7

A pipeline contains one gate valve, five regular 90° elbows, one tee (flow through the run), and 228 ft of straight pipe. All fittings are 1 in screwed steel pipe. Disregard entrance and exit losses. Determine the total equivalent length of the piping system shown.

### Solution

From App. 17.D, the individual and total equivalent lengths are

1	gate valve	$1 \times 0.84 \text{ ft}$	=	0.84 ft
5	regular elbows	$5 \times 5.2 \text{ ft}$	=	26.00 ft
1	tee run	$1 \times 3.2 \text{ ft}$	=	3.20 ft
	straight pipe		=	228.00 ft
	total $L_t$		=	258.04 ft

## 16. VALVE FLOW COEFFICIENTS

Valve flow capacities depend on the geometry of the inside of the valve. The *flow coefficient*,  $C_v$ , for a valve (particularly a control valve) relates the flow quantity (in gallons per minute) of a fluid with specific gravity to

the pressure drop (in pounds per square inch). (The flow coefficient for a valve is not the same as the coefficient of flow for an orifice or venturi meter.) As Eq. 17.48 shows, the flow coefficient is not dimensionally homogeneous.

Metricated countries use a similar concept with a different symbol,  $K_v$ , (not the same as the loss coefficient,  $K$ ) to distinguish the valve flow coefficient from customary U.S. units.  $K_v$  is defined<sup>17</sup> as the flow rate in cubic meters per hour of water at a temperature of 16°C with a pressure drop across the valve of 1 bar. To further distinguish it from its U.S. counterpart,  $K_v$  may also be referred to as a *flow factor*.  $C_v$  and  $K_v$  are linearly related by Eq. 17.49.

$$\dot{V}_{\text{m}^3/\text{h}} = K_v \sqrt{\frac{\Delta p_{\text{bars}}}{\text{SG}}} \quad [\text{SI}] \quad 17.48(a)$$

$$Q_{\text{gpm}} = C_v \sqrt{\frac{\Delta p_{\text{psi}}}{\text{SG}}} \quad [\text{U.S.}] \quad 17.48(b)$$

$$K_v = 0.86 C_v \quad 17.49$$

When selecting a control valve for a particular application, the value of  $C_v$  is first calculated. Depending on the application and installation,  $C_v$  may be further modified by dividing by *piping geometry* and *Reynolds number factors*. (These additional procedures are often specified by the valve manufacturer.) Then, a valve with the required value of  $C_v$  is selected.

Although the flow coefficient concept is generally limited to control valves, its use can be extended to all fittings and valves. The relationship between  $C_v$  and the loss coefficient,  $K$ , is

$$C_v = \frac{29.9 d_{\text{in}}^2}{\sqrt{K}} \quad [\text{U.S.}] \quad 17.50$$

## 17. SHEAR STRESS IN CIRCULAR PIPES

Shear stress in fluid always acts to oppose the motion of the fluid. (That is the reason the term *pipe friction* is used.) Shear stress for a fluid in laminar flow can be calculated from the basic definition of absolute viscosity.

$$\tau = \mu \frac{dv}{dy} \quad 17.51$$

In the case of the flow in a circular pipe,  $dr$  can be substituted for  $dy$  in the expression for *shear rate (velocity gradient)*,  $dv/dy$ .

$$\tau = \mu \frac{dv}{dr} \quad 17.52$$

Equation 17.53 calculates the shear stress between fluid layers a distance  $r$  from the pipe centerline in terms of the pressure drop across a length  $L$  of the pipe.<sup>18</sup> Equation 17.53 is valid for both laminar and turbulent flows.

$$\tau = \frac{(p_1 - p_2)r}{2L} \quad [r \leq \frac{D}{2}] \quad 17.53$$

The quantity  $(p_1 - p_2)$  can be calculated from the Darcy equation. (See Eq. 17.27.) If  $v$  is the average flow velocity, the shear stress at the wall (where  $r = D/2$ ) is

$$\tau_{\text{wall}} = \frac{f \rho v^2}{8} \quad [\text{SI}] \quad 17.54(a)$$

$$\tau_{\text{wall}} = \frac{f \rho v^2}{8 g_c} \quad [\text{U.S.}] \quad 17.54(b)$$

Equation 17.53 can be rearranged to give the relationship between the pressure gradient along the flow path and the shear stress at the wall.

$$\frac{dp}{dL} = \frac{4\tau_{\text{wall}}}{D} \quad 17.55$$

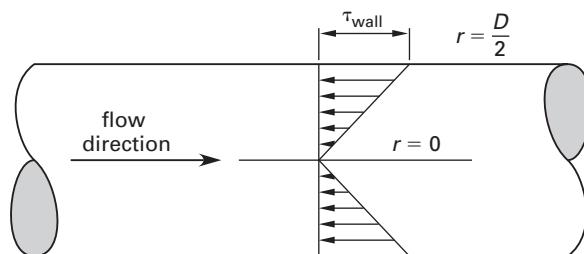

Equation 17.54 can be combined with the Hagen-Poiseuille equation (given in Eq. 17.24) if the flow is laminar. ( $v$  in Eq. 17.56 is the average velocity of fluid flow.)

$$\tau = \frac{16\mu v r}{D^2} \quad [\text{laminar; } r \leq \frac{D}{2}] \quad 17.56$$

At the pipe wall,  $r = D/2$ , and the shear stress is maximum. (See Fig. 17.5.)

$$\tau_{\text{wall}} = \frac{8\mu v}{D} \quad 17.57$$

**Figure 17.5** Shear Stress Distribution in a Circular Pipe

<sup>17</sup>Several definitions of both  $C_v$  and  $K_v$  are in use. A definition of  $C_v$  based on Imperial gallons is used in Great Britain. Definitions of  $K_v$  based on pressure drops in kilograms-force and volumes in liters per minute are in use. Other differences in the definition include the applicable temperature, which may be given as 5–30°C or 5–40°C instead of 16°C.

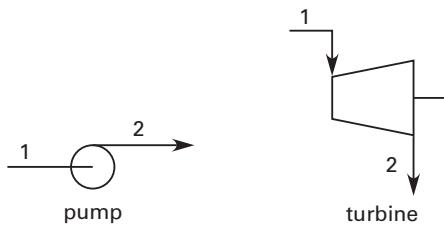

<sup>18</sup>In highly turbulent flow, shear stress is not caused by viscous effects but rather by momentum effects. Equation 17.53 is derived from a shell momentum balance. Such an analysis requires the concept of *momentum flux*. In a circular pipe with laminar flow, momentum flux is maximum at the pipe wall, zero at the flow centerline, and varies linearly in between.

## 18. INTRODUCTION TO PUMPS AND TURBINES

A *pump* adds energy to the fluid flowing through it. (See Fig. 17.6.) The amount of energy that a pump puts into the fluid stream can be determined by the difference between the total energy on either side of the pump. The specific energy added (a positive number) on a per-unit mass basis (i.e., ft-lbf/lbm or J/kg) is given by Eq. 17.58. In most situations, a pump will add primarily pressure energy.

$$E_A = E_{t,2} - E_{t,1} \quad 17.58$$

**Figure 17.6** Pump and Turbine Representation

The *head added* by a pump,  $h_A$ , is

$$h_A = \frac{E_A}{g} \quad [\text{SI}] \quad 17.59(a)$$

$$h_A = \frac{E_A g_c}{g} \quad [\text{U.S.}] \quad 17.59(b)$$

The specific energy added by a pump can also be calculated from the input power if the mass flow rate is known. The input power to the pump will be the output power of the electric motor or engine driving the pump.

$$E_A = \frac{\left(1000 \frac{\text{W}}{\text{kW}}\right) P_{\text{kW,input}} \eta_{\text{pump}}}{\dot{m}} \quad [\text{SI}] \quad 17.60(a)$$

$$E_A = \frac{\left(550 \frac{\text{ft-lbf}}{\text{sec-hp}}\right) P_{\text{hp,input}} \eta_{\text{pump}}}{\dot{m}} \quad [\text{U.S.}] \quad 17.60(b)$$

The *water horsepower* (WHP, also known as the *hydraulic horsepower* and *theoretical horsepower*) is the amount of power actually entering the fluid.

$$\text{WHP} = P_{\text{hp,input}} \eta_{\text{pump}} \quad 17.61$$

A *turbine* extracts energy from the fluid flowing through it. As with a pump, the energy extraction can be obtained by determining the total energy on both sides of the turbine and taking the difference. The energy extracted

(a positive number) on a per-unit mass basis is given by Eq. 17.62.

$$E_E = E_{t,1} - E_{t,2} \quad 17.62$$

## 19. EXTENDED BERNOULLI EQUATION

The original Bernoulli equation assumes frictionless flow and does not consider the effects of pumps and turbines. When friction is present and when there are minor losses such as fittings and other energy-related devices in a pipeline, the energy balance is affected. The *extended Bernoulli equation* takes these additional factors into account.

$$(E_p + E_v + E_z)_1 + E_A = (E_p + E_v + E_z)_2 + E_E + E_f + E_m \quad 17.63$$

$$\begin{aligned} \frac{p_1}{\rho} + \frac{v_1^2}{2} + z_1 g + E_A \\ = \frac{p_2}{\rho} + \frac{v_2^2}{2} + z_2 g + E_E + E_f + E_m \quad [\text{SI}] \quad 17.64(a) \end{aligned}$$

$$\begin{aligned} \frac{p_1}{\rho} + \frac{v_1^2}{2g_c} + \frac{z_1 g}{g_c} + E_A \\ = \frac{p_2}{\rho} + \frac{v_2^2}{2g_c} + \frac{z_2 g}{g_c} + E_E + E_f + E_m \quad [\text{U.S.}] \quad 17.64(b) \end{aligned}$$

As defined,  $E_A$ ,  $E_E$ , and  $E_f$  are all positive terms. None of the terms in Eq. 17.63 and Eq. 17.64 are negative.

The concepts of sources and sinks can be used to decide whether the friction, pump, and turbine terms appear on the left or right side of the Bernoulli equation. An *energy source* puts energy into the system. The incoming fluid and a pump contribute energy to the system. An *energy sink* removes energy from the system. The leaving fluid, friction, and a turbine remove energy from the system. In an energy balance, all energy must be accounted for, and the energy sources just equal the energy sinks.

$$\sum E_{\text{sources}} = \sum E_{\text{sinks}} \quad 17.65$$

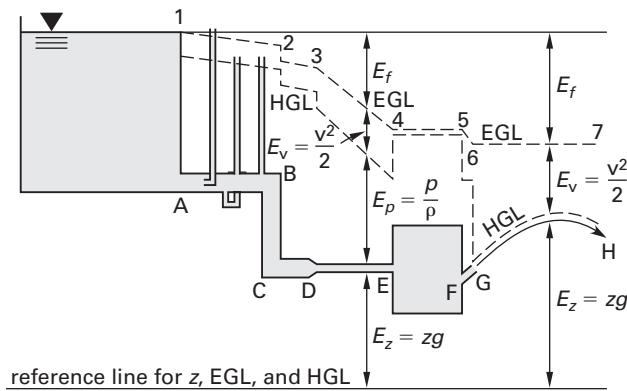

Therefore, the energy added by a pump always appears on the entrance side of the Bernoulli equation. Similarly, the frictional energy loss always appears on the discharge side.

## 20. ENERGY AND HYDRAULIC GRADE LINES WITH FRICTION

The *energy grade line* (EGL, also known as *total energy line*) is a graph of the total energy versus position in a pipeline. Since a pitot tube measures total (stagnation) energy, EGL will always coincide with the elevation of a pitot-piezometer fluid column. When friction is present, the EGL will always slope down, in the direction of

flow. Figure 17.7 illustrates the EGL for a complex pipe network. The difference between  $EGL_{\text{frictionless}}$  and  $EGL_{\text{with friction}}$  is the energy loss due to friction.

**Figure 17.7** Energy and Hydraulic Grade Lines

The EGL line in Fig. 17.7 is discontinuous at point 2, since the friction in pipe section B–C cannot be portrayed without disturbing the spatial correlation of points in the figure. Since the friction loss is proportional to  $v^2$ , the slope is steeper when the fluid velocity increases (i.e., when the pipe decreases in flow area), as it does in section D–E. Disregarding air friction, the EGL becomes horizontal at point 6 when the fluid becomes a free jet.

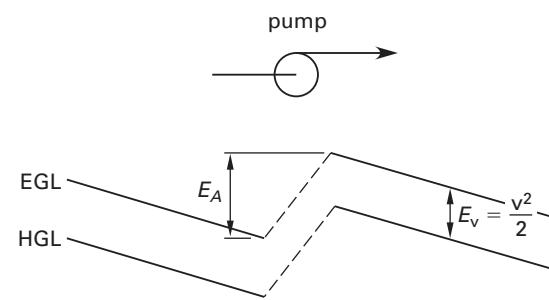

The *hydraulic grade line* (HGL) is a graph of the sum of pressure and potential energies versus position in the pipeline. (That is, the EGL and HGL differ by the kinetic energy.) The HGL will always coincide with the height of the fluid column in a static piezometer tube. The reference point for elevation is arbitrary, and the pressure energy is usually referenced to atmospheric pressure. Therefore, the pressure energy,  $E_p$ , for a free jet will be zero, and the HGL will consist only of the potential energy, as shown in section G–H.

The easiest way to draw the energy and hydraulic grade lines is to start with the EGL. The EGL can be drawn simply by recognizing that the rate of divergence from the horizontal  $EGL_{\text{frictionless}}$  line is proportional to  $v^2$ . Then, since EGL and HGL differ by the velocity head, the HGL can be drawn parallel to the EGL when the pipe diameter is constant. The larger the pipe diameter, the closer the two lines will be.

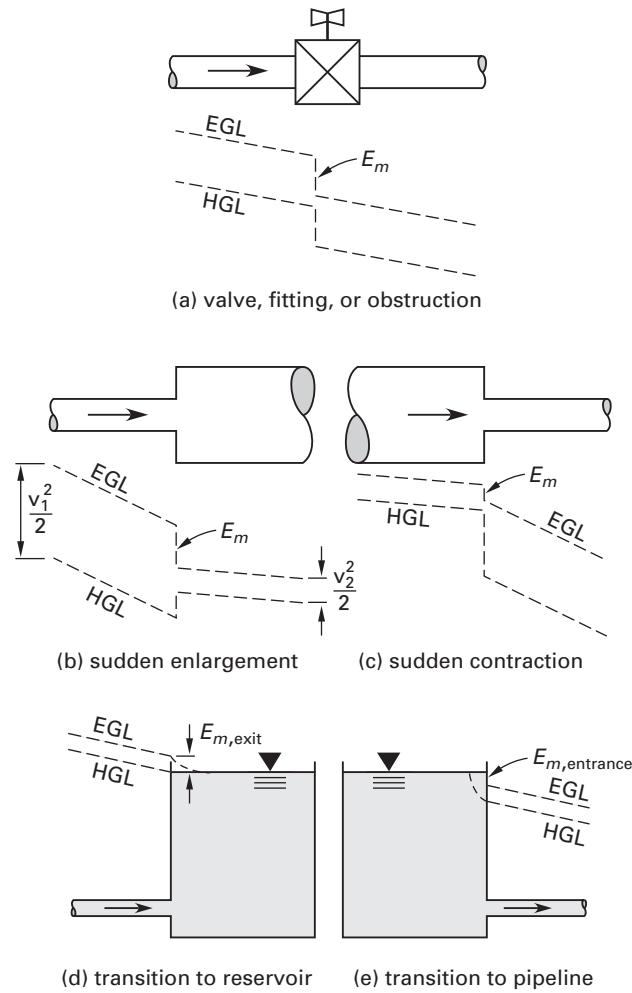

The EGL for a pump will increase in elevation by  $E_A$  across the pump. (The actual energy “path” taken by the fluid is unknown, and a dotted line is used to indicate a lack of knowledge about what really happens in the pump.) The placement of the HGL for a pump will depend on whether the pump increases the fluid velocity and elevation, as well as the fluid pressure. In most cases, only the pressure will be increased. Figure 17.8 illustrates the HGL for the case of a pressure increase only.

The EGL and HGL for minor losses (fittings, contractions, expansions, etc.) are shown in Fig. 17.9.

**Figure 17.8** EGL and HGL for a Pump

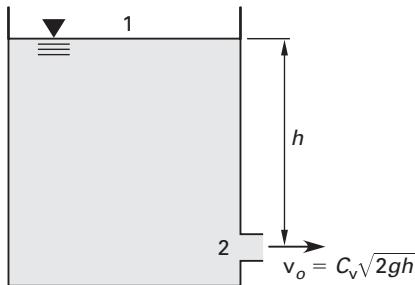

**Figure 17.9** EGL and HGL for Minor Losses

## 21. DISCHARGE FROM TANKS

The velocity of a jet issuing from an orifice in a tank can be determined by comparing the total energies at the free fluid surface and the jet itself. (See Fig. 17.10.) At the fluid surface,  $p_1 = 0$  (atmospheric) and  $v_1 = 0$ . ( $v_1$  is

**Figure 17.10** Discharge from a Tank

known as the *velocity of approach*.) The only energy the fluid has is potential energy. At the jet,  $p_2 = 0$ . All of the potential energy difference ( $z_1 - z_2$ ) has been converted to kinetic energy. The theoretical velocity of the jet can be derived from the Bernoulli equation. Equation 17.66 is known as the equation for *Torricelli's speed of efflux*.

$$v_t = \sqrt{2gh} \quad 17.66$$

$$h = z_1 - z_2 \quad 17.67$$

The actual jet velocity is affected by the orifice geometry. The *coefficient of velocity*,  $C_v$ , is an empirical factor that accounts for the friction and turbulence at the orifice. Typical values of  $C_v$  are given in Table 17.5.

$$v_o = C_v \sqrt{2gh} \quad 17.68$$

$$C_v = \frac{\text{actual velocity}}{\text{theoretical velocity}} = \frac{v_o}{v_t} \quad 17.69$$

The specific energy loss due to turbulence and friction at the orifice is calculated as a multiple of the jet's kinetic energy.

$$E_f = \left( \frac{1}{C_v^2} - 1 \right) \frac{v_o^2}{2} = (1 - C_v^2)gh \quad [\text{SI}] \quad 17.70(a)$$

$$E_f = \left( \frac{1}{C_v^2} - 1 \right) \frac{v_o^2}{2g_c} = (1 - C_v^2)h \times \frac{g}{g_c} \quad [\text{U.S.}] \quad 17.70(b)$$

The total head producing discharge (*effective head*) is the difference in elevations that would produce the same velocity from a frictionless orifice.

$$h_{\text{effective}} = C_v^2 h \quad 17.71$$

The orifice guides quiescent water from the tank into the jet geometry. Unless the orifice is very smooth and the transition is gradual, momentum effects will continue to cause the jet to contract after it has passed through. The velocity calculated from Eq. 17.68 is usually assumed to be the velocity at the *vena contracta*, the section of smallest cross-sectional area. (See Fig. 17.11.)

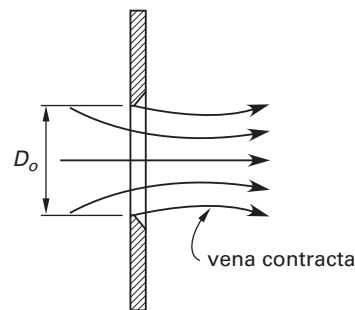

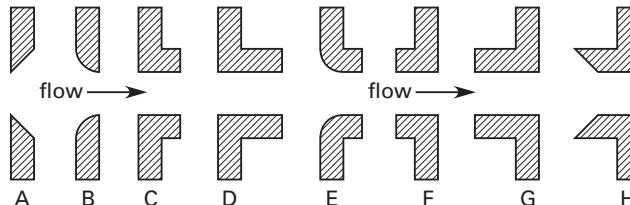

**Figure 17.11** Vena Contracta of a Fluid Jet**Table 17.5** Approximate Orifice Coefficients,  $C$ , for Turbulent Water

illustration	description	$C_d$	$C_c$	$C_v$
A	sharp-edged	0.62	0.63	0.98
B	round-edged	0.98	1.00	0.98
C	short tube* (fluid separates from walls)	0.61	1.00	0.61
D	sharp tube (no separation)	0.82	1.00	0.82
E	short tube with rounded entrance	0.97	0.99	0.98
F	reentrant tube, length less than one-half of pipe diameter	0.54	0.55	0.99
G	reentrant tube, length two to three pipe diameters	0.72	1.00	0.72
H	Borda	0.51	0.52	0.98
(none)	smooth, well-tapered nozzle	0.98	0.99	0.99

\*A short tube has a length less than approximately three pipe diameters.

For a thin plate or sharp-edged orifice, the vena contracta is often assumed to be located approximately one half an orifice diameter past the orifice, although the actual distance can vary from  $0.3D_o$  to  $0.8D_o$ . The area of the vena contracta can be calculated from the orifice area and the *coefficient of contraction*,  $C_c$ . For water flowing with a high Reynolds number through a small sharp-edged orifice, the contracted area is approximately 61–63% of the orifice area.

$$A_{\text{vena contracta}} = C_c A_o \quad 17.72$$

$$C_c = \frac{A_{\text{vena contracta}}}{A_o} \quad 17.73$$

The theoretical discharge rate from a tank is  $\dot{V}_t = A_o \sqrt{2gh}$ . However, this relationship needs to be corrected for friction and contraction by multiplying by  $C_v$  and  $C_c$ . The *coefficient of discharge*,  $C_d$ , is the product of the coefficients of velocity and contraction.

$$\dot{V} = C_c v_o A_o = C_d v_t A_o = C_d A_o \sqrt{2gh} \quad 17.74$$

$$C_d = C_v C_c = \frac{\dot{V}}{\dot{V}_t} \quad 17.75$$

## 22. DISCHARGE FROM PRESSURIZED TANKS

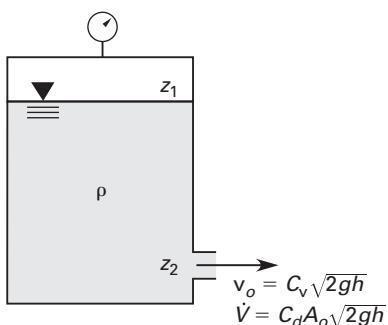

If the gas or vapor above the liquid in a tank is at gage pressure  $p$ , and the discharge is to atmospheric pressure, the head causing discharge will be

$$h = z_1 - z_2 + \frac{p}{\rho g} \quad [\text{SI}] \quad 17.76(a)$$

$$h = z_1 - z_2 + \frac{p}{\rho} \times \frac{g_c}{g} = z_1 - z_2 + \frac{p}{\gamma} \quad [\text{U.S.}] \quad 17.76(b)$$

The discharge velocity can be calculated from Eq. 17.68 using the increased discharge head. (See Fig. 17.12.)

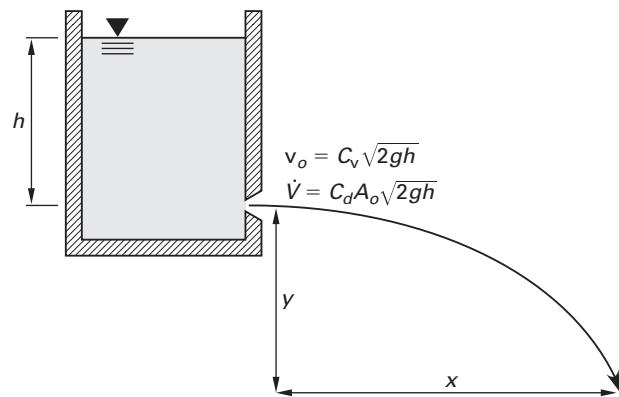

**Figure 17.12** Discharge from a Pressurized Tank

## 23. COORDINATES OF A FLUID STREAM

Fluid discharged from an orifice in a tank gets its initial velocity from the conversion of potential energy. After discharge, no additional energy conversion occurs, and all subsequent velocity changes are due to external forces. (See Fig. 17.13.)

**Figure 17.13** Coordinates of a Fluid Stream

In the absence of air friction (drag), there are no decelerating or accelerating forces in the  $x$ -direction on the fluid stream. The  $x$ -component of velocity is constant. Projectile motion equations can be used to predict the path of the fluid stream.

$$v_x = v_o \quad [\text{horizontal discharge}] \quad 17.77$$

$$x = v_o t = v_o \sqrt{\frac{2y}{g}} = 2C_v \sqrt{hy} \quad 17.78$$

After discharge, the fluid stream is acted upon by a constant gravitational acceleration. The  $y$ -component of velocity is zero at discharge but increases linearly with time.

$$v_y = gt \quad 17.79$$

$$y = \frac{gt^2}{2} = \frac{gx^2}{2v_o^2} = \frac{x^2}{4hC_v^2} \quad 17.80$$

## 24. DISCHARGE FROM LARGE ORIFICES

When an orifice diameter is large compared with the discharge head, the jet velocity at the top edge of the orifice will be less than the velocity at the bottom edge. Since the velocity is related to the square root of the head, the distance used to calculate the effective jet velocity should be measured from the fluid surface to a point above the centerline of the orifice.

This correction is generally neglected, however, since it is small for heads of more than twice the orifice diameter. Furthermore, if an orifice is intended to work regularly with small heads, the orifice should be calibrated

in place. The discrepancy can then be absorbed into the discharge coefficient,  $C_d$ .

## 25. TIME TO EMPTY A TANK

If the fluid in an open or vented tank is not replenished at the rate of discharge, the static head forcing discharge through the orifice will decrease with time. If the tank has a varying cross section,  $A_t$ , Eq. 17.81 specifies the basic relationship between the change in elevation and elapsed time. (The negative sign indicates that  $z$  decreases as  $t$  increases.)

$$\dot{V}dt = -A_t dz \quad 17.81$$

If  $A_t$  can be expressed as a function of  $h$ , Eq. 17.82 can be used to determine the time to lower the fluid elevation from  $z_1$  to  $z_2$ .

$$t = \int_{z_1}^{z_2} \frac{-A_t dz}{C_d A_o \sqrt{2g}} \quad 17.82$$

For a tank with a constant cross-sectional area,  $A_t$ , the time required to lower the fluid elevation is

$$t = \frac{2A_t(\sqrt{z_1} - \sqrt{z_2})}{C_d A_o \sqrt{2g}} \quad 17.83$$

If a tank is replenished at a rate of  $\dot{V}_{in}$ , Eq. 17.84 can be used to calculate the discharge time. If the tank is replenished at a rate greater than the discharge rate,  $t$  in Eq. 17.84 will represent the time to raise the fluid level from  $z_1$  to  $z_2$ .

$$t = \int_{z_1}^{z_2} \frac{A_t dz}{C_d A_o \sqrt{2g} - \dot{V}_{in}} \quad 17.84$$

If the tank is not open or vented but is pressurized, the elevation terms,  $z_1$  and  $z_2$ , in Eq. 17.83 must be replaced by the total head terms,  $h_1$  and  $h_2$ , that include the effects of pressurization. (See Eq. 17.86.)

### Example 17.8

A vertical, cylindrical tank 15 ft in diameter discharges 150°F water ( $\rho = 61.20 \text{ lbm/ft}^3$ ) through a sharp-edged, 1 in diameter orifice ( $C_d = 0.62$ ) in the tank bottom. The original water depth is 12 ft. The tank is continually pressurized to 50 psig. How long does it take, in seconds, to empty the tank?

*Solution*

The area of the orifice is

$$A_o = \frac{\pi D^2}{4} = \frac{\pi (1 \text{ in})^2}{4(12 \text{ in})^2} = 0.00545 \text{ ft}^2$$

The tank area is constant with respect to depth.

$$A_t = \frac{\pi D^2}{4} = \frac{\pi (15 \text{ ft})^2}{4} = 176.7 \text{ ft}^2$$

The total initial head includes the effect of the pressurization. Use Eq. 17.76.

$$\begin{aligned} h_1 &= z_1 - z_2 + \frac{p}{\rho g} \\ &= 12 \text{ ft} + \frac{(50 \frac{\text{lbf}}{\text{in}^2})(12 \frac{\text{in}}{\text{ft}})^2}{61.2 \frac{\text{lbm}}{\text{ft}^3}} \times \frac{32.2 \frac{\text{lbf}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2}}{32.2 \frac{\text{ft}}{\text{sec}^2}} \\ &= 12 \text{ ft} + 117.6 \text{ ft} \\ &= 129.6 \text{ ft} \end{aligned}$$

When the fluid has reached the level of the orifice, the fluid potential head will be zero, but the pressurization will remain.

$$h_2 = 117.6 \text{ ft}$$

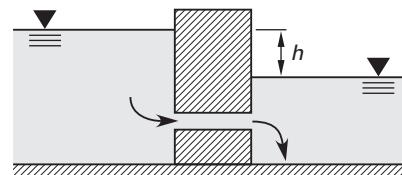

The time needed to empty the tank is given by Eq. 17.83.

$$\begin{aligned} t &= \frac{2A_t(\sqrt{z_1} - \sqrt{z_2})}{C_d A_o \sqrt{2g}} \\ &= \frac{(2)(176.7 \text{ ft}^2)(\sqrt{129.6 \text{ ft}} - \sqrt{117.6 \text{ ft}})}{(0.62)(0.00545 \text{ ft}^2)\sqrt{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})}} \\ &= 7036 \text{ sec} \end{aligned}$$

## 26. PRESSURE CULVERTS

A culvert is a water path (usually a large diameter pipe) used to channel water around or through an obstructing feature. (See Fig. 17.14.) Commonly, a culvert is a concrete pipe or corrugated metal pipe (CMP). (See App. 17.F.) In most instances, a culvert is used to restore a natural water path obstructed by a manufactured feature. For example, when a road is built across (perpendicular to) a natural drainage, a culvert is used to channel water under the road.

Figure 17.14 Simple Pipe Culvert

Because culverts often operate only partially full and with low heads, Torricelli's equation does not apply. Therefore, most culvert designs are empirical. However, if the entrance and exit of a culvert are both

submerged, the culvert will flow full, and the discharge will be independent of the barrel slope. Equation 17.85 can be used to calculate the discharge.

$$\dot{V} = C_d A v = C_d A \sqrt{2gh_{\text{effective}}} \quad 17.85$$

If the culvert is long (more than 60 ft or 20 m), or if the entrance is not gradual, the available energy will be divided between friction and velocity heads. The effective head used in Eq. 17.85 should be

$$h_{\text{effective}} = h - h_{f,\text{barrel}} - h_{m,\text{entrance}} \quad 17.86$$

The friction loss in the barrel can be found in the usual manner, from either the Darcy equation or the Hazen-Williams equation. The entrance loss is calculated using the standard method of loss coefficients. Representative values of the loss coefficient,  $K$ , are given in Table 17.6. Since the fluid velocity is not initially known but is needed to find the friction factor, a trial-and-error solution will be necessary.

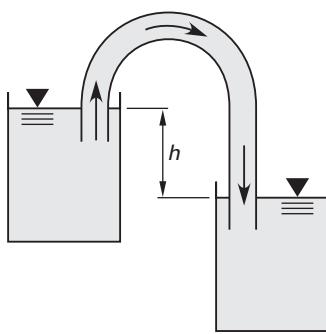

**Table 17.6** Representative Loss Coefficients,  $K$ , for Culvert Entrances

entrance	$K$
smooth and gradual transition	0.08
flush vee or bell shape	0.10
projecting vee or bell shape	0.15
flush, square-edged	0.50
projecting, square-edged	0.90

## 27. SIPHONS

A *siphon* is a bent or curved tube that carries fluid from a fluid surface at a high elevation to another fluid surface at a lower elevation. Normally, it would not seem difficult to have a fluid flow to a lower elevation. However, the fluid seems to flow "uphill" in a portion of a siphon. Figure 17.15 illustrates a siphon.

**Figure 17.15** Siphon

Starting a siphon requires the tube to be completely filled with liquid. Then, since the fluid weight is greater in the longer arm than in the shorter arm, the fluid in the longer arm "falls" out of the siphon, "pulling" more liquid into the shorter arm and over the bend.

Operation of a siphon is essentially independent of atmospheric pressure. The theoretical discharge is the same as predicted by the Torricelli equation. A correction for discharge is necessary, but little data is available on typical values of  $C_d$ . Therefore, siphons should be tested and calibrated in place.

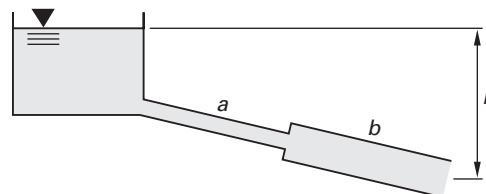

$$\dot{V} = C_d A v = C_d A \sqrt{2gh} \quad 17.87$$

## 28. SERIES PIPE SYSTEMS

A system of pipes in series consists of two or more lengths of different-diameter pipes connected end-to-end. In the case of the series pipe from a reservoir discharging to the atmosphere shown in Fig. 17.16, the available head will be split between the velocity head and the friction loss.

$$h = h_v + h_f \quad 17.88$$

**Figure 17.16** Series Pipe System

If the flow rate or velocity in any part of the system is known, the friction loss can easily be found as the sum of the friction losses in the individual sections. The solution is somewhat more simple than it first appears to be, since the velocity of all sections can be written in terms of only one velocity.

$$h_{f,t} = h_{f,a} + h_{f,b} \quad 17.89$$

$$A_a v_a = A_b v_b \quad 17.90$$

If neither the velocity nor the flow quantity is known, a trial-and-error solution will be required, since a friction factor must be known to calculate  $h_f$ . A good starting point is to assume fully turbulent flow.

When velocity and flow rate are both unknown, the following procedure using the Darcy friction factor can be used.<sup>19</sup>

*step 1:* Calculate the relative roughness,  $\epsilon/D$ , for each section. Use the Moody diagram to determine  $f_a$  and  $f_b$  for fully turbulent flow (i.e., the horizontal portion of the curve).

<sup>19</sup>If Hazen-Williams constants are given for the pipe sections, the procedure for finding the unknown velocities is similar, although considerably more difficult since  $v^2$  and  $v^{1.85}$  cannot be combined. A first approximation, however, can be obtained by replacing  $v^{1.85}$  in the Hazen-Williams equation for friction loss. A trial and error method can then be used to find velocity.

*step 2:* Write all of the velocities in terms of one unknown velocity.

$$\dot{V}_a = \dot{V}_b \quad 17.91$$

$$v_b = \left( \frac{A_a}{A_b} \right) v_a \quad 17.92$$

*step 3:* Write the total friction loss in terms of the unknown velocity.

$$\begin{aligned} h_{f,t} &= \frac{f_a L_a v_a^2}{2 D_a g} + \left( \frac{f_b L_b}{2 D_b g} \right) \left( \frac{A_a}{A_b} \right)^2 v_a^2 \\ &= \left( \frac{v_a^2}{2g} \right) \left( \frac{f_a L_a}{D_a} + \left( \frac{f_b L_b}{D_b} \right) \left( \frac{A_a}{A_b} \right)^2 \right) \end{aligned} \quad 17.93$$

*step 4:* Solve for the unknown velocity using the Bernoulli equation between the free reservoir surface ( $p = 0$ ,  $v = 0$ ,  $z = h$ ) and the discharge point ( $p = 0$ , if free discharge;  $z = 0$ ). Include pipe friction, but disregard minor losses for convenience.

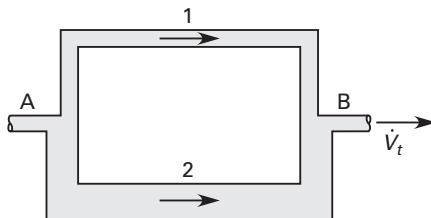

$$h = \frac{v_b^2}{2g} + h_{f,t} = \left( \frac{v_a^2}{2g} \right) \left( \left( \frac{A_a}{A_b} \right)^2 \left( 1 + \frac{f_b L_b}{D_b} \right) + \frac{f_a L_a}{D_a} \right) \quad 17.94$$

*step 5:* Using the value of  $v_a$ , calculate  $v_b$ . Calculate the Reynolds number, and check the values of  $f_a$  and  $f_b$  from step 4. Repeat steps 3 and 4 if necessary.

## 29. PARALLEL PIPE SYSTEMS

Adding a second pipe in parallel with a first is a standard method of increasing the capacity of a line. A *pipe loop* is a set of two pipes placed in parallel, both originating and terminating at the same junction. The two pipes are referred to as *branches* or *legs*. (See Fig. 17.17.)

Figure 17.17 Parallel Pipe System

There are three principles that govern the distribution of flow between the two branches.

- The flow divides in such a manner as to make the head loss in each branch the same.

$$h_{f,1} = h_{f,2} \quad 17.95$$

- The head loss between the junctions A and B is the same as the head loss in branches 1 and 2.

$$h_{f,A-B} = h_{f,1} = h_{f,2} \quad 17.96$$

- The total flow rate is the sum of the flow rates in the two branches.

$$\dot{V}_t = \dot{V}_1 + \dot{V}_2 \quad 17.97$$

If the pipe diameters are known, Eq. 17.95 and Eq. 17.97 can be solved simultaneously for the branch velocities. For first estimates, it is common to neglect minor losses, the velocity head, and the variation in the friction factor,  $f$ , with velocity.

If the system has only two parallel branches, the unknown branch flows can be determined by solving Eq. 17.98 and Eq. 17.100 simultaneously.

$$\frac{f_1 L_1 v_1^2}{2 D_1 g} = \frac{f_2 L_2 v_2^2}{2 D_2 g} \quad 17.98$$

$$\dot{V}_1 + \dot{V}_2 = \dot{V}_t \quad 17.99$$

$$\frac{\pi}{4} (D_1^2 v_1 + D_2^2 v_2) = \dot{V}_t \quad 17.100$$

However, if the system has three or more parallel branches, it is easier to use the following iterative procedure. This procedure can be used for problems (a) where the flow rate is unknown but the pressure drop between the two junctions is known, or (b) where the total flow rate is known but the pressure drop and velocity are both unknown. In both cases, the solution iteratively determines the friction coefficients,  $f$ .

*step 1:* Solve the friction head loss,  $h_f$ , expression (either Darcy or Hazen-Williams) for velocity in each branch. If the pressure drop is known, first convert it to friction head loss.

$$v = \sqrt{\frac{2 D g h_f}{f L}} \quad [\text{Darcy}] \quad 17.101$$

$$v = \frac{0.355 C D^{0.63} h_f^{0.54}}{L^{0.54}} \quad [\text{Hazen-Williams; SI}] \quad 17.102(a)$$

$$v = \frac{0.550 C D^{0.63} h_f^{0.54}}{L^{0.54}} \quad [\text{Hazen-Williams; U.S.}] \quad 17.102(b)$$

*step 2:* Solve for the flow rate in each branch. If they are unknown, friction factors,  $f$ , must be assumed for each branch. The fully turbulent assumption

provides a good initial estimate. (The value of  $k'$  will be different for each branch.)

$$\dot{V} = Av = A\sqrt{\frac{2Dgh_f}{fL}} \\ = k'\sqrt{h_f} \quad [\text{Darcy}] \quad 17.103$$

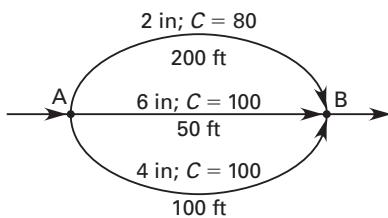

*step 3:* Write the expression for the conservation of flow. Calculate the friction head loss from the total flow rate. For example, for a three-branch system,

$$\dot{V}_t = \dot{V}_1 + \dot{V}_2 + \dot{V}_3 \\ = (k'_1 + k'_2 + k'_3)\sqrt{h_f} \quad 17.104$$

*step 4:* Check the assumed values of the friction factor. Repeat as necessary.

### Example 17.9

3 ft<sup>3</sup>/sec of water enter the parallel pipe network shown at junction A. All pipes are schedule-40 steel with the nominal sizes shown. Minor losses are insignificant. What is the total friction head loss between junctions A and B?

*Solution*

*step 1:* Collect the pipe dimensions from App. 16.B.

	2 in	4 in	6 in
flow area	0.0233 ft <sup>2</sup>	0.0884 ft <sup>2</sup>	0.2006 ft <sup>2</sup>
diameter	0.1723 ft	0.3355 ft	0.5054 ft

Follow the procedure given in Sec. 17.29.

$$h_f = \frac{3.022 v^{1.85} L}{C^{1.85} D^{1.165}} \\ v = \frac{0.550 CD^{0.63} h_f^{0.54}}{L^{0.54}}$$

The velocity (expressed in ft/sec) in the 2 in diameter pipe branch is

$$v_{2\text{in}} = \frac{(0.550)(80)(0.1723 \text{ ft})^{0.63} h_f^{0.54}}{(200 \text{ ft})^{0.54}} \\ = 0.831 h_f^{0.54}$$

The friction head loss is the same in all parallel branches. The velocities in the other two branches are

$$v_{6\text{in}} = 4.327 h_f^{0.54} \\ v_{4\text{in}} = 2.299 h_f^{0.54}$$

*step 2:* The flow rates are

$$\dot{V} = Av \\ \dot{V}_{2\text{in}} = (0.0233 \text{ ft}^2)0.831 h_f^{0.54} \\ = 0.0194 h_f^{0.54} \\ \dot{V}_{6\text{in}} = (0.2006 \text{ ft}^2)4.327 h_f^{0.54} \\ = 0.8680 h_f^{0.54} \\ \dot{V}_{4\text{in}} = (0.0884 \text{ ft}^2)2.299 h_f^{0.54} \\ = 0.2032 h_f^{0.54}$$

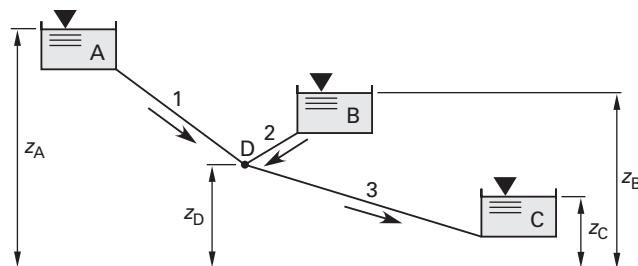

*step 3:* The total flow rate is

$$\dot{V}_t = \dot{V}_{2\text{in}} + \dot{V}_{6\text{in}} + \dot{V}_{4\text{in}} \\ 3 \frac{\text{ft}^3}{\text{sec}} = 0.0194 h_f^{0.54} + 0.8680 h_f^{0.54} + 0.2032 h_f^{0.54} \\ = (0.0194 + 0.8680 + 0.2032) h_f^{0.54} \\ h_f = 6.5 \text{ ft}$$

### 30. MULTIPLE RESERVOIR SYSTEMS

In the *three-reservoir problem*, there are many possible choices for the unknown quantity (pipe length, diameter, head, flow rate, etc.). In all but the simplest cases, the solution technique is by trial and error based on conservation of mass and energy. (See Fig. 17.18.)

**Figure 17.18** Three-Reservoir System

For simplification, velocity heads and minor losses are usually insignificant and can be neglected. However, the presence of a pump in any of the lines must be included in the solution procedure. This is most easily done by adding the pump head to the elevation of the reservoir feeding the pump. If the pump head is not known or

depends on the flow rate, it must be determined iteratively as part of the solution procedure.

**Case 1:** Given all lengths, diameters, and elevations, find all flow rates.

Although an analytical solution method is possible, this type of problem is easily solved iteratively. The following procedure makes an initial estimate of a flow rate and uses it to calculate the pressure at the junction,  $p_D$ . Since this method may not converge if the initial estimate of  $\dot{V}_1$  is significantly in error, it is helpful to use other information (e.g., normal pipe velocities) to obtain the initial estimate. (See Sec. 17.3.) An alternate procedure is simply to make several estimates of  $p_D$  and calculate the corresponding values of flow rate.

*step 1:* Assume a reasonable value for  $\dot{V}_1$ . Calculate the corresponding friction loss,  $h_{f,1}$ . Use the Bernoulli equation to find the corresponding value of  $p_D$ . Disregard minor losses and velocity head.

$$v_1 = \frac{\dot{V}_1}{A_1} \quad 17.105$$

$$z_A = z_D + \frac{p_D}{\gamma} + h_{f,1} \quad 17.106$$

*step 2:* Use the value of  $p_D$  to calculate  $h_{f,2}$ . Use the friction loss to determine  $v_2$ . Use  $v_2$  to determine  $\dot{V}_2$ . If flow is out of reservoir B,  $h_{f,2}$  should be added. If  $z_D + (p_D/\gamma) > z_B$ , flow will be into reservoir B. In this case,  $h_{f,2}$  should be subtracted.

$$z_B = z_D + \frac{p_D}{\gamma} \pm h_{f,2} \quad 17.107$$

$$\dot{V}_2 = v_2 A_2 \quad 17.108$$

*step 3:* Similarly, use the value of  $p_D$  to calculate  $h_{f,3}$ . Use the friction loss to determine  $v_3$ . Use  $v_3$  to determine  $\dot{V}_3$ .

$$z_C = z_D + \frac{p_D}{\gamma} - h_{f,3} \quad 17.109$$

$$\dot{V}_3 = v_3 A_3 \quad 17.110$$

*step 4:* Check if  $\dot{V}_1 \pm \dot{V}_2 = \dot{V}_3$ . If it does not, repeat steps 1 through 4. After the second iteration, plot  $\dot{V}_1 \pm \dot{V}_2 - \dot{V}_3$  versus  $\dot{V}_1$ . Interpolate or extrapolate the value of  $\dot{V}_1$  that makes the difference zero.

**Case 2:** Given  $\dot{V}_1$  and all lengths, diameters, and elevations except  $z_C$ , find  $z_C$ .

*step 1:* Calculate  $v_1$ .

$$v_1 = \frac{\dot{V}_1}{A_1} \quad 17.111$$

*step 2:* Calculate the corresponding friction loss,  $h_{f,1}$ . Use the Bernoulli equation to find the corresponding value of  $p_D$ . Disregard minor losses and velocity head.

$$z_A = z_D + \frac{p_D}{\gamma} + h_{f,1} \quad 17.112$$

*step 3:* Use the value  $p_D$  to calculate  $h_{f,2}$ . Use the friction loss to determine  $v_2$ . Use  $v_2$  to determine  $\dot{V}_2 A_2$ . If flow is out of reservoir B,  $h_{f,2}$  should be added. If  $z_D + (p_D/\gamma) > z_B$ , flow will be into reservoir B. In this case,  $h_{f,2}$  should be subtracted.

$$z_B = z_D + \frac{p_D}{\gamma} \pm h_{f,2} \quad 17.113$$

$$\dot{V}_2 = v_2 A_2 \quad 17.114$$

*step 4:* From the conservation of mass, the flow rate into reservoir C is

$$\dot{V}_3 = \dot{V}_1 \pm \dot{V}_2 \quad 17.115$$

*step 5:* The velocity in pipe 3 is

$$v_3 = \frac{\dot{V}_3}{A_3} \quad 17.116$$

*step 6:* Calculate  $h_{f,3}$ .

*step 7:* Disregarding minor losses and velocity head, the elevation of the surface in reservoir C is

$$z_C = z_D + \frac{p_D}{\gamma} - h_{f,3} \quad 17.117$$

**Case 3:** Given  $\dot{V}_1$ , all lengths, all elevations, and all diameters except  $D_3$ , find  $D_3$ .

*step 1:* Repeat step 1 from case 2.

*step 2:* Repeat step 2 from case 2.

*step 3:* Repeat step 3 from case 2.

*step 4:* Repeat step 4 from case 2.

*step 5:* Calculate  $h_{f,3}$  from

$$z_C = z_D + \frac{p_D}{\gamma} - h_{f,3} \quad 17.118$$

*step 6:* Calculate  $D_3$  from  $h_{f,3}$ .

**Case 4:** Given all lengths, diameters, and elevations except  $z_D$ , find all flow rates.

*step 1:* Calculate the head loss between each reservoir and junction D. Combine as many terms as possible into constant  $k'$ .

$$\begin{aligned} \dot{V} &= Av = A \sqrt{\frac{2Dgh_f}{fL}} \\ &= k' \sqrt{h_f} \quad [\text{Darcy}] \end{aligned} \quad 17.119$$

$$\begin{aligned} \dot{V} &= Av = \frac{A(0.550)CD^{0.63}h_f^{0.54}}{L^{0.54}} \\ &= k'h_f^{0.54} \quad [\text{Hazen-Williams; U.S.}] \end{aligned} \quad 17.120$$

*step 2:* Assume that the flow direction in all three pipes is toward junction D. Write the conservation equation for junction D.

$$\dot{V}_{D,t} = \dot{V}_1 + \dot{V}_2 + \dot{V}_3 = 0 \quad 17.121$$

$$k'_1 \sqrt{h_{f,1}} + k'_2 \sqrt{h_{f,2}} + k'_3 \sqrt{h_{f,3}} = 0 \quad [\text{Darcy}] \quad 17.122$$

$$k'_1 h_{f,1}^{0.54} + k'_2 h_{f,2}^{0.54} + k'_3 h_{f,3}^{0.54} = 0 \quad [\text{Hazen-Williams}] \quad 17.123$$

*step 3:* Write the Bernoulli equation between each reservoir and junction D. Since  $p_A = p_B = p_C = 0$ , and  $v_A = v_B = v_C = 0$ , the friction loss in branch 1 is

$$h_{f,1} = z_A - z_D - \frac{p_D}{\gamma} \quad 17.124$$

However,  $z_D$  and  $p_D$  can be combined since they are related constants in any particular situation. Define the correction,  $\delta_D$ , as

$$\delta_D = z_D + \frac{p_D}{\gamma} \quad 17.125$$

Then, the friction head losses in the branches are

$$h_{f,1} = z_A - \delta_D \quad 17.126$$

$$h_{f,2} = z_B - \delta_D \quad 17.127$$

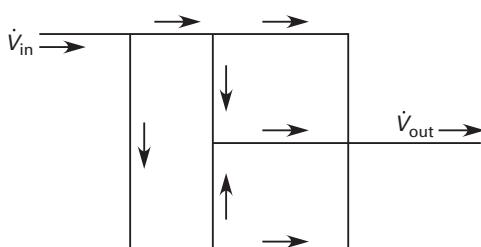

$$h_{f,3} = z_C - \delta_D \quad 17.128$$

*step 4:* Assume a value for  $\delta_D$ . Calculate the corresponding  $h_f$  values. Use Eq. 17.119 to find  $\dot{V}_1$ ,  $\dot{V}_2$ , and  $\dot{V}_3$ . Calculate the corresponding  $\dot{V}_t$  value. Repeat until  $\dot{V}_t$  converges to zero. It is not necessary to calculate  $p_D$  or  $z_D$  once all of the flow rates are known.

### 31. PIPE NETWORKS

Network flows in a *multiloop system* cannot be determined by any closed-form equation. (See Fig. 17.19.) Most real-world problems involving multiloop systems are analyzed iteratively on a computer. Computer programs are based on the *Hardy Cross method*, which can also be performed manually when there are only a few loops. In this method, flows in all of the branches are first assumed, and adjustments are made in consecutive iterations to the assumed flow.

Figure 17.19 Multiloop System

The Hardy Cross method is based on the following principles.

*Principle 1:* Conservation—The flows entering a junction equal the flows leaving the junction.

*Principle 2:* The algebraic sum of head losses around any closed loop is zero.

The friction head loss has the form  $h_f = K' \dot{V}^n$ , with  $h_f$  having units of feet. ( $K'$  used in Eq. 17.103 is equal to  $\sqrt{1/K'}$ .) The Darcy friction factor,  $f$ , is usually assumed to be the same in all parts of the network. For a Darcy head loss, the exponent is  $n = 2$ . For a Hazen-Williams loss,  $n = 1.85$ .

- For  $\dot{V}$  in  $\text{ft}^3/\text{sec}$ ,  $L$  in feet, and  $D$  in feet, the friction coefficient is

$$K' = \frac{0.02517 f L}{D^5} \quad [\text{Darcy}] \quad 17.129$$

$$K' = \frac{4.727 L}{D^{4.87} C^{1.85}} \quad [\text{Hazen-Williams}] \quad 17.130$$

- For  $\dot{V}$  in  $\text{gal}/\text{min}$ ,  $L$  in feet, and  $d$  in inches, the friction coefficient is

$$K' = \frac{0.03109 f L}{d^5} \quad [\text{Darcy}] \quad 17.131$$

$$K' = \frac{10.44 L}{d^{4.87} C^{1.85}} \quad [\text{Hazen-Williams}] \quad 17.132$$

- For  $\dot{V}$  in  $\text{gal}/\text{min}$ ,  $L$  in feet, and  $D$  in feet, the friction coefficient is

$$K' = \frac{1.251 \times 10^{-7} f L}{D^5} \quad [\text{Darcy}] \quad 17.133$$

$$K' = \frac{5.862 \times 10^{-5} L}{D^{4.87} C^{1.85}} \quad [\text{Hazen-Williams}] \quad 17.134$$

- For  $\dot{V}$  in MGD (millions of gallons per day),  $L$  in feet, and  $D$  in feet, the friction coefficient is

$$K' = \frac{0.06026 f L}{D^5} \quad [\text{Darcy}] \quad 17.135$$

$$K' = \frac{10.59 L}{D^{4.87} C^{1.85}} \quad [\text{Hazen-Williams}] \quad 17.136$$

If  $\dot{V}_a$  is the assumed flow in a pipe, the true value,  $\dot{V}$ , can be calculated from the difference (correction),  $\delta$ .

$$\dot{V} = \dot{V}_a + \delta \quad 17.137$$

The friction loss term for the assumed value and its correction can be expanded as a series. Since the correction is small, higher order terms can be omitted.

$$\begin{aligned} h_f &= K'(\dot{V}_a + \delta)^n \\ &\approx K' \dot{V}_a^n + n K' \delta \dot{V}_a^{n-1} \end{aligned} \quad 17.138$$

From Principle 2, the sum of the friction drops is zero around a loop. The correction,  $\delta$ , is the same for all pipes in the loop and can be taken out of the summation. Since the loop closes on itself, all elevations can be omitted.

$$\sum h_f = \sum K' \dot{V}_a^n + n\delta \sum K' \dot{V}_a^{n-1} = 0 \quad 17.139$$

This equation can be solved for  $\delta$ .

$$\begin{aligned} \delta &= \frac{-\sum K' \dot{V}_a^n}{n \sum |K' \dot{V}_a^{n-1}|} \\ &= -\frac{\sum h_f}{n \sum \left| \frac{h_f}{\dot{V}_a} \right|} \end{aligned} \quad 17.140$$

The Hardy Cross procedure is as follows.

*step 1:* Determine the value of  $n$ . For a Darcy head loss, the exponent is  $n = 2$ . For a Hazen-Williams loss,  $n = 1.85$ .

*step 2:* Arbitrarily select a positive direction (e.g., clockwise).

*step 3:* Label all branches and junctions in the network.

*step 4:* Separate the network into independent loops such that each branch is included in at least one loop.

*step 5:* Calculate  $K'$  for each branch in the network.

*step 6:* Assume consistent and reasonable flow rates and directions for each branch in the network.

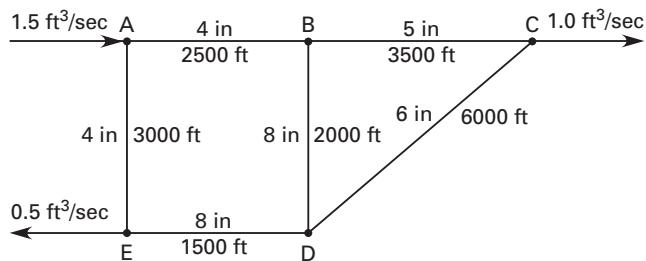

*step 7:* Calculate the correction,  $\delta$ , for each independent loop. (The numerator is the sum of head losses around the loop, taking signs into consideration.) It is not necessary for the loop to be at the same elevation everywhere. Disregard elevations. Since the loop closes on itself, all elevations can be omitted.

*step 8:* Apply the correction,  $\delta$ , to each branch in the loop. The correction must be applied in the same sense to each branch in the loop. If clockwise has been taken as the positive direction, then  $\delta$  is added to clockwise flows and subtracted from counterclockwise flows.

*step 9:* Repeat steps 7 and 8 until the correction is sufficiently small.

### Example 17.10

A two-loop pipe network is shown. All junctions are at the same elevation. The Darcy friction factor is 0.02 for all pipes in the network. For convenience, use the nominal pipe sizes shown in the figure. Determine the flows in all branches.

### Solution

*step 1:* The Darcy friction factor is given, so  $n = 2$ .

*step 2:* Select clockwise as the positive direction.

*step 3:* Use the junction letters in the illustration.

*step 4:* Two independent loops are needed. Work with loops ABDE and BCD. (Loop ABCDE could also be used but would be more complex than loop BCD.)

*step 5:* Work with branch AB.

$$D_{AB} = \frac{4 \text{ in}}{12 \frac{\text{in}}{\text{ft}}} = 0.3333 \text{ ft}$$

Use Eq. 17.129.

$$\begin{aligned} K'_{AB} &= \frac{0.02517 f L}{D^5} = \frac{(0.02517)(0.02)(2500 \text{ ft})}{(0.3333 \text{ ft})^5} \\ &= 306.0 \end{aligned}$$

Similarly,

$$K'_{BC} = 140.5$$

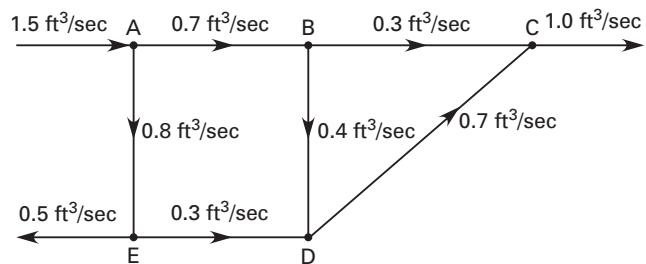

$$K'_{DC} = 96.8$$

$$K'_{BD} = 7.7$$

$$K'_{ED} = 5.7$$

$$K'_{AE} = 367.4$$

*step 6:* Assume the direction and flow rates shown.

step 7: Use Eq. 17.140.

$$\delta = \frac{-\sum K' \dot{V}_a^n}{n \sum |K' \dot{V}_a^{n-1}|}$$

$$\delta_{ABDE} = \frac{-\left( (306.0) \left( 0.7 \frac{\text{ft}^3}{\text{sec}} \right)^2 + (7.7) \left( 0.4 \frac{\text{ft}^3}{\text{sec}} \right)^2 \right.}{(2) \left( (306.0) \left( 0.7 \frac{\text{ft}^3}{\text{sec}} \right) + (7.7) \left( 0.4 \frac{\text{ft}^3}{\text{sec}} \right) \right.} \\ \left. - (5.7) \left( 0.3 \frac{\text{ft}^3}{\text{sec}} \right)^2 - (367.4) \left( 0.8 \frac{\text{ft}^3}{\text{sec}} \right)^2 \right)}{\left. + (5.7) \left( 0.3 \frac{\text{ft}^3}{\text{sec}} \right) + (367.4) \left( 0.8 \frac{\text{ft}^3}{\text{sec}} \right) \right)} \\ = 0.08 \text{ ft}^3/\text{sec}$$

$$\delta_{BCD} = \frac{-\left( (140.5) \left( 0.3 \frac{\text{ft}^3}{\text{sec}} \right)^2 - (96.8) \left( 0.7 \frac{\text{ft}^3}{\text{sec}} \right)^2 \right.}{(2) \left( (140.5) \left( 0.3 \frac{\text{ft}^3}{\text{sec}} \right) + (96.8) \left( 0.7 \frac{\text{ft}^3}{\text{sec}} \right) \right.} \\ \left. - (7.7) \left( 0.4 \frac{\text{ft}^3}{\text{sec}} \right)^2 \right)}{\left. + (7.7) \left( 0.4 \frac{\text{ft}^3}{\text{sec}} \right) \right)} \\ = 0.16 \text{ ft}^3/\text{sec}$$

step 8: The corrected flows are

$$\dot{V}_{AB} = 0.7 \frac{\text{ft}^3}{\text{sec}} + 0.08 \frac{\text{ft}^3}{\text{sec}} = 0.78 \text{ ft}^3/\text{sec}$$

$$\dot{V}_{BC} = 0.3 \frac{\text{ft}^3}{\text{sec}} + 0.16 \frac{\text{ft}^3}{\text{sec}} = 0.46 \text{ ft}^3/\text{sec}$$

$$\dot{V}_{DC} = 0.7 \frac{\text{ft}^3}{\text{sec}} - 0.16 \frac{\text{ft}^3}{\text{sec}} = 0.54 \text{ ft}^3/\text{sec}$$

$$\dot{V}_{BD} = 0.4 \frac{\text{ft}^3}{\text{sec}} + 0.08 \frac{\text{ft}^3}{\text{sec}} - 0.16 \frac{\text{ft}^3}{\text{sec}} \\ = 0.32 \text{ ft}^3/\text{sec}$$

$$\dot{V}_{ED} = 0.3 \frac{\text{ft}^3}{\text{sec}} - 0.08 \frac{\text{ft}^3}{\text{sec}} = 0.22 \text{ ft}^3/\text{sec}$$

$$\dot{V}_{AE} = 0.8 \frac{\text{ft}^3}{\text{sec}} - 0.08 \frac{\text{ft}^3}{\text{sec}} = 0.72 \text{ ft}^3/\text{sec}$$

## 32. FLOW MEASURING DEVICES

A device that measures flow can be calibrated to indicate either velocity or volumetric flow rate. There are many methods available to obtain the flow rate. Some are indirect, requiring the use of transducers and solid-state electronics, and others can be evaluated using the Bernoulli equation. Some are more appropriate for one variety of fluid than others, and some are limited to specific ranges of temperature and pressure.

Table 17.7 categorizes a few common flow measurement methods. Many other methods and variations thereof exist, particularly for specialized industries. Some of the methods listed are so basic that only a passing mention will be made of them. Others, particularly those that can be analyzed with energy and mass conservation laws, will be covered in greater detail in subsequent sections.

**Table 17.7** Flow Measuring Devices

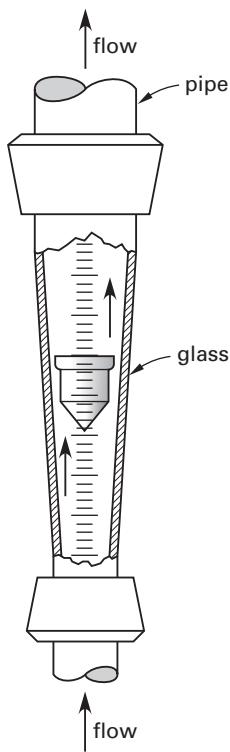

- I direct (primary) measurements
  - positive-displacement meters
  - volume tanks
  - weight and mass scales
- II indirect (secondary) measurements
  - obstruction meters
    - flow nozzles
    - orifice plate meters
    - variable-area meters
    - venturi meters
  - velocity probes
    - direction sensing probes
    - pitot-static meters
    - pitot tubes
    - static pressure probes
  - miscellaneous methods
    - hot-wire meters
    - magnetic flow meters
    - mass flow meters
    - sonic flow meters
    - turbine and propeller meters

The utility meters used to measure gas and water usage are examples of *displacement meters*. Such devices are cyclical, fixed-volume devices with counters to record the numbers of cycles. Displacement devices are generally unpowered, drawing on only the pressure energy to overcome mechanical friction. Most configurations for positive-displacement pumps (e.g., reciprocating piston, helical screw, and nutating disk) have also been converted to measurement devices.

The venturi nozzle, orifice plate, and flow nozzle are examples of *obstruction meters*. These devices rely on a decrease in static pressure to measure the flow velocity. One disadvantage of these devices is that the pressure drop is proportional to the square of the velocity, limiting the range over which any particular device can be used.

An obstruction meter that somewhat overcomes the velocity range limitation is the *variable-area meter*, also known as a *rotameter*, illustrated in Fig. 17.20.<sup>20</sup> This device consists of a float (which is actually more dense than the fluid) and a transparent sight tube. With proper design, the effects of fluid density and viscosity can be minimized. The sight glass can be directly calibrated in volumetric flow rate, or the height of the float above the zero position can be used in a volumetric calculation.

**Figure 17.20** Variable-Area Rotameter

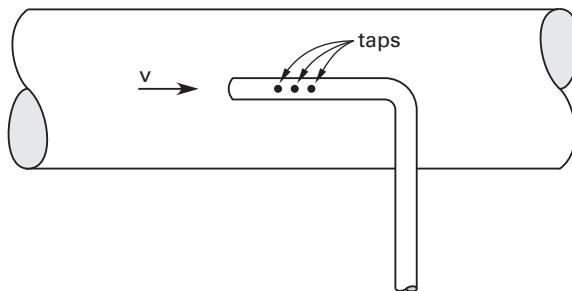

It is necessary to be able to measure static pressures in order to use obstruction meters and pitot-static tubes. In some cases, a *static pressure probe* is used. Figure 17.21 illustrates a simplified static pressure probe. In practice, such probes are sensitive to burrs and irregularities in the tap openings, orientation to the flow (i.e., yaw), and interaction with the pipe walls and other probes. A *direction-sensing probe* overcomes some of these problems.

A weather station *anemometer* used to measure wind velocity is an example of a simple *turbine meter*. Similar devices are used to measure the speed of a stream or river, in which case the name *current meter* may be used. Turbine meters are further divided into cup-type meters and propeller-type meters, depending on the orientation of the turbine axis relative to the flow direction. (The turbine axis and flow direction are

<sup>20</sup>The rotameter has its own disadvantages, however. It must be installed vertically; the fluid cannot be opaque; and it is more difficult to manufacture for use with high-temperature, high-pressure fluids.

**Figure 17.21** Simple Static Pressure Probe

parallel for propeller-type meters; they are perpendicular for cup-type meters.) Since the wheel motion is proportional to the flow velocity, the velocity is determined by counting the number of revolutions made by the wheel per unit time.

More sophisticated turbine flowmeters use a reluctance-type pickup coil to detect wheel motion. The permeability of a magnetic circuit changes each time a wheel blade passes the pole of a permanent magnet in the meter body. This change is detected to indicate velocity or flow rate.

A *hot-wire anemometer* measures velocity by determining the cooling effect of fluid (usually a gas) flowing over an electrically heated tungsten, platinum, or nickel wire. Cooling is primarily by convection; radiation and conduction are neglected. Circuitry can be used either to keep the current constant (in which case, the changing resistance or voltage is measured) or to keep the temperature constant (in which case, the changing current is measured). Additional circuitry can be used to compensate for thermal lag if the velocity changes rapidly.

Modern *magnetic flowmeters* (*magmeter*, *electromagnetic flowmeter*) measure fluid velocity by detecting a voltage (potential difference, electromotive force) that is generated in response to the fluid passing through a magnetic field applied by the meter. The magnitude of the induced voltage is predicted by *Faraday's law of induction*, which states that the induced voltage is equal to the negative of the time rate of change of a magnetic field. The voltage is not affected by changes in fluid viscosity, temperature, or density. From Faraday's law, the induced voltage is proportional to the fluid velocity. For a magmeter with a dimensionless instrument constant,  $k$ , and a magnetic field strength,  $B$ , the induced voltage will be

$$V = kBvD_{\text{pipe}}$$

17.141

Since no parts of the meter extend into the flow, magmeters are ideal for corrosive fluids and slurries of large particles. Normally, the fluid has to be at least slightly electrically conductive, making magmeters ideal for measuring liquid metal flow. It may be necessary to dope electrically neutral fluids with precise quantities of conductive ions in order to obtain measurements by this method. Most magmeters have integral instrumentation and are direct-reading.

In an *ultrasonic flowmeter*, two electric or magnetic transducers are placed a short distance apart on the outside of the pipe. One transducer serves as a transmitter of ultrasonic waves; the other transducer is a receiver. As an ultrasonic wave travels from the transmitter to the receiver, its velocity will be increased (or decreased) by the relative motion of the fluid. The phase shift between the fluid-carried waves and the waves passing through a stationary medium can be measured and converted to fluid velocity.

### 33. PITOT-STATIC GAUGE

Measurements from pitot tubes are used to determine total (stagnation) energy. Piezometer tubes and wall taps are used to measure static pressure energy. The difference between the total and static energies is the kinetic energy of the flow. Figure 17.22 illustrates a comparative method of directly measuring the velocity head for an incompressible fluid.

$$\frac{v^2}{2} = \frac{p_t - p_s}{\rho} = hg \quad [\text{SI}] \quad 17.142(a)$$

$$\frac{v^2}{2g_c} = \frac{p_t - p_s}{\rho} = h \times \frac{g}{g_c} \quad [\text{U.S.}] \quad 17.142(b)$$

$$v = \sqrt{2gh} \quad 17.143$$

The pitot tube and static pressure tap shown in Fig. 17.22 can be combined into a *pitot-static gauge*. (See Fig. 17.23.) In a pitot-static gauge, one end of the manometer is acted upon by the static pressure (also referred to as the *transverse pressure*). The other end of the manometer experiences the total (stagnation or impact) pressure. The difference in elevations of the manometer fluid columns is the velocity head. This distance must be corrected if the density of the flowing fluid is significant.

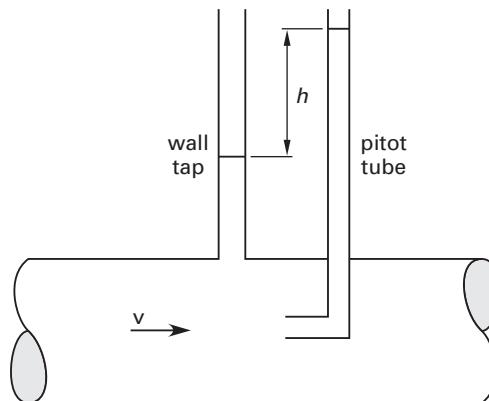

$$\frac{v^2}{2} = \frac{p_t - p_s}{\rho} = \frac{h(\rho_m - \rho)}{\rho} \quad [\text{SI}] \quad 17.144(a)$$

$$\frac{v^2}{2g_c} = \frac{p_t - p_s}{\rho} = \frac{h(\rho_m - \rho)}{\rho} \times \frac{g}{g_c} \quad [\text{U.S.}] \quad 17.144(b)$$

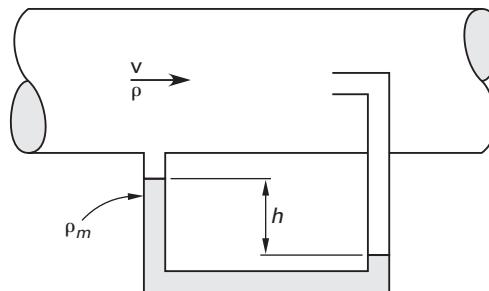

$$v = \sqrt{\frac{2gh(\rho_m - \rho)}{\rho}} \quad 17.145$$

Another correction, which is seldom made, is to multiply the velocity calculated from Eq. 17.145 by  $C_I$ , the *coefficient of the instrument*. Since the flow past the pitot-static tube is slightly faster than the free-fluid velocity,

**Figure 17.22 Comparative Velocity Head Measurement**

**Figure 17.23 Pitot-Static Gauge**

the static pressure measured will be slightly lower than the true value. This makes the indicated velocity slightly higher than the true value.  $C_I$ , a number close to but less than 1.0, corrects for this.

Pitot tube measurements are sensitive to the condition of the opening and errors in installation alignment. The *yaw angle* (i.e., the acute angle between the pitot tube axis and the flow streamline) should be zero.

A pitot-static tube indicates the velocity at only one point in a pipe. If the flow is laminar, and if the pitot-static tube is in the center of the pipe,  $v_{max}$  will be determined. The average velocity, however, will be only half the maximum value.

$$v = v_{max} = v_{ave} \quad [\text{turbulent}] \quad 17.146$$

$$v = v_{max} = 2v_{ave} \quad [\text{laminar}] \quad 17.147$$

**Example 17.11**

Water ( $62.4 \text{ lbm/ft}^3$ ;  $\rho = 1000 \text{ kg/m}^3$ ) is flowing through a pipe. A pitot-static gauge with a mercury manometer registers 3 in (0.076 m) of mercury. What is the velocity of the water in the pipe?

*SI Solution*

The density of mercury is  $\rho = 13580 \text{ kg/m}^3$ . The velocity can be calculated directly from Eq. 17.145.

$$\begin{aligned} v &= \sqrt{\frac{2gh(\rho_m - \rho)}{\rho}} \\ &= \sqrt{\frac{(2)(9.81 \frac{\text{m}}{\text{s}^2})(0.076 \text{ m})}{1000 \frac{\text{kg}}{\text{m}^3}}} \\ &\quad \times \left( 13580 \frac{\text{kg}}{\text{m}^3} - 1000 \frac{\text{kg}}{\text{m}^3} \right) \\ &= 4.33 \text{ m/s} \end{aligned}$$

*Customary U.S. Solution*

The density of mercury is  $\rho = 848.6 \text{ lbm/ft}^3$ .

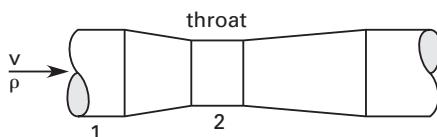

From Eq. 17.145,

$$\begin{aligned} v &= \sqrt{\frac{2gh(\rho_m - \rho)}{\rho}} \\ &= \sqrt{\frac{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})(3 \text{ in})}{\left(62.4 \frac{\text{lbm}}{\text{ft}^3}\right)\left(12 \frac{\text{in}}{\text{ft}}\right)}} \\ &\quad \times \left( 848.6 \frac{\text{lbm}}{\text{ft}^3} - 62.4 \frac{\text{lbm}}{\text{ft}^3} \right) \\ &= 14.24 \text{ ft/sec} \end{aligned}$$

**34. VENTURI METER**

Figure 17.24 illustrates a simple *venturi*. (Sometimes the venturi is called a *converging-diverging nozzle*.) This flow-measuring device can be inserted directly into a pipeline. Since the diameter changes are gradual, there is very little friction loss. Static pressure measurements are taken at the throat and upstream of the diameter change. These measurements are traditionally made by a manometer.

**Figure 17.24** Venturi Meter

The analysis of *venturi meter performance* is relatively simple. The traditional derivation of upstream velocity starts by assuming a horizontal orientation and frictionless, incompressible, and turbulent flow. Then, the Bernoulli equation is written for points 1 and 2. Equation 17.148 shows that the static pressure decreases as the velocity increases. This is known as the *venturi effect*.

$$\frac{v_1^2}{2} + \frac{p_1}{\rho} = \frac{v_2^2}{2} + \frac{p_2}{\rho} \quad [\text{SI}] \quad 17.148(a)$$

$$\frac{v_1^2}{2g_c} + \frac{p_1}{\rho} = \frac{v_2^2}{2g_c} + \frac{p_2}{\rho} \quad [\text{U.S.}] \quad 17.148(b)$$

The two velocities are related by the continuity equation.

$$A_1 v_1 = A_2 v_2 \quad 17.149$$

Combining Eq. 17.148 and Eq. 17.149 and eliminating the unknown  $v_1$  produces an expression for the throat velocity. A *coefficient of velocity* is used to account for the small effect of friction. ( $C_v$  is very close to 1.0, usually 0.98 or 0.99.)

$$\begin{aligned} v_2 &= C_v v_{2,\text{ideal}} \\ &= \left( \frac{C_v}{\sqrt{1 - \left( \frac{A_2}{A_1} \right)^2}} \right) \sqrt{\frac{2(p_1 - p_2)}{\rho}} \quad [\text{SI}] \quad 17.150(a) \end{aligned}$$

$$\begin{aligned} v_2 &= C_v v_{2,\text{ideal}} \\ &= \left( \frac{C_v}{\sqrt{1 - \left( \frac{A_2}{A_1} \right)^2}} \right) \sqrt{\frac{2g_c(p_1 - p_2)}{\rho}} \quad [\text{U.S.}] \quad 17.150(b) \end{aligned}$$

The *velocity of approach factor*,  $F_{va}$ , also known as the *meter constant*, is the reciprocal of the first term of the denominator of the first term of Eq. 17.150. The *beta ratio* can be incorporated into the formula for  $F_{va}$ .

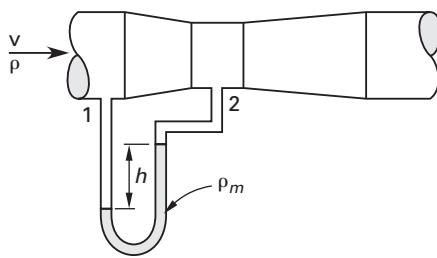

$$\beta = \frac{D_2}{D_1} \quad 17.151$$

$$F_{va} = \frac{1}{\sqrt{1 - \left( \frac{A_2}{A_1} \right)^2}} = \frac{1}{\sqrt{1 - \beta^4}} \quad 17.152$$

If a manometer is used to measure the pressure difference directly, Eq. 17.150 can be rewritten in terms of the manometer fluid reading. (See Fig. 17.25.)

$$\begin{aligned} v_2 &= C_v v_{2,\text{ideal}} = \left( \frac{C_v}{\sqrt{1 - \beta^4}} \right) \sqrt{\frac{2g(\rho_m - \rho)h}{\rho}} \\ &= C_v F_{va} \sqrt{\frac{2g(\rho_m - \rho)h}{\rho}} \end{aligned} \quad 17.153$$

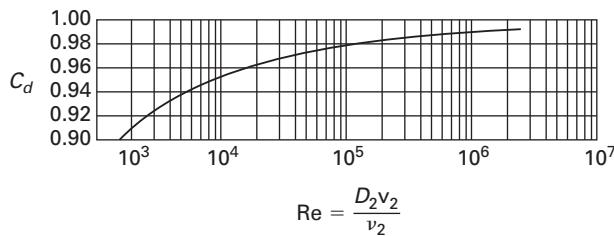

**Figure 17.25** Venturi Meter with Manometer

The flow rate through a venturi meter can be calculated from the throat area. There is an insignificant amount of contraction of the flow as it passes through the throat, and the *coefficient of contraction* is seldom encountered in venturi meter work. The *coefficient of discharge* ( $C_d = C_c C_v$ ) is essentially the same as the coefficient of velocity. Values of  $C_d$  range from slightly less than 0.90 to over 0.99, depending on the Reynolds number.  $C_d$  is seldom less than 0.95 for turbulent flow. (See Fig. 17.26.)

$$\dot{V} = C_d A_2 v_{2,\text{ideal}} \quad 17.154$$

**Figure 17.26** Typical Venturi Meter Discharge Coefficients (long radius venturi meter)

The product  $C_d F_{va}$  is known as the *coefficient of flow* or *flow coefficient*, not to be confused with the coefficient of discharge.<sup>21</sup> This factor is used for convenience, since it combines the losses with the meter constant.

$$C_f = C_d F_{va} = \frac{C_d}{\sqrt{1 - \beta^4}} \quad 17.155$$

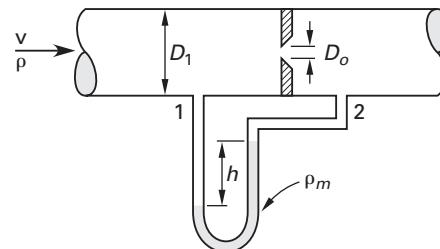

<sup>21</sup>Some writers use the symbol  $K$  for the flow coefficient.

$$\dot{V} = C_f A_2 \sqrt{\frac{2g(\rho_m - \rho)h}{\rho}} \quad 17.156$$

### 35. ORIFICE METER

The *orifice meter* (or *orifice plate*) is used more frequently than the venturi meter to measure flow rates in small pipes. It consists of a thin or sharp-edged plate with a central, round hole through which the fluid flows. Such a plate is easily clamped between two flanges in an existing pipeline. (See Fig. 17.27.)

**Figure 17.27** Orifice Meter with Differential Manometer

While (for small pipes) the orifice meter may consist of a thin plate without significant thickness, various types of bevels and rounded edges are also used with thicker plates. There is no significant difference in the analysis procedure between "flat plate," "sharp-edged," or "square-edged" orifice meters. Any effect that the orifice edges have is accounted for in the discharge and flow coefficient correlations. Similarly, the direction of the bevel will affect the coefficients but not the analysis method.

As with the venturi meter, pressure taps are used to obtain the static pressure upstream of the orifice plate and at the *vena contracta* (i.e., at the point of minimum pressure).<sup>22</sup> A differential manometer connected to the two taps conveniently indicates the difference in static pressures.

Although the orifice meter is simpler and less expensive than a venturi meter, its discharge coefficient is much less than that of a venturi meter.  $C_d$  usually ranges from 0.55 to 0.75, with values of 0.60 and 0.61 often being quoted. (The coefficient of contraction has a large effect,

<sup>22</sup>Calibration of the orifice meter is sensitive to tap placement. Upstream taps are placed between one-half and two pipe diameters upstream from the orifice. (An upstream distance of one pipe diameter is often quoted and used.) There are three tap-placement options: flange, vena contracta, and standardized. Flange taps are used with prefabricated orifice meters that are inserted (by flange bolting) in pipes. If the location of the vena contracta is known, a tap can be placed there. However, the location of the vena contracta depends on the diameter ratio  $\beta = D_o/D$  and varies from approximately 0.4 to 0.7 pipe diameters downstream. Due to the difficulty of locating the vena contracta, the standardized  $1D-1/2D$  configuration is often used. The upstream tap is one diameter before the orifice; the downstream tap is one-half diameter after the orifice. Since approaching flow should be stable and uniform, care must be taken not to install the orifice meter less than approximately five diameters after a bend or elbow.

since  $C_d = C_v C_c$ .) Also, its pressure recovery is poor (i.e., there is a permanent pressure reduction), and it is susceptible to inaccuracies from wear and abrasion.<sup>23</sup>

The derivation of the governing equations for an orifice meter is similar to that of the venturi meter. (The obvious falsity of assuming frictionless flow through the orifice is corrected by the coefficient of discharge.) The major difference is that the coefficient of contraction is taken into consideration in writing the mass continuity equation, since the pressure is measured at the vena contracta, not the orifice.

$$A_2 = C_c A_o \quad 17.157$$

$$v_o = \left( \frac{C_d}{\sqrt{1 - \left( \frac{C_c A_o}{A_1} \right)^2}} \right) \sqrt{\frac{2(p_1 - p_2)}{\rho}} \quad [\text{SI}] \quad 17.158(a)$$

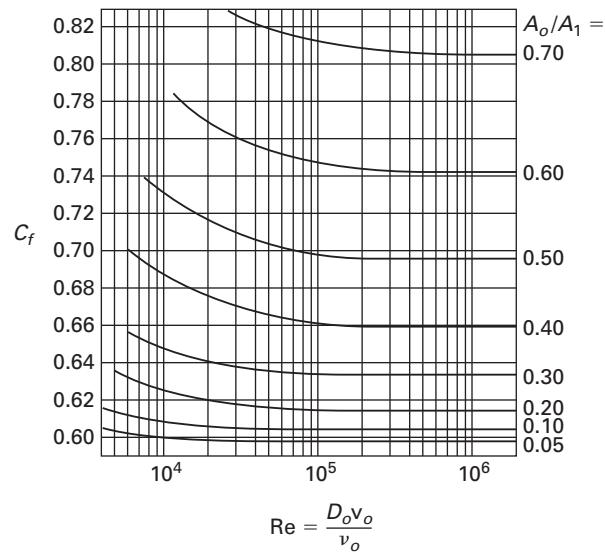

$$v_o = \left( \frac{C_d}{\sqrt{1 - \left( \frac{C_c A_o}{A_1} \right)^2}} \right) \sqrt{\frac{2g_c(p_1 - p_2)}{\rho}} \quad [\text{U.S.}] \quad 17.158(b)$$

If a manometer is used to indicate the differential pressure  $p_1 - p_2$ , the velocity at the vena contracta can be calculated from Eq. 17.159.

$$v_o = \left( \frac{C_d}{\sqrt{1 - \left( \frac{C_c A_o}{A_1} \right)^2}} \right) \sqrt{\frac{2g(\rho_m - \rho)h}{\rho}} \quad 17.159$$

The *velocity of approach factor*,  $F_{va}$ , for an orifice meter is defined differently than for a venturi meter, since it takes into consideration the contraction of the flow. However, the velocity of approach factor is still combined with the coefficient of discharge into the flow coefficient,  $C_f$ . Figure 17.28 illustrates how the flow coefficient varies with the area ratio and the Reynolds number.

**Figure 17.28** Typical Flow Coefficients for Orifice Plates

$$F_{va} = \frac{1}{\sqrt{1 - \left( \frac{C_c A_o}{A_1} \right)^2}} \quad 17.160$$

$$C_f = C_d F_{va} \quad 17.161$$

The flow rate through an orifice meter is given by Eq. 17.162.

$$\dot{V} = C_f A_o \sqrt{\frac{2g(\rho_m - \rho)h}{\rho}} = C_f A_o \sqrt{\frac{2(p_1 - p_2)}{\rho}} \quad [\text{SI}] \quad 17.162(a)$$

$$\dot{V} = C_f A_o \sqrt{\frac{2g(\rho_m - \rho)h}{\rho}} = C_f A_o \sqrt{\frac{2g_c(p_1 - p_2)}{\rho}} \quad [\text{U.S.}] \quad 17.162(b)$$

### Example 17.12

150°F water ( $\rho = 61.2 \text{ lbm/ft}^3$ ) flows in an 8 in schedule-40 steel pipe at the rate of 2.23 ft<sup>3</sup>/sec. A sharp-edged orifice with a 7 in diameter hole is placed in the line. A mercury differential manometer is used to record the pressure difference. (Mercury has a density of 848.6 lbm/ft<sup>3</sup>.) If the orifice has a flow coefficient,  $C_f$ , of 0.62, what deflection in inches of mercury is observed?

*Solution*

The orifice area is

$$A_o = \frac{\pi D_o^2}{4} = \frac{\pi \left( \frac{7 \text{ in}}{12 \frac{\text{in}}{\text{ft}}} \right)^2}{4} = 0.2673 \text{ ft}^2$$

<sup>23</sup>The actual loss varies from 40% to 90% of the differential pressure. The loss depends on the diameter ratio  $\beta = D_o/D_1$ , and is not particularly sensitive to the Reynolds number for turbulent flow. For  $\beta = 0.5$ , the loss is 73% of the measured pressure difference,  $p_1 - p_2$ . This decreases to approximately 56% of the pressure difference when  $\beta = 0.65$  and to 38%, when  $\beta = 0.8$ . For any diameter ratio, the pressure drop coefficient,  $K$ , in multiples of the orifice velocity head is  $K = (1 - \beta^2)/C_f^2$ .

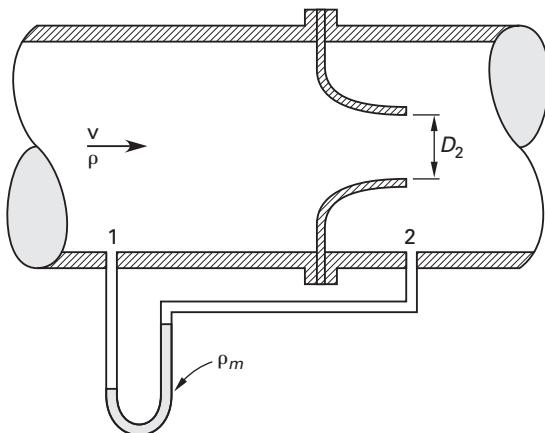

Equation 17.162 is solved for  $h$ .

$$\begin{aligned} h &= \frac{V^2 \rho}{2g C_f^2 A_o^2 (\rho_m - \rho)} \\ &= \frac{\left(2.23 \frac{\text{ft}^3}{\text{sec}}\right)^2 \left(61.2 \frac{\text{lbm}}{\text{ft}^3}\right) \left(12 \frac{\text{in}}{\text{ft}}\right)}{(2)\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)(0.62)^2} \\ &\quad \times (0.2673 \text{ ft}^2)^2 \left(848.6 \frac{\text{lbm}}{\text{ft}^3} - 61.2 \frac{\text{lbm}}{\text{ft}^3}\right) \\ &= 2.62 \text{ in} \end{aligned}$$

### 36. FLOW NOZZLE

A typical flow nozzle is illustrated in Fig. 17.29. This device consists only of a converging section. It is somewhat between an orifice plate and a venturi meter in performance, possessing some of the advantages and disadvantages of each. The venturi performance equations can be used for the flow nozzle.

**Figure 17.29** Flow Nozzle

The geometry of the nozzle entrance is chosen to prevent separation of the fluid from the wall. The converging portion and the subsequent parallel section keep the coefficients of velocity and contraction close to 1.0. However, the absence of a diffuser section disrupts the orderly return of fluid to its original condition. The permanent pressure drop is more similar to that of the orifice meter than the venturi meter.

Since the nozzle geometry greatly affects the nozzle's performance, values of  $C_d$  and  $C_f$  have been established for only a limited number of specific proprietary nozzles.<sup>24</sup>

<sup>24</sup>Some of the proprietary nozzles for which detailed performance data exist are the ASME long-radius nozzle (low- $\beta$  and high- $\beta$  series) and the International Standards Association (ISA) nozzle (German standard nozzle).

### 37. FLOW MEASUREMENTS OF COMPRESSIBLE FLUIDS

Volume measurements of compressible fluids (i.e., gases) are not very meaningful. The volume of a gas will depend on its temperature and pressure. For that reason, flow quantities of gases discharged should be stated as mass flow rates.

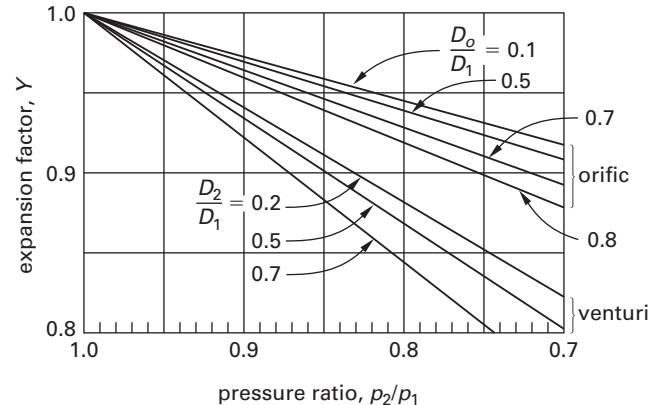

$$\dot{m} = \rho_2 A_2 v_2 \quad 17.163$$

Equation 17.163 requires that the velocity and area be measured at the same point. More importantly, the density must be measured at that point as well. However, it is common practice in flow measurement work to use the density of the upstream fluid at position 1. (This is not the stagnation density.)

The significant error introduced by this simplification is corrected by the use of an *expansion factor*,  $Y$ . For venturi meters and flow nozzles, values of the expansion factor are generally calculated theoretical values. Values of  $Y$  are determined experimentally for orifice plates. (See Fig. 17.30.)

$$\dot{m} = Y \rho_1 A_2 v_2 \quad 17.164$$

**Figure 17.30** Approximate Expansion Factors,  $k = 1.4$  (air)

Geankoplis, Christie J., *Transport Processes and Unit Operations*, 3rd, © 1993. Printed and electronically reproduced by permission of Pearson Education, Inc., New York, New York.

Derivation of the theoretical formula for the expansion factor for venturi meters and flow nozzles is based on thermodynamic principles and an assumption of adiabatic flow.

$$Y = \sqrt{\frac{(1 - \beta^4) \left( \left(\frac{p_2}{p_1}\right)^{2/k} - \left(\frac{p_2}{p_1}\right)^{(k+1)/k} \right)}{\left(\frac{k-1}{k}\right) \left(1 - \frac{p_2}{p_1}\right) \left(1 - \beta^4 \left(\frac{p_2}{p_1}\right)^{2/k}\right)}} \quad 17.165$$

Once the expansion factor is known, it can be used with the standard flow rate,  $\dot{V}$ , equations for venturi meters, flow nozzles, and orifice meters. For example, for a venturi meter, the mass flow rate would be calculated from Eq. 17.166.

$$\dot{m} = Y \dot{m}_{\text{ideal}} = \left( \frac{Y C_d A_2}{\sqrt{1 - \beta^4}} \right) \sqrt{2 \rho_1 (p_1 - p_2)} \quad [\text{SI}] \quad 17.166(a)$$

$$\dot{m} = Y \dot{m}_{\text{ideal}} = \left( \frac{Y C_d A_2}{\sqrt{1 - \beta^4}} \right) \sqrt{2 g_c \rho_1 (p_1 - p_2)} \quad [\text{U.S.}] \quad 17.166(b)$$

### 38. IMPULSE-MOMENTUM PRINCIPLE

(The convention of this section is to make  $F$  and  $x$  positive when they are directed toward the right.  $F$  and  $y$  are positive when directed upward. Also, the fluid is assumed to flow horizontally from left to right, and it has no initial  $y$ -component of velocity.)

The *momentum*,  $\mathbf{P}$  (also known as *linear momentum* to distinguish it from *angular momentum*, which is not considered here), of a moving object is a vector quantity defined as the product of the object's mass and velocity.<sup>25</sup>

$$\mathbf{P} = m\mathbf{v} \quad [\text{SI}] \quad 17.167(a)$$

$$\mathbf{P} = \frac{m\mathbf{v}}{g_c} \quad [\text{U.S.}] \quad 17.167(b)$$

The *impulse*,  $\mathbf{I}$ , of a constant force is calculated as the product of the force and the length of time the force is applied.

$$\mathbf{I} = \mathbf{F}\Delta t \quad 17.168$$

The *impulse-momentum principle (law of conservation of momentum)* states that the impulse applied to a body is equal to the change in momentum. Equation 17.169 is one way of stating Newton's second law of motion.

$$\mathbf{I} = \Delta\mathbf{P} \quad 17.169$$

$$F\Delta t = m\Delta\mathbf{v} = m(\mathbf{v}_2 - \mathbf{v}_1) \quad [\text{SI}] \quad 17.170(a)$$

$$F\Delta t = \frac{m\Delta\mathbf{v}}{g_c} = \frac{m(\mathbf{v}_2 - \mathbf{v}_1)}{g_c} \quad [\text{U.S.}] \quad 17.170(b)$$

For fluid flow, there is a mass flow rate,  $\dot{m}$ , but no mass per se. Since  $\dot{m} = m/\Delta t$ , the impulse-momentum equation can be rewritten as follows.

$$F = \dot{m}\Delta v \quad [\text{SI}] \quad 17.171(a)$$

$$F = \frac{\dot{m}\Delta v}{g_c} \quad [\text{U.S.}] \quad 17.171(b)$$

Equation 17.171 calculates the constant force required to accelerate or retard a fluid stream. This would occur when fluid enters a reduced or enlarged flow area. If the flow area decreases, for example, the fluid will be accelerated by a wall force up to the new velocity. Ultimately, this force must be resisted by the pipe supports.

As Eq. 17.171 illustrates, fluid momentum is not always conserved, since it is generated by the external force,  $F$ . Examples of external forces are gravity (considered zero for horizontal pipes), gage pressure, friction, and turning forces from walls and vanes. Only if these external forces are absent is fluid momentum conserved.

Since force is a vector, it can be resolved into its  $x$ - and  $y$ -components of force.

$$F_x = \dot{m}\Delta v_x \quad [\text{SI}] \quad 17.172(a)$$

$$F_x = \frac{\dot{m}\Delta v_x}{g_c} \quad [\text{U.S.}] \quad 17.172(b)$$

$$F_y = \dot{m}\Delta v_y \quad [\text{SI}] \quad 17.173(a)$$

$$F_y = \frac{\dot{m}\Delta v_y}{g_c} \quad [\text{U.S.}] \quad 17.173(b)$$

If the flow is initially at velocity  $v$  but is directed through an angle  $\theta$  with respect to the original direction, the  $x$ - and  $y$ -components of velocity can be calculated from Eq. 17.174 and Eq. 17.175.

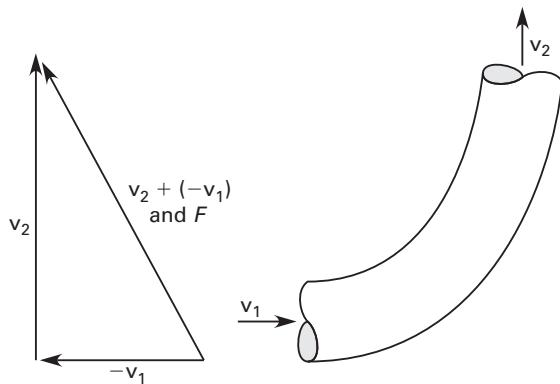

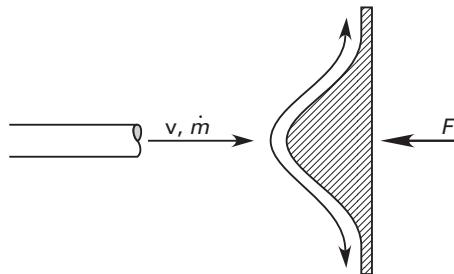

$$\Delta v_x = v(\cos \theta - 1) \quad 17.174$$

$$\Delta v_y = v \sin \theta \quad 17.175$$

Since  $F$  and  $v$  are vector quantities and  $\Delta t$  and  $m$  are scalars,  $F$  must have the same direction as  $v_2 - v_1$ . (See Fig. 17.31.) This provides an intuitive method of determining the direction in which the force acts. Essentially, one needs to ask, "In which direction must the force act in order to push the fluid stream into its new direction?" (The force,  $F$ , is the force on the fluid. The force on the pipe walls or pipe supports has the same magnitude but is opposite in direction.)

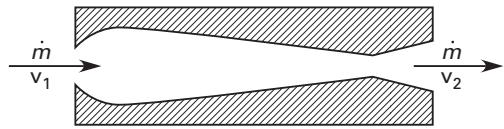

If a jet is completely stopped by a flat plate placed perpendicular to its flow, then  $\theta = 90^\circ$  and  $\Delta v_x = -v$ . If a jet is turned around so that it ends up returning to where it originated, then  $\theta = 180^\circ$  and  $\Delta v_x = -2v$ . A positive  $\Delta v$  indicates an increase in velocity. A negative  $\Delta v$  indicates a decrease in velocity.

<sup>25</sup>The symbol  $B$  is also used for momentum. In many texts, however, momentum is given no symbol at all.

**Figure 17.31** Force on a Confined Fluid Stream**Figure 17.33** Jet on a Vertical Plate

### 39. JET PROPULSION

A basic application of the impulse-momentum principle is the analysis of jet propulsion. Air enters a jet engine and is mixed with fuel. The air and fuel mixture is compressed and ignited, and the exhaust products leave the engine at a greater velocity than was possessed by the original air. The change in momentum of the air produces a force on the engine. (See Fig. 17.32.)

**Figure 17.32** Jet Engine

The governing equation for a jet engine is Eq. 17.176. The mass of the jet fuel is small compared with the air mass, and the fuel mass is commonly disregarded.

$$F_x = \dot{m}(v_2 - v_1) \quad 17.176$$

$$F_x = \dot{V}_2 \rho_2 v_2 - \dot{V}_1 \rho_1 v_1 \quad [\text{SI}] \quad 17.177(a)$$

$$F_x = \frac{\dot{V}_2 \rho_2 v_2 - \dot{V}_1 \rho_1 v_1}{g_c} \quad [\text{U.S.}] \quad 17.177(b)$$

### 40. OPEN JET ON A VERTICAL FLAT PLATE

Figure 17.33 illustrates an open jet on a vertical flat plate. The fluid approaches the plate with no vertical component of velocity; it leaves the plate with no horizontal component of velocity. (This is another way of saying there is no splash-back.) Therefore, all of the velocity in the  $x$ -direction is canceled. (The minus sign in Eq. 17.178 indicates that the force is opposite the initial velocity direction.)

$$\Delta v = -v \quad 17.178$$

$$F_x = -\dot{m}v \quad [\text{SI}] \quad 17.179(a)$$

$$F_x = \frac{-\dot{m}v}{g_c} \quad [\text{U.S.}] \quad 17.179(b)$$

Since the flow is divided, half going up and half going down, the net velocity change in the  $y$ -direction is zero. There is no force in the  $y$ -direction on the fluid.

### 41. OPEN JET ON A HORIZONTAL FLAT PLATE

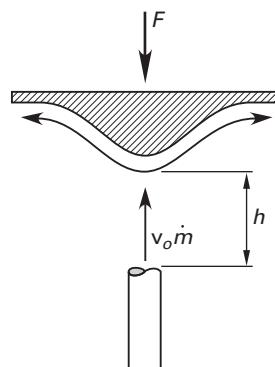

If a jet of fluid is directed upward, its velocity will decrease due to the effect of gravity. The force exerted on the fluid by the plate will depend on the fluid velocity at the plate surface,  $v_y$ , not the original jet velocity,  $v_o$ . All of this velocity is canceled. Since the flow divides evenly in both horizontal directions ( $\Delta v_x = 0$ ), there is no force component in the  $x$ -direction. (See Fig. 17.34.)

$$v_y = \sqrt{v_o^2 - 2gh} \quad 17.180$$

$$\Delta v_y = -\sqrt{v_o^2 - 2gh} \quad 17.181$$

$$F_y = -\dot{m}\sqrt{v_o^2 - 2gh} \quad [\text{SI}] \quad 17.182(a)$$

$$F_y = \frac{-\dot{m}\sqrt{v_o^2 - 2gh}}{g_c} \quad [\text{U.S.}] \quad 17.182(b)$$

**Figure 17.34** Open Jet on a Horizontal Plate

## 42. OPEN JET ON AN INCLINED PLATE

An open jet will be diverted both up and down (but not laterally) by a stationary, inclined plate, as shown in Fig. 17.35. In the absence of friction, the velocity in each diverted flow will be  $v$ , the same as in the approaching jet. The fractions  $f_1$  and  $f_2$  of the jet that are diverted up and down can be found from Eq. 17.183 through Eq. 17.186.

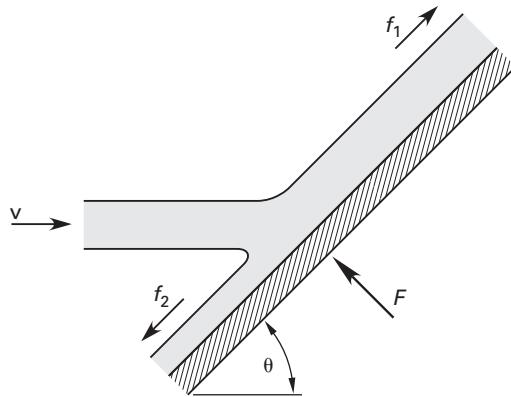

$$f_1 = \frac{1 + \cos \theta}{2} \quad 17.183$$

$$f_2 = \frac{1 - \cos \theta}{2} \quad 17.184$$

$$f_1 - f_2 = \cos \theta \quad 17.185$$

$$f_1 + f_2 = 1.0 \quad 17.186$$

**Figure 17.35** Open Jet on an Inclined Plate

If the flow along the plate is frictionless, there will be no force component parallel to the plate. The force perpendicular to the plate is given by Eq. 17.187.

$$F = \dot{m}v \sin \theta \quad [\text{SI}] \quad 17.187(a)$$

$$F = \frac{\dot{m}v \sin \theta}{g_c} \quad [\text{U.S.}] \quad 17.187(b)$$

## 43. OPEN JET ON A SINGLE STATIONARY BLADE

Figure 17.36 illustrates a fluid jet being turned through an angle  $\theta$  by a stationary blade (also called a *vane*). It is common to assume that  $|v_2| = |v_1|$ , although this will not be strictly true if friction between the blade and fluid is considered. Since the fluid is both decelerated (in the  $x$ -direction) and accelerated (in the  $y$ -direction), there will be two components of force on the fluid.

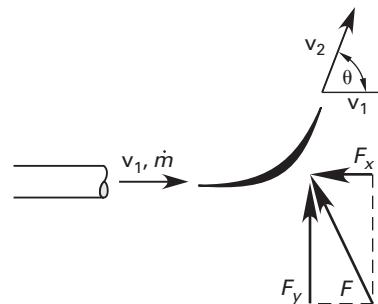

$$\Delta v_x = v_2 \cos \theta - v_1 \quad 17.188$$

$$\Delta v_y = v_2 \sin \theta \quad 17.189$$

$$F_x = \dot{m}(v_2 \cos \theta - v_1) \quad [\text{SI}] \quad 17.190(a)$$

$$F_x = \frac{\dot{m}(v_2 \cos \theta - v_1)}{g_c} \quad [\text{U.S.}] \quad 17.190(b)$$

**Figure 17.36** Open Jet on a Stationary Blade

$$F_y = \dot{m}v_2 \sin \theta \quad [\text{SI}] \quad 17.191(a)$$

$$F_y = \frac{\dot{m}v_2 \sin \theta}{g_c} \quad [\text{U.S.}] \quad 17.191(b)$$

$$F = \sqrt{F_x^2 + F_y^2} \quad 17.192$$

## 44. OPEN JET ON A SINGLE MOVING BLADE

If a blade is moving away at velocity  $v_b$  from the source of the fluid jet, only the *relative velocity difference* between the jet and blade produces a momentum change. Furthermore, not all of the fluid jet overtakes the moving blade. The equations used for the single stationary blade can be used by substituting  $(v - v_b)$  for  $v$  and by using the effective mass flow rate,  $\dot{m}_{\text{eff}}$ . (See Fig. 17.37.)

$$\Delta v_x = (v - v_b)(\cos \theta - 1) \quad 17.193$$

$$\Delta v_y = (v - v_b)\sin \theta \quad 17.194$$

$$\dot{m}_{\text{eff}} = \left( \frac{v - v_b}{v} \right) \dot{m} \quad 17.195$$

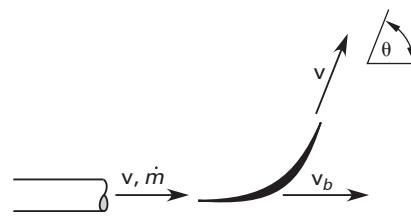

$$F_x = \dot{m}_{\text{eff}}(v - v_b)(\cos \theta - 1) \quad [\text{SI}] \quad 17.196(a)$$

$$F_x = \frac{\dot{m}_{\text{eff}}(v - v_b)(\cos \theta - 1)}{g_c} \quad [\text{U.S.}] \quad 17.196(b)$$

$$F_y = \dot{m}_{\text{eff}}(v - v_b)\sin \theta \quad [\text{SI}] \quad 17.197(a)$$

$$F_y = \frac{\dot{m}_{\text{eff}}(v - v_b)\sin \theta}{g_c} \quad [\text{U.S.}] \quad 17.197(b)$$

**Figure 17.37** Open Jet on a Moving Blade

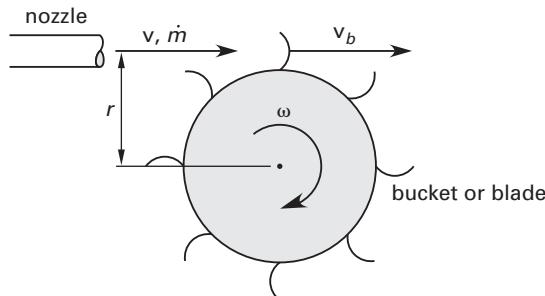

## 45. OPEN JET ON A MULTIPLE-BLADED WHEEL

An *impulse turbine* consists of a series of blades (buckets or vanes) mounted around a wheel. (See Fig. 17.38.) The tangential velocity of the blades is approximately parallel to the jet. The effective mass flow rate,  $\dot{m}_{\text{eff}}$ , used in calculating the reaction force is the full discharge rate, since when one blade moves away from the jet, other blades will have moved into position. All of the fluid discharged is captured by the blades. Equation 17.196 and Eq. 17.197 are applicable if the total flow rate is used. The tangential blade velocity is

$$v_b = \frac{2\pi r n_{\text{rpm}}}{60} = \omega r \quad 17.198$$

**Figure 17.38** Impulse Turbine

## 46. IMPULSE TURBINE POWER

The total power potential of a fluid jet can be calculated from the kinetic energy of the jet and the mass flow rate.<sup>26</sup> (This neglects the pressure energy, which is small by comparison.)

$$P_{\text{jet}} = \frac{\dot{m}v^2}{2} \quad [\text{SI}] \quad 17.199(a)$$

$$P_{\text{jet}} = \frac{\dot{m}v^2}{2g_c} \quad [\text{U.S.}] \quad 17.199(b)$$

The power transferred from a fluid jet to the blades of a turbine is calculated from the  $x$ -component of force on the blades. The  $y$ -component of force does no work.

$$P = F_x v_b \quad 17.200$$

$$P = \dot{m}v_b(v - v_b)(1 - \cos\theta) \quad [\text{SI}] \quad 17.201(a)$$

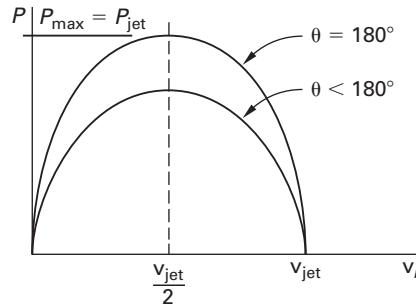

$$P = \frac{\dot{m}v_b(v - v_b)(1 - \cos\theta)}{g_c} \quad [\text{U.S.}] \quad 17.201(b)$$

The maximum theoretical blade velocity is the velocity of the jet:  $v_b = v$ . This is known as the *runaway speed* and

<sup>26</sup>The full jet discharge is used in this section. If only a single blade is involved, the effective mass flow rate,  $\dot{m}_{\text{eff}}$ , must be used.

can only be achieved when the turbine is unloaded. If Eq. 17.201 is maximized with respect to  $v_b$ , the maximum power will occur when the blade is traveling at half of the jet velocity:  $v_b = v/2$ . The power (force) is also affected by the deflection angle of the blade. Power is maximized when  $\theta = 180^\circ$ . Figure 17.39 illustrates the relationship between power and the variables  $\theta$  and  $v_b$ .

**Figure 17.39** Turbine Power

Putting  $\theta = 180^\circ$  and  $v_b = v/2$  into Eq. 17.201 results in  $P_{\text{max}} = \dot{m}v^2/2$ , which is the same as  $P_{\text{jet}}$  in Eq. 17.199. If the machine is 100% efficient, 100% of the jet power can be transferred to the machine.

## 47. CONFINED STREAMS IN PIPE BENDS

As presented in Sec. 17.38, momentum can also be changed by pressure forces. Such is the case when fluid enters a pipe fitting or bend. (See Fig. 17.40.) Since the fluid is confined, the forces due to static pressure must be included in the analysis. (The effects of gravity and friction are neglected.)

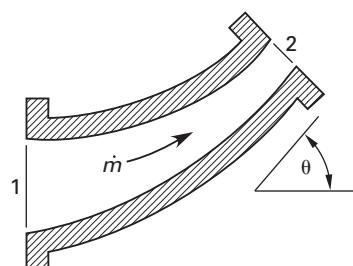

$$F_x = p_2 A_2 \cos\theta - p_1 A_1 + \dot{m}(v_2 \cos\theta - v_1) \quad [\text{SI}] \quad 17.202(a)$$

$$F_x = p_2 A_2 \cos\theta - p_1 A_1 + \frac{\dot{m}(v_2 \cos\theta - v_1)}{g_c} \quad [\text{U.S.}] \quad 17.202(b)$$

$$F_y = (p_2 A_2 + \dot{m}v_2) \sin\theta \quad [\text{SI}] \quad 17.203(a)$$

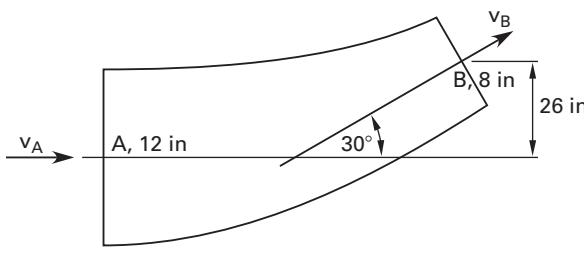

$$F_y = \left( p_2 A_2 + \frac{\dot{m}v_2}{g_c} \right) \sin\theta \quad [\text{U.S.}] \quad 17.203(b)$$

**Figure 17.40** Pipe Bend

**Example 17.13**

60°F water ( $\rho = 62.4 \text{ lbm/ft}^3$ ) at 40 psig enters a 12 in  $\times$  8 in reducing elbow at 8 ft/sec and is turned through an angle of 30°. Water leaves 26 in higher in elevation. (a) What is the resultant force exerted on the water by the elbow? (b) What other forces should be considered in the design of supports for the fitting?

*Solution*

(a) The velocity and pressure at point B are both needed. The velocity is easily calculated from the continuity equation.

$$A_A = \frac{\pi D_A^2}{4} = \frac{\pi \left(\frac{12 \text{ in}}{12 \frac{\text{in}}{\text{ft}}}\right)^2}{4}$$

$$= 0.7854 \text{ ft}^2$$

$$A_B = \frac{\pi D_B^2}{4} = \frac{\pi \left(\frac{8 \text{ in}}{12 \frac{\text{in}}{\text{ft}}}\right)^2}{4}$$

$$= 0.3491 \text{ ft}^2$$

$$v_B = \frac{v_A A_A}{A_B}$$

$$= \left(8 \frac{\text{ft}}{\text{sec}}\right) \left(\frac{0.7854 \text{ ft}^2}{0.3491 \text{ ft}^2}\right)$$

$$= 18 \text{ ft/sec}$$

$$p_A = \left(40 \frac{\text{lbf}}{\text{in}^2}\right) \left(12 \frac{\text{in}}{\text{ft}}\right)^2$$

$$= 5760 \text{ lbf/ft}^2$$

The Bernoulli equation is used to calculate  $p_B$ . (Gage pressures are used for this calculation. Absolute pressures

could also be used, but the addition of  $p_{\text{atm}}/\rho$  to both sides of the Bernoulli equation would not affect  $p_B$ .)

$$\frac{p_A}{\rho} + \frac{v_A^2}{2g_c} = \frac{p_B}{\rho} + \frac{v_B^2}{2g_c} + \frac{zg}{g_c}$$

$$\frac{5760 \frac{\text{lbf}}{\text{ft}^2}}{62.4 \frac{\text{lbm}}{\text{ft}^3}} + \frac{\left(8 \frac{\text{ft}}{\text{sec}}\right)^2}{(2)(32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2})}$$

$$= \frac{p_B}{62.4 \frac{\text{lbm}}{\text{ft}^3}} + \frac{\left(18 \frac{\text{ft}}{\text{sec}}\right)^2}{(2)(32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2})}$$

$$+ \frac{26 \text{ in}}{12 \frac{\text{in}}{\text{ft}}} \times \frac{32.2 \frac{\text{ft}}{\text{sec}^2}}{32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2}}$$

$$p_B = 5373 \text{ lbf/ft}^2$$

The mass flow rate is

$$\dot{m} = \dot{V}\rho = vA\rho = \left(8 \frac{\text{ft}}{\text{sec}}\right)(0.7854 \text{ ft}^2)\left(62.4 \frac{\text{lbm}}{\text{ft}^3}\right)$$

$$= 392.1 \text{ lbm/sec}$$

From Eq. 17.202,

$$F_x = p_2 A_2 \cos \theta - p_1 A_1 + \frac{\dot{m}(v_2 \cos \theta - v_1)}{g_c}$$

$$= \left(5373 \frac{\text{lbf}}{\text{ft}^2}\right)(0.3491 \text{ ft}^2)(\cos 30^\circ)$$

$$- \left(5760 \frac{\text{lbf}}{\text{ft}^2}\right)(0.7854 \text{ ft}^2)$$

$$+ \frac{\left(392.1 \frac{\text{lbm}}{\text{sec}}\right) \left(\left(18 \frac{\text{ft}}{\text{sec}}\right)(\cos 30^\circ) - 8 \frac{\text{ft}}{\text{sec}}\right)}{32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2}}$$

$$= -2807 \text{ lbf}$$

From Eq. 17.203,

$$F_y = \left(p_2 A_2 + \frac{\dot{m}v_2}{g_c}\right) \sin \theta$$

$$= \left(\left(5373 \frac{\text{lbf}}{\text{ft}^2}\right)(0.3491 \text{ ft}^2)\right. \\ \left. + \frac{\left(392.1 \frac{\text{lbm}}{\text{sec}}\right)\left(18 \frac{\text{ft}}{\text{sec}}\right)}{32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2}}\right) \sin 30^\circ$$

$$= 1047 \text{ lbf}$$

The resultant force on the water is

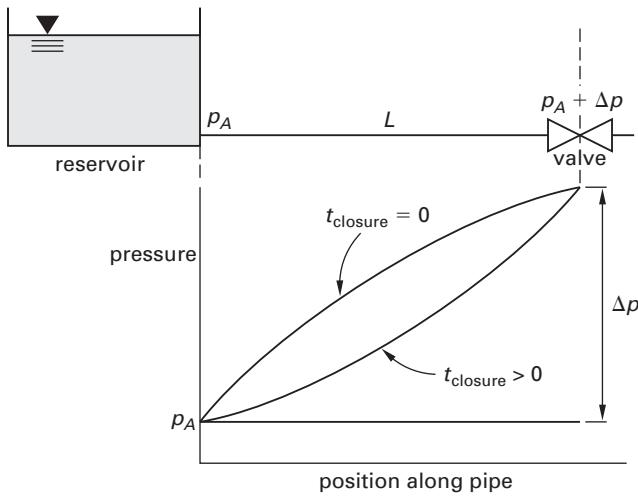

$$R = \sqrt{F_x^2 + F_y^2} = \sqrt{(-2807 \text{ lbf})^2 + (1047 \text{ lbf})^2} \\ = 2996 \text{ lbf}$$

(b) In addition to counteracting the resultant force,  $R$ , the support should be designed to carry the weight of the elbow and the water in it. Also, the support must carry a part of the pipe and water weight tributary to the elbow.

## 48. WATER HAMMER

*Water hammer* in a long pipe is an increase in fluid pressure caused by a sudden velocity decrease. (See Fig. 17.41.) The sudden velocity decrease will usually be caused by a valve closing. Analysis of the water hammer phenomenon can take two approaches, depending on whether or not the pipe material is assumed to be elastic.

Figure 17.41 Water Hammer

The *water hammer wave speed*,  $a$ , is given by Eq. 17.204. The first term on the right-hand side represents the effect of fluid compressibility, and the second term represents the effect of pipe elasticity.

$$\frac{1}{a^2} = \frac{dp}{dp} + \frac{\rho}{A} \frac{dA}{dp} \quad 17.204$$

For a compressible fluid within an inelastic (rigid) pipe,  $dA/dp = 0$ , and the wave speed is simply the speed of sound in the fluid.

$$a = \sqrt{\frac{dp}{d\rho}} = \sqrt{\frac{E}{\rho}} \quad [\text{inelastic pipe; consistent units}] \quad 17.205$$

If the pipe material is assumed to be inelastic (such as cast iron, ductile iron, and concrete), the time required

for the water hammer shock wave to travel from the suddenly closed valve to a point of interest depends only on the velocity of sound in the fluid,  $a$ , and the distance,  $L$ , between the two points. This is also the time required to bring all of the fluid in the pipe to rest.

$$t = \frac{L}{a} \quad 17.206$$

When the water hammer shock wave reaches the original source of water, the pressure wave will dissipate. A rarefaction wave (at the pressure of the water source) will return at velocity  $a$  to the valve. The time for the compression shock wave to travel to the source and the rarefaction wave to return to the valve is given by Eq. 17.207. This is also the length of time that the pressure is constant at the valve.

$$t = \frac{2L}{a} \quad 17.207$$

The fluid pressure increase resulting from the shock wave is calculated by equating the kinetic energy change of the fluid with the average pressure during the compression process. The pressure increase is independent of the length of pipe. If the velocity is decreased by an amount  $\Delta v$  instantaneously, the increase in pressure will be

$$\Delta p = \rho a \Delta v \quad [\text{SI}] \quad 17.208(a)$$

$$\Delta p = \frac{\rho a \Delta v}{g_c} \quad [\text{U.S.}] \quad 17.208(b)$$

It is interesting that the pressure increase at the valve depends on  $\Delta v$  but not on the actual length of time it takes to close the valve, as long as the valve is closed when the wave returns to it. Therefore, there is no difference in pressure buildups at the valve for an “instantaneous closure,” “rapid closure,” or “sudden closure.”<sup>27</sup> It is only necessary for the closure to occur rapidly.

Water hammer does not necessarily occur just because a return shockwave increases the pressure. When the velocity is low—less than 7 ft/sec (2.1 m/s), with 5 ft/sec (1.5 m/s) recommended—there is not enough force generated to create water hammer. The cost of using larger pipe, fittings, and valves is the disadvantage of keeping velocity low.

Having a very long pipe is equivalent to assuming an instantaneous closure. When the pipe is long, the time for the shock wave to travel round-trip is much longer than the time to close the valve. The valve will be closed when the rarefaction wave returns to the valve.

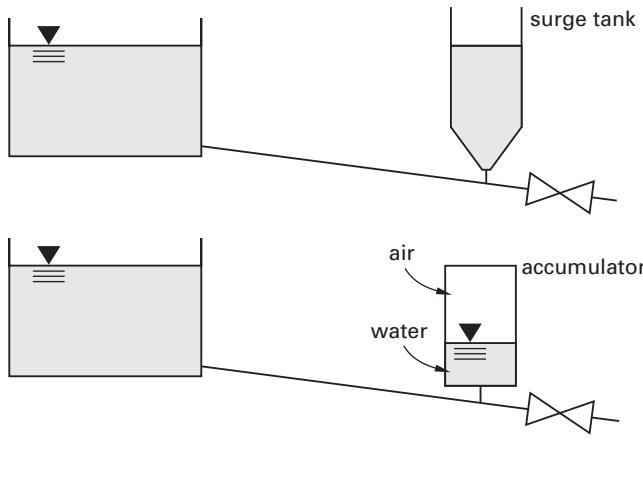

If the pipe is short, it will be difficult to close the valve before the rarefaction wave returns to the valve. With a short pipe, the pressure buildup will be less than is predicted by Eq. 17.208. (Having a short pipe is equivalent to the case of “slow closure.”) The actual pressure

<sup>27</sup>The pressure elsewhere along the pipe, however, will be lower for slow closures than for instantaneous closures.

history is complex, and no simple method exists for calculating the pressure buildup in short pipes.

Installing a *surge tank*, *accumulator*, *slow-closing valve* (e.g., a gate valve), or *pressure-relief valve* in the line will protect against water hammer damage. (See Fig. 17.42.) The surge tank (or *surge chamber*) is an open tank or reservoir. Since the water is unconfined, large pressure buildups do not occur. An accumulator is a closed tank that is partially filled with air. Since the air is much more compressible than the water, it will be compressed by the water hammer shock wave. The energy of the shock wave is dissipated when the air is compressed.

**Figure 17.42** Water Hammer Protective Devices

For an incompressible fluid within an elastic pipe,  $d\rho/dp$  in Eq. 17.205 is zero. In that case, the wave speed is

$$a = \sqrt{\frac{A}{\rho} \frac{dp}{dA}} \quad [\text{elastic pipe; consistent units}] \quad 17.209$$

For long elastic pipes (the common assumption for steel and plastic), the degree of pipe anchoring and longitudinal stress propagation affect the wave velocity. Longitudinal stresses resulting from circumferential stresses (i.e., Poisson's effect) must be considered by including a Poisson's effect factor,  $c_P$ . In Eq. 17.210, for pipes anchored at their upstream ends only,  $c_P = 1 - 0.5\nu_{\text{pipe}}$ ; for pipes anchored throughout,  $c_P = 1 - \nu_{\text{pipe}}^2$ ; for anchored pipes with expansion joints throughout,  $c_P = 1$  (i.e., the commonly used *Korteweg formula*). Pipe sections joined with gasketed integral bell ends and gasketed ends satisfy the requirement for expansion joints. Equation 17.210 shows that the wave velocity can be reduced by increasing the pipe diameter.

$$a = \sqrt{\frac{E_{\text{fluid}} t_{\text{pipe}} E_{\text{pipe}}}{t_{\text{pipe}} E_{\text{pipe}} + c_P D_{\text{pipe}} E_{\text{fluid}}}} \quad 17.210$$

At room temperature, the modulus of elasticity of ductile steel is approximately  $2.9 \times 10^7 \text{ lbf/in}^2$  (200 GPa); for ductile cast iron,  $2.2-2.5 \times 10^7 \text{ lbf/in}^2$  (150–170 GPa); for PVC,  $3.5-4.1 \times 10^5 \text{ lbf/in}^2$  (2.4–2.8 GPa); for ABS,  $3.2-3.5 \times 10^5 \text{ lbf/in}^2$  (2.2–2.4 GPa).

### Example 17.14

Water ( $\rho = 1000 \text{ kg/m}^3$ ,  $E = 2 \times 10^9 \text{ Pa}$ ), is flowing at 4 m/s through a long length of 4 in schedule-40 steel pipe ( $D_i = 0.102 \text{ m}$ ,  $t = 0.00602 \text{ m}$ ,  $E = 2 \times 10^{11} \text{ Pa}$ ) with expansion joints when a valve suddenly closes completely. What is the theoretical increase in pressure?

### Solution

For pipes with expansion joints,  $c_P = 1$ . From Eq. 17.210, the modulus of elasticity to be used in calculating the speed of sound is

$$\begin{aligned} a &= \sqrt{\frac{E_{\text{fluid}} t_{\text{pipe}} E_{\text{pipe}}}{t_{\text{pipe}} E_{\text{pipe}} + c_P D_{\text{pipe}} E_{\text{fluid}}}} \\ &= \sqrt{\frac{(2 \times 10^9 \text{ Pa})(0.00602 \text{ m})(2 \times 10^{11} \text{ Pa})}{(0.00602 \text{ m})(2 \times 10^{11} \text{ Pa})}} \\ &\quad + (1)(0.102 \text{ m})(2 \times 10^9 \text{ Pa}) \\ &= \sqrt{1000 \frac{\text{kg}}{\text{m}^3}} \\ &= 1307.75 \text{ m/s} \end{aligned}$$

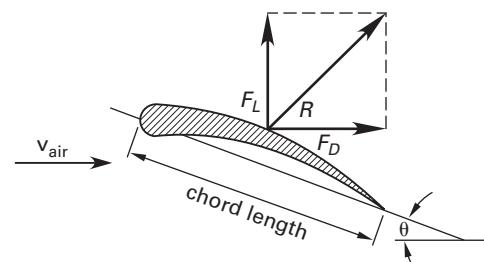

From Eq. 17.208, the pressure increase is

$$\begin{aligned} \Delta p &= \rho a \Delta v = \left(1000 \frac{\text{kg}}{\text{m}^3}\right) \left(1307.75 \frac{\text{m}}{\text{s}}\right) \left(4 \frac{\text{m}}{\text{s}}\right) \\ &= 5.23 \times 10^6 \text{ Pa} \end{aligned}$$

### 49. LIFT

*Lift* is an upward force that is exerted on an object (flat plate, airfoil, rotating cylinder, etc.) as the object passes through a fluid. Lift combines with drag to form the resultant force on the object, as shown in Fig. 17.43.

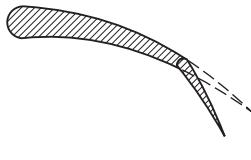

**Figure 17.43** Lift and Drag on an Airfoil

The generation of lift from air flowing over an airfoil is predicted by Bernoulli's equation. Air molecules must travel a longer distance over the top surface of the airfoil than over the lower surface, and, therefore, they travel faster over the top surface. Since the total energy of the air is constant, the increase in kinetic energy comes at the expense of pressure energy. The static pressure on the top of the airfoil is reduced, and a net upward force is produced.

Within practical limits, the lift produced can be increased at lower speeds by increasing the curvature of the wing. This increased curvature is achieved by the use of *flaps*. (See Fig. 17.44.) When a plane is traveling slowly (e.g., during takeoff or landing), its flaps are extended to create the lift needed.

**Figure 17.44** Use of Flaps in an Airfoil

The lift produced can be calculated from Eq. 17.211, whose use is not limited to airfoils.

$$F_L = \frac{C_L A \rho v^2}{2} \quad [\text{SI}] \quad 17.211(a)$$

$$F_L = \frac{C_L A \rho v^2}{2g_c} \quad [\text{U.S.}] \quad 17.211(b)$$

The dimensions of an airfoil or wing are frequently given in terms of chord length and aspect ratio. The *chord length* (or just *chord*) is the front-to-back dimension of the airfoil. The *aspect ratio* is the ratio of the *span* (wing length) to chord length. The area,  $A$ , in Eq. 17.211 is the airfoil's area projected onto the plane of the chord.

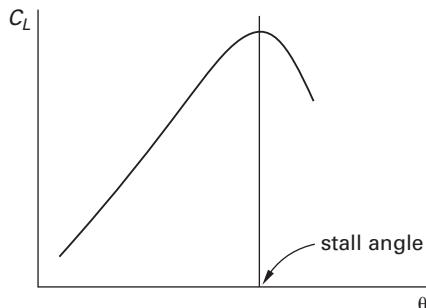

$$A = \text{chord length} \times \text{span} \quad \left[ \begin{array}{l} \text{rectangular} \\ \text{airfoil} \end{array} \right] \quad 17.212$$

The dimensionless *coefficient of lift*,  $C_L$ , modifies the effectiveness of the airfoil. The coefficient of lift depends on the shape of the airfoil, the Reynolds number, and the angle of attack. The theoretical coefficient of lift for a thin flat plate in two-dimensional flow at a low angle of attack,  $\theta$ , is given by Eq. 17.213. Actual airfoils are able to achieve only 80–90% of this theoretical value.

$$C_L = 2\pi \sin \theta \quad [\text{flat plate}] \quad 17.213$$

The coefficient of lift for an airfoil cannot be increased without limit merely by increasing  $\theta$ . Eventually, the *stall angle* is reached, at which point the coefficient of lift decreases dramatically. (See Fig. 17.45.)

**Figure 17.45** Typical Plot of Lift Coefficient

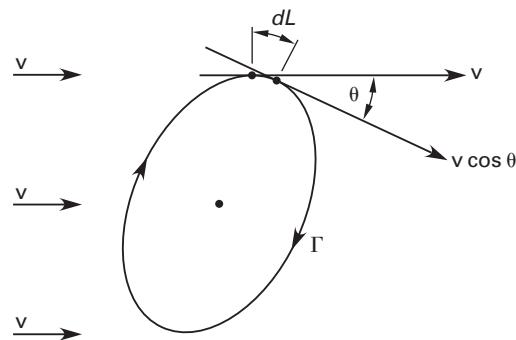

## 50. CIRCULATION

A theoretical concept for calculating the lift generated by an object (an airfoil, propeller, turbine blade, etc.) is *circulation*. Circulation,  $\Gamma$ , is defined by Eq. 17.214.<sup>28</sup> Its units are length<sup>2</sup>/time.

$$\Gamma = \oint v \cos \theta \, dL \quad 17.214$$

Figure 17.46 illustrates an arbitrary closed curve drawn around a point (or body) in steady flow. The tangential components of velocity,  $v$ , at all points around the curve are  $v \cos \theta$ . It is a fundamental theorem that circulation has the same value for every closed curve that can be drawn around a body.

**Figure 17.46** Circulation Around a Point

Lift on a body traveling with relative velocity  $v$  through a fluid of density  $\rho$  can be calculated from the circulation by using Eq. 17.215.<sup>29</sup>

$$F_L = \rho v \Gamma \times \text{chord length} \quad 17.215$$

<sup>28</sup>Equation 17.214 is analogous to the calculation of work being done by a constant force moving around a curve. If the force makes an angle of  $\theta$  with the direction of motion, the work done as the force moves a distance,  $dl$ , around a curve is  $W = \oint F \cos \theta \, dl$ . In calculating circulation, velocity takes the place of force.

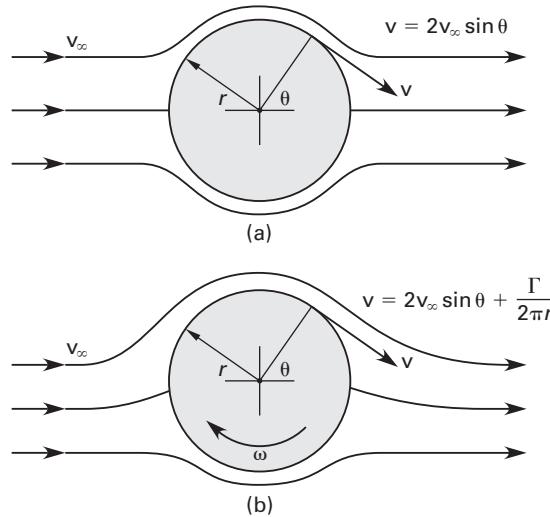

<sup>29</sup> $U$  is the traditional symbol of velocity in circulation studies.

There is no actual circulation of air "around" an airfoil, but this mathematical concept can be used, nevertheless. However, since the flow of air "around" an airfoil is not symmetrical in path or velocity, experimental determination of  $C_L$  is favored over theoretical calculations of circulation.

## 51. LIFT FROM ROTATING CYLINDERS

When a cylinder is placed transversely to a relative airflow of velocity  $v_\infty$ , the velocity at a point on the surface of the cylinder is  $2v_\infty \sin \theta$ . Since the flow is symmetrical, however, no lift is produced. (See Fig. 17.47.)

**Figure 17.47 Flow Over a Cylinder**

If the cylinder with radius  $r$  and length  $L$  rotates at angular velocity  $\omega$  (in units of rad/sec) while moving with a relative velocity  $v_\infty$  through the air, the *Kutta-Joukowsky result (theorem)* can be used to calculate the lift per unit length of cylinder.<sup>30</sup> This is known as the *Magnus effect*.

$$\frac{F_L}{L} = \rho v_\infty \Gamma \quad [\text{SI}] \quad 17.216(a)$$

$$\frac{F_L}{L} = \frac{\rho v_\infty \Gamma}{g_c} \quad [\text{U.S.}] \quad 17.216(b)$$

$$\Gamma = 2\pi r^2 \omega \quad 17.217$$

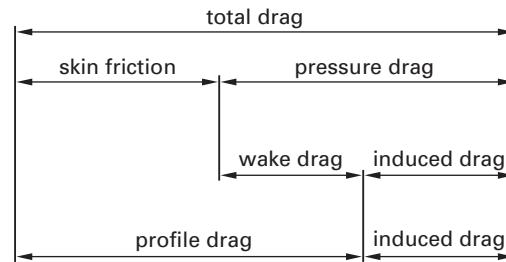

Equation 17.216 assumes that there is no slip (i.e., that the air drawn around the cylinder by rotation moves at  $\omega$ ), and in that ideal case, the maximum coefficient of lift is  $4\pi$ . Practical rotating devices, however, seldom achieve a coefficient of lift in excess of 9 or 10, and even then, the power expenditure to keep the cylinder rotating is excessive.

<sup>30</sup>A similar analysis can be used to explain why a pitched baseball curves. The rotation of the ball produces a force that changes the path of the ball as it travels.

## 52. DRAG

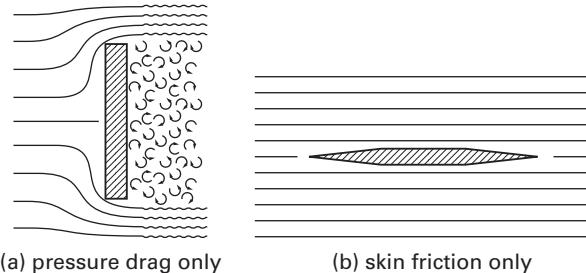

*Drag* is a frictional force that acts parallel but opposite to the direction of motion. The total drag force is made up of *skin friction* and *pressure drag* (also known as *form drag*). These components, in turn, can be subdivided and categorized into *wake drag*, *induced drag*, and *profile drag*. (See Fig. 17.48.)

**Figure 17.48 Components of Total Drag**

Most aeronautical engineering books contain descriptions of these drag terms. However, the difference between the situations where either skin friction drag or pressure drag predominates is illustrated in Fig. 17.49.

**Figure 17.49 Extreme Cases of Pressure Drag and Skin Friction**

Total drag is most easily calculated from the dimensionless *drag coefficient*,  $C_D$ . The drag coefficient depends only on the Reynolds number.

$$F_D = \frac{C_D A \rho v^2}{2} \quad [\text{SI}] \quad 17.218(a)$$

$$F_D = \frac{C_D A \rho v^2}{2 g_c} \quad [\text{U.S.}] \quad 17.218(b)$$

In most cases, the area,  $A$ , in Eq. 17.218 is the projected area (i.e., the *frontal area*) normal to the stream. This is appropriate for spheres, cylinders, and automobiles. In a few cases (e.g., for airfoils and flat plates) as determined by how  $C_D$  was derived, the area is a projection of the object onto a plane parallel to the stream.

Typical drag coefficients for production cars vary from approximately 0.25 to approximately 0.70, with most modern cars being nearer the lower end. By comparison,

other low-speed drag coefficients are approximately 0.05 (aircraft wing), 0.10 (sphere in turbulent flow), and 1.2 (flat plate). (See Table 17.8.)

**Table 17.8** Typical Ranges of Vehicle Drag Coefficients

vehicle	low	medium	high
experimental race	0.17	0.21	0.23
sports	0.27	0.31	0.38
performance	0.32	0.34	0.38
'60s muscle car	0.38	0.44	0.50
sedan	0.34	0.39	0.50
motorcycle	0.50	0.90	1.00
truck	0.60	0.90	1.00
tractor-trailer	0.60	0.77	1.20

Used with permission from *Unit Operations*, by George Granger Brown, et al., John Wiley & Sons, Inc., © 1950.

*Aero horsepower* is a term used by automobile manufacturers to designate the power required to move a car horizontally at 50 mi/hr (80.5 km/h) against the drag force. Aero horsepower varies from approximately 7 hp (5.2 kW) for a streamlined subcompact car (approximate drag coefficient 0.35) to approximately 100 hp (75 kW) for a box-shaped truck (approximate drag coefficient 0.9).

In aerodynamic studies performed in *wind tunnels*, accuracy in lift and drag measurement is specified in *drag counts*. One drag count is equal to a  $C_D$  (or,  $C_L$ ) of 0.0001. Drag counts are commonly used when describing the effect of some change to a fuselage or wing geometry. For example, an increase in  $C_D$  from 0.0450 to 0.0467 would be reported at an increase of 17 counts. Some of the best wind tunnels can measure  $C_D$  down to 1 count; most can only get to about 5 counts. Outside of the wind tunnel, an accuracy of 1 count is the target in computational fluid dynamics.

### 53. DRAG ON SPHERES AND DISKS

The drag coefficient varies linearly with the Reynolds number for laminar flow around a sphere or disk. In laminar flow, the drag is almost entirely due to skin friction. For Reynolds numbers below approximately 0.4, experiments have shown that the drag coefficient can be calculated from Eq. 17.219.<sup>31</sup> In calculating the Reynolds number, the sphere or disk diameter should be used as the characteristic dimension.

$$C_D = \frac{24}{Re} \quad 17.219$$

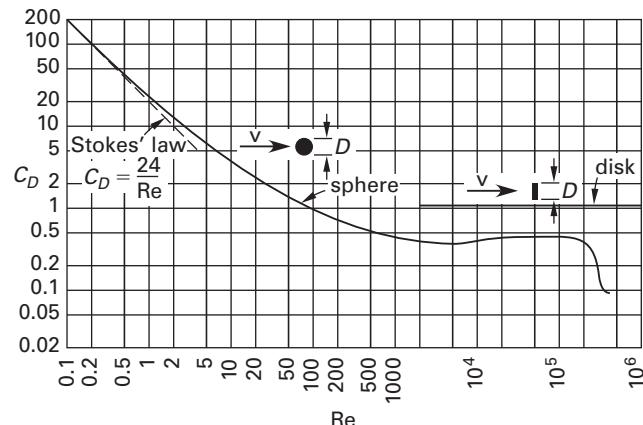

Substituting this value of  $C_D$  into Eq. 17.218 results in *Stokes' law* (see Eq. 17.220), which is applicable to laminar slow motion (ascent or descent) of spherical particles and bubbles through a fluid. Stokes' law is based on the assumptions that (a) flow is laminar, (b) Newton's law of

viscosity is valid, and (c) all higher-order velocity terms ( $v^2$ , etc.) are negligible.

$$F_D = 6\pi\mu vR = 3\pi\mu vD \quad 17.220$$

The drag coefficients for disks and spheres operating outside the region covered by Stokes' law have been determined experimentally. In the turbulent region, pressure drag is predominant. Figure 17.50 can be used to obtain approximate values for  $C_D$ .

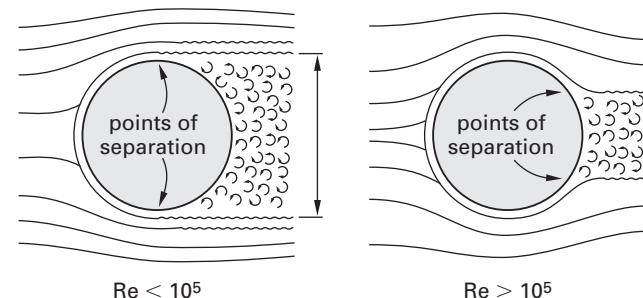

**Figure 17.50** Drag Coefficients for Spheres and Circular Flat Disks

Binder, *Fluid Mechanics*, 5th, © 1973. Printed and electronically reproduced by permission of Pearson Education, Inc., New York, New York.

Figure 17.50 shows that there is a dramatic drop in the drag coefficient around  $Re = 10^5$ . The explanation for this is that the point of separation of the boundary layer shifts, decreasing the width of the wake. (See Fig. 17.51.) Since the drag force is primarily pressure drag at higher Reynolds numbers, a reduction in the wake reduces the pressure drag. Therefore, anything that can be done to a sphere (scuffing or wetting a baseball, dimpling a golf ball, etc.) to induce a smaller wake will reduce the drag. There can be no shift in the boundary layer separation point for a thin disk, since the disk has no depth in the direction of flow. Therefore, the drag coefficient for a thin disk remains the same at all turbulent Reynolds numbers.

**Figure 17.51** Turbulent Flow Around a Sphere at Various Reynolds Numbers

<sup>31</sup>Some sources report that the region in which Stokes' law applies extends to  $Re = 1.0$ .

## 54. TERMINAL VELOCITY

The velocity of an object falling through a fluid will continue to increase until the drag force equals the net downward force (i.e., the weight less the buoyant force). The maximum velocity attained is known as the *terminal velocity* (*settling velocity*).

$$F_D = mg - F_b \quad \begin{matrix} \text{[at terminal]} \\ \text{velocity} \end{matrix} \quad [\text{SI}] \quad 17.221(a)$$

$$F_D = \frac{mg}{g_c} - F_b \quad \begin{matrix} \text{[at terminal]} \\ \text{velocity} \end{matrix} \quad [\text{U.S.}] \quad 17.221(b)$$

If the drag coefficient is known, the terminal velocity can be calculated from Eq. 17.222. For small, heavy objects falling in air, the buoyant force (represented by the  $\rho_{\text{fluid}}$  term) can be neglected.<sup>32</sup>

$$v_{\text{terminal}} = \sqrt{\frac{2(mg - F_b)}{C_D A \rho_{\text{fluid}}}} = \sqrt{\frac{2Vg(\rho_{\text{object}} - \rho_{\text{fluid}})}{C_D A \rho_{\text{fluid}}}} \quad 17.222$$

For a sphere of diameter  $D$ , the terminal velocity is

$$v_{\text{terminal,sphere}} = \sqrt{\frac{4Dg(\rho_{\text{sphere}} - \rho_{\text{fluid}})}{3C_D \rho_{\text{fluid}}}} \quad 17.223$$

If the spherical particle is very small, Stokes' law may apply. In that case, the terminal velocity can be calculated from Eq. 17.224.

$$v_{\text{terminal}} = \frac{D^2 g (\rho_{\text{sphere}} - \rho_{\text{fluid}})}{18\mu} \quad \begin{matrix} \text{[laminar]} \\ \text{[SI]} \end{matrix} \quad 17.224(a)$$

$$v_{\text{terminal}} = \frac{D^2 (\rho_{\text{sphere}} - \rho_{\text{fluid}})}{18\mu} \times \frac{g}{g_c} \quad \begin{matrix} \text{[laminar]} \\ \text{[U.S.]} \end{matrix} \quad 17.224(b)$$

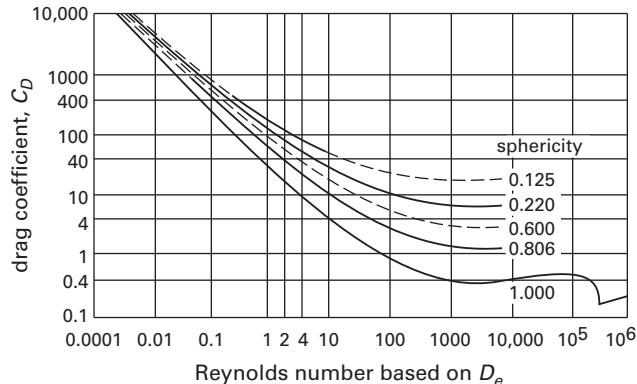

## 55. NONSPHERICAL PARTICLES

Few particles are actually spherical. One method of overcoming the complexity of dealing with the flow of real particles is to correlate performance with *sphericity*,  $\psi$ . (See Fig. 17.52.) For a particle and a sphere with the same volume, the sphericity is defined by Eq. 17.225 as the ratio of surface areas. Sphericity is always less than or equal to 1.0. The *equivalent diameter* is the diameter of a sphere having the same volume as the particle.

$$\psi = \frac{A_{\text{sphere}}}{A_{\text{particle}}} \quad 17.225$$

<sup>32</sup>A skydiver's terminal velocity can vary from approximately 120 mi/hr (54 m/s) in horizontal configuration to 200 mi/hr (90 m/s) in vertical configuration.

Figure 17.52 Drag Coefficients for Nonspherical Particles

## 56. FLOW AROUND A CYLINDER

The characteristic drag coefficient plot for cylinders placed normal to the fluid flow is similar to the plot for spheres. The plot shown in Fig. 17.53 is for infinitely long cylinders, since there is additional wake drag at the cylinder ends. In calculating the Reynolds number, the cylinder diameter should be used as the characteristic dimension.

Figure 17.53 Drag Coefficient for Cylinders

### Example 17.15

A 50 ft (15 m) high flagpole is manufactured from a uniformly smooth cylinder 10 in (25 cm) in diameter. The surrounding air is at 40°F (0°C) and 14.6 psia (100 kPa). What is the total drag force on the flagpole in a 30 mi/hr (50 km/h) gust? (Neglect variations in the wind speed with height above the ground.)

*SI Solution*

At 0°C, the absolute viscosity of air is

$$\mu_0^\circ\text{C} = 1.709 \times 10^{-5} \text{ Pa}\cdot\text{s}$$

The density of the air is

$$\rho = \frac{p}{RT} = \frac{(100 \text{ kPa}) \left( 1000 \frac{\text{Pa}}{\text{kPa}} \right)}{\left( 287.03 \frac{\text{J}}{\text{kg}\cdot\text{K}} \right) (0^\circ\text{C} + 273^\circ)} = 1.276 \text{ kg/m}^3$$

The kinematic viscosity is

$$\nu = \frac{\mu}{\rho} = \frac{1.709 \times 10^{-5} \text{ Pa}\cdot\text{s}}{1.276 \frac{\text{kg}}{\text{m}^3}} = 1.339 \times 10^{-5} \text{ m}^2/\text{s}$$

The wind speed is

$$v = \frac{(50 \frac{\text{km}}{\text{h}}) \left( 1000 \frac{\text{m}}{\text{km}} \right)}{3600 \frac{\text{s}}{\text{h}}} = 13.89 \text{ m/s}$$

The characteristic dimension of a cylinder is its diameter. The Reynolds number is

$$Re = \frac{Lv}{\nu} = \frac{Dv}{\nu} = \frac{\left( \frac{25 \text{ cm}}{100 \frac{\text{cm}}{\text{m}}} \right) \left( 13.89 \frac{\text{m}}{\text{s}} \right)}{1.339 \times 10^{-5} \frac{\text{m}^2}{\text{s}}} = 2.59 \times 10^5$$

From Fig. 17.53, the drag coefficient is approximately 1.2.

The frontal area of the flagpole is

$$A = DL = \frac{(25 \text{ cm})(15 \text{ m})}{100 \frac{\text{cm}}{\text{m}}} = 3.75 \text{ m}^2$$

From Eq. 17.218(a), the drag on the flagpole is

$$F_D = \frac{C_D A \rho v^2}{2} = \frac{(1.2)(3.75 \text{ m}^2) \left( 1.276 \frac{\text{kg}}{\text{m}^3} \right) \left( 13.89 \frac{\text{m}}{\text{s}} \right)^2}{2} = 554 \text{ N}$$

*Customary U.S. Solution*

At 40°F, the absolute viscosity of air is

$$\mu_{40^\circ\text{F}} = 3.62 \times 10^{-7} \text{ lbf}\cdot\text{sec}/\text{ft}^2$$

The density of the air is

$$\rho = \frac{p}{RT} = \frac{\left( 14.6 \frac{\text{lbf}}{\text{in}^2} \right) \left( 12 \frac{\text{in}}{\text{ft}} \right)^2}{\left( 53.35 \frac{\text{ft-lbf}}{\text{lbm}\cdot\text{R}} \right) (40^\circ\text{F} + 460^\circ)} = 0.0788 \text{ lbm}/\text{ft}^3$$

The kinematic viscosity is

$$\nu = \frac{\mu g_c}{\rho} = \frac{\left( 3.62 \times 10^{-7} \frac{\text{lbf}\cdot\text{sec}}{\text{ft}^2} \right) \left( 32.2 \frac{\text{lbm}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2} \right)}{0.0788 \frac{\text{lbm}}{\text{ft}^3}} = 1.479 \times 10^{-4} \text{ ft}^2/\text{sec}$$

The wind speed is

$$v = \frac{(30 \frac{\text{mi}}{\text{hr}}) \left( 5280 \frac{\text{ft}}{\text{mi}} \right)}{3600 \frac{\text{sec}}{\text{hr}}} = 44 \text{ ft/sec}$$

The characteristic dimension of a cylinder is its diameter. The Reynolds number is

$$Re = \frac{Lv}{\nu} = \frac{Dv}{\nu} = \frac{\left( \frac{10 \text{ in}}{12 \frac{\text{in}}{\text{ft}}} \right) \left( 44 \frac{\text{ft}}{\text{sec}} \right)}{1.479 \times 10^{-4} \frac{\text{ft}^2}{\text{sec}}} = 2.48 \times 10^5$$

From Fig. 17.53, the drag coefficient is approximately 1.2.

The frontal area of the flagpole is

$$A = DL = \frac{(10 \text{ in})(50 \text{ ft})}{12 \frac{\text{in}}{\text{ft}}} = 41.67 \text{ ft}^2$$

From Eq. 17.218(b), the drag on the flagpole is

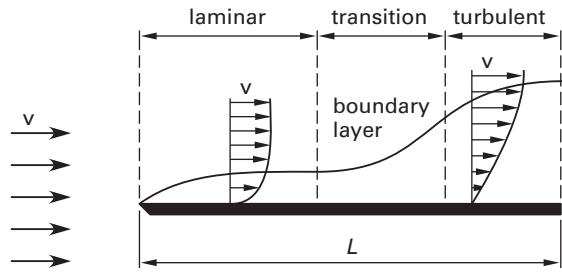

$$F_D = \frac{C_D A \rho v^2}{2g_c} = \frac{(1.2)(41.67 \text{ ft}^2) \left( 0.0788 \frac{\text{lbm}}{\text{ft}^3} \right) \left( 44 \frac{\text{ft}}{\text{sec}} \right)^2}{(2) \left( 32.2 \frac{\text{lbm}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2} \right)} = 118.5 \text{ lbf}$$

## 57. FLOW OVER A PARALLEL FLAT PLATE

The drag experienced by a flat plate oriented parallel to the direction of flow is almost totally skin friction drag. (See Fig. 17.54.) Prandtl's *boundary layer theory* can be used to evaluate the frictional effects. Such an analysis

predicts that the shape of the boundary layer profile is a function of the Reynolds number. The characteristic dimension used in calculating the Reynolds number is the chord length,  $L$  (i.e., the dimension of the plate parallel to the flow).

**Figure 17.54** Flow Over a Parallel Flat Plate (one side)

When skin friction predominates, it is common to use the symbol  $C_f$  (i.e., the *skin friction coefficient*) for the drag coefficient. For laminar flow over a smooth, flat plate, the drag coefficient based on the boundary layer theory is given by Eq. 17.226, which is known as the *Blasius solution*.<sup>33</sup> The critical Reynolds number for laminar flow over a flat plate is often reported to be 530,000. However, the transition region between laminar flow and turbulent flow actually occupies the Reynolds number range of 100,000–1,000,000.

$$C_f = \frac{1.328}{\sqrt{\text{Re}}} \quad [\text{laminar flow}] \quad 17.226$$

Prandtl reported that the skin friction coefficient for turbulent flow is

$$C_f = \frac{0.455}{(\log \text{Re})^{2.58}} \quad [\text{turbulent flow}] \quad 17.227$$

The drag force is calculated from Eq. 17.228. The factor 2 appears because there is friction on two sides of the flat plate. The area,  $A$ , is

$$F_D = 2 \left( \frac{C_f A \rho v^2}{2} \right) = C_f A \rho v^2 \quad [\text{SI}] \quad 17.228(a)$$

$$F_D = 2 \left( \frac{C_f A \rho v^2}{2 g_c} \right) = \frac{C_f A \rho v^2}{g_c} \quad [\text{U.S.}] \quad 17.228(b)$$

## 58. SIMILARITY

Similarity considerations between a *model* (subscript  $m$ ) and a full-sized object (subscript  $p$ , for *prototype*) imply that the model can be used to predict the performance of the prototype. Such a model is said to be *mechanically similar* to the prototype.

<sup>33</sup>Other correlations substitute the coefficient 1.44, the original value calculated by Prandtl, for 1.328 in Eq. 17.226. The Blasius solution is considered to be more accurate.

Complete *mechanical similarity* requires both geometric and dynamic similarity.<sup>34</sup> *Geometric similarity* means that the model is true to scale in length, area, and volume. The *model scale (length ratio)* is defined as

$$L_r = \frac{\text{size of model}}{\text{size of prototype}} \quad 17.229$$

The area and volume ratios are based on the model scale.

$$\frac{A_m}{A_p} = L_r^2 \quad 17.230$$

$$\frac{V_m}{V_p} = L_r^3 \quad 17.231$$

*Dynamic similarity* means that the ratios of all types of forces are equal for the model and the prototype. These forces result from inertia, gravity, viscosity, elasticity (i.e., fluid compressibility), surface tension, and pressure.

The number of possible ratios of forces is large. For example, the ratios of viscosity/inertia, inertia/gravity, and inertia/surface tension are only three of the ratios of forces that must match for every corresponding point on the model and prototype. Fortunately, some force ratios can be neglected because the forces are negligible or are self-canceling.

In some cases, the geometric scale may be deliberately distorted. For example, with scale models of harbors and rivers, the water depth might be only a fraction of an inch if the scale is maintained precisely. Not only will the surface tension be excessive, but the shifting of the harbor or river bed may not be properly observed. Therefore, the vertical scale is chosen to be different from the horizontal scale. Such models are known as *distorted models*. Experience is needed to interpret observations made of distorted models.

The following sections deal with the most common similarity problems, but not all. For example, similarity of steady laminar flow in a horizontal pipe requires the Stokes number, similarity of high-speed (near-sonic) aircraft requires the Mach number, and similarity of capillary rise in a tube requires the *Eötvös number* ( $g \rho L^2 / \sigma$ ).

## 59. VISCOUS AND INERTIAL FORCES DOMINATE

For completely submerged objects, such as the items listed in Table 17.9, surface tension is negligible. The fluid can be assumed to be incompressible for low velocity. Gravity does not change the path of the fluid particles significantly during the passage of the object.

Only inertial, viscous, and pressure forces are significant. Because they are the only forces that are acting, these three forces are in equilibrium. Since they are in equilibrium, knowing any two forces will define the third

<sup>34</sup>Complete mechanical similarity also requires kinematic and thermal similarity, which are not discussed in this book.

**Table 17.9** Applications of Reynolds Number Similarity

aircraft (subsonic)
airfoils (subsonic)
closed-pipe flow (turbulent)
drainage through tank orifices
fans
flow meters
open channel flow (without wave action)
pumps
submarines
torpedoes
turbines

force. This third force is dependent and can be omitted from the similarity analysis. For submerged objects, pressure is traditionally chosen as the dependent force.

The dimensionless ratio of the inertial forces to the viscous forces is the Reynolds number. Equating the model's and prototype's Reynolds numbers will ensure similarity.<sup>35</sup>

$$\text{Re}_m = \text{Re}_p \quad 17.232$$

$$\frac{L_m v_m}{\nu_m} = \frac{L_p v_p}{\nu_p} \quad 17.233$$

If the model is tested in the same fluid and at the same temperature in which the prototype is expected to operate, setting the Reynolds numbers equal is equivalent to setting  $L_m v_m = L_p v_p$ .

### Example 17.16

A  $1/30$  size scale model of a helicopter fuselage is tested in a wind tunnel at 120 mi/hr (190 km/h). The conditions in the wind tunnel are 50 psia and  $100^{\circ}\text{F}$  (350 kPa and  $50^{\circ}\text{C}$ ). What is the corresponding speed of a prototype traveling in 14 psia and  $40^{\circ}\text{F}$  still air (100 kPa,  $0^{\circ}\text{C}$ )?

#### SI Solution

The absolute viscosity of air at atmospheric pressure is

$$\mu_{p,0^{\circ}\text{C}} = 1.709 \times 10^{-5} \text{ Pa}\cdot\text{s}$$

$$\mu_{m,50^{\circ}\text{C}} = 1.951 \times 10^{-5} \text{ Pa}\cdot\text{s}$$

The densities of air at the two conditions are

$$\begin{aligned} \rho_p &= \frac{p}{RT} = \frac{(100 \text{ kPa})(1000 \frac{\text{Pa}}{\text{kPa}})}{(287.03 \frac{\text{J}}{\text{kg}\cdot\text{K}})(50^{\circ}\text{C} + 273)} \\ &= 1.276 \text{ kg/m}^3 \end{aligned}$$

<sup>35</sup>An implied assumption is that the drag coefficients are the same for the model and the prototype. In the case of pipe flow, it is assumed that flow will be in the turbulent region with the same relative roughness.

$$\begin{aligned} \rho_m &= \frac{p}{RT} = \frac{(350 \text{ kPa})(1000 \frac{\text{Pa}}{\text{kPa}})}{(287.03 \frac{\text{J}}{\text{kg}\cdot\text{K}})(50^{\circ}\text{C} + 273)} \\ &= 3.775 \text{ kg/m}^3 \end{aligned}$$

The kinematic viscosities are

$$\begin{aligned} \nu_p &= \frac{\mu}{\rho} = \frac{1.709 \times 10^{-5} \text{ Pa}\cdot\text{s}}{1.276 \frac{\text{kg}}{\text{m}^3}} \\ &= 1.339 \times 10^{-5} \text{ m}^2/\text{s} \end{aligned}$$

$$\begin{aligned} \nu_m &= \frac{\mu}{\rho} = \frac{1.951 \times 10^{-5} \text{ Pa}\cdot\text{s}}{3.775 \frac{\text{kg}}{\text{m}^3}} \\ &= 5.168 \times 10^{-6} \text{ m}^2/\text{s} \end{aligned}$$

From Eq. 17.233,

$$\begin{aligned} v_p &= v_m \left( \frac{L_m}{L_p} \right) \left( \frac{\nu_p}{\nu_m} \right) \\ &= \frac{\left( 190 \frac{\text{km}}{\text{h}} \right) \left( \frac{1}{30} \right) \left( 1.339 \times 10^{-5} \frac{\text{m}^2}{\text{s}} \right)}{5.168 \times 10^{-6} \frac{\text{m}^2}{\text{s}}} \\ &= 16.4 \text{ km/h} \end{aligned}$$

#### Customary U.S. Solution

Since surface tension and gravitational forces on the air particles are insignificant and since the flow velocities are low, viscous and inertial forces dominate. The Reynolds numbers of the model and prototype are equated.

The kinematic viscosity of air must be evaluated at the respective temperatures and pressures. Absolute viscosity is essentially independent of pressure.

$$\mu_{p,40^{\circ}\text{F}} = 3.62 \times 10^{-7} \text{ lbf}\cdot\text{sec}/\text{ft}^2$$

$$\mu_{m,100^{\circ}\text{F}} = 3.96 \times 10^{-7} \text{ lbf}\cdot\text{sec}/\text{ft}^2$$

The densities of air at the two conditions are

$$\begin{aligned} \rho_p &= \frac{p}{RT} = \frac{\left( 14 \frac{\text{lbf}}{\text{in}^2} \right) \left( 12 \frac{\text{in}}{\text{ft}} \right)^2}{\left( 53.35 \frac{\text{ft-lbf}}{\text{lbfm}\cdot\text{R}} \right) (40^{\circ}\text{F} + 460)} \\ &= 0.0756 \text{ lbm}/\text{ft}^3 \end{aligned}$$

$$\begin{aligned} \rho_m &= \frac{p}{RT} = \frac{\left( 50 \frac{\text{lbf}}{\text{in}^2} \right) \left( 12 \frac{\text{in}}{\text{ft}} \right)^2}{\left( 53.35 \frac{\text{ft-lbf}}{\text{lbfm}\cdot\text{R}} \right) (100^{\circ}\text{F} + 460)} \\ &= 0.241 \text{ lbm}/\text{ft}^3 \end{aligned}$$

The kinematic viscosities are

$$\nu_p = \frac{\mu g_c}{\rho} = \frac{\left(3.62 \times 10^{-7} \frac{\text{lbf}\cdot\text{sec}}{\text{ft}^2}\right) g_c}{0.0756 \frac{\text{lbm}}{\text{ft}^3}} = (4.79 \times 10^{-6} \frac{\text{ft}^2}{\text{sec}}) g_c$$

$$\nu_m = \frac{\mu g_c}{\rho} = \frac{\left(3.96 \times 10^{-7} \frac{\text{lbf}\cdot\text{sec}}{\text{ft}^2}\right) g_c}{0.241 \frac{\text{lbm}}{\text{ft}^3}} = (1.64 \times 10^{-6} \frac{\text{ft}^2}{\text{sec}}) g_c$$

From Eq. 17.233,

$$\frac{v_p}{v_m} = \frac{\left(\frac{L_m}{L_p}\right) \left(\frac{\nu_p}{\nu_m}\right)}{\left(\frac{120 \frac{\text{mi}}{\text{hr}}}{30}\right) \left(4.79 \times 10^{-6} \frac{\text{ft}^2}{\text{sec}}\right) g_c} = \frac{\left(1.64 \times 10^{-6} \frac{\text{ft}^2}{\text{sec}}\right) g_c}{11.7 \frac{\text{mi}}{\text{hr}}} = 11.7 \frac{\text{mi}}{\text{hr}}$$

## 60. INERTIAL AND GRAVITATIONAL FORCES DOMINATE

Table 17.10 lists the cases when elasticity and surface tension forces can be neglected but gravitational forces cannot. Omitting these two forces from the similarity calculations leaves pressure, inertia, viscosity, and gravity forces, which are in equilibrium. Pressure is chosen as the dependent force and is omitted from the analysis.

There are only two possible combinations of the remaining three forces. The ratio of inertial to viscous forces is the Reynolds number. The ratio of the inertial forces to the gravitational forces is the *Froude number*, Fr.<sup>36</sup> The Froude number is used when gravitational forces are significant, such as in wave motion produced by a ship or seaplane hull.

$$Fr = \frac{v^2}{Lg} \quad 17.234$$

Similarity is ensured when Eq. 17.235 and Eq. 17.236 are satisfied.

$$Re_m = Re_p \quad 17.235$$

$$Fr_m = Fr_p \quad 17.236$$

<sup>36</sup>There are two definitions of the Froude number. Dimensional analysis determines the Froude number as Eq. 17.234 ( $v^2/Lg$ ), a form that is used in model similitude. However, in open channel flow studies performed by civil engineers, the Froude number is taken as the square root of Eq. 17.234. Whether the derived form or its square root is used can sometimes be determined from the application. If the Froude number is squared (e.g., as in  $dE/dx = 1 - Fr^2$ ), the square root form is probably needed. In similarity problems, it doesn't make any difference which definition is used.

**Table 17.10** Applications of Froude Number Similarity

- bow waves from ships
- flow over spillways
- flow over weirs
- motion of a fluid jet
- open channel flow with varying surface levels
- oscillatory wave action
- seaplane hulls
- surface ships
- surface wave action
- surge and flood waves

As an alternative, Eq. 17.235 and Eq. 17.236 can be solved simultaneously. This results in the following requirement for similarity, which indicates that it is necessary to test the model in a manufactured liquid with a specific viscosity.

$$\frac{\nu_m}{\nu_p} = \left(\frac{L_m}{L_p}\right)^{3/2} = L_r^{3/2} \quad 17.237$$

Sometimes it is not possible to satisfy Eq. 17.235 and Eq. 17.236. This occurs when a model fluid viscosity is called for that is not available. If only one of the equations is satisfied, the model is said to be *partially similar*. In such a case, corrections based on other factors are used.

Another problem with trying to achieve similarity in open channel flow problems is the need to scale surface drag. It can be shown that the ratio of Manning's roughness constants is given by Eq. 17.238. In some cases, it may not be possible to create a surface smooth enough to satisfy this requirement.

$$n_r = L_r^{1/6} \quad 17.238$$

## 61. SURFACE TENSION FORCE DOMINATES

Table 17.11 lists some of the cases where surface tension is the predominant force. Such cases can be handled by equating the Weber numbers, We, of the model and prototype.<sup>37</sup> The *Weber number* is the ratio of inertial force to surface tension.

$$We = \frac{v^2 L \rho}{\sigma} \quad 17.239$$

$$We_m = We_p \quad 17.240$$

**Table 17.11** Applications of Weber Number Similarity

- air entrainment
- bubbles
- droplets
- waves

<sup>37</sup>There are two definitions of the Weber number. The alternate definition is the square root of Eq. 17.239. In similarity problems, it does not make any difference which definition of the Weber number is used.

## 1. HYDRAULIC MACHINES

Pumps and turbines are the two basic types of hydraulic machines discussed in this chapter. Pumps convert mechanical energy into fluid energy, increasing the energy possessed by the fluid. Turbines convert fluid energy into mechanical energy, extracting energy from the fluid.

## 2. TYPES OF PUMPS

Pumps can be classified according to how energy is transferred to the fluid: intermittently or continuously.

The most common types of *positive displacement pumps* (*PD pumps*) are *reciprocating action pumps* (which use pistons, plungers, diaphragms, or bellows) and *rotary action pumps* (which use vanes, screws, lobes, or progressing cavities). Such pumps discharge a fixed volume for each stroke or revolution. Energy is added intermittently to the fluid.

*Kinetic pumps* transform fluid kinetic energy into fluid static pressure energy. The pump imparts the kinetic energy; the pump mechanism or housing is constructed in a manner that causes the transformation. *Jet pumps* and *ejector pumps* fall into the kinetic pump category, but centrifugal pumps are the primary examples.

In the operation of a *centrifugal pump*, liquid flowing into the *suction side* (the *inlet*) is captured by the *impeller* and thrown to the outside of the pump casing. Within the casing, the velocity imparted to the fluid by the impeller is converted into pressure energy. The fluid leaves the pump through the *discharge line* (the *exit*). It is a characteristic of most centrifugal pumps that the fluid is turned approximately 90° from the original flow direction. (See Table 18.1.)

**Table 18.1** Generalized Characteristics of Positive Displacement and Kinetic Pumps

characteristic	positive displacement pumps	kinetic pumps
flow rate	low	high
pressure rise per stage	high	low
constant quantity over operating range	flow rate	pressure rise
self-priming	yes	no
discharge stream	pulsing	steady
works with high viscosity fluids	yes	no

## 3. RECIPROCATING POSITIVE DISPLACEMENT PUMPS

*Reciprocating positive displacement* (PD) pumps can be used with all fluids, and are useful with viscous fluids and slurries (up to about 8000 Saybolt seconds universal (SSU), when the fluid is sensitive to shear, and when a

high discharge pressure is required.<sup>1</sup> By entrapping a volume of fluid in the cylinder, reciprocating pumps provide a fixed-displacement volume per cycle. They are self-priming and inherently leak-free. Within the pressure limits of the line and pressure relief valve and the current capacity of the motor circuit, reciprocating pumps can provide an infinite discharge pressure.<sup>2</sup>

There are three main types of reciprocating pumps: power, direct-acting, and diaphragm. A *power pump* is a *cylinder-operated pump*. It can be single-acting or double-acting. A *single-acting pump* discharges liquid (or takes suction) only on one side of the piston, and there is only one transfer operation per crankshaft revolution. A *double-acting pump* discharges from both sides, and there are two transfers per revolution of the crank.

Traditional reciprocating pumps with pistons and rods can be either single-acting or double-acting and are suitable up to approximately 2000 psi (14 MPa). *Plunger pumps* are only single-acting and are suitable up to approximately 10,000 psi (70 MPa).

*Simplex pumps* have one cylinder, *duplex pumps* have two cylinders, *triplex pumps* have three cylinders, and so forth. *Direct-acting pumps* (sometimes referred to as *steam pumps*) are always double-acting. They use steam, unburned fuel gas, or compressed air as a motive fluid.

PD pumps are limited by both their NPSHR characteristics, acceleration head, and (for rotary pumps) slip.<sup>3</sup> Because the flow is unsteady, a certain amount of energy, the *acceleration head*,  $h_{ac}$ , is required to accelerate the fluid flow each stroke or cycle. If the acceleration head is too large, the NPSHR requirements may not be attainable. Acceleration head can be reduced by increasing the pipe diameter, shortening the suction piping, decreasing the pump speed, or placing a *pulsation damper (stabilizer)* in the suction line.<sup>4</sup>

Generally, friction losses with pulsating flows are calculated based on the maximum velocity attained by the fluid. Since this is difficult to determine, the maximum velocity can be approximated by multiplying the average velocity (calculated from the rated capacity) by the factors in Table 18.2.

When the suction line is “short,” the acceleration head can be calculated from the length of the suction line, the average velocity in the line, and the rotational speed.<sup>5</sup>

<sup>1</sup>For viscosities of SSU greater than 240, multiply SSU viscosity by 0.216 to get viscosity in centistokes.

<sup>2</sup>For this reason, a relief valve should be included in every installation of positive displacement pumps. Rotary pumps typically have integral relief valves, but external relief valves are often installed to provide easier adjusting, cleaning, and inspection.

<sup>3</sup>Manufacturers of PD pumps prefer the term *net positive inlet pressure* (NPIP) to NPSH. NPIPA corresponds to NPSHA; NPIPR corresponds to NPSHR. Pressure and head are related by  $p = \gamma h$ .

<sup>4</sup>Pulsation dampers are not needed with rotary-action PD pumps, as the discharge is essentially constant.

<sup>5</sup>With a properly designed pulsation damper, the effective length of the suction line is reduced to approximately 10 pipe diameters.

**Table 18.2** Typical  $v_{max}/v_{ave}$  Velocity Ratios<sup>a,b</sup>

pump type	single-acting	double-acting
simplex	3.2	2.0
duplex	1.6	1.3
triplex	1.1	1.1
quadriplex	1.1	1.1
quintuplex and up	1.05	1.05

<sup>a</sup>Without stabilization. With properly sized stabilizers, use 1.05–1.1 for all cases.

<sup>b</sup>Multiply the values by 1.3 for metering pumps where lost fluid motion is relied on for capacity control.

In Eq. 18.1,  $C$  and  $K$  are dimensionless factors.  $K$  represents the relative compressibility of the liquid. (Typical values are 1.4 for hot water; 1.5 for amine, glycol, and cold water; and 2.5 for hot oil.) Values of  $C$  are given in Table 18.3.

$$h_{ac} = \frac{C}{K} \left( \frac{L_{\text{suction}} v_{\text{ave}} n}{g} \right) \quad 18.1$$

**Table 18.3** Typical Acceleration Head  $C$ -Values\*

pump type	single-acting	double-acting
simplex	0.4	0.2
duplex	0.2	0.115
triplex	0.066	0.066
quadriplex	0.040	0.040
quintuplex and up	0.028	0.028

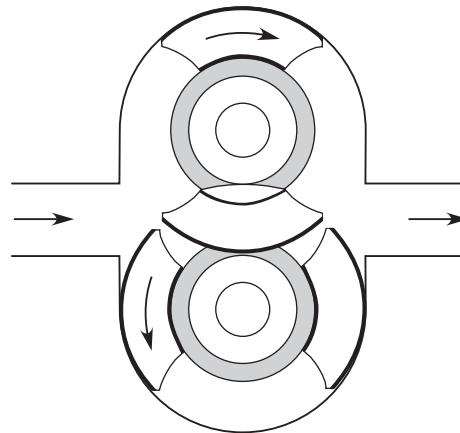

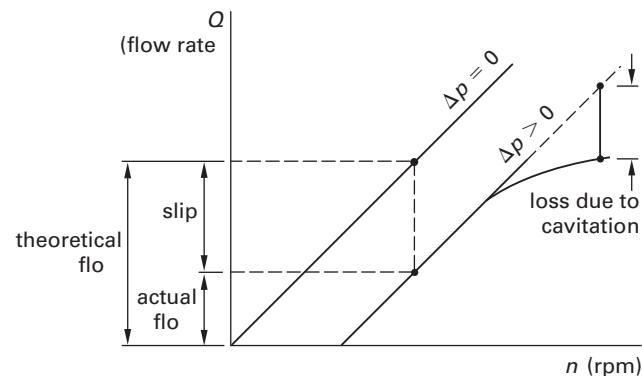

\*Typical values for common connecting rod lengths and crank radii.

#### 4. ROTARY PUMPS

Rotary pumps are positive displacement (PD) pumps that move fluid by means of screws, progressing cavities, gears, lobes, or vanes turning within a fixed casing (the *stator*). Rotary pumps are useful for high viscosities (up to  $4 \times 10^6$  SSU for screw pumps). The rotation creates a cavity of fixed volume near the pump input; atmospheric or external pressure forces the fluid into that cavity. Near the outlet, the cavity is collapsed, forcing the fluid out. Figure 18.1 illustrates the external circumferential piston rotary pump.

Discharge from rotary pumps is relatively smooth. Acceleration head is negligible. Pulsation dampers and suction stabilizers are not required.

*Slip* in rotary pumps is the amount (sometimes expressed as a percentage) of each rotational fluid volume that “leaks” back to the suction line on each revolution. Slip reduces pump capacity. It is a function of clearance, differential pressure, and viscosity. Slip is proportional to the third power of the clearance between the rotating element and the casing. Slip decreases with increases in viscosity; it increases linearly with increases in differential pressure. Slip is not affected by rotational speed. The *volumetric efficiency* is defined in terms of

**Figure 18.1** External Circumferential Piston Rotary Pump**Figure 18.2** Slip in Rotary Pumps

volumetric flow rate,  $Q$ , by Eq. 18.2. Figure 18.2 illustrates the relationship between flow rate, speed, slip, and differential pressure.

$$\eta_v = \frac{Q_{\text{actual}}}{Q_{\text{ideal}}} = \frac{Q_{\text{ideal}} - Q_{\text{slip}}}{Q_{\text{ideal}}} \quad 18.2$$

Except for screw pumps, rotary pumps are generally not used for handling abrasive fluids or materials with suspended solids.

#### 5. DIAPHRAGM PUMPS

Hydraulically operated *diaphragm pumps* have a diaphragm that completely separates the pumped fluid from the rest of the pump. A reciprocating plunger pressurizes and moves a hydraulic fluid that, in turn, flexes the diaphragm. Single-ball check valves in the suction and discharge lines determine the direction of flow during both phases of the diaphragm action.

Metering is a common application of diaphragm pumps. Diaphragm metering pumps have no packing and are essentially leakproof. This makes them ideal when fugitive emissions are undesirable. Diaphragm pumps are

suitable for pumping a wide range of materials, from liquefied gases to coal slurries, though the upper viscosity limit is approximately 3500 SSU. Within the limits of their reactivities, hazardous and reactive materials can also be handled.

Diaphragm pumps are limited by capacity, suction pressure, and discharge pressure and temperature. Because of their construction and size, most diaphragm pumps are limited to discharge pressures of 5000 psi (35 MPa) or less, and most high-capacity pumps are limited to 2000 psi (14 MPa). Suction pressures are similarly limited to 5000 psi (35 MPa). A pressure range of 3–9 psi (20–60 kPa) is often quoted as the minimum liquid-side pressure for metering applications.

The discharge is inherently pulsating, and dampers or stabilizers are often used. (The acceleration head term is required when calculating NPSHR.) The discharge can be smoothed out somewhat by using two or three (i.e., duplex or triplex) plungers.

Diaphragms are commonly manufactured from stainless steel (type 316) and polytetrafluoroethylene (PTFE) or other elastomers. PTFE diaphragms are suitable in the range of  $-50^{\circ}\text{F}$  to  $300^{\circ}\text{F}$  ( $-45^{\circ}\text{C}$  to  $150^{\circ}\text{C}$ ) while metal diaphragms (and some ketone resin diaphragms) are used up to approximately  $400^{\circ}\text{F}$  ( $200^{\circ}\text{C}$ ) with life expectancy being reduced at higher temperatures. Although most diaphragm pumps usually operate below 200 spm (strokes per minute), diaphragm life will be improved by limiting the maximum speed to 100 spm.

## 6. CENTRIFUGAL PUMPS

Centrifugal pumps and their impellers can be classified according to the way energy is imparted to the fluid. Each category of pump is suitable for a different application and (specific) speed range. (See Table 18.9 later in this chapter.) Figure 18.3 illustrates a typical centrifugal pump and its schematic symbol.

*Radial-flow impellers* impart energy primarily by centrifugal force. Fluid enters the impeller at the hub and flows radially to the outside of the casing. Radial-flow pumps are suitable for adding high pressure at low fluid flow rates. *Axial-flow impellers* impart energy to the fluid by acting as compressors. Fluid enters and exits along the axis of rotation. Axial-flow pumps are suitable for adding low pressures at high fluid flow rates.<sup>6</sup>

Radial-flow pumps can be designed for either single- or double-suction operation. In a *single-suction pump*, fluid enters from only one side of the impeller. In a *double-suction pump*, fluid enters from both sides of the impeller.<sup>7</sup> (That is, the impeller is two-sided.) Operation is

<sup>6</sup>There is a third category of centrifugal pumps known as *mixed flow pumps*. Mixed flow pumps have operational characteristics between those of radial flow and axial flow pumps.

<sup>7</sup>The double-suction pump can handle a greater fluid flow rate than a single-suction pump with the same specific speed. Also, the double-suction pump will have a lower NPSHR.

similar to having two single-suction pumps in parallel. (See Fig. 18.4.)

Figure 18.3 Centrifugal Pump and Symbol

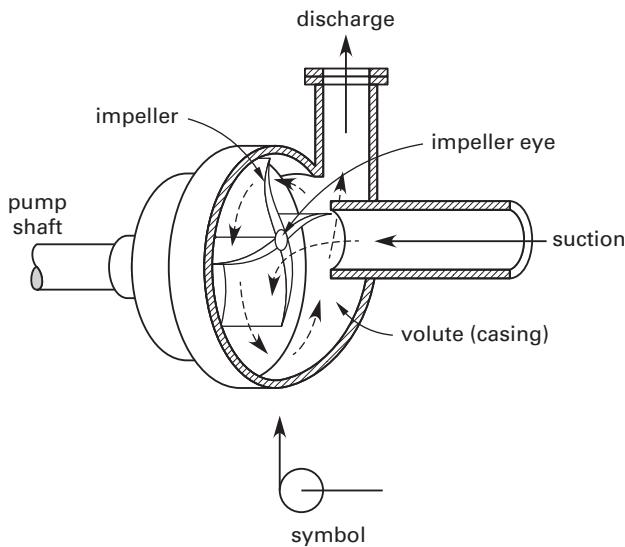

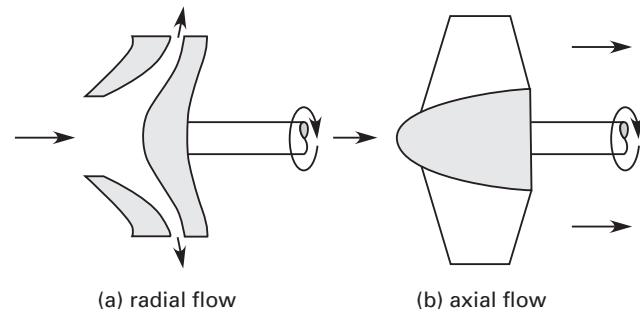

Figure 18.4 Radial- and Axial-Flow Impellers

A *multiple-stage pump* consists of two or more impellers within a single casing. The discharge of one stage feeds the input of the next stage, and operation is similar to having several pumps in series. In this manner, higher heads are achieved than would be possible with a single impeller.

The *pitch (circular blade pitch)* is the impeller's circumference divided by the number of impeller vanes. The impeller *tip speed* is calculated from the impeller diameter and rotational speed. The impeller "tip speed" is actually the tangential velocity at the periphery. Tip speed is typically somewhat less than 1000 ft/sec (300 m/s).

$$v_{\text{tip}} = \frac{\pi D n}{60 \frac{\text{sec}}{\text{min}}} = \frac{D \omega}{2} \quad 18.3$$

## 7. SEWAGE PUMPS

The primary consideration in choosing a pump for sewage and large solids is resistance to clogging. Centrifugal pumps should always be the single-suction type with

nonclog, open impellers. (Double-suction pumps are prone to clogging because rags catch and wrap around the shaft extending through the impeller eye.) Clogging can be further minimized by limiting the number of impeller blades to two or three, providing for large passageways, and using a bar screen ahead of the pump.

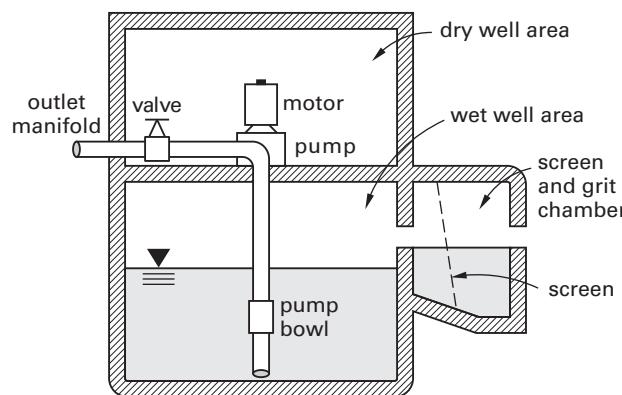

Though made of heavy construction, nonclog pumps are constructed for ease of cleaning and repair. Horizontal pumps usually have a split casing, half of which can be removed for maintenance. A hand-sized cleanout opening may also be built into the casing. A sewage pump should normally be used with a grit chamber for prolonged bearing life.

The solids-handling capacity of a pump may be specified in terms of the largest sphere that can pass through it without clogging, usually about 80% of the inlet diameter. For example, a wastewater pump with a 6 in (150 mm) inlet should be able to pass a 4 in (100 mm) sphere. The pump must be capable of handling spheres with diameters slightly larger than the bar screen spacing.

Figure 18.5 shows a simplified wastewater pump installation. Not shown are instrumentation and water level measurement devices, baffles, lighting, drains for the dry well, electrical power, pump lubrication equipment, and access ports. (Totally submerged pumps do not require dry wells. However, such pumps without dry wells are more difficult to access, service, and repair.)

The multiplicity and redundancy of pumping equipment is not apparent from Fig. 18.5. The number of pumps used in a wastewater installation largely depends on the expected demand, pump capacity, and design criteria for backup operation. It is good practice to install pumps in sets of two, with a third backup pump being available for each set of pumps that performs the same function. The number of pumps and their capacities should be able to handle the peak flow when one pump in the set is out of service.

**Figure 18.5** Typical Wastewater Pump Installation (greatly simplified)

## 8. SLUDGE PUMPS AND GRAVITY FLOW

Centrifugal and reciprocating pumps are extensively used for pumping sludge. Progressive cavity screw impeller pumps are also used.

As further described in Sec. 18.28, the pumping power is proportional to the specific gravity. Accordingly, pumping power for dilute and well-digested sludges is typically only 10–25% higher than for water. However, most sludges are non-Newtonian fluids, often flow in a laminar mode, and have characteristics that may change with the season. Also, sludge characteristics change greatly during the pumping cycle; engineering judgment and rules of thumb are often important in choosing sludge pumps. For example, a general rule is to choose sludge pumps capable of developing at least 50–100% excess head.

One method of determining the required pumping power is to multiply the power required for pumping pure water by a service factor. Historical data is the best method of selecting this factor. Choice of initial values is a matter of judgment. Guidelines are listed in Table 18.4.

**Table 18.4** Typical Pumping Power Multiplicative Factors

solids concentration	digested sludge	untreated, primary, and concentrated sludge
0%	1.0	1.0
2%	1.2	1.4
4%	1.3	2.5
6%	1.7	4.1
8%	2.2	7.0
10%	3.0	10.0

Derived from *Wastewater Engineering: Treatment, Disposal, Reuse*, 3rd ed., by Metcalf & Eddy, et al., © 1991, with permission from The McGraw-Hill Companies, Inc.

Generally, sludge will thin out during a pumping cycle. The most dense sludge components will be pumped first, with more watery sludge appearing at the end of the pumping cycle. With a constant power input, the reduction in load at the end of pumping cycles may cause centrifugal pumps to operate far from the desired operating point and to experience overload failures. The operating point should be evaluated with high-, medium-, and low-density sludges.

To avoid cavitation, sludge pumps should always be under a positive suction head of at least 4 ft (1.2 m), and suction lifts should be avoided. The minimum diameters of suction and discharge lines for pumped sludge are typically 6 in (150 mm) and 4 in (100 mm), respectively.

Not all sludge is moved by pump action. Some installations rely on gravity flow to move sludge. The minimum diameter of sludge gravity transfer lines is typically 8 in (200 mm), and the recommended minimum slope is 3%.

To avoid clogging due to settling, sludge velocity should be above the transition from laminar to turbulent flow,

known as the *critical velocity*. The critical velocity for most sludges is approximately 3.5 ft/sec (1.1 m/s). Velocity ranges of 5–8 ft/sec (1.5–2.4 m/s) are commonly quoted and are adequate.

## 9. TERMINOLOGY OF HYDRAULIC MACHINES AND PIPE NETWORKS

A pump has an inlet (designated the *suction*) and an outlet (designated the *discharge*). The subscripts *s* and *d* refer to the inlet and outlet of the pump, not of the pipeline.

All of the terms that are discussed in this section are *head* terms and, as such, have units of length. When working with hydraulic machines, it is common to hear such phrases as “a pressure head of 50 feet” and “a static discharge head of 15 meters.” The term *head* is often substituted for pressure or pressure drop. Any head term (*pressure head*, *atmospheric head*, *vapor pressure head*, etc.) can be calculated from pressure by using Eq. 18.4.<sup>8</sup>

$$h = \frac{p}{g\rho} \quad [\text{SI}] \quad 18.4(a)$$

$$h = \frac{p}{\rho} \times \frac{g_c}{g} = \frac{p}{\gamma} \quad [\text{U.S.}] \quad 18.4(b)$$

Some of the terms used in the description of pipe networks appear to be similar (e.g., suction head and total suction head). The following general rules will help to clarify the meanings.

*rule 1:* The word *suction* or *discharge* limits the quantity to the suction line or discharge line, respectively. The absence of either word implies that both the suction and discharge lines are included. Example: discharge head.

*rule 2:* The word *static* means that static head only is included (not velocity head, friction head, etc.). Example: static suction head.

*rule 3:* The word *total* means that static head, velocity head, and friction head are all included. (Total does not mean the combination of suction and discharge.) Example: total suction head.

The following terms are commonly encountered.

- *friction head*,  $h_f$ : The head required to overcome resistance to flow in the pipes, fittings, valves, entrances, and exits.

$$h_f = \frac{fLv^2}{2Dg} \quad 18.5$$

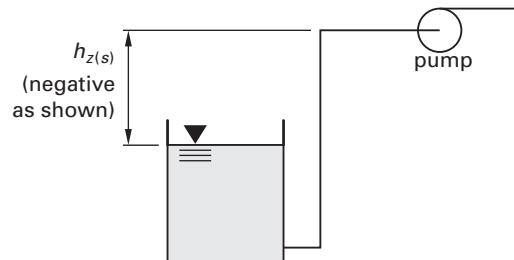

- *velocity head*,  $h_v$ : The specific kinetic energy of the fluid. Also known as *dynamic head*.<sup>9</sup>

$$h_v = \frac{v^2}{2g} \quad 18.6$$

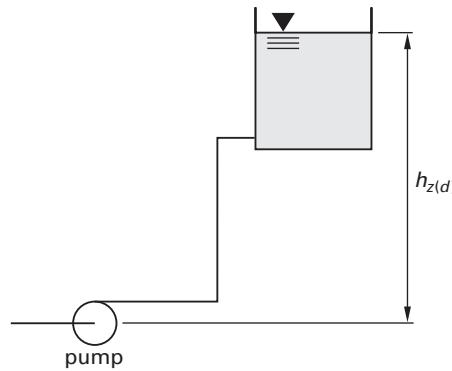

- *static suction head*,  $h_{z(s)}$ : The vertical distance above the centerline of the pump inlet to the free level of the fluid source. If the free level of the fluid is below the pump inlet,  $h_{z(s)}$  will be negative and is known as *static suction lift*. (See Fig. 18.6.)
- *static discharge head*,  $h_{z(d)}$ : The vertical distance above the centerline of the pump inlet to the point of free discharge or surface level of the discharge tank. (See Fig. 18.7.)

The ambiguous term *effective head* is not commonly used when discussing hydraulic machines, but when used, the term most closely means *net head* (i.e., starting head less losses). Consider a hydroelectric turbine that is fed by water with a static head of  $H$ . After frictional and other losses, the net head available to the turbine will be less than  $H$ . The turbine output will coincide with an ideal turbine being acted upon by the net or effective head. Similarly, the actual increase in pressure across a pump will be the effective head added (i.e., the head net of internal losses and geometric effects).

**Figure 18.6** Static Suction Lift

**Figure 18.7** Static Discharge Head

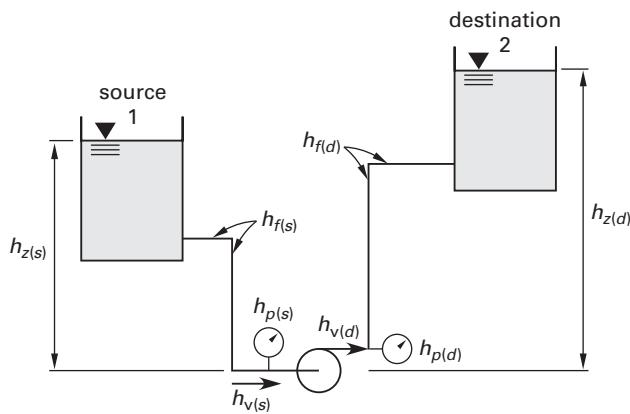

<sup>8</sup>Equation 18.4 can be used to define *pressure head*, *atmospheric head*, and *vapor pressure head*, whose meanings and derivations should be obvious.

<sup>9</sup>The term *dynamic* is not as consistently applied as are the terms described in the rules. In particular, it is not clear whether dynamic head includes friction head.

**Example 18.1**

Write the symbolic equations for the following terms:  
 (a) the total suction head, (b) the total discharge head, and (c) the total head added.

**Solution**

(a) The *total suction head* at the pump inlet is the sum of static (pressure) head and velocity head at the pump suction.

$$h_{t(s)} = h_{p(s)} + h_{v(s)}$$

Total suction head can also be calculated from the conditions existing at the source (1), in which case suction line friction would also be considered. (With an open reservoir,  $h_{p(1)}$  will be zero if gage pressures are used, and  $h_{v(1)}$  will be zero if the source is large.)

$$h_{t(s)} = h_{p(1)} + h_{z(s)} + h_{v(1)} - h_{f(s)}$$

(b) The *total discharge head* at the pump outlet is the sum of the static (pressure) and velocity heads at the pump outlet. Friction head is zero since the fluid has not yet traveled through any length of pipe when it is discharged.

$$h_{t(d)} = h_{p(d)} + h_{v(d)}$$

The total discharge head can also be evaluated at the destination (2) if the friction head,  $h_{f(d)}$ , between the discharge and the destination is known. (With an open reservoir,  $h_{p(2)}$  will be zero if gage pressures are used, and  $h_{v(2)}$  will be zero if the destination is large.)

$$h_{t(d)} = h_{p(2)} + h_{z(d)} + h_{v(2)} + h_{f(d)}$$

(c) The *total head added* by the pump is the total discharge head less the total suction head.

$$h_t = h_A = h_{t(d)} - h_{t(s)}$$

Assuming suction from and discharge to reservoirs exposed to the atmosphere and assuming negligible reservoir velocities,

$$h_t = h_A \approx h_{z(d)} - h_{z(s)} + h_{f(d)} + h_{f(s)}$$

**10. PUMPING POWER**

The energy (head) added by a pump can be determined from the difference in total energy on either side of the pump. Writing the Bernoulli equation for the discharge and suction conditions produces Eq. 18.7, an equation for the *total dynamic head*, often abbreviated TDH.

$$h_A = h_t = h_{t(d)} - h_{t(s)} \quad 18.7$$

$$h_A = \frac{p_d - p_s}{\rho g} + \frac{v_d^2 - v_s^2}{2g} + z_d - z_s \quad [\text{SI}] \quad 18.8(a)$$

$$h_A = \frac{(p_d - p_s)g_c}{\rho g} + \frac{v_d^2 - v_s^2}{2g} + z_d - z_s \quad [\text{U.S.}] \quad 18.8(b)$$

In most applications, the change in velocity and potential heads is either zero or small in comparison to the increase in pressure head. Equation 18.8 then reduces to Eq. 18.9.

$$h_A = \frac{p_d - p_s}{\rho g} \quad [\text{SI}] \quad 18.9(a)$$

$$h_A = \frac{p_d - p_s}{\rho} \times \frac{g_c}{g} \quad [\text{U.S.}] \quad 18.9(b)$$

It is important to recognize that the variables in Eq. 18.8 and Eq. 18.9 refer to the conditions at the pump's immediate inlet and discharge, not to the distant ends of the suction and discharge lines. However, the total dynamic head added by a pump can be calculated in another way. For example, for a pump raising water from one open reservoir to another, the total dynamic head would consider the total elevation rise, the velocity head (often negligible), and the friction losses in the suction and discharge lines.

The head added by the pump can also be calculated from the impeller and fluid speeds. Equation 18.10 is useful for radial- and mixed-flow pumps for which the incoming fluid has little or no rotational velocity component (i.e., up to a specific speed of approximately 2000 U.S. or 40 SI). In Eq. 18.10,  $v_{\text{impeller}}$  is the tangential impeller velocity at the radius being considered, and  $v_{\text{fluid}}$  is the average tangential velocity imparted to the fluid by the impeller. The impeller efficiency,  $\eta_{\text{impeller}}$ , is typically 0.85–0.95. This is much higher than the total pump efficiency because it does not include mechanical and fluid friction losses. (See Sec. 18.11.)

$$h_A = \frac{\eta_{\text{impeller}} V_{\text{impeller}} V_{\text{fluid}}}{g} \quad 18.10$$

Head added can be thought of as the energy added per unit mass. The total pumping power depends on the head added,  $h_A$ , and the mass flow rate. For example, the product  $\dot{m}h_A$  has the units of foot-pounds per second (in customary U.S. units), which can be easily converted to horsepower. Pump output power is known as *hydraulic power* or *water power*. Hydraulic power is the net power actually transferred to the fluid.

Horsepower is a common unit of power, which results in the terms *hydraulic horsepower* and *water horsepower*, WHP, being used to designate the power that is transferred into the fluid. Various relationships for finding the hydraulic horsepower are given in Table 18.5.

The unit of power in SI units is the watt (kilowatt). Table 18.6 can be used to determine *hydraulic kilowatts*, WkW.

**Table 18.5** Hydraulic Horsepower Equations<sup>a</sup>

	$Q$ (gal/min)	$\dot{m}$ (lbm/sec)	$\dot{V}$ (ft <sup>3</sup> /sec)
$h_A$ in feet	$\frac{h_A Q(\text{SG})}{3956}$	$\frac{h_A \dot{m}}{550} \times \frac{g}{g_c}$	$\frac{h_A \dot{V}(\text{SG})}{8.814}$
$\Delta p$ in psi <sup>b</sup>	$\frac{\Delta p Q}{1714}$	$\frac{\Delta p \dot{m}}{(238.3)(\text{SG})} \times \frac{g}{g_c}$	$\frac{\Delta p \dot{V}}{3.819}$
$\Delta p$ in psf <sup>b</sup>	$\frac{\Delta p Q}{2.468 \times 10^5}$	$\frac{\Delta p \dot{m}}{(34,320)(\text{SG})} \times \frac{g}{g_c}$	$\frac{\Delta p \dot{V}}{550}$
$W$ in $\frac{\text{ft-lbf}}{\text{lbm}}$	$\frac{W Q(\text{SG})}{3956}$	$\frac{W \dot{m}}{550}$	$\frac{W \dot{V}(\text{SG})}{8.814}$

(Multiply horsepower by 0.7457 to obtain kilowatts.)

<sup>a</sup>based on  $\rho_{\text{water}} = 62.4 \text{ lbm/ft}^3$  and  $g = 32.2 \text{ ft/sec}^2$

<sup>b</sup>Velocity head changes must be included in  $\Delta p$ .

**Table 18.6** Hydraulic Kilowatt Equations<sup>a</sup>

	$Q$ (L/s)	$\dot{m}$ (kg/s)	$\dot{V}$ (m <sup>3</sup> /s)
$h_A$ in meters	$\frac{9.81 h_A Q(\text{SG})}{1000}$	$\frac{9.81 h_A \dot{m}}{1000}$	$9.81 h_A \dot{V}(\text{SG})$
$\Delta p$ in kPa <sup>b</sup>	$\frac{\Delta p Q}{1000}$	$\frac{\Delta p \dot{m}}{1000(\text{SG})}$	$\Delta p \dot{V}$
$W$ in $\frac{\text{J}}{\text{kg}}$	$\frac{W Q(\text{SG})}{1000}$	$\frac{W \dot{m}}{1000}$	$W \dot{V}(\text{SG})$

(Multiply kilowatts by 1.341 to obtain horsepower.)

<sup>a</sup>based on  $\rho_{\text{water}} = 1000 \text{ kg/m}^3$  and  $g = 9.81 \text{ m/s}^2$

<sup>b</sup>Velocity head changes must be included in  $\Delta p$ .

### Example 18.2

A pump adds 550 ft of pressure head to 100 lbm/sec of water ( $\rho = 62.4 \text{ lbm/ft}^3$  or  $1000 \text{ kg/m}^3$ ). (a) Complete the following table of performance data. (b) What is the hydraulic power in horsepower and kilowatts?

item	customary U.S.	SI
$\dot{m}$	100 lbm/sec	— kg/s
$h$	550 ft	— m
$\Delta p$	— lbf/ft <sup>2</sup>	— kPa
$\dot{V}$	— ft <sup>3</sup> /sec	— m <sup>3</sup> /s
$W$	— ft-lbf/lbm	— J/kg
$P$	— hp	— kW

*Solution*

(a) Work initially with the customary U.S. data.

$$\begin{aligned}\Delta p &= \rho h \times \frac{g}{g_c} = (62.4 \frac{\text{lbm}}{\text{ft}^3})(550 \text{ ft}) \times \frac{g}{g_c} \\ &= 34,320 \text{ lbf/ft}^2\end{aligned}$$

$$\dot{V} = \frac{\dot{m}}{\rho} = \frac{100 \frac{\text{lbm}}{\text{sec}}}{62.4 \frac{\text{lbm}}{\text{ft}^3}} = 1.603 \text{ ft}^3/\text{sec}$$

$$\begin{aligned}W &= h \times \frac{g}{g_c} = 550 \text{ ft} \times \frac{g}{g_c} \\ &= 550 \text{ ft-lbf/lbm}\end{aligned}$$

Convert to SI units.

$$\dot{m} = \frac{100 \frac{\text{lbm}}{\text{sec}}}{2.201 \frac{\text{lbm}}{\text{kg}}} = 45.43 \text{ kg/s}$$

$$h = \frac{550 \text{ ft}}{3.281 \frac{\text{ft}}{\text{m}}} = 167.6 \text{ m}$$

$$\begin{aligned}\Delta p &= \left(34,320 \frac{\text{lbf}}{\text{ft}^2}\right) \left(\frac{1}{(12 \frac{\text{in}}{\text{ft}})^2}\right) \left(6.895 \frac{\text{kPa}}{\text{lbf/in}^2}\right) \\ &= 1643 \text{ kPa}\end{aligned}$$

$$\dot{V} = \left(1.603 \frac{\text{ft}^3}{\text{sec}}\right) \left(0.0283 \frac{\text{m}^3}{\text{ft}^3}\right) = 0.0454 \text{ m}^3/\text{s}$$

$$\begin{aligned}W &= \left(550 \frac{\text{ft-lbf}}{\text{lbm}}\right) \left(1.356 \frac{\text{J}}{\text{ft-lbf}}\right) \left(2.201 \frac{\text{lbm}}{\text{kg}}\right) \\ &= 1642 \text{ J/kg}\end{aligned}$$

(b) From Table 18.5, the hydraulic horsepower is

$$\begin{aligned}\text{WHP} &= \frac{h_A \dot{m}}{550} \times \frac{g}{g_c} \\ &= \frac{(550 \text{ ft})(100 \frac{\text{lbm}}{\text{sec}})}{550 \frac{\text{ft-lbf}}{\text{hp-sec}}} \times \frac{g}{g_c} \\ &= 100 \text{ hp}\end{aligned}$$

From Table 18.6, the power is

$$\text{WkW} = \frac{\Delta p \dot{m}}{(1000)(\text{SG})} = \frac{(1643 \text{ kPa})(45.43 \frac{\text{kg}}{\text{s}})}{\left(1000 \frac{\text{W}}{\text{kW}}\right)(1.0)} \\ = 74.6 \text{ kW}$$

## 11. PUMPING EFFICIENCY

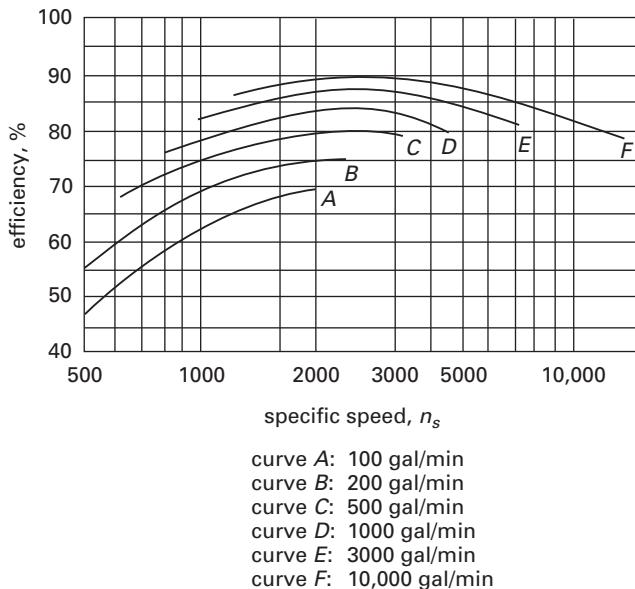

Hydraulic power is the net energy actually transferred to the fluid per unit time. The input power delivered by the motor to the pump is known as the *brake pump power*. The term *brake horsepower*, BHP, is commonly used to designate both the quantity and its units. Due to frictional losses between the fluid and the pump and mechanical losses in the pump itself, the brake pump power will be greater than the hydraulic power.

The ratio of hydraulic power to brake pump power is the pump efficiency,  $\eta_p$ . Figure 18.8 gives typical pump efficiencies as a function of the pump's specific speed. The difference between the brake and hydraulic powers is known as the *friction power* (or *friction horsepower*, FHP).

$$\text{BHP} = \frac{\text{WHP}}{\eta_p} \quad 18.11$$

$$\text{FHP} = \text{BHP} - \text{WHP} \quad 18.12$$

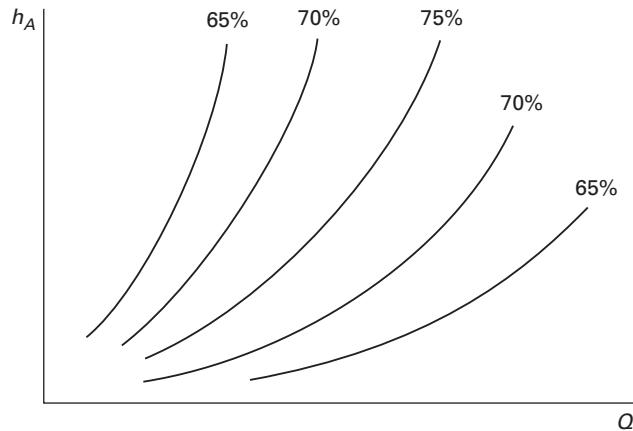

**Figure 18.8** Average Pump Efficiency Versus Specific Speed

Pumping efficiency is not constant for any specific pump; rather, it depends on the operating point and the speed of the pump. (See Sec. 18.23.) A pump's characteristic efficiency curves will be published by its manufacturer.

With pump characteristic curves given by the manufacturer, the efficiency is not determined from the intersection of the system curve and the efficiency curve. (See Sec. 18.22.) Rather, the efficiency is a function of only the flow rate. Therefore, the operating efficiency is read from the efficiency curve directly above or below the operating point. (See Sec. 18.23 and Fig. 18.9.)

**Figure 18.9** Typical Centrifugal Pump Efficiency Curves

Efficiency curves published by a manufacturer will not include such losses in the suction elbow, discharge diffuser, couplings, bearing frame, seals, or pillow blocks. Up to 15% of the motor horsepower may be lost to these factors. Upon request, the manufacturer may provide the pump's installed *wire-to-water efficiency* (i.e., the fraction of the electrical power drawn that is converted to hydraulic power).

The pump must be driven by an engine or motor.<sup>10</sup> The power delivered to the motor is greater than the power delivered to the pump, as accounted for by the motor efficiency,  $\eta_m$ . If the pump motor is electrical, its input power requirements will be stated in kilowatts.<sup>11</sup>

$$P_{m,\text{hp}} = \frac{\text{BHP}}{\eta_m} \quad 18.13$$

$$P_{m,\text{kW}} = \frac{0.7457 \text{ BHP}}{\eta_m} \quad 18.14$$

The *overall efficiency* of the pump installation is the product of the pump and motor efficiencies.

$$\eta = \eta_p \eta_m = \frac{\text{WHP}}{P_{m,\text{hp}}} \quad 18.15$$

## 12. COST OF ELECTRICITY

The power utilization of pump motors is usually measured in kilowatts. The kilowatt usage represents the rate that energy is transferred by the pump motor. The total amount of work,  $W$ , done by the pump motor is

<sup>10</sup>The source of power is sometimes called the *prime mover*.

<sup>11</sup>A watt is a joule per second.

found by multiplying the rate of energy usage (i.e., the delivered power,  $P$ ), by the length of time the pump is in operation.

$$W = Pt \quad 18.16$$

Although the units horsepower-hours are occasionally encountered, it is more common to measure electrical work in *kilowatt-hours* (kW-hr). Accordingly, the cost of electrical energy is stated per kW-hr (e.g., \$0.10 per kW-hr).

$$\text{cost} = \frac{W_{\text{kW-hr}}(\text{cost per kW-hr})}{n_m} \quad 18.17$$

### 13. STANDARD MOTOR SIZES AND SPEEDS

An effort should be made to specify standard motor sizes when selecting the source of pumping power. Table 18.7 lists NEMA (National Electrical Manufacturers Association) standard motor sizes by horsepower *nameplate rating*.<sup>12</sup> Other motor sizes may also be available by special order.

**Table 18.7** NEMA Standard Motor Sizes (brake horsepower)

$\frac{1}{8}^*$	$\frac{1}{6}^*$	$\frac{1}{4}^*$	$\frac{1}{3}^*$	$\frac{1}{2}^*$	$\frac{3}{4}^*$		
1,	1.5,	2,	3,	5,	7.5	10,	15
20,	25,	30,	40,	50,	60,	75,	100
125,	150,	200,	250,	300,	350,	400,	450
500,	600,	700,	800,	900,	1000,	1250,	1500
1750,	2000,	2250,	2500,	2750,	3000,	3500,	4000
4500,	5000,	6000,	7000,	8000			

\*fractional horsepower series

For industrial-grade motors, the rated (nameplate) power is the power at the output shaft that the motor can produce continuously while operating at the nameplate ambient conditions and without exceeding a particular temperature rise dependent on its wiring type. However, if a particular motor is housed in a larger, open frame that has better cooling, it will be capable of producing more power than the nameplate rating. NEMA defines the *service factor*, SF, as the amount of continual overload capacity designed into a motor without reducing its useful life (provided voltage, frequency, and ambient temperature remain normal). Common motor service factors are 1.0, 1.15, and 1.25. When a motor develops more than the nameplate power, efficiency, power factor, and operating temperature will be affected adversely.

$$SF = \frac{P_{\text{max continuous}}}{P_{\text{rated}}} \quad 18.18$$

<sup>12</sup>The nameplate rating gets its name from the information stamped on the motor's identification plate. Besides the horsepower rating, other nameplate data used to classify the motor are the service class, voltage, full-load current, speed, number of phases, frequency of the current, and maximum ambient temperature (or, for older motors, the motor temperature rise).

Larger horsepower motors are usually three-phase induction motors. The *synchronous speed*,  $n$  in rpm, of such motors is the speed of the rotating field, which depends on the number of poles per stator phase and the frequency,  $f$ . The number of poles must be an even number. The frequency is typically 60 Hz, as in the United States, or 50 Hz, as in European countries. Table 18.8 lists common synchronous speeds.

$$n = \frac{120f}{\text{no. of poles}} \quad 18.19$$

**Table 18.8** Common Synchronous Speeds

number of poles	$n$ (rpm)	
	60 Hz	50 Hz
2	3600	3000
4	1800	1500
6	1200	1000
8	900	750
10	720	600
12	600	500
14	514	428
18	400	333
24	300	250
48	150	125

Induction motors do not run at their synchronous speeds when loaded. Rather, they run at slightly less than synchronous speed. The deviation is known as the *slip*. Slip is typically around 4% and is seldom greater than 10% at full load for motors in the 1–75 hp range.

slip (in rpm)

$$= \text{synchronous speed} - \text{actual speed} \quad 18.20$$

slip (in percent)

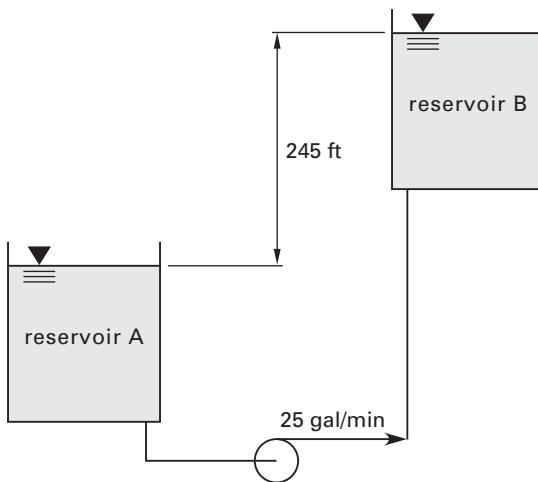

$$= \frac{\text{synchronous speed} - \text{actual speed}}{\text{synchronous speed}} \times 100\% \quad 18.21$$

Induction motors may also be specified in terms of their kVA (kilovolt-amp) ratings. The kVA rating is not the same as the power in kilowatts, although one can be derived from the other if the motor's *power factor* is known. Such power factors typically range from 0.8 to 0.9, depending on the installation and motor size.

$$\text{kVA rating} = \frac{\text{motor power in kW}}{\text{power factor}} \quad 18.22$$

#### Example 18.3

A pump driven by an electrical motor moves 25 gal/min of water from reservoir A to reservoir B, lifting the water a total of 245 ft. The efficiencies of the pump and motor are 64% and 84%, respectively. Electricity costs \$0.08/kW-hr. Neglect velocity head, friction, and minor losses. (a) What minimum size motor is required? (b) How much does it cost to operate the pump for 6 hr?

*Solution*

(a) The head added is 245 ft. Using Table 18.5 and incorporating the pump efficiency, the motor power required is

$$P = \frac{h_A Q (\text{SG})}{3956 \eta_p} = \frac{(245 \text{ ft}) \left( 25 \frac{\text{gal}}{\text{min}} \right) (1.0)}{\left( 3956 \frac{\text{ft-gal}}{\text{hp-min}} \right) (0.64)} \\ = 2.42 \text{ hp}$$

From Table 18.7, select a 3 hp motor.

(b) The developed power, not the motor's rated power, is used. From Eq. 18.16 and Eq. 18.17,

$$\text{cost} = (\text{cost per kW-hr}) \left( \frac{Pt}{\eta_m} \right) \\ = \left( 0.08 \frac{\$}{\text{kW-hr}} \right) \left( 0.7457 \frac{\text{kW}}{\text{hp}} \right) \left( \frac{(2.42 \text{ hp})(6 \text{ hr})}{0.84} \right) \\ = \$1.03$$

#### 14. PUMP SHAFT LOADING

The torque on a pump or motor shaft can be calculated from the brake power and rotational speed.

$$T_{\text{in-lbf}} = \frac{63,025 P_{\text{hp}}}{n} \quad 18.23$$

$$T_{\text{ft-lbf}} = \frac{5252 P_{\text{hp}}}{n} \quad 18.24$$

$$T_{\text{N-m}} = \frac{9549 P_{\text{kW}}}{n} \quad 18.25$$

The actual (developed) torque can be calculated from the change in momentum of the fluid flow. For radial impellers, the fluid enters through the eye and is turned

90°. The direction change is related to the increase in momentum and the shaft torque. When fluid is introduced axially through the eye of the impeller, the tangential velocity at the inlet (eye),  $v_{t(s)}$ , is zero.<sup>13</sup>

$$T_{\text{actual}} = \dot{m}(v_{t(d)} r_{\text{impeller}} - v_{t(s)} r_{\text{eye}}) \quad [\text{SI}] \quad 18.26(a)$$

$$T_{\text{actual}} = \frac{\dot{m}}{g_c} (v_{t(d)} r_{\text{impeller}} - v_{t(s)} r_{\text{eye}}) \quad [\text{U.S.}] \quad 18.26(b)$$

Centrifugal pumps can be driven directly from a motor, or a speed changer can be used. Rotary pumps generally require a speed reduction. *Gear motors* have integral speed reducers. V-belt drives are widely used because of their initial low cost, although timing belts and chains can be used in some applications.

When a belt or chain is used, the pump's and motor's maximum overhung loads must be checked. This is particularly important for high-power, low-speed applications (such as rotary pumps). *Overhung load* is the side load (force) put on shafts and bearings. The overhung load is calculated from Eq. 18.27. The empirical factor  $K$  is 1.0 for chain drives, 1.25 for timing belts, and 1.5 for V-belts.

$$\text{overhung load} = \frac{2KT}{D_{\text{sheave}}} \quad 18.27$$

If a direct drive cannot be used and the overhung load is excessive, the installation can be modified to incorporate a jack shaft or outboard bearing.

#### Example 18.4

A centrifugal pump delivers 275 lbm/sec (125 kg/s) of water while turning at 850 rpm. The impeller has straight radial vanes and an outside diameter of 10 in (25.4 cm). Water enters the impeller through the eye. The driving motor delivers 30 hp (22 kW). What are the (a) theoretical torque, (b) pump efficiency, and (c) total dynamic head?

*SI Solution*

(a) From Eq. 18.3, the impeller's tangential velocity is

$$v_t = \frac{\pi D n}{60 \frac{\text{s}}{\text{min}}} = \frac{\pi (25.4 \text{ cm}) \left( 850 \frac{\text{rev}}{\text{min}} \right)}{\left( 60 \frac{\text{s}}{\text{min}} \right) \left( 100 \frac{\text{cm}}{\text{m}} \right)} \\ = 11.3 \text{ m/s}$$

<sup>13</sup>The tangential component of fluid velocity is sometimes referred to as the *velocity of whirl*.

Since water enters axially, the incoming water has no tangential component. From Eq. 18.26, the developed torque is

$$T = \dot{m}v_{t(d)}r_{\text{impeller}} = \frac{\left(125 \frac{\text{kg}}{\text{s}}\right)\left(11.3 \frac{\text{m}}{\text{s}}\right)\left(\frac{25.4 \text{ cm}}{2}\right)}{100 \frac{\text{cm}}{\text{m}}} \\ = 179.4 \text{ N}\cdot\text{m}$$

(b) From Eq. 18.25, the developed power is

$$P_{\text{kW}} = \frac{nT_{\text{N}\cdot\text{m}}}{9549} = \frac{\left(850 \frac{\text{rev}}{\text{min}}\right)(179.4 \text{ N}\cdot\text{m})}{9549 \frac{\text{N}\cdot\text{m}}{\text{kW}\cdot\text{min}}} \\ = 15.97 \text{ kW}$$

The pump efficiency is

$$\eta_p = \frac{P_{\text{developed}}}{P_{\text{input}}} = \frac{15.97 \text{ kW}}{22 \text{ kW}} \\ = 0.726 \quad (72.6\%)$$

(c) From Table 18.6, the total dynamic head is

$$h_A = \frac{P}{\dot{m}g} = \frac{(15.97 \text{ kW})(1000 \frac{\text{W}}{\text{kW}})}{\left(125 \frac{\text{kg}}{\text{s}}\right)(9.81 \frac{\text{m}}{\text{s}^2})} \\ = 13.0 \text{ m}$$

#### Customary U.S. Solution

(a) From Eq. 18.3, the impeller's tangential velocity is

$$v_t = \frac{\pi Dn}{60 \frac{\text{sec}}{\text{min}}} = \frac{\pi(10 \text{ in})(850 \frac{\text{rev}}{\text{min}})}{\left(60 \frac{\text{sec}}{\text{min}}\right)\left(12 \frac{\text{in}}{\text{ft}}\right)} \\ = 37.09 \text{ ft/sec}$$

Since water enters axially, the incoming water has no tangential component. From Eq. 18.26, the developed torque is

$$T = \frac{\dot{m}v_{t(d)}r_{\text{impeller}}}{g_c} = \frac{\left(275 \frac{\text{lbm}}{\text{sec}}\right)\left(37.08 \frac{\text{ft}}{\text{sec}}\right)\left(\frac{10 \text{ in}}{2}\right)}{\left(32.2 \frac{\text{lbm}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2}\right)\left(12 \frac{\text{in}}{\text{ft}}\right)} \\ = 131.9 \text{ ft-lbf}$$

(b) From Eq. 18.24, the developed power is

$$P_{\text{hp}} = \frac{T_{\text{ft-lbf}}n}{5252} = \frac{(131.9 \text{ ft-lbf})(850 \frac{\text{rev}}{\text{min}})}{5252 \frac{\text{ft-lbf}}{\text{hp}\cdot\text{min}}} \\ = 21.35 \text{ hp}$$

The pump efficiency is

$$\eta_p = \frac{P_{\text{developed}}}{P_{\text{input}}} = \frac{21.35 \text{ hp}}{30 \text{ hp}} \\ = 0.712 \quad (71.2\%)$$

(c) From Table 18.5, the total dynamic head is

$$h_A = \frac{\left(550 \frac{\text{ft-lbf}}{\text{hp}\cdot\text{sec}}\right)P_{\text{hp}}}{\dot{m}} \times \frac{g_c}{g} \\ = \frac{\left(550 \frac{\text{ft-lbf}}{\text{hp}\cdot\text{sec}}\right)(21.35 \text{ hp})}{275 \frac{\text{lbm}}{\text{sec}}} \times \frac{32.2 \frac{\text{lbm}\cdot\text{ft}}{\text{lbf}\cdot\text{sec}^2}}{32.2 \frac{\text{ft}}{\text{sec}^2}} \\ = 42.7 \text{ ft}$$

## 15. SPECIFIC SPEED

The capacity and efficiency of a centrifugal pump are partially governed by the impeller design. For a desired flow rate and added head, there will be one optimum impeller design. The quantitative index used to optimize the impeller design is known as *specific speed*,  $n_s$ , also known as *impeller specific speed*. Table 18.9 lists the impeller designs that are appropriate for different specific speeds.<sup>14</sup>

**Table 18.9** Specific Speed Versus Impeller Design

impeller type	approximate range of specific speed (rpm)	
	customary U.S. units	SI units
radial vane	500 to 1000	10 to 20
Francis (mixed vane)	2000 to 3000	40 to 60
mixed flow	4000 to 7000	80 to 140
axial flow	9000 and above	180 and above

(Divide customary U.S. specific speed by 51.64 to obtain SI specific speed.)

<sup>14</sup>Specific speed is useful for more than just selecting an impeller type. Maximum suction lift, pump efficiency, and net positive suction head required (NPSHR) can be correlated with specific speed.

Highest heads per stage are developed at low specific speeds. However, for best efficiency, specific speed should be greater than 650 (13 in SI units). If the specific speed for a given set of conditions drops below 650 (13), a multiple-stage pump should be selected.<sup>15</sup>

Specific speed is a function of a pump's capacity, head, and rotational speed at peak efficiency, as shown in Eq. 18.28. For a given pump and impeller configuration, the specific speed remains essentially constant over a range of flow rates and heads. ( $Q$  or  $V$  in Eq. 18.28 is half of the full flow rate for double-suction pumps.)

$$n_s = \frac{n\sqrt{V}}{h_A^{0.75}} \quad [\text{SI}] \quad 18.28(a)$$

$$n_s = \frac{n\sqrt{Q}}{h_A^{0.75}} \quad [\text{U.S.}] \quad 18.28(b)$$

A common definition of specific speed is the speed (in rpm) at which a *homologous pump* would have to turn in order to deliver 1 gal/min at 1 ft total added head.<sup>16</sup> This definition is implicit to Eq. 18.28 but is not very useful otherwise. While specific speed is not dimensionless, the units are meaningless. Specific speed may be assigned units of rpm, but most often it is expressed simply as a pure number.

The numerical range of acceptable performance for each impeller type is redefined when SI units are used. The SI specific speed is obtained by dividing the customary U.S. specific speed by 51.64.

Specific speed can be used to determine the type of impeller needed. Once a pump is selected, its specific speed and Eq. 18.28 can be used to determine other operational parameters (e.g., maximum rotational speed). Specific speed can be used with Fig. 18.8 to obtain an approximate pump efficiency.

### Example 18.5

A centrifugal pump powered by a direct-drive induction motor is needed to discharge 150 gal/min against a 300 ft total head when turning at the fully loaded speed of 3500 rpm. What type of pump should be selected?

*Solution*

From Eq. 18.28, the specific speed is

$$n_s = \frac{n\sqrt{Q}}{h_A^{0.75}} = \frac{\left(3500 \frac{\text{rev}}{\text{min}}\right) \sqrt{150 \frac{\text{gal}}{\text{min}}}}{(300 \text{ ft})^{0.75}} = 595$$

<sup>15</sup>Partial emission, forced vortex centrifugal pumps allow operation down to specific speeds of 150 (3 in SI). Such pumps have been used for low-flow, high-head applications, such as high-pressure petrochemical cracking processes.

<sup>16</sup>Homologous pumps are geometrically similar. This means that each pump is a scaled up or down version of the others. Such pumps are said to belong to a *homologous family*.

From Table 18.9, the pump should be a radial vane type. However, pumps achieve their highest efficiencies when specific speed exceeds 650. (See Fig. 18.8.) To increase the specific speed, the rotational speed can be increased, or the total added head can be decreased. Since the pump is direct-driven and 3600 rpm is the maximum speed for induction motors, the total added head should be divided evenly between two stages, or two pumps should be used in series. (See Table 18.8.)

In a two-stage system, the specific speed would be

$$n_s = \frac{\left(3500 \frac{\text{rev}}{\text{min}}\right) \sqrt{150 \frac{\text{gal}}{\text{min}}}}{\left(\frac{300 \text{ ft}}{2}\right)^{0.75}} = 1000$$

This is satisfactory for a radial vane pump.

### Example 18.6

An induction motor turning at 1200 rpm is to be selected to drive a single-stage, single-suction centrifugal water pump through a direct drive. The total dynamic head added by the pump is 26 ft. The flow rate is 900 gal/min. What minimum size motor should be selected?

*Solution*

The specific speed is

$$n_s = \frac{n\sqrt{Q}}{h_A^{0.75}} = \frac{\left(1200 \frac{\text{rev}}{\text{min}}\right) \sqrt{900 \frac{\text{gal}}{\text{min}}}}{(26 \text{ ft})^{0.75}} = 3127$$

From Fig. 18.8, the pump efficiency will be approximately 82%.

From Table 18.5, the minimum motor horsepower is

$$P_{hp} = \frac{h_A Q (\text{SG})}{3956 \eta_p} = \frac{(26 \text{ ft}) \left(900 \frac{\text{gal}}{\text{min}}\right) (1.0)}{\left(3956 \frac{\text{ft-gal}}{\text{hp-min}}\right) (0.82)} = 7.2 \text{ hp}$$

From Table 18.7, select a 7.5 hp or larger motor.

### Example 18.7

A single-stage pump driven by a 3600 rpm motor is currently delivering 150 gal/min. The total dynamic head is 430 ft. What would be the approximate increase in efficiency per stage if the single-stage pump is replaced by a double-stage pump?

**Solution**

The specific speed is

$$n_s = \frac{n\sqrt{Q}}{h_A^{0.75}} = \frac{\left(3600 \frac{\text{rev}}{\text{min}}\right) \sqrt{150 \frac{\text{gal}}{\text{min}}}}{(430 \text{ ft})^{0.75}} = 467$$

From Fig. 18.8, the approximate efficiency is 45%.

In a two-stage pump, each stage adds half of the head. The specific speed per stage would be

$$n_s = \frac{n\sqrt{Q}}{h_A^{0.75}} = \frac{\left(3600 \frac{\text{rev}}{\text{min}}\right) \sqrt{150 \frac{\text{gal}}{\text{min}}}}{\left(\frac{430 \text{ ft}}{2}\right)^{0.75}} = 785$$

From Fig. 18.8, the efficiency for this configuration is approximately 60%.

The increase in stage efficiency is  $60\% - 45\% = 15\%$ . Whether or not the cost of multistaging is worthwhile in this low-volume application would have to be determined.

## 16. CAVITATION

*Cavitation* is a spontaneous vaporization of the fluid inside the pump, resulting in a degradation of pump performance. Wherever the fluid pressure is less than the vapor pressure, small pockets of vapor will form. These pockets usually form only within the pump itself, although cavitation slightly upstream within the suction line is also possible. As the vapor pockets reach the surface of the impeller, the local high fluid pressure collapses them. Noise, vibration, impeller pitting, and structural damage to the pump casing are manifestations of cavitation.

Cavitation can be caused by any of the following conditions.

- discharge head far below the pump head at peak efficiency
- high suction lift or low suction head
- excessive pump speed
- high liquid temperature (i.e., high vapor pressure)

## 17. NET POSITIVE SUCTION HEAD

The occurrence of cavitation is predictable. Cavitation will occur when the net pressure in the fluid drops below the vapor pressure. This criterion is commonly stated in terms of head: Cavitation occurs when the available head is less than the required head for satisfactory operation. (See Eq. 18.34.)

The minimum fluid energy required at the pump inlet for satisfactory operation (i.e., the required head) is

known as the *net positive suction head required*, NPSHR.<sup>17</sup> NPSHR is a function of the pump and will be given by the pump manufacturer as part of the pump performance data.<sup>18</sup> NPSHR is dependent on the flow rate. However, if NPSHR is known for one flow rate, it can be determined for another flow rate from Eq. 18.34.

$$\frac{\text{NPSHR}_2}{\text{NPSHR}_1} = \left(\frac{Q_2}{Q_1}\right)^2 \quad 18.29$$

*Net positive suction head available*, NPSHA, is the actual total fluid energy at the pump inlet. There are two different methods for calculating NPSHA, both of which are correct and will yield identical answers. Equation 18.30 is based on the conditions at the fluid surface at the top of an open fluid source (e.g., tank or reservoir). There is a potential energy term but no kinetic energy term. Equation 18.31 is based on the conditions at the immediate entrance (suction, subscript *s*) to the pump. At that point, some of the potential head has been converted to velocity head. Frictional losses are implicitly part of the reduced pressure head, as is the atmospheric pressure head. Since the pressure head,  $h_{p(s)}$ , is absolute, it includes the atmospheric pressure head, and the effect of higher altitudes is explicit in Eq. 18.30 and implicit in Eq. 18.31. If the source was pressurized instead of being open to the atmosphere, the pressure head would replace  $h_{\text{atm}}$  in Eq. 18.30 but would be implicit in  $h_{p(s)}$  in Eq. 18.31.

$$\text{NPSHA} = h_{\text{atm}} + h_{z(s)} - h_{f(s)} - h_{\text{vp}} \quad 18.30$$

$$\text{NPSHA} = h_{p(s)} + h_{v(s)} - h_{\text{vp}} \quad 18.31$$

The net positive suction head available (NPSHA) for most positive displacement pumps includes a term for acceleration head.<sup>19</sup>

$$\text{NPSHA} = h_{\text{atm}} + h_{z(s)} - h_{f(s)} - h_{\text{vp}} - h_{\text{ac}} \quad 18.32$$

$$\text{NPSHA} = h_{p(s)} + h_{v(s)} - h_{\text{vp}} - h_{\text{ac}} \quad 18.33$$

If NPSHA is less than NPSHR, the fluid will cavitate. The criterion for cavitation is given by Eq. 18.34. (In practice, it is desirable to have a safety margin.)

$$\text{NPSHA} < \text{NPSHR} \quad \begin{matrix} [\text{criterion for}] \\ \text{cavitation} \end{matrix} \quad 18.34$$

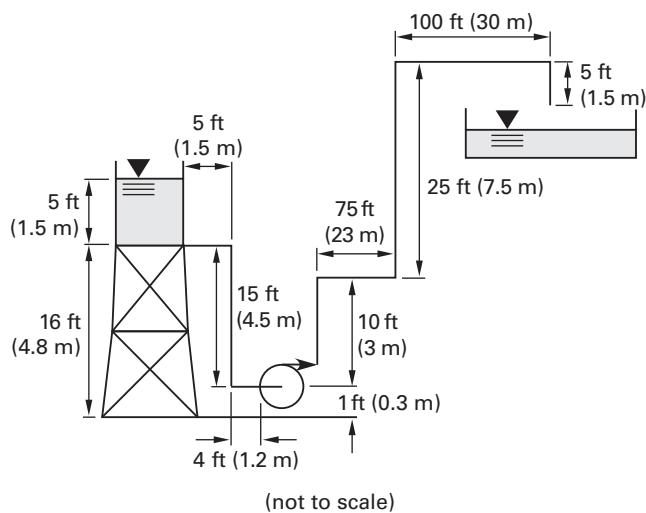

<sup>17</sup>If NPSHR (a head term) is multiplied by the fluid specific weight, it is known as the *net inlet pressure required*, NIPR. Similarly, NPSHA can be converted to NIPA.

<sup>18</sup>It is also possible to calculate NPSHR from other information, such as suction specific speed. However, this still depends on information provided by the manufacturer.

<sup>19</sup>The friction loss and the acceleration terms are both maximum values, but they do not occur in phase. Combining them is conservative.

**Example 18.8**

2.0 ft<sup>3</sup>/sec (56 L/s) of 60°F (16°C) water are pumped from an elevated feed tank to an open reservoir through 6 in (15.2 cm), schedule-40 steel pipe, as shown. The friction loss for the piping and fittings in the suction line is 2.6 ft (0.9 m). The friction loss for the piping and fittings in the discharge line is 13 ft (4.3 m). The atmospheric pressure is 14.7 psia (101 kPa). What is the NPSHA?

*SI Solution*

The density of water is approximately 1000 kg/m<sup>3</sup>. The atmospheric head is

$$h_{\text{atm}} = \frac{p}{\rho g} = \frac{(101 \text{ kPa})(1000 \frac{\text{Pa}}{\text{kPa}})}{\left(1000 \frac{\text{kg}}{\text{m}^3}\right)(9.81 \frac{\text{m}}{\text{s}^2})} = 10.3 \text{ m}$$

For 16°C water, the vapor pressure is approximately 0.01818 bars. The vapor pressure head is

$$h_{\text{vp}} = \frac{p}{\rho g} = \frac{(0.01818 \text{ bar})(1 \times 10^5 \frac{\text{Pa}}{\text{bar}})}{\left(1000 \frac{\text{kg}}{\text{m}^3}\right)(9.81 \frac{\text{m}}{\text{s}^2})} = 0.2 \text{ m}$$

From Eq. 18.30, the NPSHA is

$$\begin{aligned} \text{NPSHA} &= h_{\text{atm}} + h_{z(s)} - h_{f(s)} - h_{\text{vp}} \\ &= 10.3 \text{ m} + 1.5 \text{ m} + 4.8 \text{ m} - 0.3 \text{ m} \\ &\quad - 0.9 \text{ m} - 0.2 \text{ m} \\ &= 15.2 \text{ m} \end{aligned}$$

*Customary U.S. Solution*

The specific weight of water is approximately 62.4 lbf/ft<sup>3</sup>. The atmospheric head is

$$\begin{aligned} h_{\text{atm}} &= \frac{p}{\gamma} = \frac{(14.7 \frac{\text{lbf}}{\text{in}^2})(12 \frac{\text{in}}{\text{ft}})^2}{62.4 \frac{\text{lbf}}{\text{ft}^3}} \\ &= 33.9 \text{ ft} \end{aligned}$$

For 60°F water, the vapor pressure head is 0.59 ft. Use 0.6 ft.

From Eq. 18.30, the NPSHA is

$$\begin{aligned} \text{NPSHA} &= h_{\text{atm}} + h_{z(s)} - h_{f(s)} - h_{\text{vp}} \\ &= 33.9 \text{ ft} + 5 \text{ ft} + 16 \text{ ft} - 1 \text{ ft} - 2.6 \text{ ft} - 0.6 \text{ ft} \\ &= 50.7 \text{ ft} \end{aligned}$$

**18. PREVENTING CAVITATION**

Cavitation is prevented by increasing NPSHA or decreasing NPSHR. NPSHA can be increased by

- increasing the height of the fluid source
- lowering the pump
- reducing friction and minor losses by shortening the suction line or using a larger pipe size
- reducing the temperature of the fluid at the pump entrance
- pressurizing the fluid supply tank
- reducing the flow rate or velocity (i.e., reducing the pump speed)

NPSHR can be reduced by

- placing a throttling valve or restriction in the discharge line<sup>20</sup>
- using an oversized pump
- using a double-suction pump
- using an impeller with a larger eye
- using an inducer

High NPSHR applications, such as boiler feed pumps needing 150–250 ft (50–80 m), should use one or more booster pumps in front of each high-NPSHR pump. Such booster pumps are typically single-stage, double-suction pumps running at low speed. Their NPSHR can be 25 ft (8 m) or less.

Throttling the input line to a pump and venting or evacuating the receiving tank both increase cavitation. Throttling the input line increases the friction head and

<sup>20</sup>This will increase the total head,  $h_A$ , added by the pump, thereby reducing the pump's output and driving the pump's operating point into a region of lower NPSHR.

decreases NPSHA. Evacuating the receiving tank increases the flow rate, increasing NPSHR while simultaneously increasing the friction head and reducing NPSHA.

## 19. CAVITATION COEFFICIENT

The *cavitation coefficient* (or *cavitation number*),  $\sigma$ , is a dimensionless number that can be used in modeling and extrapolating experimental results. The actual cavitation coefficient is compared with the *critical cavitation number* obtained experimentally. If the actual cavitation number is less than the critical cavitation number, cavitation will occur. Absolute pressure must be used for the fluid pressure term,  $p$ .

$$\sigma < \sigma_{cr} \quad [\text{criterion for cavitation}] \quad 18.35$$

$$\sigma = \frac{2(p - p_{vp})}{\rho v^2} = \frac{\text{NPSHA}}{h_A} \quad [\text{SI}] \quad 18.36(a)$$

$$\sigma = \frac{2g_c(p - p_{vp})}{\rho v^2} = \frac{\text{NPSHA}}{h_A} \quad [\text{U.S.}] \quad 18.36(b)$$

The two forms of Eq. 18.36 yield slightly different results. The first form is essentially the ratio of the net pressure available for collapsing a vapor bubble to the velocity pressure creating the vapor. It is useful in model experiments. The second form is applicable to tests of production model pumps.

## 20. SUCTION SPECIFIC SPEED

The formula for *suction specific speed*,  $n_{ss}$ , can be derived by substituting NPSHR for total head in the expression for specific speed.  $Q$  and  $\dot{V}$  are halved for double-suction pumps.

$$n_{ss} = \frac{n\sqrt{\dot{V}}}{(\text{NPSHR in m})^{0.75}} \quad [\text{SI}] \quad 18.37(a)$$

$$n_{ss} = \frac{n\sqrt{Q}}{(\text{NPSHR in ft})^{0.75}} \quad [\text{U.S.}] \quad 18.37(b)$$

Suction specific speed is an index of the suction characteristics of the impeller. Ideally, it should be approximately 8500 (165 in SI) for both single- and double-suction pumps. This assumes the pump is operating at or near its point of optimum efficiency.

Suction specific speed can be used to determine the maximum recommended operating speed by substituting 8500 (165 in SI) for  $n_{ss}$  in Eq. 18.37 and solving for  $n$ .

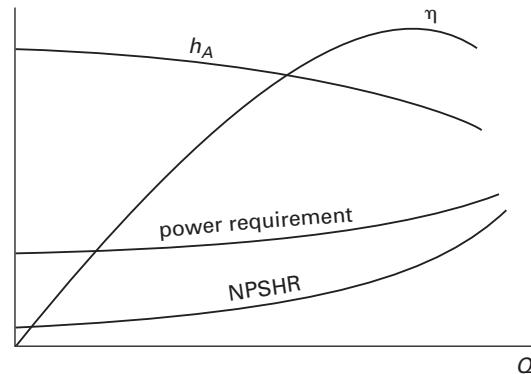

If the suction specific speed is known, it can be used to determine the NPSHR. If the pump is known to be operating at or near its optimum efficiency, an approximate NPSHR value can be found by substituting 8500 (165 in SI) for  $n_{ss}$  in Eq. 18.37 and solving for NPSHR.

*Suction specific speed available*, SA, is obtained when NPSHA is substituted for total head in the expression for specific speed. The suction specific speed available must be less than the suction specific speed required to prevent cavitation.<sup>21</sup>

## 21. PUMP PERFORMANCE CURVES

For a given impeller diameter and constant speed, the head added will decrease as the flow rate increases. This is shown graphically on the *pump performance curve* (*pump curve*) supplied by the pump manufacturer. Other operating characteristics (e.g., power requirement, NPSHR, and efficiency) also vary with flow rate, and these are usually plotted on a common graph, as shown in Fig. 18.10.<sup>22</sup> Manufacturers' pump curves show performance over a limited number of calibration speeds. If an operating point is outside the range of published curves, the affinity laws can be used to estimate the speed at which the pump gives the required performance.

Figure 18.10 Pump Performance Curves

On the pump curve, the *shutoff point* (also known as *churn*) corresponds to a closed discharge valve (i.e., zero flow); the *rated point* is where the pump operates with rated 100% of capacity and head; the *overload point* corresponds to 65% of the rated head.

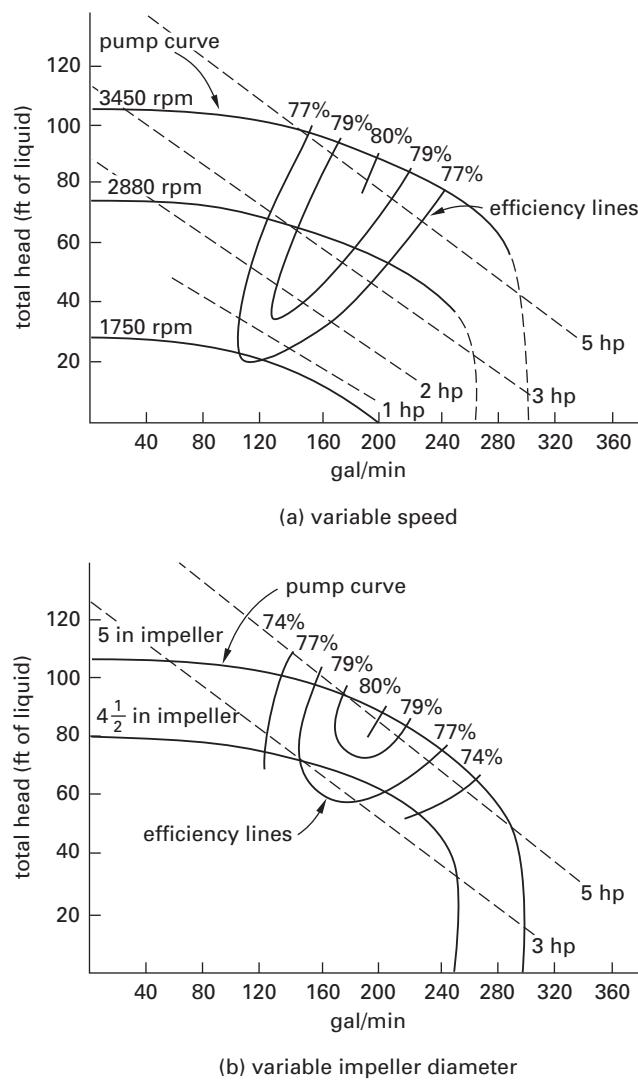

Figure 18.10 is for a pump with a fixed impeller diameter and rotational speed. The characteristics of a pump operated over a range of speeds or for different impeller diameters are illustrated in Fig. 18.11.

## 22. SYSTEM CURVES

A *system curve* (or *system performance curve*) is a plot of the static and friction energy losses experienced by the fluid for different flow rates. Unlike the pump curve,

<sup>21</sup>Since speed and flow rate are constants, this is another way of saying NPSHA must equal or exceed NPSHR.

<sup>22</sup>The term *pump curve* is commonly used to designate the  $h_A$  versus  $Q$  characteristics, whereas *pump characteristics curve* refers to all of the pump data.

**Figure 18.11** Centrifugal Pump Characteristics Curves

which depends only on the pump, the system curve depends only on the configuration of the suction and discharge lines. (The following equations assume equal pressures at the fluid source and destination surfaces, which is the case for pumping from one atmospheric reservoir to another. The velocity head is insignificant and is disregarded.)

$$h_A = h_z + h_f \quad 18.38$$

$$h_z = h_{z(d)} - h_{z(s)} \quad 18.39$$

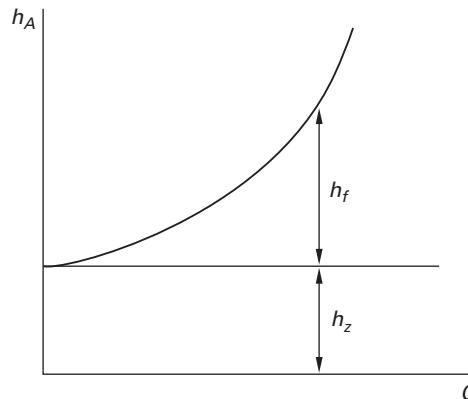

$$h_f = h_{f(s)} + h_{f(d)} \quad 18.40$$

If the fluid reservoirs are large, or if the fluid reservoir levels are continually replenished, the net static suction head ( $h_{z(d)} - h_{z(s)}$ ) will be constant for all flow rates. The friction loss,  $h_f$ , varies with  $v^2$  (and, therefore, with  $Q^2$ ) in the Darcy friction formula. This makes it easy to

find friction losses for other flow rates (subscript 2) once one friction loss (subscript 1) is known.<sup>23</sup>

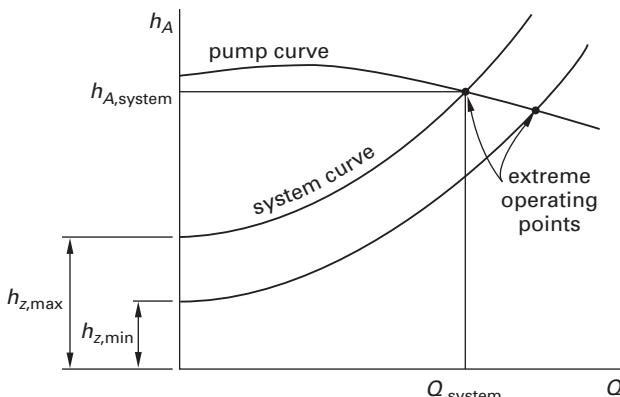

$$\frac{h_{f,1}}{h_{f,2}} = \left( \frac{Q_1}{Q_2} \right)^2 \quad 18.41$$

Figure 18.12 illustrates a system curve following Eq. 18.38 with a positive added head (i.e., a fluid source below the fluid destination). The system curve is shifted upward, intercepting the vertical axis at some positive value of  $h_A$ .

**Figure 18.12** System Curve

### 23. OPERATING POINT

The intersection of the pump curve and the system curve determines the *operating point*, as shown in Fig. 18.13. The operating point defines the system head and system flow rate.

**Figure 18.13** Extreme Operating Points

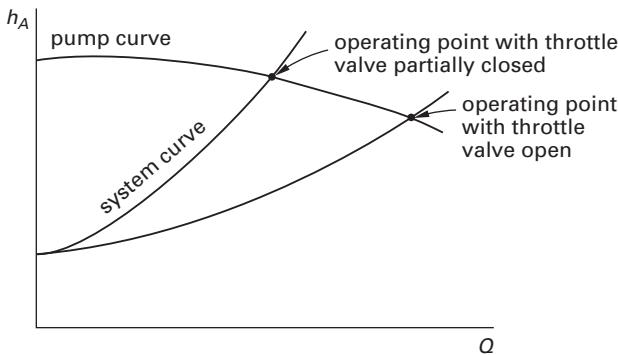

<sup>23</sup>Equation 18.41 implicitly assumes that the friction factor,  $f$ , is constant. This may be true over a limited range of flow rates, but it is not true over large ranges. Nevertheless, Eq. 18.41 is often used to quickly construct preliminary versions of the system curve.

When selecting a pump, the system curve is plotted on manufacturers' pump curves for different speeds and/or impeller diameters (i.e., Fig. 18.11). There will be several possible operating points corresponding to the various pump curves shown. Generally, the design operating point should be close to the highest pump efficiency. This, in turn, will determine speed and impeller diameter.

In some systems, the static head varies as the source reservoir is drained or as the destination reservoir fills. The system head is then defined by a pair of matching system friction curves intersecting the pump curve. The two intersection points are called the *extreme operating points*—the maximum and minimum capacity requirements.

After a pump is installed, it may be desired to change the operating point. This can be done without replacing the pump by placing a throttling valve in the discharge line. The operating point can then be moved along the pump curve by partially opening or closing the valve, as is illustrated in Fig. 18.14. (A throttling valve should never be placed in the suction line since that would reduce NPSHA.)

**Figure 18.14** Throttling the Discharge

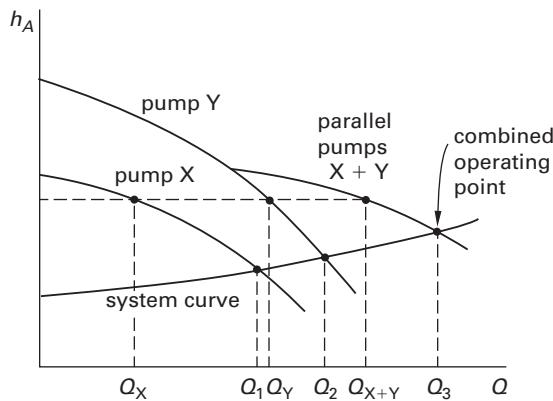

## 24. PUMPS IN PARALLEL

Parallel operation is obtained by having two pumps discharging into a common header. This type of connection is advantageous when the system demand varies greatly or when high reliability is required. A single pump providing total flow would have to operate far from its optimum efficiency at one point or another. With two pumps in parallel, one can be shut down during low demand. This allows the remaining pump to operate close to its optimum efficiency point.

Figure 18.15 illustrates that parallel operation increases the capacity of the system while maintaining the same total head.

The performance curve for a set of pumps in parallel can be plotted by adding the capacities of the two pumps at various heads. A second pump will operate only when its discharge head is greater than the discharge head of the

**Figure 18.15** Pumps Operating in Parallel

pump already running. Capacity does not increase at heads above the maximum head of the smaller pump.

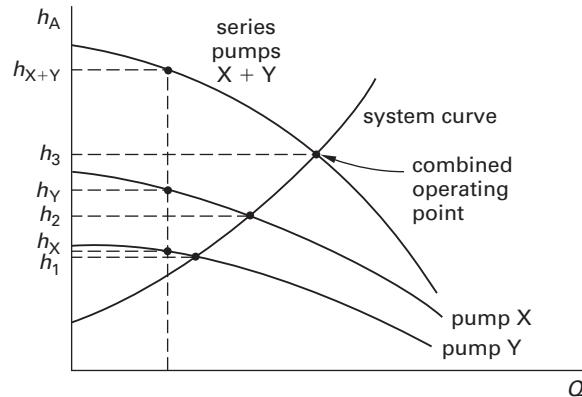

When the parallel performance curve is plotted with the system head curve, the operating point is the intersection of the system curve with the  $X + Y$  curve. With pump X operating alone, the capacity is given by  $Q_1$ . When pump Y is added, the capacity increases to  $Q_3$  with a slight increase in total head.

## 25. PUMPS IN SERIES

Series operation is achieved by having one pump discharge into the suction of the next. This arrangement is used primarily to increase the discharge head, although a small increase in capacity also results. (See Fig. 18.16.)

The performance curve for a set of pumps in series can be plotted by adding the heads of the two pumps at various capacities.

**Figure 18.16** Pumps Operating in Series

## 26. AFFINITY LAWS

Most parameters (impeller diameter, speed, and flow rate) determining a specific pump's performance can be modified. If the impeller diameter is held constant

and the speed is varied, the following ratios are maintained with no change in efficiency.<sup>24</sup>

$$\frac{Q_2}{Q_1} = \frac{n_2}{n_1} \quad 18.42$$

$$\frac{h_2}{h_1} = \left( \frac{n_2}{n_1} \right)^2 = \left( \frac{Q_2}{Q_1} \right)^2 \quad 18.43$$

$$\frac{P_2}{P_1} = \left( \frac{n_2}{n_1} \right)^3 = \left( \frac{Q_2}{Q_1} \right)^3 \quad 18.44$$

If the speed is held constant and the impeller size is reduced (i.e., the impeller is trimmed), while keeping the pump body, volute, shaft diameter, and suction and discharge openings the same, the following ratios may be used.<sup>25</sup>

$$\frac{Q_2}{Q_1} = \frac{D_2}{D_1} \quad 18.45$$

$$\frac{h_2}{h_1} = \left( \frac{D_2}{D_1} \right)^2 \quad 18.46$$

$$\frac{P_2}{P_1} = \left( \frac{D_2}{D_1} \right)^3 \quad 18.47$$

The affinity laws are based on the assumption that the efficiency stays the same. In reality, larger pumps are somewhat more efficient than smaller pumps, and extrapolations to greatly different sizes should be avoided. Equation 18.48 can be used to estimate the efficiency of a differently sized pump. The dimensionless exponent,  $n$ , varies from 0 to approximately 0.26, with 0.2 being a typical value.

$$\frac{1 - \eta_{\text{smaller}}}{1 - \eta_{\text{larger}}} = \left( \frac{D_{\text{larger}}}{D_{\text{smaller}}} \right)^n \quad 18.48$$

### Example 18.9

A pump operating at 1770 rpm delivers 500 gal/min against a total head of 200 ft. Changes in the piping system have increased the total head to 375 ft. At what speed should this pump be operated to achieve this new head at the same efficiency?

*Solution*

From Eq. 18.43,

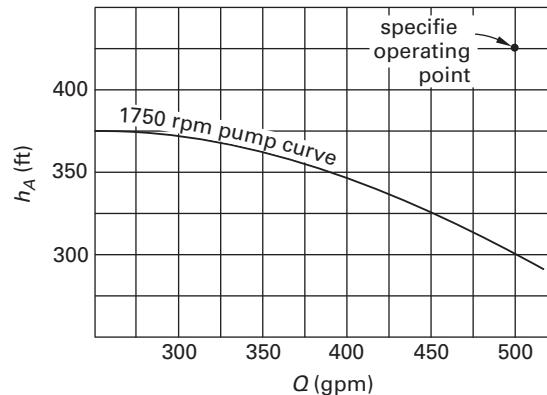

$$\begin{aligned} n_2 &= n_1 \sqrt{\frac{h_2}{h_1}} = (1770 \frac{\text{rev}}{\text{min}}) \sqrt{\frac{375 \text{ ft}}{200 \text{ ft}}} \\ &= 2424 \text{ rpm} \end{aligned}$$

<sup>24</sup>See Sec. 18.27 if the entire pump is scaled to a different size.

<sup>25</sup>One might ask, "How is it possible to change a pump's impeller diameter?" In practice, a different impeller may be available from the manufacturer, but more often the impeller is taken out and shaved down on a lathe. Equation 18.45, Eq. 18.46, and Eq. 18.47 are limited in use to radial flow machines, and with reduced accuracy, to mixed-flow impellers. Changing the impeller diameter significantly impacts other design relationships, and the accuracy of performance prediction decreases if the diameter is changed much more than 20%.

### Example 18.10

A pump is required to pump 500 gal/min against a total dynamic head of 425 ft. The hydraulic system has no static head change. Only the 1750 rpm performance curve is known for the pump. At what speed must the pump be turned to achieve the desired performance with no change in efficiency or impeller size?

*Solution*

A flow of 500 gal/min with a head of 425 ft does not correspond to any point on the 1750 rpm curve.

From Eq. 18.43, the quantity  $h/Q^2$  is constant.

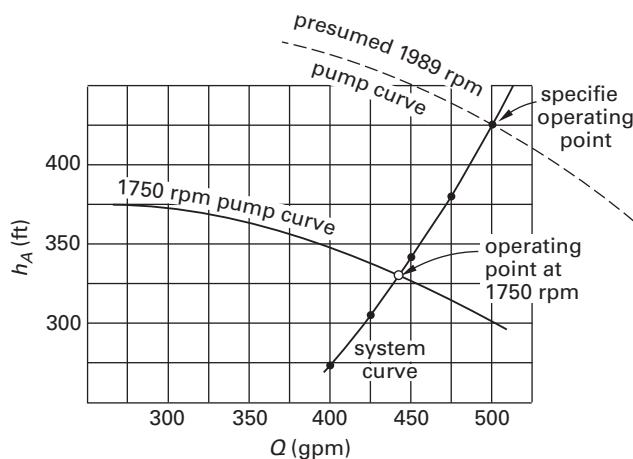

$$\frac{h}{Q^2} = \frac{425 \text{ ft}}{\left( 500 \frac{\text{gal}}{\text{min}} \right)^2} = 1.7 \times 10^{-3} \text{ ft-min}^2/\text{gal}^2$$

In order to use the affinity laws, the operating point on the 1750 rpm curve must be determined. Random values of  $Q$  are chosen and the corresponding values of  $h$  are determined such that the ratio  $h/Q^2$  is unchanged.

$Q$	$h$
475	383
450	344
425	307
400	272

These points are plotted as the system curve. The intersection of the system and 1750 rpm pump curve at 440 gal/min defines the operating point at 1750 rpm. From Eq. 18.42, the required pump speed is

$$\begin{aligned} n_2 &= \frac{n_1 Q_2}{Q_1} = \frac{(1750 \frac{\text{rev}}{\text{min}}) \left( 500 \frac{\text{gal}}{\text{min}} \right)}{440 \frac{\text{gal}}{\text{min}}} \\ &= 1989 \text{ rpm} \end{aligned}$$

## 27. PUMP SIMILARITY

The performance of one pump can be used to predict the performance of a *dynamically similar (homologous)* pump. This can be done by using Eq. 18.49 through Eq. 18.54.

$$\frac{n_1 D_1}{\sqrt{h_1}} = \frac{n_2 D_2}{\sqrt{h_2}} \quad 18.49$$

$$\frac{Q_1}{D_1^2 \sqrt{h_1}} = \frac{Q_2}{D_2^2 \sqrt{h_2}} \quad 18.50$$

$$\frac{P_1}{\rho_1 D_1^2 h_1^{1.5}} = \frac{P_2}{\rho_2 D_2^2 h_2^{1.5}} \quad 18.51$$

$$\frac{Q_1}{n_1 D_1^3} = \frac{Q_2}{n_2 D_2^3} \quad 18.52$$

$$\frac{P_1}{\rho_1 n_1^3 D_1^5} = \frac{P_2}{\rho_2 n_2^3 D_2^5} \quad 18.53$$

$$\frac{n_1 \sqrt{Q_1}}{h_1^{0.75}} = \frac{n_2 \sqrt{Q_2}}{h_2^{0.75}} \quad 18.54$$

These *similarity laws* (also known as *scaling laws*) assume that both pumps

- operate in the turbulent region
- have the same pump efficiency
- operate at the same percentage of wide-open flow

Similar pumps also will have the same specific speed and cavitation number.

As with the affinity laws, these relationships assume that the efficiencies of the larger and smaller pumps are the same. In reality, larger pumps will be more efficient than smaller pumps. Therefore, extrapolations to much larger or much smaller sizes should be avoided.

### Example 18.11

A 6 in pump operating at 1770 rpm discharges 1500 gal/min of cold water ( $\text{SG} = 1.0$ ) against an 80 ft head at 85% efficiency. A homologous 8 in pump

operating at 1170 rpm is being considered as a replacement. (a) What total head and capacity can be expected from the new pump? (b) What would be the new motor horsepower requirement?

*Solution*

(a) From Eq. 18.49,

$$h_2 = \left( \frac{D_2 n_2}{D_1 n_1} \right)^2 h_1 = \left( \frac{(8 \text{ in})(1170 \frac{\text{rev}}{\text{min}})}{(6 \text{ in})(1770 \frac{\text{rev}}{\text{min}})} \right)^2 (80 \text{ ft}) \\ = 62.14 \text{ ft}$$

From Eq. 18.52,

$$Q_2 = \left( \frac{n_2 D_2^3}{n_1 D_1^3} \right) Q_1 = \left( \frac{(1170 \frac{\text{rev}}{\text{min}})(8 \text{ in})^3}{(1770 \frac{\text{rev}}{\text{min}})(6 \text{ in})^3} \right) \left( 1500 \frac{\text{gal}}{\text{min}} \right) \\ = 2350 \text{ gal/min}$$

(b) From Table 18.5, the hydraulic horsepower is

$$\text{WHP}_2 = \frac{h_2 Q_2 (\text{SG})}{3956} = \frac{(62.14 \text{ ft}) \left( 2350 \frac{\text{gal}}{\text{min}} \right) (1.0)}{3956 \frac{\text{ft-gal}}{\text{hp-min}}} \\ = 36.91 \text{ hp}$$

From Eq. 18.48,

$$\eta_{\text{larger}} = 1 - \frac{1 - \eta_{\text{smaller}}}{\left( \frac{D_{\text{larger}}}{D_{\text{smaller}}} \right)^n} = 1 - \frac{1 - 0.85}{\left( \frac{8 \text{ in}}{6 \text{ in}} \right)^{0.2}} = 0.858$$

$$\text{BHP}_2 = \frac{\text{WHP}_2}{\eta_p} = \frac{36.92 \text{ hp}}{0.858} = 43.0 \text{ hp}$$

## 28. PUMPING LIQUIDS OTHER THAN COLD WATER

Many liquid pump parameters are determined from tests with cold, clear water at 85°F (29°C). The following guidelines can be used when pumping water at other temperatures or when pumping other liquids.

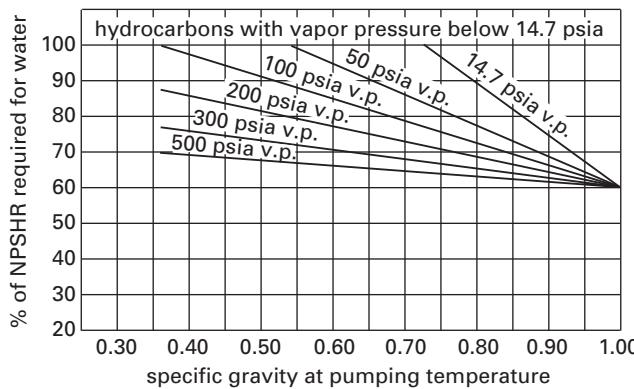

- Head developed is independent of the liquid's specific gravity. Pump performance curves from tests with water can be used with other Newtonian fluids (e.g., gasoline, alcohol, and aqueous solutions) having similar viscosities.
- The hydraulic horsepower depends on the specific gravity of the liquid. If the pump characteristic curve is used to find the operating point, multiply the horsepower reading by the specific gravity. Table 18.5 and Table 18.6 incorporate the specific gravity term in the calculation of hydraulic power where required.

- Efficiency is not affected by changes in temperature that cause only the specific gravity to change.
- Efficiency is nominally affected by changes in temperature that cause the viscosity to change. Equation 18.55 is an approximate relationship suggested by the Hydraulics Institute when extrapolating the efficiency (in decimal form) from cold water to hot water.  $n$  is an experimental exponent established by the pump manufacturer, generally in the range of 0.05–0.1.

$$\eta_{\text{hot}} = 1 - (1 - \eta_{\text{cold}}) \left( \frac{\nu_{\text{hot}}}{\nu_{\text{cold}}} \right)^n \quad 18.55$$

- NPSHA depends significantly on liquid temperature.
- NPSHR is not significantly affected by variations in the liquid temperature.
- When hydrocarbons are pumped, the NPSHR determined from cold water can usually be reduced. This reduction is apparently due to the slow vapor release of complex organic liquids. If the hydrocarbon's vapor pressure at the pumping temperature is known, Fig. 18.17 will give the percentage of the cold-water NPSHR.
- Pumping many fluids requires expertise that goes far beyond simply extrapolating parameters in proportion to the fluid's specific gravity. Such special cases include pumping liquids containing abrasives, liquids that solidify, highly corrosive liquids, liquids with vapor or gas, highly viscous fluids, paper stock, and hazardous fluids.
- Head, flow rate, and efficiency are all reduced when pumping highly viscous non-Newtonian fluids. No exact method exists for determining the reduction factors, other than actual tests of an installation using both fluids. Some sources have published charts of correction factors based on tests over limited viscosity and size ranges.<sup>26</sup>

**Figure 18.17** Hydrocarbon NPSHR Correction Factor

<sup>26</sup>A chart published by the Hydraulics Institute is widely distributed.

### Example 18.12

A centrifugal pump has an NIPR (NPSHR) of 12 psi based on cold water. 10°F liquid isobutane has a specific gravity of 0.60 and a vapor pressure of 15 psia. What NPSHR should be used with 10°F liquid isobutane?

*Solution*

From Fig. 18.17, the intersection of a specific gravity of 0.60 and 15 psia is above the horizontal 100% line. The full NIPR of 12 psi should be used.

### 29. TURBINE SPECIFIC SPEED

Like centrifugal pumps, turbines are classified according to the manner in which the impeller extracts energy from the fluid flow. This is measured by the turbine-specific speed equation, which is different from the equation used to calculate specific speed for pumps.

$$n_s = \frac{n\sqrt{P_{\text{kW}}}}{h_t^{1.25}} \quad [\text{SI}] \quad 18.56(a)$$

$$n_s = \frac{n\sqrt{P_{\text{hp}}}}{h_t^{1.25}} \quad [\text{U.S.}] \quad 18.56(b)$$

### 30. IMPULSE TURBINES

An *impulse turbine* consists of a rotating shaft (called a *turbine runner*) on which buckets or blades are mounted. (This is commonly called a *Pelton wheel*.<sup>27</sup>) A jet of water (or other fluid) hits the buckets and causes the turbine to rotate. The kinetic energy of the jet is converted into rotational kinetic energy. The jet is essentially at atmospheric pressure. (See Fig. 18.18.)

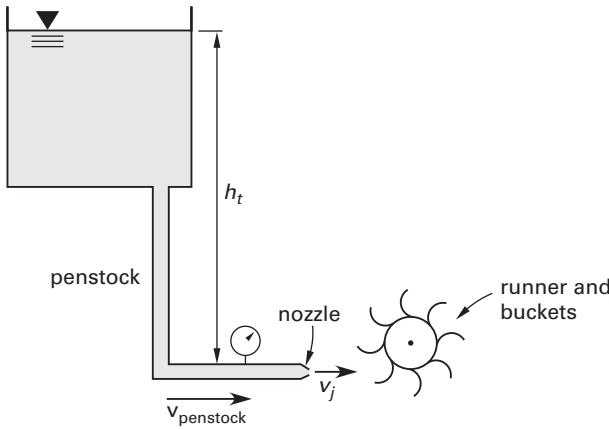

Impulse turbines are generally employed where the available head is very high, above 800–1600 ft (250–500 m). (There is no exact value for the limiting head, thus the range. What is important is that impulse turbines are *high-head turbines*.)

The total available head in this installation is  $h_t$ , but not all of this energy can be extracted. Some of the energy is lost to friction in the penstock. Minor losses also occur, but these small losses are usually disregarded. In the penstock, immediately before entering the nozzle, the remaining head is divided between the pressure head and the velocity head.<sup>28</sup>

$$h' = h_t - h_f = (h_p + h_v)_{\text{penstock}} \quad 18.57$$

<sup>27</sup>In a Pelton wheel turbine, the spoon-shaped buckets are divided into two halves, with a ridge between the halves. Half of the water is thrown to each side of the bucket. A Pelton wheel is known as a *tangential turbine (tangential wheel)* because the centerline of the jet is directed at the periphery of the wheel.

<sup>28</sup>Care must be taken to distinguish between the conditions existing in the penstock, the nozzle throat, and the jet itself. The velocity in the nozzle throat and jet will be the same, but this is different from the penstock velocity. Similarly, the pressure in the jet is zero, although it is nonzero in the penstock.

**Figure 18.18** Impulse Turbine Installation

Another loss,  $h_n$ , occurs in the nozzle itself. The head remaining to turn the turbine is

$$\begin{aligned} h'' &= h' - h_n \\ &= h_t - h_f - h_n \end{aligned} \quad 18.58$$

$h_f$  is calculated from either the Darcy or the Hazen-Williams equation. The nozzle loss is calculated from the *nozzle coefficient (coefficient of velocity)*,  $C_v$ .

$$h_n = h'(1 - C_v^2) \quad 18.59$$

The total head at the nozzle exit is converted into velocity head according to the Torricelli equation.

$$v_j = \sqrt{2gh'} = C_v \sqrt{2gh'} \quad 18.60$$

In order to maximize power output, buckets are usually designed to partially reverse the direction of the water jet flow. The forces on the turbine buckets can be found from the impulse-momentum equations. If the water is turned through an angle  $\theta$  and the wheel's *tangential velocity* is  $v_b$ , the energy transmitted by each unit mass of water to the turbine runner is<sup>29</sup>

$$E = v_b(v_j - v_b)(1 - \cos \theta) \quad [\text{SI}] \quad 18.61(a)$$

$$E = \left( \frac{v_b(v_j - v_b)}{g_c} \right) (1 - \cos \theta) \quad [\text{U.S.}] \quad 18.61(b)$$

$$v_b = \frac{2\pi nr}{60 \frac{\text{sec}}{\text{min}}} = \omega r \quad 18.62$$

The theoretical *turbine power* is found by multiplying Eq. 18.61 by the mass flow rate. The actual power will be less than the theoretical output. Efficiencies are in the range of 80–90%, with the higher efficiencies being associated with turbines having two or more jets per

<sup>29</sup> $\theta = 180^\circ$  would be ideal. However, the actual angle is limited to approximately  $165^\circ$  to keep the deflected jet out of the way of the incoming jet.

runner. For a mass flow rate in kg/s, the theoretical power (in kilowatts) will be as shown in Eq. 18.63(a). For a mass flow rate in lbm/sec, the theoretical horsepower will be as shown in Eq. 18.63(b).

$$P_{\text{th}} = \frac{\dot{m}E}{1000 \frac{\text{W}}{\text{kW}}} \quad [\text{SI}] \quad 18.63(a)$$

$$P_{\text{th}} = \frac{\dot{m}E}{550 \frac{\text{ft-lbf}}{\text{hp-sec}}} \quad [\text{U.S.}] \quad 18.63(b)$$

### Example 18.13

A Pelton wheel impulse turbine develops 100 hp (brake) while turning at 500 rpm. The water is supplied from a penstock with an internal area of  $0.3474 \text{ ft}^2$ . The water subsequently enters a nozzle with a reduced flow area. The total head is 200 ft before nozzle loss. The turbine efficiency is 80%, and the nozzle coefficient,  $C_v$ , is 0.95. Disregard penstock friction losses. What are the (a) flow rate (in  $\text{ft}^3/\text{sec}$ ), (b) area of the jet, and (c) pressure head in the penstock just before the nozzle?

*Solution*

(a) Use Eq. 18.60, with  $h' = 200 \text{ ft}$ , to find the jet velocity.

$$\begin{aligned} v_j &= C_v \sqrt{2gh'} = 0.95 \sqrt{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})(200 \text{ ft})} \\ &= 107.8 \text{ ft/sec} \end{aligned}$$

From Eq. 18.59, the nozzle loss is

$$\begin{aligned} h_n &= h'(1 - C_v^2) = (200 \text{ ft})(1 - (0.95)^2) \\ &= 19.5 \text{ ft} \end{aligned}$$

For any generated power, the actual flow rate must be greater than the ideal flow rate in order to overcome losses. Dividing by the efficiency increases the flow rate. From Table 18.5, the flow rate is

$$\begin{aligned} \dot{V} &= \frac{8.814P}{h_A(\text{SG})\eta} = \frac{\left(8.814 \frac{\text{ft}^4}{\text{hp-sec}}\right)(100 \text{ hp})}{(200 \text{ ft} - 19.5 \text{ ft})(1)(0.8)} \\ &= 6.104 \text{ ft}^3/\text{sec} \end{aligned}$$

(b) The jet area is

$$A_j = \frac{\dot{V}}{v_j} = \frac{6.104 \frac{\text{ft}^3}{\text{sec}}}{107.8 \frac{\text{ft}}{\text{sec}}} = 0.0566 \text{ ft}^2$$

(c) The velocity in the penstock is

$$v_{\text{penstock}} = \frac{\dot{V}}{A} = \frac{6.104 \frac{\text{ft}^3}{\text{sec}}}{0.3474 \frac{\text{ft}^2}{}} = 17.57 \frac{\text{ft}}{\text{sec}}$$

The pressure head in the penstock is

$$\begin{aligned} h_p &= h' - h_v = h' - \frac{v^2}{2g} \\ &= 200 \text{ ft} - \frac{(17.57 \frac{\text{ft}}{\text{sec}})^2}{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})} \\ &= 195.2 \text{ ft} \end{aligned}$$

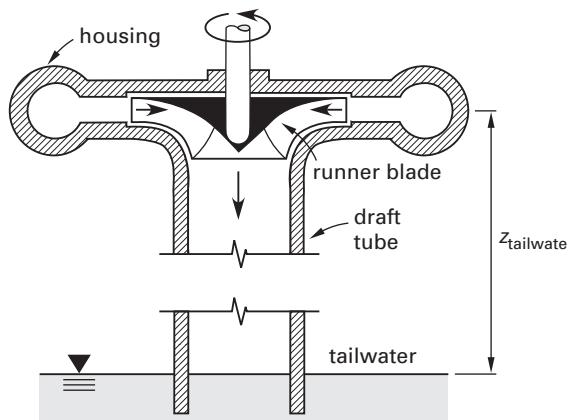

### 31. REACTION TURBINES

*Reaction turbines* (also known as *Francis turbines* or *radial-flow turbines*) are essentially centrifugal pumps operating in reverse. (See Fig. 18.19.) They are used when the total available head is small, typically below 600–800 ft (183–244 m). However, their energy conversion efficiency is higher than that of impulse turbines, typically in the 85–95% range.

In a reaction turbine, water enters the turbine housing with a pressure greater than atmospheric pressure. The water completely surrounds the turbine runner (impeller) and continues through the draft tube. There is no vacuum or air pocket between the turbine and the tailwater.

All of the power, affinity, and similarity relationships used with centrifugal pumps can be used with reaction turbines.

Figure 18.19 Reaction Turbine

#### Example 18.14

A reaction turbine with a draft tube develops 500 hp (brake) when 50 ft<sup>3</sup>/sec water flow through it. Water

enters the turbine at 20 ft/sec with a 100 ft pressure head. The elevation of the turbine above the tailwater level is 10 ft. Disregarding friction, what are the (a) total available head and (b) turbine efficiency?

*Solution*

(a) The available head is the difference between the forebay and tailwater elevations. The tailwater depression is known, but the height of the forebay above the turbine is not known. However, at the turbine entrance, this unknown potential energy has been converted to pressure and velocity head. The total available head (exclusive of friction) is

$$\begin{aligned} h_t &= z_{\text{forebay}} - z_{\text{tailwater}} = h_p + h_v - z_{\text{tailwater}} \\ &= 100 \text{ ft} + \frac{(20 \frac{\text{ft}}{\text{sec}})^2}{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})} - (-10 \text{ ft}) \\ &= 116.2 \text{ ft} \end{aligned}$$

(b) From Table 18.5, the theoretical hydraulic horsepower is

$$\begin{aligned} P_{\text{th}} &= \frac{h_A \dot{V} (\text{SG})}{8.814} = \frac{(116.2 \text{ ft}) \left( 50 \frac{\text{ft}^3}{\text{sec}} \right) (1.0)}{8.814 \frac{\text{ft}^4}{\text{hp}\cdot\text{sec}}} \\ &= 659.2 \text{ hp} \end{aligned}$$

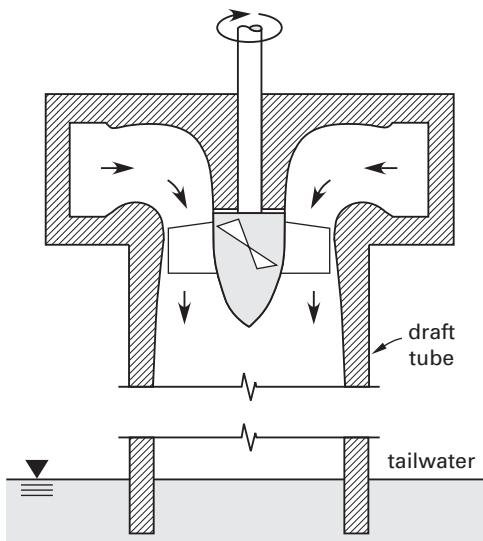

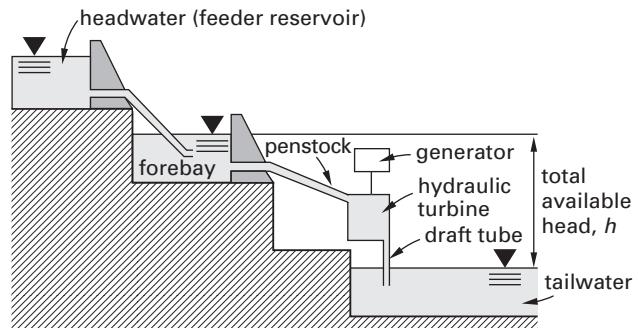

The efficiency of the turbine is

$$\eta = \frac{P_{\text{brake}}}{P_{\text{th}}} = \frac{500 \text{ hp}}{659.2 \text{ hp}} = 0.758 \quad (75.8\%)$$

### 32. TYPES OF REACTION TURBINES

Each of the three types of turbines is associated with a range of specific speeds.

- *Axial-flow reaction turbines* (also known as *propeller turbines*) are used for low heads, high rotational speeds, and large flow rates. (See Fig. 18.20.) These propeller turbines operate with specific speeds in the 70–260 range (266–988 in SI). Their best efficiencies, however, are produced with specific speeds between 120 and 160 (460 and 610 in SI).
- For *mixed-flow reaction turbines*, the specific speed varies from 10 to 90 (38 to 342 in SI). Best efficiencies are found in the 40 to 60 (150 to 230 in SI) range with heads below 600 ft to 800 ft (180 m to 240 m).
- *Radial-flow reaction turbines* have the lowest flow rates and specific speeds but are used when heads are high. These turbines have specific speeds between 1 and 20 (3.8 and 76 in SI).

**Figure 18.20** Axial-Flow Turbine**Figure 18.21** Typical Hydroelectric Plant

### 33. HYDROELECTRIC GENERATING PLANTS

In a typical hydroelectric generating plant using reaction turbines, the turbine is generally housed in a *powerhouse*, with water conducted to the turbine through the *penstock* piping. Water originates in a reservoir, dam, or *forebay* (in the instance where the reservoir is a long distance from the turbine). (See Fig. 18.21.)

After the water passes through the turbine, it is discharged through the draft tube to the receiving reservoir, known as the *tailwater*. The difference between the

elevations of the turbine and the surface of the tailwater is the *tailwater depression*. The *draft tube* is used to keep the turbine up to 15 ft (5 m) above the tailwater surface, while still being able to extract the total available head. If a draft tube is not employed, water may be returned to the tailwater by way of a channel known as the *tail race*. The turbine, draft tube, and all related parts comprise what is known as the *setting*.

When a forebay is not part of the generating plant's design, it will be desirable to provide a *surge chamber* in order to relieve the effects of rapid changes in flow rate. In the case of a sudden power demand, the surge chamber would provide an immediate source of water, without waiting for a contribution from the feeder reservoir. Similarly, in the case of a sudden decrease in discharge through the turbine, the excess water would surge back into the surge chamber.

<i>n</i>	normal
<i>o</i>	channel or culvert barrel
<i>s</i>	spillway
<i>t</i>	total
<i>w</i>	weir

## 1. INTRODUCTION

An *open channel* is a fluid passageway that allows part of the fluid to be exposed to the atmosphere. This type of channel includes natural waterways, canals, culverts, flumes, and pipes flowing under the influence of gravity (as opposed to pressure conduits, which always flow full). A *reach* is a straight section of open channel with uniform shape, depth, slope, and flow quantity.

There are difficulties in evaluating open channel flow. The unlimited geometric cross sections and variations in roughness have contributed to a relatively small number of scientific observations upon which to estimate the required coefficients and exponents. Therefore, the analysis of open channel flow is more empirical and less exact than that of pressure conduit flow. This lack of precision, however, is more than offset by the percentage error in runoff calculations that generally precede the channel calculations.

Flow can be categorized on the basis of the channel material, for example, concrete or metal pipe or earth material. Except for a short discussion of erodible canals in Sec. 19.36, this chapter assumes the channel is non-erodible.

## 2. TYPES OF FLOW

Flow in open channels is almost always turbulent; laminar flow will occur only in very shallow channels or at very low fluid velocities. However, within the turbulent category are many somewhat confusing categories of flow. Flow can be a function of time and location. If the flow quantity (volume per unit of time across an area in flow) is invariant, it is said to be *steady flow*. (Flow that varies with time, such as stream flow during a storm, known as *varied flow*, is not covered in this chapter.) If the flow cross section does not depend on the location along the channel, it is said to be *uniform flow*. Steady flow can also be *nonuniform*, as in the case of a river with a varying cross section or on a steep slope. Furthermore, uniform channel construction does not ensure uniform flow, as will be seen in the case of hydraulic jumps.

Table 19.1 summarizes some of the more common categories and names of steady open channel flow. All of the subcategories are based on variations in depth and flow area with respect to location along the channel.

## 3. MINIMUM VELOCITIES

The minimum permissible velocity in a sewer or other nonerodible channel is the lowest that prevents sedimentation and plant growth. Velocity ranges of 2 ft/sec to 3 ft/sec (0.6 m/s to 0.9 m/s) keep all but the heaviest silts in suspension. 2.5 ft/sec (0.75 m/s) is considered the minimum to prevent plant growth.

**Table 19.1** Categories of Steady Open Channel Flow

subcritical flow ( <i>tranquil flow</i> )
uniform flow
normal flow
nonuniform flow
accelerating flow
decelerating flow (decelerated flow)
critical flow
supercritical flow ( <i>rapid flow, shooting flow</i> )
uniform flow
normal flow
nonuniform flow
accelerating flow
decelerating flow

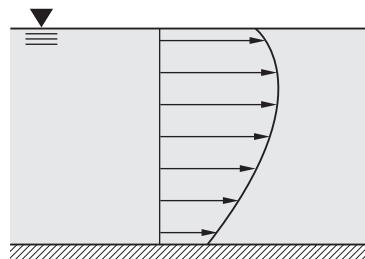

## 4. VELOCITY DISTRIBUTION

Due to the adhesion between the wetted surface of the channel and the water, the velocity will not be uniform across the area in flow. The velocity term used in this chapter is the *mean velocity*. The mean velocity, when multiplied by the flow area, gives the flow quantity.

$$Q = Av \quad 19.1$$

The location of the mean velocity depends on the distribution of velocities in the waterway, which is generally quite complex. The procedure for measuring the velocity of a channel (called *stream gauging*) involves measuring the average channel velocity at multiple locations and depths across the channel width. These sub-average velocities are averaged to give a grand average (mean) flow velocity. (See Fig. 19.1.)

**Figure 19.1** Velocity Distribution in an Open Channel

## 5. PARAMETERS USED IN OPEN CHANNEL FLOW

The *hydraulic radius* is the ratio of the area in flow to the wetted perimeter.<sup>1</sup>

$$R = \frac{A}{P} \quad 19.2$$

<sup>1</sup>The hydraulic radius is also referred to as the *hydraulic mean depth*. However, this name is easily confused with "mean depth" and "hydraulic depth," both of which have different meanings. Therefore, the term "hydraulic mean depth" is not used in this chapter.

**Table 19.2** Hydraulic Parameters of Basic Channel Sections

section	area, $A$	wetted perimeter, $P$	hydraulic radius, $R$
rectangle	$dw$	$2d + w$	$\frac{dw}{w + 2d}$
trapezoid	$(b + \frac{d}{\tan \theta})d$	$b + 2(\frac{d}{\sin \theta})$	$\frac{bd \sin \theta + d^2 \cos \theta}{b \sin \theta + 2d}$
triangle	$\frac{d^2}{\tan \theta}$	$\frac{2d}{\sin \theta}$	$\frac{d \cos \theta}{2}$
circle	$\frac{1}{8}(\theta - \sin \theta)D^2$ [ $\theta$ in radians]	$\frac{1}{2}\theta D$ [ $\theta$ in radians]	$\frac{1}{4}(1 - \frac{\sin \theta}{\theta})D$ [ $\theta$ in radians]

For a circular channel flowing either full or half-full, the hydraulic radius is one-fourth of the *hydraulic diameter*,  $D_h/4$ . The hydraulic radii of other channel shapes are easily calculated from the basic definition. Table 19.2 summarizes parameters for the basic shapes. For very wide channels such as rivers, the hydraulic radius is approximately equal to the depth.

The *hydraulic depth* is the ratio of the area in flow to the width of the channel at the fluid surface.<sup>2</sup>

$$D_h = \frac{A}{T} \quad 19.3$$

The uniform flow *section factor* represents a frequently occurring variable group. The section factor is often evaluated against depth of flow when working with discharge from irregular cross sections.

$$\text{section factor} = AR^{2/3} \quad [\text{general uniform flow}] \quad 19.4$$

$$\text{section factor} = A\sqrt{D_h} \quad [\text{critical flow only}] \quad 19.5$$

The *slope*,  $S$ , is the gradient of the energy line. In general, the slope can be calculated from the Bernoulli

equation as the energy loss per unit length of channel. For small slopes typical of almost all natural waterways, the channel length and horizontal run are essentially identical.

$$S = \frac{dE}{dL} \quad 19.6$$

If the flow is uniform, the slope of the energy line will parallel the water surface and channel bottom, and the *energy gradient* will equal the *geometric slope*,  $S_0$ .

$$S_0 = \frac{\Delta z}{L} \approx S \quad [\text{uniform flow}] \quad 19.7$$

Any open channel performance equation can be written using the geometric slope,  $S_0$ , instead of the hydraulic slope,  $S$ , but only under the condition of uniform flow.

In most problems, the geometric slope is a function of the terrain and is known. However, it may be necessary to calculate the slope that results in some other specific parameter. The slope that produces flow at some normal depth,  $d$ , is called the *normal slope*. The slope that produces flow at some critical depth,  $d_c$ , is called the *critical slope*. Both are determined by solving the Manning equation for slope.

<sup>2</sup>For a rectangular channel,  $D_h = d$ .

## 6. GOVERNING EQUATIONS FOR UNIFORM FLOW

Since water is incompressible, the continuity equation is

$$A_1 v_1 = A_2 v_2 \quad 19.8$$

The most common equation used to calculate the flow velocity in open channels is the 1768 *Chezy equation*.<sup>3</sup>

$$v = C\sqrt{RS} \quad 19.9$$

Various methods for evaluating the *Chezy coefficient*,  $C$ , or "Chezy's C," have been proposed.<sup>4</sup> If the channel is small and very smooth, Chezy's own formula can be used. The friction factor,  $f$ , is dependent on the Reynolds number and can be found in the usual manner from the Moody diagram.

$$C = \sqrt{\frac{8g}{f}} \quad 19.10$$

If the channel is large and the flow is fully turbulent, the friction loss will not depend so much on the Reynolds number as on the channel roughness. The 1888 *Manning formula* is frequently used to evaluate the constant  $C$ .<sup>5</sup> The value of  $C$  depends only on the channel roughness and geometry. (The conversion constant 1.49 in Eq. 19.11(b) is reported as 1.486 by some authorities. 1.486 is the correct SI-to-English conversion, but it is doubtful whether this equation warrants four significant digits.)

$$C = \left(\frac{1}{n}\right)R^{1/6} \quad [\text{SI}] \quad 19.11(a)$$

$$C = \left(\frac{1.49}{n}\right)R^{1/6} \quad [\text{U.S.}] \quad 19.11(b)$$

$n$  is the *Manning roughness coefficient* (*Manning constant*). Typical values of Manning's  $n$  are given in App. 19.A. Judgment is needed in selecting values since tabulated values often differ by as much as 30%. More important to recognize for sewer work is the layer of slime that often coats the sewer walls. Since the slime characteristics can change with location in the sewer, there can be variations in Manning's roughness coefficient along the sewer length.

<sup>3</sup>Pronounced "Shay'-zee." This equation does not appear to be dimensionally consistent. However, the coefficient  $C$  is not a pure number. Rather, it has units of length<sup>1/2</sup>/time (i.e., acceleration<sup>1/2</sup>).

<sup>4</sup>Other methods of evaluating  $C$  include the *Kutter equation* (also known as the *G.K. formula*) and the *Bazin formula*. These methods are interesting from a historical viewpoint, but both have been replaced by the Manning equation.

<sup>5</sup>This equation was originally proposed in 1868 by Gaukler and again in 1881 by Hagen, both working independently. For some reason, the Frenchman Flamant attributed the equation to an Irishman, R. Manning. In Europe and many other places, the Manning equation may be known as the *Strickler equation*.

Combining Eq. 19.9 and Eq. 19.11 produces the *Manning equation*, also known as the *Chezy-Manning equation*.

$$v = \left(\frac{1}{n}\right)R^{2/3}\sqrt{S} \quad [\text{SI}] \quad 19.12(a)$$

$$v = \left(\frac{1.49}{n}\right)R^{2/3}\sqrt{S} \quad [\text{U.S.}] \quad 19.12(b)$$

All of the coefficients and constants in the Manning equation may be combined into the *conveyance*,  $K$ .

$$\begin{aligned} Q &= vA = \left(\frac{1}{n}\right)AR^{2/3}\sqrt{S} \\ &= K\sqrt{S} \end{aligned} \quad [\text{SI}] \quad 19.13(a)$$

$$\begin{aligned} Q &= vA = \left(\frac{1.49}{n}\right)AR^{2/3}\sqrt{S} \\ &= K\sqrt{S} \end{aligned} \quad [\text{U.S.}] \quad 19.13(b)$$

### Example 19.1

A rectangular channel on a 0.002 slope is constructed of finished concrete. The channel is 8 ft (2.4 m) wide. Water flows at a depth of 5 ft (1.5 m). What is the flow rate?

*SI Solution*

The hydraulic radius is

$$\begin{aligned} R &= \frac{A}{P} = \frac{(2.4 \text{ m})(1.5 \text{ m})}{1.5 \text{ m} + 2.4 \text{ m} + 1.5 \text{ m}} \\ &= 0.667 \text{ m} \end{aligned}$$

From App. 19.A, the roughness coefficient for finished concrete is 0.012. The Manning coefficient is determined from Eq. 19.11(a).

$$\begin{aligned} C &= \left(\frac{1}{n}\right)R^{1/6} = \left(\frac{1}{0.012}\right)(0.667 \text{ m})^{1/6} \\ &= 77.9 \end{aligned}$$

The flow rate is

$$\begin{aligned} Q &= vA = C\sqrt{RSA} \\ &= \left(77.9 \frac{\sqrt{\text{m}}}{\text{s}}\right) \sqrt{(0.667 \text{ m})(0.002)}(1.5 \text{ m})(2.4 \text{ m}) \\ &= 10.2 \text{ m}^3/\text{s} \end{aligned}$$

*Customary U.S. Solution*

The hydraulic radius is

$$\begin{aligned} R &= \frac{A}{P} = \frac{(8 \text{ ft})(5 \text{ ft})}{5 \text{ ft} + 8 \text{ ft} + 5 \text{ ft}} \\ &= 2.22 \text{ ft} \end{aligned}$$

From App. 19.A, the roughness coefficient for finished concrete is 0.012. The Manning coefficient is determined from Eq. 19.11(b).

$$\begin{aligned} C &= \left(\frac{1.49}{n}\right) R^{1/6} \\ &= \left(\frac{1.49}{0.012}\right) (2.22 \text{ ft})^{1/6} \\ &= 141.8 \end{aligned}$$

The flow rate is

$$\begin{aligned} Q &= vA = C\sqrt{RSA} \\ &= \left(141.8 \frac{\sqrt{\text{ft}}}{\text{sec}}\right) \sqrt{(2.22 \text{ ft})(0.002)(8 \text{ ft})(5 \text{ ft})} \\ &= 377.9 \text{ ft}^3/\text{sec} \end{aligned}$$

## 7. VARIATIONS IN THE MANNING CONSTANT

The value of  $n$  also depends on the depth of flow, leading to a value ( $n_{\text{full}}$ ) specifically intended for use with full flow. (It is seldom clear from tabulations, such as App. 19.A, whether the values are for full flow or general use.) The variation in  $n$  can be taken into consideration using *Camp's correction*, shown in App. 19.C. However, this degree of sophistication cannot be incorporated into an analysis problem unless a specific value of  $n$  is known for a specific depth of flow.

For most calculations, however,  $n$  is assumed to be constant. The accuracy of other parameters used in open-flow calculations often does not warrant considering the variation of  $n$  with depth, and the choice to use a constant or varying  $n$ -value is left to the engineer.

If it is desired to acknowledge variations in  $n$  with respect to depth, it is expedient to use tables or graphs of hydraulic elements prepared for that purpose. Table 19.3 lists such hydraulic elements under the assumption that  $n$  varies. Appendix 19.C can be used for both varying and constant  $n$ .

**Table 19.3** Circular Channel Ratios (varying  $n$ )

$\frac{d}{D}$	$\frac{Q}{Q_{\text{full}}}$	$\frac{v}{v_{\text{full}}}$
0.1	0.02	0.31
0.2	0.07	0.48
0.3	0.14	0.61
0.4	0.26	0.71
0.5	0.41	0.80
0.6	0.56	0.88
0.7	0.72	0.95
0.8	0.87	1.01
0.9	0.99	1.04
0.95	1.02	1.03
1.00	1.00	1.00

### Example 19.2

2.5 ft<sup>3</sup>/sec (0.07 m<sup>3</sup>/s) of water flow in a 20 in (0.5 m) diameter sewer line ( $n = 0.015$ ,  $S = 0.001$ ). The Manning coefficient,  $n$ , varies with depth. Flow is uniform and steady. What are the velocity and depth?

*SI Solution*

The hydraulic radius is

$$R = \frac{D}{4} = \frac{0.5 \text{ m}}{4} = 0.125 \text{ m}$$

From Eq. 19.12(a),

$$\begin{aligned} v_{\text{full}} &= \left(\frac{1}{n}\right) R^{2/3} \sqrt{S} \\ &= \left(\frac{1}{0.015}\right) (0.125 \text{ m})^{2/3} \sqrt{0.001} \\ &= 0.53 \text{ m/s} \end{aligned}$$

If the pipe was flowing full, it would carry  $Q_{\text{full}}$ .

$$\begin{aligned} Q_{\text{full}} &= v_{\text{full}} A \\ &= \left(0.53 \frac{\text{m}}{\text{s}}\right) \left(\frac{\pi}{4}\right) (0.5 \text{ m})^2 \\ &= 0.10 \text{ m}^3/\text{s} \\ \frac{Q}{Q_{\text{full}}} &= \frac{0.07 \frac{\text{m}^3}{\text{s}}}{0.10 \frac{\text{m}^3}{\text{s}}} = 0.7 \end{aligned}$$

From App. 19.C,  $d/D = 0.68$ , and  $v/v_{\text{full}} = 0.94$ .

$$\begin{aligned} v &= (0.94) \left(0.53 \frac{\text{m}}{\text{s}}\right) = 0.50 \text{ m/s} \\ d &= (0.68)(0.5 \text{ m}) = 0.34 \text{ m} \end{aligned}$$

*Customary U.S. Solution*

The hydraulic radius is

$$R = \frac{D}{4} = \frac{12 \frac{\text{in}}{\text{ft}}}{4} = 0.417 \text{ ft}$$

From Eq. 19.12(b),

$$\begin{aligned} v_{\text{full}} &= \left(\frac{1.49}{n}\right) R^{2/3} \sqrt{S} \\ &= \left(\frac{1.49}{0.015}\right) (0.417 \text{ ft})^{2/3} \sqrt{0.001} \\ &= 1.75 \text{ ft/sec} \end{aligned}$$

If the pipe was flowing full, it would carry  $Q_{\text{full}}$ .

$$\begin{aligned} Q_{\text{full}} &= v_{\text{full}} A \\ &= \left(1.75 \frac{\text{ft}}{\text{sec}}\right) \left(\frac{\pi}{4}\right) \left(\frac{20 \text{ in}}{12 \frac{\text{in}}{\text{ft}}}\right)^2 \\ &= 3.82 \text{ ft}^3/\text{sec} \\ \frac{Q}{Q_{\text{full}}} &= \frac{2.5 \frac{\text{ft}^3}{\text{sec}}}{3.82 \frac{\text{ft}^3}{\text{sec}}} = 0.65 \end{aligned}$$

From App. 19.C,  $d/D = 0.66$ , and  $v/v_{\text{full}} = 0.92$ .

$$\begin{aligned} v &= (0.92) \left(1.75 \frac{\text{ft}}{\text{sec}}\right) = 1.61 \text{ ft/sec} \\ d &= (0.66)(20 \text{ in}) = 13.2 \text{ in} \end{aligned}$$

## 8. HAZEN-WILLIAMS VELOCITY

The empirical Hazen-Williams open channel velocity equation was developed in the early 1920s. It is still occasionally used in the United States for sizing gravity sewers. It is applicable to water flows at reasonably high Reynolds numbers and is based on sound dimensional analysis. However, the constants and exponents were developed experimentally.

The equation uses the Hazen-Williams coefficient,  $C$ , to characterize the roughness of the channel. Since the equation is used only for water within "normal" ambient conditions, the effects of temperature, pressure, and viscosity are disregarded. The primary advantage of this approach is that the coefficient,  $C$ , depends only on the roughness, not on the fluid characteristics. This is also the method's main disadvantage, since professional judgment is required in choosing the value of  $C$ .

$$v = 0.85 CR^{0.63} S_0^{0.54} \quad [\text{SI}] \quad 19.14(a)$$

$$v = 1.318 CR^{0.63} S_0^{0.54} \quad [\text{U.S.}] \quad 19.14(b)$$

## 9. NORMAL DEPTH

When the depth of flow is constant along the length of the channel (i.e., the depth is neither increasing nor decreasing), the flow is said to be *uniform*. The depth of flow in that case is known as the *normal depth*,  $d_n$ . If the normal depth is known, it can be compared with the actual depth of flow to determine if the flow is uniform.<sup>6</sup>

The difficulty with which the normal depth is calculated depends on the cross section of the channel. If the width is very large compared to the depth, the flow cross section will essentially be rectangular and the Manning

equation can be used. (Equation 19.15 assumes that the hydraulic radius equals the normal depth.)

$$d_n = \left(\frac{nQ}{w\sqrt{S}}\right)^{3/5} \quad [w \gg d_n] \quad [\text{SI}] \quad 19.15(a)$$

$$d_n = 0.788 \left(\frac{nQ}{w\sqrt{S}}\right)^{3/5} \quad [w \gg d_n] \quad [\text{U.S.}] \quad 19.15(b)$$

Normal depth in circular channels can be calculated directly only under limited conditions. If the circular channel is flowing full, the normal depth is the inside pipe diameter.

$$D = d_n = 1.548 \left(\frac{nQ}{\sqrt{S}}\right)^{3/8} \quad [\text{full}] \quad [\text{SI}] \quad 19.16(a)$$

$$D = d_n = 1.335 \left(\frac{nQ}{\sqrt{S}}\right)^{3/8} \quad [\text{full}] \quad [\text{U.S.}] \quad 19.16(b)$$

If a circular channel is flowing half full, the normal depth is half of the inside pipe diameter.

$$D = 2d_n = 2.008 \left(\frac{nQ}{\sqrt{S}}\right)^{3/8} \quad [\text{half full}] \quad [\text{SI}] \quad 19.17(a)$$

$$D = 2d_n = 1.731 \left(\frac{nQ}{\sqrt{S}}\right)^{3/8} \quad [\text{half full}] \quad [\text{U.S.}] \quad 19.17(b)$$

For other cases of uniform flow (trapezoidal, triangular, etc.), it is more difficult to determine normal depth. Various researchers have prepared tables and figures to assist in the calculations. For example, Table 19.3 is derived from App. 19.C and can be used for circular channels flowing other than full or half full.

In the absence of tables or figures, trial-and-error solutions are required. The appropriate expressions for the flow area and hydraulic radius are used in the Manning equation. Trial values are used in conjunction with graphical techniques, linear interpolation, or extrapolation to determine the normal depth. The Manning equation is solved for flow rate with various assumed values of  $d_n$ . The calculated value is compared to the actual known flow quantity, and the normal depth is approached iteratively.

For a rectangular channel whose width is small compared to the depth, the hydraulic radius and area in flow are

$$R = \frac{wd_n}{w + 2d_n} \quad 19.18$$

$$A = wd_n \quad 19.19$$

$$Q = \left(\frac{1}{n}\right) wd_n \left(\frac{wd_n}{w + 2d_n}\right)^{2/3} \sqrt{S} \quad [\text{rectangular}]$$

[\text{SI}] 19.20(a)

<sup>6</sup>Normal depth is a term that applies only to uniform flow. The two alternate depths that can occur in nonuniform flow are not normal depths.

$$Q = \left(\frac{1.49}{n}\right) w d_n \left(\frac{w d_n}{w + 2d_n}\right)^{2/3} \sqrt{S} \quad [\text{rectangular}]$$

[U.S.] 19.20(b)

For a trapezoidal channel with exposed surface width  $w$ , base width  $b$ , side length  $s$ , and normal depth of flow  $d_n$ , the hydraulic radius and area in flow are

$$R = \frac{d_n(b + w)}{2(b + 2s)} \quad [\text{trapezoidal}] \quad 19.21$$

$$A = \frac{d_n(w + b)}{2} \quad [\text{trapezoidal}] \quad 19.22$$

For a symmetrical triangular channel with exposed surface width  $w$ , side slope  $1:z$  (vertical:horizontal), and normal depth of flow  $d_n$ , the hydraulic radius and area in flow are

$$R = \frac{zd_n}{2\sqrt{1+z^2}} \quad [\text{triangular}] \quad 19.23$$

$$A = zd_n^2 \quad [\text{triangular}] \quad 19.24$$

## 10. ENERGY AND FRICTION RELATIONSHIPS

Bernoulli's equation is an expression for the conservation of energy along a fluid streamline. The Bernoulli equation can also be written for two points along the bottom of an open channel.

$$\frac{p_1}{\rho g} + \frac{v_1^2}{2g} + z_1 = \frac{p_2}{\rho g} + \frac{v_2^2}{2g} + z_2 + h_f \quad [\text{SI}] \quad 19.25(a)$$

$$\frac{p_1}{\gamma} + \frac{v_1^2}{2g} + z_1 = \frac{p_2}{\gamma} + \frac{v_2^2}{2g} + z_2 + h_f \quad [\text{U.S.}] \quad 19.25(b)$$

However,  $p/\rho g = p/\gamma = d$ .

$$d_1 + \frac{v_1^2}{2g} + z_1 = d_2 + \frac{v_2^2}{2g} + z_2 + h_f \quad 19.26$$

And, since  $d_1 = d_2$  and  $v_1 = v_2$  for uniform flow at the bottom of a channel,

$$h_f = z_1 - z_2 \quad 19.27$$

$$S_0 = \frac{z_1 - z_2}{L} \quad 19.28$$

The channel slope,  $S_0$ , and the hydraulic energy gradient,  $S$ , are numerically the same for uniform flow. Therefore, the total friction loss along a channel is

$$h_f = LS \quad 19.29$$

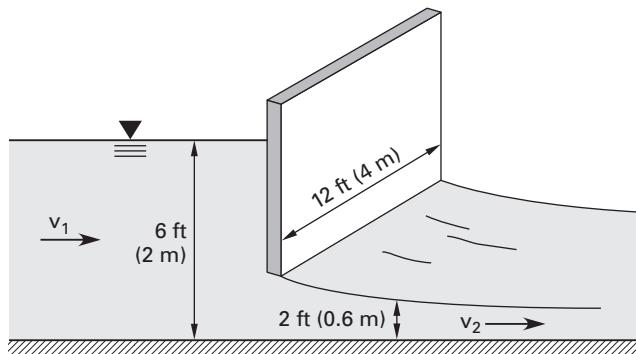

Combining Eq. 19.29 with the Manning equation results in a method for calculating friction loss. (See Eq. 19.12.)

$$h_f = \frac{Ln^2 v^2}{R^{4/3}} \quad [\text{SI}] \quad 19.30(a)$$

$$h_f = \frac{Ln^2 v^2}{2.208 R^{4/3}} \quad [\text{U.S.}] \quad 19.30(b)$$

### Example 19.3

The velocities upstream and downstream,  $v_1$  and  $v_2$ , of a 12 ft (4.0 m) wide sluice gate are both unknown. The upstream and downstream depths are 6 ft (2.0 m) and 2 ft (0.6 m), respectively. Flow is uniform and steady. What is the downstream velocity,  $v_2$ ?

#### SI Solution

Since the channel bottom is essentially level on either side of the gate,  $z_1 = z_2$ . Bernoulli's equation reduces to

$$d_1 + \frac{v_1^2}{2g} = d_2 + \frac{v_2^2}{2g}$$

$$2 \text{ m} + \frac{v_1^2}{2g} = 0.6 \text{ m} + \frac{v_2^2}{2g}$$

$v_1$  and  $v_2$  are related by continuity.

$$Q_1 = Q_2$$

$$A_1 v_1 = A_2 v_2$$

$$(2 \text{ m})(4 \text{ m})v_1 = (0.6 \text{ m})(4 \text{ m})v_2$$

$$v_1 = 0.3v_2$$

Substituting the expression for  $v_1$  into the Bernoulli equation gives

$$2 \text{ m} + \frac{(0.3v_2)^2}{(2)(9.81 \frac{\text{m}}{\text{s}^2})} = 0.6 \text{ m} + \frac{v_2^2}{(2)(9.81 \frac{\text{m}}{\text{s}^2})}$$

$$2 \text{ m} + 0.004587v_2^2 = 0.6 \text{ m} + 0.050968v_2^2$$

$$v_2 = 5.5 \text{ m/s}$$

**Customary U.S. Solution**

Since the channel bottom is essentially level on either side of the gate,  $z_1 = z_2$ . Bernoulli's equation reduces to

$$d_1 + \frac{v_1^2}{2g} = d_2 + \frac{v_2^2}{2g}$$

$$6 \text{ ft} + \frac{v_1^2}{2g} = 2 \text{ ft} + \frac{v_2^2}{2g}$$

$v_1$  and  $v_2$  are related by continuity.

$$Q_1 = Q_2$$

$$A_1 v_1 = A_2 v_2$$

$$(6 \text{ ft})(12 \text{ ft})v_1 = (2 \text{ ft})(12 \text{ ft})v_2$$

$$v_1 = \frac{v_2}{3}$$

Substituting the expression for  $v_1$  into the Bernoulli equation gives

$$6 \text{ ft} + \frac{v_2^2}{(3)^2(2)\left(\frac{\text{ft}}{\text{sec}^2}\right)} = 2 \text{ ft} + \frac{v_2^2}{(2)\left(\frac{\text{ft}}{\text{sec}^2}\right)}$$

$$6 \text{ ft} + 0.00173v_2^2 = 2 \text{ ft} + 0.0155v_2^2$$

$$v_2 = 17.0 \text{ ft/sec}$$

**Example 19.4**

In Ex. 19.1, the open channel experiencing normal flow had the following characteristics:  $S = 0.002$ ,  $n = 0.012$ ,  $v = 9.447 \text{ ft/sec}$  (2.9 m/s), and  $R = 2.22 \text{ ft}$  (0.68 m). What is the energy loss per 1000 ft (100 m)?

**SI Solution**

There are two methods for finding the energy loss. From Eq. 19.29,

$$h_f = LS = (100 \text{ m})(0.002) \\ = 0.2 \text{ m}$$

From Eq. 19.30(a),

$$h_f = \frac{Ln^2v^2}{R^{4/3}} \\ = \frac{(100 \text{ m})(0.012)^2\left(\frac{\text{m}}{\text{s}}\right)^2}{(0.68 \text{ m})^{4/3}} \\ = 0.2 \text{ m}$$

**Customary U.S. Solution**

There are two methods for finding the energy loss. From Eq. 19.29,

$$h_f = LS = (1000 \text{ ft})(0.002) \\ = 2 \text{ ft}$$

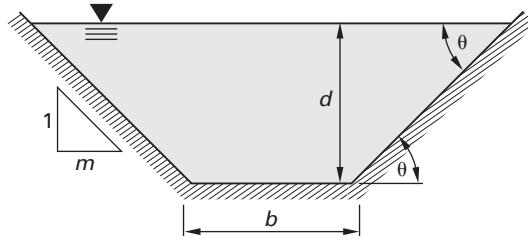

From Eq. 19.30(b),

$$h_f = \frac{Ln^2v^2}{2.208R^{4/3}} \\ = \frac{(1000 \text{ ft})(0.012)^2\left(\frac{\text{ft}}{\text{sec}}\right)^2}{(2.208)(2.22 \text{ ft})^{4/3}} \\ = 2 \text{ ft}$$

## 11. SIZING TRAPEZOIDAL AND RECTANGULAR CHANNELS

Trapezoidal and rectangular cross sections are commonly used for artificial surface channels. The flow through a trapezoidal channel is easily determined from the Manning equation when the cross section is known. However, when the cross section or uniform depth is unknown, a trial-and-error solution is required. (See Fig. 19.2.)

**Figure 19.2** Trapezoidal Cross Section

For such problems involving rectangular and trapezoidal channels, it is common to calculate and plot the *conveyance*,  $K$  (or alternatively, the product  $Kn$ ), against depth. For trapezoidal sections, it is particularly convenient to write the uniform flow,  $Q$ , in terms of a modified conveyance,  $K'$ .  $b$  is the base width of the channel,  $d$  is the depth of flow, and  $m$  is the cotangent of the side slope angle.  $m$  and the ratio  $d/b$  are treated as independent variables. Values of  $K'$  are tabulated in App. 19.F.

$$Q = \frac{K' b^{8/3} \sqrt{S_0}}{n} \quad 19.31$$

$$K' = \left( \frac{\left(1 + m\left(\frac{d}{b}\right)\right)^{5/3}}{\left(1 + 2\left(\frac{d}{b}\right)\sqrt{1 + m^2}\right)^{2/3}} \right) \left(\frac{d}{b}\right)^{5/3} \quad [\text{SI}] \quad 19.32(a)$$

$$K' = \left( \frac{1.49\left(1 + m\left(\frac{d}{b}\right)\right)^{5/3}}{\left(1 + 2\left(\frac{d}{b}\right)\sqrt{1 + m^2}\right)^{2/3}} \right) \left(\frac{d}{b}\right)^{5/3} \quad [\text{U.S.}] \quad 19.32(b)$$

$$m = \cot \theta$$

$$19.33$$

For any fixed value of  $m$ , enough values of  $K'$  are calculated over a reasonable range of the  $d/b$  ratio ( $0.05 < d/b < 0.5$ ) to define a curve. Given specific values of  $Q$ ,  $n$ ,  $S_0$ , and  $b$ , the value of  $K'$  can be calculated from the expression for  $Q$ . The graph is used to determine the ratio  $d/b$ , giving the depth of uniform flow,  $d$ , since  $b$  is known.

When the ratio of  $d/b$  is very small (less than 0.02), it is satisfactory to consider the trapezoidal channel as a wide rectangular channel with area  $A = bd$ .

## 12. MOST EFFICIENT CROSS SECTION

The most efficient open channel cross section will maximize the flow for a given Manning coefficient, slope, and flow area. Accordingly, the Manning equation requires that the hydraulic radius be maximum. For a given flow area, the wetted perimeter will be minimum.

Semicircular cross sections have the smallest wetted perimeter; therefore, the cross section with the highest efficiency is the semicircle. Although such a shape can be constructed with concrete, it cannot be used with earth channels.

The most efficient cross section is also generally assumed to minimize construction cost. This is true only in the most simplified cases, however, since the labor and material costs of excavation and formwork must be considered. Rectangular and trapezoidal channels are much easier to form than semicircular channels. So in this sense the “least efficient” (i.e., most expensive) cross section (i.e., semicircular) is also the “most efficient.” (See Fig. 19.3.)

The most efficient rectangle is one having depth equal to one-half of the width (i.e., is one-half of a square).

$$d = \frac{w}{2} \quad [\text{most efficient rectangle}] \quad 19.34$$

$$A = dw = \frac{w^2}{2} = 2d^2 \quad 19.35$$

$$P = d + w + d = 2w = 4d \quad 19.36$$

$$R = \frac{w}{4} = \frac{d}{2} \quad 19.37$$

The most efficient trapezoidal channel is always one in which the flow depth is twice the hydraulic radius. If the side slope is adjustable, the sides of the most efficient trapezoid should be inclined at  $60^\circ$  from the horizontal. Since the surface width will be equal to twice the sloping side length, the most efficient trapezoidal channel will be half of a regular hexagon (i.e., three adjacent equilateral triangles of side length  $2d/\sqrt{3}$ ). If the side slope

is any other angle, only the  $d = 2R$  criterion is applicable.

$$d = 2R \quad [\text{most efficient trapezoid}] \quad 19.38$$

$$b = \frac{2d}{\sqrt{3}} \quad 19.39$$

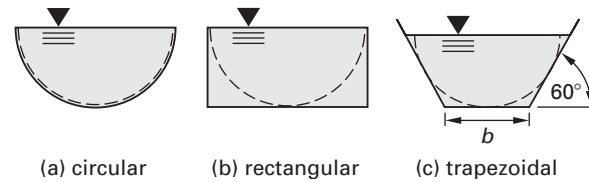

$$A = \sqrt{3}d^2 \quad 19.40$$

$$P = 3b = 2\sqrt{3}d \quad [\text{most efficient trapezoid}] \quad 19.41$$

$$R = \frac{d}{2} \quad 19.42$$

A semicircle with its center at the middle of the water surface can always be inscribed in a cross section with maximum efficiency.

**Figure 19.3** Circles Inscribed in Efficient Channels

### Example 19.5

A rubble masonry open channel is being designed to carry  $500 \text{ ft}^3/\text{sec}$  ( $14 \text{ m}^3/\text{s}$ ) of water on a 0.0001 slope. Using  $n = 0.017$ , find the most efficient dimensions for a rectangular channel.

#### SI Solution

Let the depth and width be  $d$  and  $w$ , respectively. For an efficient rectangle,  $d = w/2$ .

$$A = dw = \left(\frac{w}{2}\right)w = \frac{w^2}{2}$$

$$P = d + w + d = \frac{w}{2} + w + \frac{w}{2} = 2w$$

$$R = \frac{A}{P} = \frac{\frac{w^2}{2}}{2w} = \frac{w}{4}$$

Using Eq. 19.13(a),

$$Q = \left(\frac{1}{n}\right)AR^{2/3}\sqrt{S}$$

$$14 \frac{\text{m}^3}{\text{s}} = \left(\frac{1}{0.017}\right)\left(\frac{w^2}{2}\right)\left(\frac{w}{4}\right)^{2/3} \sqrt{0.0001}$$

$$14 \frac{\text{m}^3}{\text{s}} = 0.1167w^{8/3}$$

$$w = 6.02 \text{ m}$$

$$d = \frac{w}{2} = \frac{6.02 \text{ m}}{2} = 3.01 \text{ m}$$

## Customary U.S. Solution

Let the depth and width be  $d$  and  $w$ , respectively. For an efficient rectangle,  $d = w/2$ .

$$A = dw = \left(\frac{w}{2}\right)w = \frac{w^2}{2}$$

$$P = d + w + d = \frac{w}{2} + w + \frac{w}{2} = 2w$$

$$R = \frac{A}{P} = \frac{\frac{w^2}{2}}{2w} = \frac{w}{4}$$

Using Eq. 19.13(b),

$$Q = \left(\frac{1.49}{n}\right)AR^{2/3}\sqrt{S}$$

$$500 \frac{\text{ft}^3}{\text{sec}} = \left(\frac{1.49}{0.017}\right)\left(\frac{w^2}{2}\right)\left(\frac{w}{4}\right)^{2/3}\sqrt{0.0001}$$

$$500 \frac{\text{ft}^3}{\text{sec}} = 0.1739w^{8/3}$$

$$w = 19.82 \text{ ft}$$

$$d = \frac{w}{2} = \frac{19.82 \text{ ft}}{2} = 9.91 \text{ ft}$$

### 13. ANALYSIS OF NATURAL WATERCOURSES

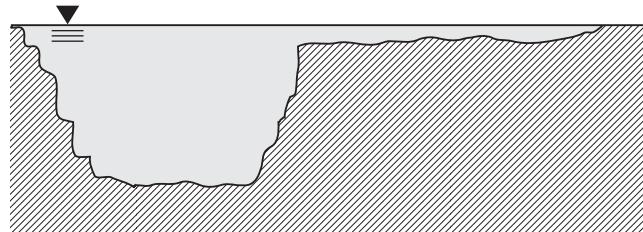

Natural watercourses do not have uniform paths or cross sections. This complicates their analysis considerably. Frequently, analyzing the flow from a river is a matter of making the most logical assumptions. Many evaluations can be solved with a reasonable amount of error.

As was seen in Eq. 19.30, the friction loss (and hence the hydraulic gradient) depends on the square of the roughness coefficient. Therefore, an attempt must be made to evaluate the roughness constant as accurately as possible. If the channel consists of a river with flood plains (as in Fig. 19.4), it should be treated as parallel channels. The flow from each subdivision can be calculated independently and the separate values added to obtain the total flow. (The common interface between adjacent subdivisions is not included in the wetted perimeter.) Alternatively, a composite value of the roughness coefficient,  $n_c$ , can be approximated from the *Horton-Einstein equation* using the individual values of  $n$  and the corresponding wetted perimeters. Equation 19.43 assumes the flow velocities and lengths are the same in all cross sections.

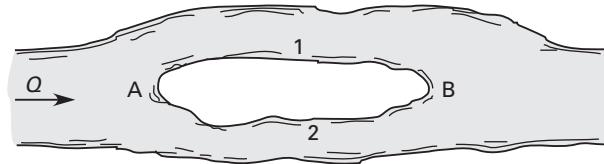

$$n_c = \left( \frac{\sum P_i n_i^{3/2}}{\sum P_i} \right)^{2/3} \quad 19.43$$

If the channel is divided (as in Fig. 19.5) by an island into two channels, some combination of flows will usually be known. For example, if the total flow,  $Q$ , is known,  $Q_1$  and  $Q_2$  may be unknown. If the slope is

**Figure 19.4** River with Flood Plain

**Figure 19.5** Divided Channel

known,  $Q_1$  and  $Q_2$  may be known. Iterative trial-and-error solutions are often required.

Since the elevation drop ( $z_A - z_B$ ) between points A and B is the same regardless of flow path,

$$S_1 = \frac{z_A - z_B}{L_1} \quad 19.44$$

$$S_2 = \frac{z_A - z_B}{L_2} \quad 19.45$$

Once the slopes are known, initial estimates  $Q_1$  and  $Q_2$  can be calculated from Eq. 19.13. The sum of  $Q_1$  and  $Q_2$  will probably not be the same as the given flow quantity,  $Q$ . In that case,  $Q$  should be prorated according to the ratios of  $Q_1$  and  $Q_2$  to  $Q_1 + Q_2$ .

If the lengths  $L_1$  and  $L_2$  are the same or almost so, the Manning equation may be solved for the slope by writing Eq. 19.46.

$$Q = Q_1 + Q_2 = \left( \left( \frac{A_1}{n_1} \right) R_1^{2/3} + \left( \frac{A_2}{n_2} \right) R_2^{2/3} \right) \sqrt{S} \quad [\text{SI}] \quad 19.46(a)$$

$$Q = Q_1 + Q_2 = 1.49 \left( \left( \frac{A_1}{n_1} \right) R_1^{2/3} + \left( \frac{A_2}{n_2} \right) R_2^{2/3} \right) \sqrt{S} \quad [\text{U.S.}] \quad 19.46(b)$$

Equation 19.46 yields only a rough estimate of the flow quantity, as the geometry and roughness of a natural channel changes considerably along its course.

### 14. FLOW MEASUREMENT WITH WEIRS

A *weir* is an obstruction in an open channel over which flow occurs. Although a dam spillway is a specific type of weir, most weirs are intended specifically for flow measurement.

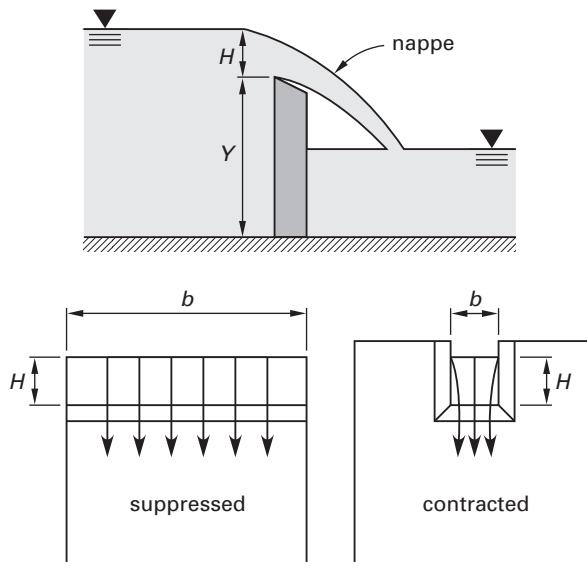

Measurement weirs consist of a vertical flat plate with sharp edges. Because of their construction, they are called *sharp-crested weirs*. Sharp-crested weirs are most frequently rectangular, consisting of a straight, horizontal crest. However, weirs may also have trapezoidal and triangular openings.

For any given width of weir opening (referred to as the *weir length*), the discharge will be a function of the head over the weir. The head (or sometimes surface elevation) can be determined by a standard *staff gauge* mounted adjacent to the weir.

The full channel flow usually goes over the weir. However, it is also possible to divert a small portion of the total flow through a measurement channel. The full channel flow rate can be extrapolated from a knowledge of the split fractions.

If a rectangular weir is constructed with an opening width less than the channel width, the falling liquid sheet (called the *nappe*) decreases in width as it falls. Because of this *contraction* of the nappe, these weirs are known as *contracted weirs*, although it is the nappe that is actually contracted, not the weir. If the opening of the weir extends the full channel width, the weir is known as a *suppressed weir*, since the contractions are suppressed. (See Fig. 19.6.)

**Figure 19.6** Contracted and Suppressed Weirs

The derivation of an expression for the quantity flowing over a weir is dependent on many simplifying assumptions. The basic weir equation (see Eq. 19.47 or Eq. 19.48) is, therefore, an approximate result requiring correction by experimental coefficients.

If it is assumed that the contractions are suppressed, upstream velocity is uniform, flow is laminar over the crest, nappe pressure is zero, the nappe is fully ventilated, and viscosity, turbulence, and surface tension

effects are negligible, then the following equation may be derived from the Bernoulli equation.

$$Q = \frac{2}{3}b\sqrt{2g}\left(\left(H + \frac{v_1^2}{2g}\right)^{3/2} - \left(\frac{v_1^2}{2g}\right)^{3/2}\right) \quad 19.47$$

If the velocity of approach,  $v_1$ , is negligible, then

$$Q = \frac{2}{3}b\sqrt{2g}H^{3/2} \quad 19.48$$

Equation 19.48 must be corrected for all of the assumptions made, primarily for a nonuniform velocity distribution. This is done by introducing an empirical discharge coefficient,  $C_1$ . Equation 19.49 is known as the *Francis weir equation*.

$$Q = \frac{2}{3}C_1 b\sqrt{2g}H^{3/2} \quad 19.49$$

Many investigations have been done to evaluate  $C_1$  analytically. Perhaps the most widely known is the coefficient formula developed by Rehbock.<sup>7</sup>

$$C_1 = \left(0.6035 + 0.0813\left(\frac{H}{Y}\right) + \frac{0.000295}{Y}\right) \times \left(1 + \frac{0.00361}{H}\right)^{3/2} \quad [\text{U.S. only}] \quad 19.50$$

$$C_1 \approx 0.602 + 0.083\left(\frac{H}{Y}\right) \quad [\text{U.S. and SI}] \quad 19.51$$

When  $H/Y < 0.2$ ,  $C_1$  approaches 0.61–0.62. In most cases, a value in this range is adequate. Other constants (i.e.,  $\frac{2}{3}$  and  $\sqrt{2g}$ ) can be taken out of Eq. 19.49. In that case,

$$Q \approx 1.84bh^{3/2} \quad [\text{SI}] \quad 19.52(a)$$

$$Q \approx 3.33bh^{3/2} \quad [\text{U.S.}] \quad 19.52(b)$$

If the contractions are not suppressed (i.e., one or both sides do not extend to the channel sides), then the actual width,  $b$ , should be replaced with the *effective width*. In Eq. 19.53,  $N$  is 1 if one side is contracted and  $N$  is 2 if there are two end contractions.

$$b_{\text{effective}} = b_{\text{actual}} - 0.1NH \quad 19.53$$

A *submerged rectangular weir* requires a more complex analysis because of the difficulty in measuring  $H$  and because the discharge depends on both the upstream

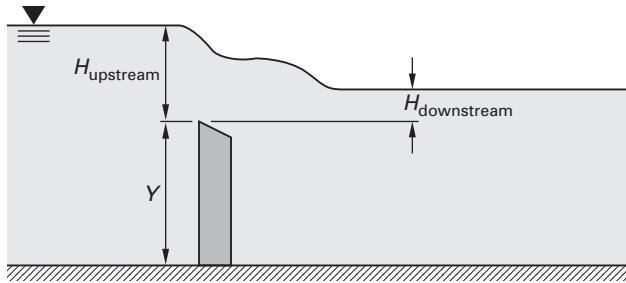

<sup>7</sup>There is much variation in how different investigators calculate the discharge coefficient,  $C_1$ . For ratios of  $H/b$  less than 5,  $C_1 = 0.622$  gives a reasonable value. With the questionable accuracy of some of the other variables used in open channel flow problems, the pursuit of greater accuracy is of dubious value.

and downstream depths. (See Fig. 19.7.) The following equation, however, may be used with little difficulty.

$$Q_{\text{submerged}} = Q_{\text{free flow}} \left( 1 - \left( \frac{H_{\text{downstream}}}{H_{\text{upstream}}} \right)^{3/2} \right)^{0.385} \quad 19.54$$

Equation 19.54 is used by first finding the flow rate,  $Q$ , from Eq. 19.49 and then correcting it with the bracketed quantity.

**Figure 19.7 Submerged Weir**

### Example 19.6

The crest of a sharp-crested, rectangular weir with two contractions is 2.5 ft (1.0 m) high above the channel bottom. The crest is 4 ft (1.6 m) long. A 4 in (100 mm) head exists over the weir. What is the velocity of approach?

*SI Solution*

$$H = \frac{100 \text{ mm}}{1000 \frac{\text{mm}}{\text{m}}} = 0.1 \text{ m}$$

The number of contractions,  $N$ , is 2. From Eq. 19.53, the effective width is

$$\begin{aligned} b_{\text{effective}} &= b_{\text{actual}} - 0.1NH = 1.6 \text{ m} - (0.1)(2)(0.1 \text{ m}) \\ &= 1.58 \text{ m} \end{aligned}$$

From Eq. 19.51, the Rehbock coefficient is

$$\begin{aligned} C_1 &\approx 0.602 + 0.083 \left( \frac{H}{Y} \right) \\ &= 0.602 + (0.083) \left( \frac{0.1}{1} \right) \\ &= 0.61 \end{aligned}$$

From Eq. 19.49, the flow is

$$\begin{aligned} Q &= \frac{2}{3} C_1 b \sqrt{2g} H^{3/2} \\ &= \left( \frac{2}{3} \right) (0.61) (1.58 \text{ m}) \sqrt{(2)(9.81 \frac{\text{m}}{\text{s}^2})(0.10 \text{ m})^{3/2}} \\ &= 0.090 \text{ m}^3/\text{s} \end{aligned}$$

$$\begin{aligned} v &= \frac{Q}{A} = \frac{0.090 \frac{\text{m}^3}{\text{s}}}{(1.6 \text{ m})(1.0 \text{ m} + 0.1 \text{ m})} \\ &= 0.051 \text{ m/s} \end{aligned}$$

*Customary U.S. Solution*

$$H = \frac{4 \text{ in}}{12 \frac{\text{in}}{\text{ft}}} = 0.333 \text{ ft}$$

The number of contractions,  $N$ , is 2. From Eq. 19.53, the effective width is

$$\begin{aligned} b_{\text{effective}} &= b_{\text{actual}} - 0.1NH = 4 \text{ ft} - (0.1)(2)(0.333 \text{ ft}) \\ &= 3.93 \text{ ft} \end{aligned}$$

From Eq. 19.50, the Rehbock coefficient is

$$\begin{aligned} C_1 &= \left( 0.6035 + 0.0813 \left( \frac{H}{Y} \right) + \frac{0.000295}{Y} \right) \\ &\quad \times \left( 1 + \frac{0.00361}{H} \right)^{3/2} \\ &= \left( 0.6035 + (0.0813) \left( \frac{0.333 \text{ ft}}{2.5 \text{ ft}} \right) + \frac{0.000295}{2.5 \text{ ft}} \right) \\ &\quad \times \left( 1 + \frac{0.00361}{0.333 \text{ ft}} \right)^{3/2} \\ &= 0.624 \end{aligned}$$

From Eq. 19.49, the flow is

$$\begin{aligned} Q &= \frac{2}{3} C_1 b \sqrt{2g} H^{3/2} \\ &= \left( \frac{2}{3} \right) (0.624) (3.93 \text{ ft}) \sqrt{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})(0.333 \text{ ft})^{3/2}} \\ &= 2.52 \text{ ft}^3/\text{sec} \end{aligned}$$

$$\begin{aligned} v &= \frac{Q}{A} = \frac{2.52 \frac{\text{ft}^3}{\text{sec}}}{(4 \text{ ft})(2.5 \text{ ft} + 0.333 \text{ ft})} \\ &= 0.222 \text{ ft/sec} \end{aligned}$$

## 15. TRIANGULAR WEIRS

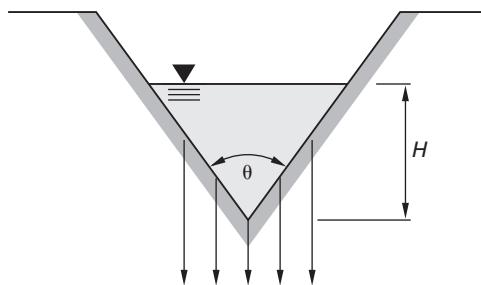

Triangular weirs (*V-notch weirs*) should be used when small flow rates are to be measured. The flow coefficient over a triangular weir depends on the notch angle,  $\theta$ , but generally varies from 0.58 to 0.61. For a  $90^\circ$  weir,  $C_2 \approx 0.593$ . (See Fig. 19.8.)

$$Q = C_2 \left( \frac{8}{15} \tan \frac{\theta}{2} \right) \sqrt{2g} H^{5/2} \quad 19.55$$

$$Q \approx 1.4H^{2.5} \quad [90^\circ \text{ weir}] \quad [\text{SI}] \quad 19.56(a)$$

$$Q \approx 2.5H^{2.5} \quad [90^\circ \text{ weir}] \quad [\text{U.S.}] \quad 19.56(b)$$

Figure 19.8 Triangular Weir

## 16. TRAPEZOIDAL WEIRS

A *trapezoidal weir* is essentially a rectangular weir with a triangular weir on either side. (See Fig. 19.9.) If the angle of the sides from the vertical is approximately  $14^\circ$  (i.e., 4 vertical and 1 horizontal), the weir is known as a *Cipoletti weir*. The discharge from the triangular ends of a Cipoletti weir approximately make up for the contractions that would reduce the flow over a rectangular weir. Therefore, no correction is theoretically necessary. This is not completely accurate, and for this reason, Cipoletti weirs are not used where great accuracy is required. The discharge is

$$Q = \frac{2}{3} C_d b \sqrt{2g} H^{3/2} \quad 19.57$$

The average value of the discharge coefficient is 0.63. The discharge from a Cipoletti weir is found by using Eq. 19.58.

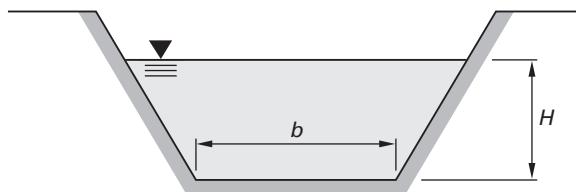

$$Q = 1.86 b H^{3/2} \quad [\text{SI}] \quad 19.58(a)$$

$$Q = 3.367 b H^{3/2} \quad [\text{U.S.}] \quad 19.58(b)$$

## 17. BROAD-CRESTED WEIRS AND SPILLWAYS

Most weirs used for flow measurement are sharp-crested. However, the flow over spillways, broad-crested weirs, and similar features can be calculated using Eq. 19.49 even though flow measurement is not the primary

Figure 19.9 Trapezoidal Weir

function of the feature. (A weir is broad-crested if the weir thickness is greater than half of the head,  $H$ .)

A *dam's spillway (overflow spillway)* is designed for a capacity based on the dam's inflow hydrograph, turbine capacity, and storage capacity. Spillways frequently have a cross section known as an *ogee*, which closely approximates the underside of a nappe from a sharp-crested weir. This cross section minimizes the cavitation that is likely to occur if the water surface breaks contact with the spillway due to upstream heads that are higher than designed for.<sup>8</sup>

Discharge from an overflow spillway is derived in the same manner as for a weir. Equation 19.59 can be used for broad-crested weirs ( $C_1 = 0.5\text{--}0.57$ ) and ogee spillways ( $C_1 = 0.60\text{--}0.75$ ).

$$Q = \frac{2}{3} C_1 b \sqrt{2g} H^{3/2} \quad 19.59$$

The *Horton equation* for broad-crested weirs combines all of the coefficients into a spillway (weir) coefficient and adds the velocity of approach to the upstream head. (See Eq. 19.60.) The *Horton coefficient*,  $C_s$ , is specific to the Horton equation. ( $C_s$  and  $C_1$  differ by a factor of about 5 and cannot easily be mistaken for each other.)

$$Q = C_s b \left( H + \frac{V^2}{2g} \right)^{3/2} \quad 19.60$$

If the velocity of approach is insignificant, the discharge is found using Eq. 19.61.

$$Q = C_s b H^{3/2} \quad 19.61$$

$C_s$  is a *spillway coefficient*, which varies from about  $3.3 \text{ ft}^{1/2}/\text{sec}$  to  $3.98 \text{ ft}^{1/2}/\text{sec}$  ( $1.8 \text{ m}^{1/2}/\text{s}$  to  $2.2 \text{ m}^{1/2}/\text{s}$ ) for ogee spillways.  $3.97 \text{ ft}^{1/2}/\text{sec}$  ( $2.2 \text{ m}^{1/2}/\text{s}$ ) is frequently used for first approximations. For broad-crested weirs,  $C_s$  varies between  $2.63 \text{ ft}^{1/2}/\text{sec}$  and  $3.33 \text{ ft}^{1/2}/\text{sec}$  ( $1.45 \text{ m}^{1/2}/\text{s}$  and  $1.84 \text{ m}^{1/2}/\text{s}$ ). (Use  $3.33 \text{ ft}^{1/2}/\text{sec}$  ( $1.84 \text{ m}^{1/2}/\text{s}$ ) for initial estimates.)  $C_s$  increases as the upstream design head above the spillway top,  $H$ , increases, and the larger values apply to the higher heads.

Broad-crested weirs and spillways can be calibrated to obtain greater accuracy in predicting flow rates.

<sup>8</sup>Cavitation and separation will not normally occur as long as the actual head,  $H$ , is less than twice the design value. The shape of the ogee spillway will be a function of the design head.

Scour protection is usually needed at the toe of a spillway to protect the area exposed to a hydraulic jump. This protection usually takes the form of an extended horizontal or sloping apron. Other measures, however, are needed if the tailwater exhibits large variations in depth.

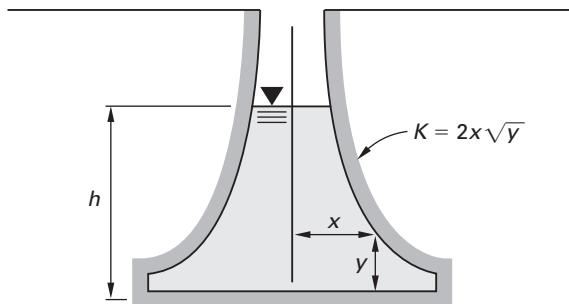

## 18. PROPORTIONAL WEIRS

The *proportional weir* (*Sutro weir*) is used in water level control because it demonstrates a linear relationship between  $Q$  and  $H$ . Figure 19.10 illustrates a proportional weir whose sides are hyperbolic in shape.

$$Q = C_d K \left( \frac{\pi}{2} \right) \sqrt{2gH} \quad 19.62$$

$$K = 2x\sqrt{y} \quad 19.63$$

**Figure 19.10** Proportional Weir

## 19. FLOW MEASUREMENT WITH PARSHALL FLUMES

The Parshall flume is widely used for measuring open channel wastewater flows. It performs well when head losses must be kept to a minimum and when there are high amounts of suspended solids. (See Fig. 19.11.)

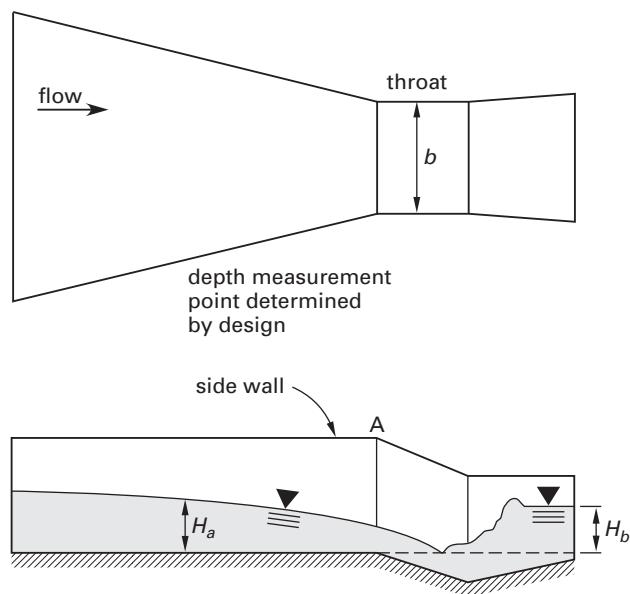

The Parshall flume is constructed with a converging upstream section, a throat, and a diverging downstream section. The walls of the flume are vertical, but the floor of the throat section drops. The length, width, and height of the flume are essentially predefined by the anticipated flow rate.<sup>9</sup>

The throat geometry in a Parshall flume has been designed to force the occurrence of critical flow (described in Sec. 19.25) at that point. Following the critical section is a short length of supercritical flow followed by a hydraulic jump. (See Sec. 19.33.) This design eliminates any dead water region where debris and silt can accumulate (as are common with flat-topped weirs).

The discharge relationship for a Parshall flume is given for submergence ratios of  $H_b/H_a$  up to 0.7. Above 0.7,

<sup>9</sup>This chapter does not attempt to design the Parshall flume, only to predict flow rates through its use.

**Figure 19.11** Parshall Flume

the true discharge is less than predicted by Eq. 19.64. Values of  $K$  are given in Table 19.4, although using a value of 4.0 is accurate for most purposes.

$$Q = K b H_a^n \quad 19.64$$

$$n = 1.522 b^{0.026} \quad 19.65$$

Above a certain tailwater height, the Parshall flume no longer operates in the *free-flow mode*. Rather, it operates in a *submerged mode*. A very high tailwater reduces the flow rate through the flume. Equation 19.64 predicts the flow rate with reasonable accuracy, however, even for 50–80% submergence (calculated as  $H_b/H_a$ ). For large submergence, the tailwater height must be known and a different analysis method must be used.

**Table 19.4** Parshall Flume  $K$ -Values

$b$ (ft (m))	$K$
0.25 (0.076)	3.97
0.50 (0.15)	4.12
0.75 (0.229)	4.09
1.0 (0.305)	4.00
1.5 (0.46)	4.00
2.0 (0.61)	4.00
3.0 (0.92)	4.00
4.0 (1.22)	4.00

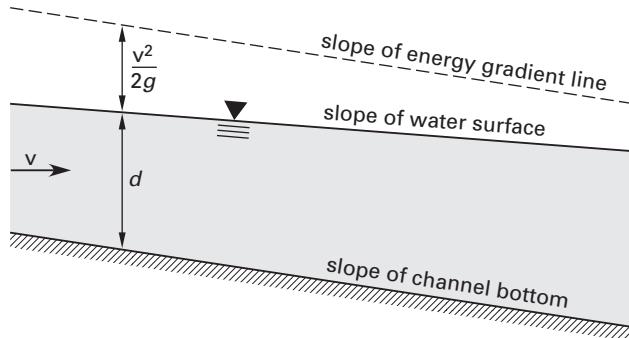

(Multiply ft by 0.3048 to obtain m.)

## 20. UNIFORM AND NONUNIFORM STEADY FLOW

Steady flow is constant-volume flow. However, the flow may be uniform or nonuniform (varied) in depth. There may be significant variations over long and short distances without any change in the flow rate.

Figure 19.12 illustrates the three definitions of “slope” existing for open channel flow. These three slopes are the slope of the channel bottom, the slope of the water surface, and the slope of the energy gradient line.

**Figure 19.12** Slopes Used in Open Channel Flow

Under conditions of uniform flow, all of these three slopes are equal since the flow quantity and flow depth are constant along the length of flow.<sup>10</sup> With nonuniform flow, however, the flow velocity and depth vary along the length of channel and the three slopes are not necessarily equal.

If water is introduced down a path with a steep slope (as after flowing over a spillway), the effect of gravity will cause the velocity to increase. As the velocity increases, the depth decreases in accordance with the continuity of flow equation. The downward velocity is opposed by friction. Because the gravitational force is constant but friction varies with the square of velocity, these two forces eventually become equal. When equal, the velocity stops increasing, the depth stops decreasing, and the flow becomes uniform. Until they become equal, however, the flow is nonuniform (varied).

## 21. SPECIFIC ENERGY

The total head possessed by a fluid is given by the Bernoulli equation.

$$E_t = \frac{p}{\rho g} + \frac{v^2}{2g} + z \quad [\text{SI}] \quad 19.66(a)$$

$$E_t = \frac{p}{\gamma} + \frac{v^2}{2g} + z \quad [\text{U.S.}] \quad 19.66(b)$$

*Specific energy*,  $E$ , is defined as the total head with respect to the channel bottom. In this case,  $z = 0$  and  $p/\gamma = d$ .

$$E = d + \frac{v^2}{2g} \quad 19.67$$

<sup>10</sup>As a simplification, this chapter deals only with channels of constant width. If the width is varied, changes in flow depth may not coincide with changes in flow quantity.

Equation 19.67 is not meant to imply that the potential energy is an unimportant factor in open channel flow problems. The concept of specific energy is used for convenience only, and it should be clear that the Bernoulli equation is still the valid energy conservation equation.

In uniform flow, total head also decreases due to the frictional effects, but specific energy is constant. In non-uniform flow, total head also decreases, but specific energy may increase or decrease.

Since  $v = Q/A$ , Eq. 19.67 can be written as

$$E = d + \frac{Q^2}{2gA^2} \quad [\text{general case}] \quad 19.68$$

For a rectangular channel, the velocity can be written in terms of the width and flow depth.

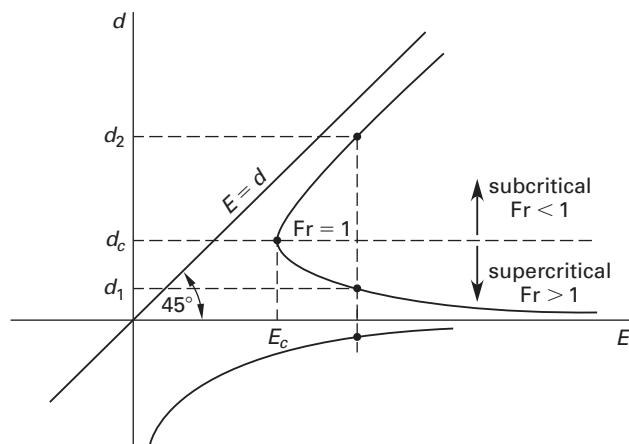

$$v = \frac{Q}{A} = \frac{Q}{wd} \quad 19.69$$

The specific energy equation for a rectangular channel is given by Eq. 19.70 and shown in Fig. 19.13.

$$E = d + \frac{Q^2}{2g(wd)^2} \quad [\text{rectangular}] \quad 19.70$$

Specific energy can be used to differentiate between flow regimes. Figure 19.13 illustrates how specific energy is affected by depth, and accordingly, how specific energy relates to critical depth (described in Sec. 19.25) and the Froude number (described in Sec. 19.27).

**Figure 19.13** Specific Energy Diagram

## 22. SPECIFIC FORCE

The *specific force* of a general channel section is the total force per unit weight acting on the water. Equivalently, specific force is the total force that a submerged object would experience. In Eq. 19.71,  $\bar{d}$  is the distance

from the free surface to the centroid of the flowing area cross section,  $A$ .

$$\frac{F}{g\rho} = \frac{Q^2}{gA} + \bar{d}A \quad [\text{SI}] \quad 19.71(a)$$

$$\frac{F}{\gamma} = \frac{Q^2}{gA} + \bar{d}A \quad [\text{U.S.}] \quad 19.71(b)$$

The first term in Eq. 19.71 represents the momentum flow through the channel per unit time and per unit mass of water. The second term is the pressure force per unit mass of water. Graphs of specific force and specific energy are similar in appearance and predict equivalent results for the critical and alternate depths. (See Sec. 19.24.)

### 23. CHANNEL TRANSITIONS

Sudden changes in channel width or bottom elevation are known as *channel transitions*. (Contractions in width are not covered in this chapter.) For sudden vertical steps in channel bottom, the Bernoulli equation, written in terms of the specific energy, is used to predict the flow behavior (i.e., the depth).

$$E_1 + z_1 = E_2 + z_2 \quad 19.72$$

$$E_1 - E_2 = z_2 - z_1 \quad 19.73$$

The maximum possible change in bottom elevation without affecting the energy equality occurs when the depth of flow over the step is equal to the critical depth ( $d_2$  equals  $d_c$ ). (See Sec. 19.25.)

### 24. ALTERNATE DEPTHS

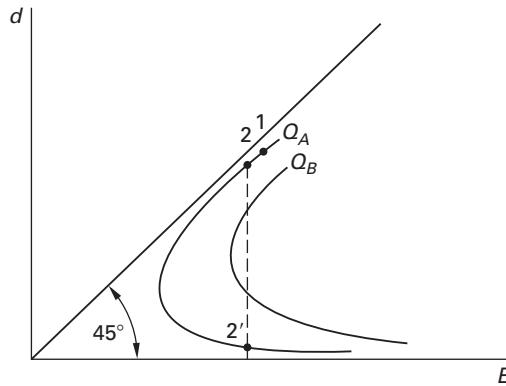

Since the area depends on the depth, fixing the channel shape and slope and assuming a depth will determine the flow rate,  $Q$ , as well as the specific energy. Since Eq. 19.70 is a cubic equation, there are three values of depth of flow,  $d$ , that will satisfy it. One of them is negative, as Fig. 19.13 shows. Since depth cannot be negative, that value can be discarded. The two remaining values are known as *alternate depths*.

For a given flow rate, the two alternate depths have the same energy. One represents a high velocity with low depth; the other represents a low velocity with high depth. The former is called *supercritical (rapid) flow*; the latter is called *subcritical (tranquil) flow*.

The Bernoulli equation cannot predict which of the two alternate depths will occur for any given flow quantity. The concept of *accessibility* is required to evaluate the two depths. Specifically, the upper and lower limbs of the energy curve are not accessible from each other unless there is a local restriction in the flow.

Energy curves can be drawn for different flow quantities, as shown in Fig. 19.14 for flow quantities  $Q_A$  and  $Q_B$ . Suppose that flow is initially at point 1. Since the flow is on the upper limb, the flow is initially subcritical. If there is a step up in the channel bottom, Eq. 19.73 predicts that the specific energy will decrease.

**Figure 19.14** Specific Energy Curve Families

However, the flow cannot arrive at point  $2'$  without the flow quantity changing (i.e., going through a specific energy curve for a different flow quantity). Therefore, point  $2'$  is not accessible from point 1 without going through point 2 first.<sup>11</sup>

If the flow is well up on the top limb of the specific energy curve (as it is in Ex. 19.7), the water level will drop only slightly. Since the upper limb is asymptotic to a  $45^\circ$  diagonal line, any change in specific energy will result in almost the same change in depth.<sup>12</sup> Therefore, the surface level will remain almost the same.

$$\Delta d \approx \Delta E \quad [\text{fully subcritical}] \quad 19.74$$

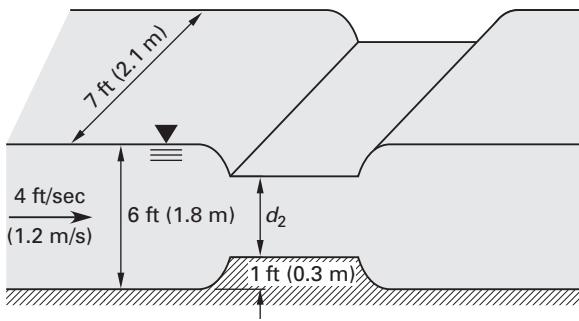

However, if the initial point on the limb is close to the critical point (i.e., the nose of the curve), then a small change in the specific energy (such as might be caused by a small variation in the channel floor) will cause a large change in depth. That is why severe turbulence commonly occurs near points of critical flow.

#### Example 19.7

4 ft/sec (1.2 m/s) of water flow in a 7 ft (2.1 m) wide, 6 ft (1.8 m) deep open channel. The flow encounters a 1.0 ft (0.3 m) step in the channel bottom. What is the depth of flow above the step?

<sup>11</sup>Actually, specific energy curves are typically plotted for flow per unit width,  $q = Q/w$ . If that is the case, a jump from one limb to the other could take place if the width were allowed to change as well as depth.

<sup>12</sup>A rise in the channel bottom does not always produce a drop in the water surface. Only if the flow is initially subcritical will the water surface drop upon encountering a step. The water surface will rise if the flow is initially supercritical.

**SI Solution**

The initial specific energy is found from Eq. 19.67.

$$\begin{aligned} E_1 &= d + \frac{v^2}{2g} \\ &= 1.8 \text{ m} + \frac{(1.2 \frac{\text{m}}{\text{s}})^2}{(2)(9.81 \frac{\text{m}}{\text{s}^2})} \\ &= 1.87 \text{ m} \end{aligned}$$

From Eq. 19.73, the specific energy above the step is

$$\begin{aligned} E_2 &= E_1 + z_1 - z_2 \\ &= 1.87 \text{ m} + 0 - 0.3 \text{ m} \\ &= 1.57 \text{ m} \end{aligned}$$

The quantity flowing is

$$\begin{aligned} Q &= Av \\ &= (2.1 \text{ m})(1.8 \text{ m})\left(1.2 \frac{\text{m}}{\text{s}}\right) \\ &= 4.54 \text{ m}^3/\text{s} \end{aligned}$$

Substituting  $Q$  into Eq. 19.70 gives

$$\begin{aligned} E &= d + \frac{Q^2}{2g(wd)^2} \\ 1.57 \text{ m} &= d_2 + \frac{\left(4.54 \frac{\text{m}^3}{\text{s}}\right)^2}{(2)(9.81 \frac{\text{m}}{\text{s}^2})(2.1 \text{ m})^2 d_2^2} \end{aligned}$$

By trial and error or a calculator's equation solver, the alternate depths are  $d_2 = 0.46 \text{ m}, 1.46 \text{ m}$ .

Since the 0.46 m depth is not accessible from the initial depth of 1.8 m, the depth over the step is 1.5 m. The drop in the water level is

$$1.8 \text{ m} - (1.46 \text{ m} + 0.3 \text{ m}) = 0.04 \text{ m}$$

**Customary U.S. Solution**

The initial specific energy is found from Eq. 19.67.

$$\begin{aligned} E_1 &= d + \frac{v^2}{2g} \\ &= 6 \text{ ft} + \frac{\left(4 \frac{\text{ft}}{\text{sec}}\right)^2}{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})} \\ &= 6.25 \text{ ft} \end{aligned}$$

From Eq. 19.73, the specific energy over the step is

$$\begin{aligned} E_2 &= E_1 + z_1 - z_2 = 6.25 \text{ ft} + 0 - 1 \text{ ft} \\ &= 5.25 \text{ ft} \end{aligned}$$

The quantity flowing is

$$\begin{aligned} Q &= Av = (7 \text{ ft})(6 \text{ ft})\left(4 \frac{\text{ft}}{\text{sec}}\right) \\ &= 168 \text{ ft}^3/\text{sec} \end{aligned}$$

Substituting  $Q$  into Eq. 19.70 gives

$$\begin{aligned} E &= d + \frac{Q^2}{2g(wd)^2} \\ 5.25 \text{ ft} &= d_2 + \frac{\left(168 \frac{\text{ft}^3}{\text{sec}}\right)^2}{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})(7 \text{ ft})^2 d_2^2} \end{aligned}$$

By trial and error or a calculator's equation solver, the alternate depths are  $d_2 = 1.6 \text{ ft}, 4.9 \text{ ft}$ .

Since the 1.6 ft depth is not accessible from the initial depth of 6 ft, the depth over the step is 4.9 ft. The drop in the water level is

$$6 \text{ ft} - (4.9 \text{ ft} + 1 \text{ ft}) = 0.1 \text{ ft}$$

## 25. CRITICAL FLOW AND CRITICAL DEPTH IN RECTANGULAR CHANNELS

There is one depth, known as the *critical depth*, that minimizes the energy of flow. (The depth is not minimized, however.) The critical depth for a given flow depends on the shape of the channel.

For a rectangular channel, if Eq. 19.70 is differentiated with respect to depth in order to minimize the specific energy, Eq. 19.75 results.

$$d_c^3 = \frac{Q^2}{gw^2} \quad [\text{rectangular}] \quad 19.75$$

Geometrical and analytical methods can be used to correlate the critical depth and the minimum specific energy.

$$d_c = \frac{2}{3}E_c \quad 19.76$$

For a rectangular channel,  $Q = d_c w v_c$ . Substituting this into Eq. 19.75 produces an equation for the *critical velocity*.

$$v_c = \sqrt{gd_c} \quad 19.77$$

The expression for critical velocity also coincides with the expression for the velocity of a low-amplitude *surface wave (surge wave)* moving in a liquid of depth  $d_c$ . Since surface disturbances are transmitted as ripples upstream (and downstream) at velocity  $v_c$ , it is apparent that a surge wave will be stationary in a channel moving at the critical velocity. Such motionless waves are known as *standing waves*.

If the flow velocity is less than the surge wave velocity (for the actual depth), then a ripple can make its way upstream. If the flow velocity exceeds the surge wave velocity, the ripple will be swept downstream.

### Example 19.8

500 ft<sup>3</sup>/sec (14 m<sup>3</sup>/s) of water flow in a 20 ft (6 m) wide rectangular channel. What are the (a) critical depth and (b) critical velocity?

*SI Solution*

(a) From Eq. 19.75, the critical depth is

$$\begin{aligned} d_c^3 &= \frac{Q^2}{gw^2} \\ &= \frac{\left(14 \frac{\text{m}^3}{\text{s}}\right)^2}{\left(9.81 \frac{\text{m}}{\text{s}^2}\right)(6 \text{ m})^2} \\ d_c &= 0.822 \text{ m} \end{aligned}$$

(b) From Eq. 19.77, the critical velocity is

$$\begin{aligned} v_c &= \sqrt{gd_c} \\ &= \sqrt{\left(9.81 \frac{\text{m}}{\text{s}^2}\right)(0.822 \text{ m})} \\ &= 2.84 \text{ m/s} \end{aligned}$$

*Customary U.S. Solution*

(a) From Eq. 19.75, the critical depth is

$$\begin{aligned} d_c^3 &= \frac{Q^2}{gw^2} \\ &= \frac{\left(500 \frac{\text{ft}^3}{\text{sec}}\right)^2}{\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)(20 \text{ ft})^2} \\ d_c &= 2.687 \text{ ft} \end{aligned}$$

(b) From Eq. 19.77, the critical velocity is

$$\begin{aligned} v_c &= \sqrt{gd_c} = \sqrt{\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)(2.687 \text{ ft})} \\ &= 9.30 \text{ ft/sec} \end{aligned}$$

## 26. CRITICAL FLOW AND CRITICAL DEPTH IN NONRECTANGULAR CHANNELS

For nonrectangular shapes (including trapezoidal channels), the critical depth can be found by trial and error from the following equation in which  $T$  is the surface width. To use Eq. 19.78, assume trial values of the critical depth, use them to calculate dependent quantities in the equation, and then verify the equality.

$$\frac{Q^2}{g} = \frac{A^3}{T} \quad [\text{nonrectangular}] \quad 19.78$$

Equation 19.78 is particularly difficult to use with circular channels. Appendix 19.D is a convenient method of determining critical depth in circular channels.

## 27. FROUDE NUMBER

The dimensionless *Froude number*,  $Fr$ , is a convenient index of the flow regime. It can be used to determine whether the flow is subcritical or supercritical.  $L$  is the *characteristic length*, also referred to as the *characteristic (length) scale*, hydraulic depth, mean hydraulic depth, and others, depending on the channel configuration.  $d$  is the depth corresponding to velocity  $v$ . For circular channels flowing half full,  $L = \pi D/8$ . For a rectangular channel,  $L = d$ . For trapezoidal and semi-circular channels, and in general,  $L$  is the area in flow divided by the top width,  $T$ .

$$Fr = \frac{v}{\sqrt{gL}} \quad 19.79$$

When the Froude number is less than one, the flow is subcritical (i.e., the depth of flow is greater than the critical depth) and the velocity is less than the critical velocity.

For convenience, the Froude number can be written in terms of the flow rate per average unit width.

$$Fr = \frac{Q}{\frac{b}{\sqrt{gd^3}}} \quad [\text{rectangular}] \quad 19.80$$

$$Fr = \frac{\frac{Q}{b_{\text{ave}}}}{\sqrt{g\left(\frac{A}{b_{\text{ave}}}\right)^3}} \quad [\text{nonrectangular}] \quad 19.81$$

When the Froude number is greater than one, the flow is supercritical. The depth is less than critical depth, and the flow velocity is greater than the critical velocity.

When the Froude number is equal to one, the flow is critical.<sup>13</sup>

The Froude number has another form. Dimensional analysis determines it to be  $v^2/gL$ , a form that is also used in analyzing similarity of models. Whether the derived form or the square root form is used can sometimes be determined by observing the form of the intended application. If the Froude number is squared (as it is in Eq. 19.82), then the square root form is probably intended. For open channel flow, the Froude number is always the square root of the derived form.

## 28. PREDICTING OPEN CHANNEL FLOW BEHAVIOR

Upon encountering a variation in the channel bottom, the behavior of an open channel flow is dependent on whether the flow is initially subcritical or supercritical. Open channel flow is governed by Eq. 19.82 in which the Froude number is the primary independent variable.

$$\frac{dd}{dx}(1 - Fr^2) + \frac{dz}{dx} = 0 \quad 19.82$$

The quantity  $dd/dx$  is the slope of the surface (i.e., it is the derivative of the depth with respect to the channel length). The quantity  $dz/dx$  is the slope of the channel bottom.

For an upward step,  $dz/dx > 0$ . If the flow is initially subcritical (i.e.,  $Fr < 1$ ), then Eq. 19.82 requires that  $dd/dx < 0$ , a drop in depth.

This logic can be repeated for other combinations of the terms. Table 19.5 lists the various behaviors of open channel flow surface levels based on Eq. 19.82.

**Table 19.5** Surface Level Change Behavior

initial flow	step up	step down
subcritical	surface drops	surface rises
supercritical	surface rises	surface drops

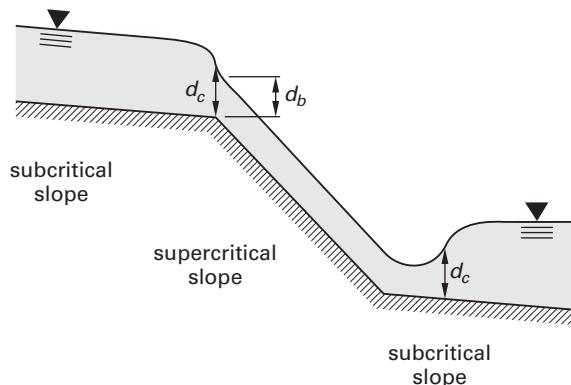

<sup>13</sup>The similarity of the Froude number to the Mach number used to classify gas flows is more than coincidental. Both bodies of knowledge employ parallel concepts.

If  $dz/dx = 0$  (i.e., a horizontal slope), then either the depth must be constant or the Froude number must be unity. The former case is obvious. The latter case predicts critical flow. Such critical flow actually occurs where the slope is horizontal over broad-crested weirs and at the top of a rounded spillway. Since broad-crested weirs and spillways produce critical flow, they represent a class of controls on flow.

## 29. OCCURRENCES OF CRITICAL FLOW

The critical depth not only minimizes the energy of flow, but also maximizes the quantity flowing for a given cross section and slope. Critical flow is generally quite turbulent because of the large changes in energy that occur with small changes in elevation and depth. Critical depth flow is often characterized by successive water surface undulations over a very short stretch of channel. (See Fig. 19.15.)

**Figure 19.15** Occurrence of Critical Depth

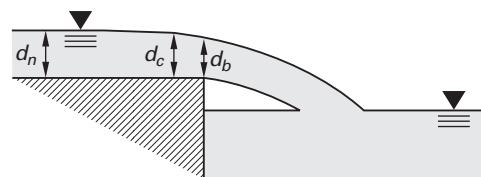

For any given discharge and cross section, there is a unique slope that will produce and maintain flow at critical depth. Once  $d_c$  is known, this critical slope can be found from the Manning equation. In all of the instances of critical depth, Eq. 19.77 can be used to calculate the actual velocity.

Critical depth occurs at free outfall from a channel of mild slope. The occurrence is at the point of curvature inversion, which is just upstream from the brink. (See Fig. 19.16.) For mild slopes, the *brink depth* is approximately

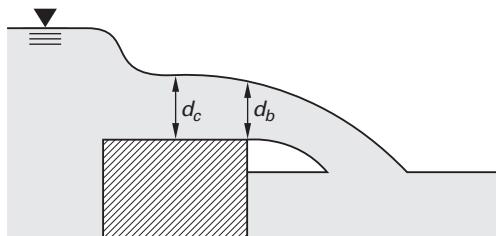

$$d_b = 0.715d_c \quad 19.83$$

**Figure 19.16** Free Outfall

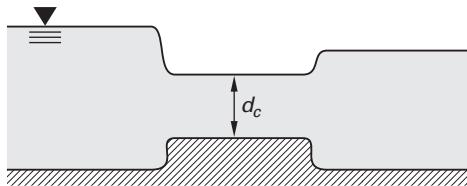

Critical flow can occur across a broad-crested weir, as shown in Fig. 19.17.<sup>14</sup> With no obstruction to hold the water, it falls from the normal depth to the critical depth, but it can fall no more than that because there is no source to increase the specific energy (to increase the velocity). This is not a contradiction of the previous free outfall case where the brink depth is less than the critical depth. The flow curvatures in free outfall are a result of the constant gravitational acceleration.

**Figure 19.17** Broad-Crested Weir

Critical depth can also occur when a channel bottom has been raised sufficiently to choke the flow. A raised channel bottom is essentially a broad-crested weir. (See Fig. 19.18.)

**Figure 19.18** Raised Channel Bottom with Choked Flow

### Example 19.9

At a particular point in an open rectangular channel ( $n = 0.013$ ,  $S = 0.002$ , and  $w = 10 \text{ ft}$  ( $3 \text{ m}$ )), the flow is  $250 \text{ ft}^3/\text{sec}$  ( $7 \text{ m}^3/\text{s}$ ) and the depth is  $4.2 \text{ ft}$  ( $1.3 \text{ m}$ ).

- Is the flow tranquil, critical, or rapid?
- What is the normal depth?
- If the channel ends in a free outfall, what is the brink depth?

### SI Solution

- From Eq. 19.75, the critical depth is

$$\begin{aligned} d_c &= \left( \frac{Q^2}{gw^2} \right)^{1/3} \\ &= \left( \frac{\left( 7 \frac{\text{m}^3}{\text{s}} \right)^2}{(3 \text{ m})^2 (9.81 \frac{\text{m}}{\text{s}^2})} \right)^{1/3} \\ &= 0.82 \text{ m} \end{aligned}$$

Since the actual depth exceeds the critical depth, the flow is tranquil.

- From Eq. 19.13,

$$Q = \left( \frac{1}{n} \right) AR^{2/3} \sqrt{S}$$

$$R = \frac{A}{P} = \frac{d_n(3 \text{ m})}{2d_n + 3 \text{ m}}$$

Substitute the expression for  $R$  into Eq. 19.13 and solve for  $d_n$ .

$$7 \frac{\text{m}^3}{\text{s}} = \left( \frac{1}{0.013} \right) d_n(3 \text{ m}) \left( \frac{d_n(3 \text{ m})}{2d_n + 3 \text{ m}} \right)^{2/3} \sqrt{0.002}$$

By trial and error or a calculator's equation solver,  $d_n = 0.97 \text{ m}$ . Since the actual and normal depths are different, the flow is nonuniform.

- From Eq. 19.83, the brink depth is

$$\begin{aligned} d_b &= 0.715 d_c = (0.715)(0.82 \text{ m}) \\ &= 0.59 \text{ m} \end{aligned}$$

### Customary U.S. Solution

- From Eq. 19.75, the critical depth is

$$\begin{aligned} d_c &= \left( \frac{Q^2}{gw^2} \right)^{1/3} \\ &= \left( \frac{\left( 250 \frac{\text{ft}^3}{\text{sec}} \right)^2}{(32.2 \frac{\text{ft}}{\text{sec}^2})(10 \text{ ft})^2} \right)^{1/3} \\ &= 2.69 \text{ ft} \end{aligned}$$

Since the actual depth exceeds the critical depth, the flow is tranquil.

<sup>14</sup>Figure 19.17 is an example of a *hydraulic drop*, the opposite of a hydraulic jump. A hydraulic drop can be recognized by the sudden decrease in depth over a short length of channel.

(b) From Eq. 19.13,

$$Q = \left(\frac{1.49}{n}\right) A R^{2/3} \sqrt{S}$$

$$R = \frac{A}{P} = \frac{d_n(10 \text{ ft})}{2d_n + 10 \text{ ft}}$$

Substitute the expression for  $R$  into Eq. 19.13 and solve for  $d_n$ .

$$250 \frac{\text{ft}^3}{\text{sec}} = \left(\frac{1.49}{0.013}\right) d_n(10 \text{ ft}) \left(\frac{d_n(10 \text{ ft})}{2d_n + 10 \text{ ft}}\right)^{2/3} \sqrt{0.002}$$

By trial and error or a calculator's equation solver,  $d_n = 3.1 \text{ ft}$ . Since the actual and normal depths are different, the flow is nonuniform.

(c) From Eq. 19.83, the brink depth is

$$\begin{aligned} d_b &= 0.715 d_c \\ &= (0.715)(2.69 \text{ ft}) \\ &= 1.92 \text{ ft} \end{aligned}$$

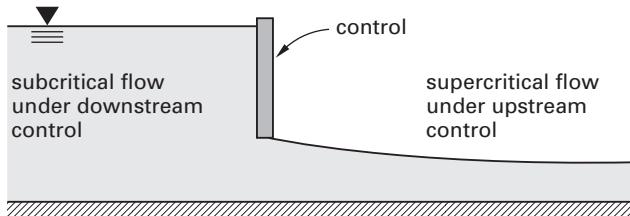

### 30. CONTROLS ON FLOW

In general, any feature that affects depth and discharge rates is known as a *control on flow*. Controls may consist of constructed control structures (weirs, gates, sluices, etc.), forced flow through critical depth (as in a free outfall), sudden changes of slope (which forces a hydraulic jump or hydraulic drop to the new normal depth), or free flow between reservoirs of different surface elevations. A downstream control may also be an upstream control, as Fig. 19.19 shows.

If flow is subcritical, then a disturbance downstream will be able to affect the upstream conditions. Since the flow velocity is less than the critical velocity, a ripple will be able to propagate upstream to signal a change in the downstream conditions. Any object downstream that affects the flow rate, velocity, or depth upstream is known as a *downstream control*.

If a flow is supercritical, then a downstream obstruction will have no effect upstream, since disturbances cannot propagate upstream faster than the flow velocity. The only effect on supercritical flow is from an upstream obstruction. Such an obstruction is said to be an *upstream control*.

**Figure 19.19** Control on Flow

### 31. FLOW CHOKING

A channel feature that causes critical flow to occur is known as a *choke*, and the corresponding flow past the feature and downstream is known as *choked flow*.

In the case of vertical transitions (i.e., upward or downward steps in the channel bottom), choked flow will occur when the step size is equal to the difference between the upstream specific energy and the critical flow energy.

$$\Delta z = E_1 - E_c \quad [\text{choked flow}] \quad 19.84$$

In the case of a rectangular channel, combining Eq. 19.67 and Eq. 19.77 the maximum variation in channel bottom will be

$$\begin{aligned} \Delta z &= E_1 - \left(d_c + \frac{v_c^2}{2g}\right) \\ &= E_1 - \frac{3}{2}d_c \end{aligned} \quad 19.85$$

The flow downstream from a choke point can be subcritical or supercritical, depending on the downstream conditions. If there is a downstream control, such as a sluice gate, the flow downstream will be subcritical. If there is additional gravitational acceleration (as with flow down the side of a dam spillway), then the flow will be supercritical.

### 32. VARIED FLOW

*Accelerated flow* occurs in any channel where the actual slope exceeds the friction loss per foot.

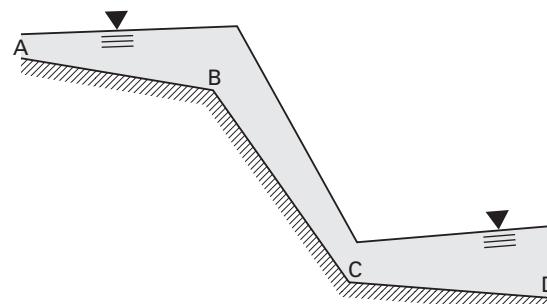

$$S_0 > \frac{h_f}{L} \quad 19.86$$

*Decelerated flow* occurs when the actual slope is less than the unit friction loss.

$$S_0 < \frac{h_f}{L} \quad 19.87$$

In sections AB and CD of Fig. 19.20, the slopes are less than the energy gradient, so the flows are decelerated. In section BC, the slope is greater than the energy gradient, so the velocity increases (i.e., the flow is accelerated). If section BC were long enough, the friction loss

**Figure 19.20** Varied Flow

would eventually become equal to the accelerating energy and the flow would become uniform.

The distance between points 1 and 2 with two known depths in accelerated or decelerated flow can be determined from the average velocity. Equation 19.88 and Eq. 19.89 assume that the friction losses are the same for varied flow as for uniform flow.

$$S_{\text{ave}} = \left( \frac{n v_{\text{ave}}}{R_{\text{ave}}^{2/3}} \right)^2 \quad [\text{SI}] \quad 19.88(a)$$

$$S_{\text{ave}} = \left( \frac{n v_{\text{ave}}}{1.49 R_{\text{ave}}^{2/3}} \right)^2 \quad [\text{U.S.}] \quad 19.88(b)$$

$$v_{\text{ave}} = \frac{1}{2}(v_1 + v_2) \quad 19.89$$

$S$  is the slope of the energy gradient from Eq. 19.88, not the channel slope  $S_0$ . The usual method of finding the *depth profile* is to start at a point in the channel where  $d_2$  and  $v_2$  are known. Then, assume a depth  $d_1$ , find  $v_1$  and  $S$ , and solve for  $L$ . Repeat as needed.

$$L = \frac{\left( d_1 + \frac{v_1^2}{2g} \right) - \left( d_2 + \frac{v_2^2}{2g} \right)}{S - S_0} \quad 19.90$$

$$= \frac{E_1 - E_2}{S - S_0}$$

In Eq. 19.89 and Eq. 19.90,  $d_1$  is always the smaller of the two depths.

### Example 19.10

How far from the point described in Ex. 19.9 will the depth be 4 ft (1.2 m)?

*SI Solution*

The difference between 1.3 m and 1.2 m is small, so a one-step calculation will probably be sufficient.

$$d_1 = 1.2 \text{ m}$$

$$v_1 = \frac{Q}{A} = \frac{7 \frac{\text{m}^3}{\text{s}}}{(1.2 \text{ m})(3 \text{ m})} = 1.94 \text{ m/s}$$

$$E_1 = d_1 + \frac{v_1^2}{2g} = 1.2 \text{ m} + \frac{\left(1.94 \frac{\text{m}}{\text{s}}\right)^2}{(2)(9.81 \frac{\text{m}}{\text{s}^2})} = 1.39 \text{ m}$$

$$R_1 = \frac{A_1}{P_1} = \frac{(1.2 \text{ m})(3 \text{ m})}{1.2 \text{ m} + 3 \text{ m} + 1.2 \text{ m}} = 0.67 \text{ m}$$

$$d_2 = 1.3 \text{ m}$$

$$v_2 = \frac{7 \frac{\text{m}^3}{\text{s}}}{(1.3 \text{ m})(3 \text{ m})} = 1.79 \text{ m/s}$$

$$E_2 = d_2 + \frac{v_2^2}{2g} = 1.3 \text{ m} + \frac{\left(1.79 \frac{\text{m}}{\text{s}}\right)^2}{(2)(9.81 \frac{\text{m}}{\text{s}^2})} = 1.46 \text{ m}$$

$$R_2 = \frac{A_2}{P_2} = \frac{(1.3 \text{ m})(3 \text{ m})}{1.3 \text{ m} + 3 \text{ m} + 1.3 \text{ m}} = 0.70 \text{ m}$$

$$v_{\text{ave}} = \frac{1}{2}(v_1 + v_2) = \left(\frac{1}{2}\right)\left(1.94 \frac{\text{m}}{\text{s}} + 1.79 \frac{\text{m}}{\text{s}}\right) = 1.865 \text{ m/s}$$

$$R_{\text{ave}} = \frac{1}{2}(R_1 + R_2) = \left(\frac{1}{2}\right)(0.70 \text{ m} + 0.67 \text{ m}) = 0.685 \text{ m}$$

From Eq. 19.88,

$$S = \left( \frac{n v_{\text{ave}}}{R_{\text{ave}}^{2/3}} \right)^2 = \left( \frac{(0.013)\left(1.865 \frac{\text{m}}{\text{s}}\right)}{(0.685 \text{ m})^{2/3}} \right)^2 = 0.000973$$

From Eq. 19.90,

$$L = \frac{E_1 - E_2}{S - S_0} = \frac{1.39 \text{ m} - 1.46 \text{ m}}{0.000973 - 0.002} = 68.2 \text{ m}$$

*Customary U.S. Solution*

The difference between 4 ft and 4.2 ft is small, so a one-step calculation will probably be sufficient.

$$d_1 = 4 \text{ ft}$$

$$v_1 = \frac{Q}{A} = \frac{250 \frac{\text{ft}^3}{\text{sec}}}{(4 \text{ ft})(10 \text{ ft})} = 6.25 \text{ ft/sec}$$

$$E_1 = d_1 + \frac{v_1^2}{2g}$$

$$= 4 \text{ ft} + \frac{\left(6.25 \frac{\text{ft}}{\text{sec}}\right)^2}{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})}$$

$$= 4.607 \text{ ft}$$

$$R_1 = \frac{A_1}{P_1} = \frac{(4 \text{ ft})(10 \text{ ft})}{4 \text{ ft} + 10 \text{ ft} + 4 \text{ ft}}$$

$$= 2.22 \text{ ft}$$

$$d_2 = 4.2 \text{ ft}$$

$$v_2 = \frac{250 \frac{\text{ft}^3}{\text{sec}}}{(4.2 \text{ ft})(10 \text{ ft})}$$

$$= 5.95 \text{ ft/sec}$$

$$E_2 = d_2 + \frac{v_2^2}{2g} = 4.2 \text{ ft} + \frac{\left(5.95 \frac{\text{ft}}{\text{sec}}\right)^2}{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})}$$

$$= 4.75 \text{ ft}$$

$$R_2 = \frac{A_2}{P_2} = \frac{(4.2 \text{ ft})(10 \text{ ft})}{4.2 \text{ ft} + 10 \text{ ft} + 4.2 \text{ ft}}$$

$$= 2.28 \text{ ft}$$

$$v_{\text{ave}} = \frac{1}{2}(v_1 + v_2)$$

$$= \left(\frac{1}{2}\right)\left(6.25 \frac{\text{ft}}{\text{sec}} + 5.95 \frac{\text{ft}}{\text{sec}}\right)$$

$$= 6.1 \text{ ft/sec}$$

$$R_{\text{ave}} = \frac{1}{2}(R_1 + R_2)$$

$$= \left(\frac{1}{2}\right)(2.22 \text{ ft} + 2.28 \text{ ft})$$

$$= 2.25 \text{ ft}$$

From Eq. 19.88,

$$S = \left(\frac{n v_{\text{ave}}}{1.49 R_{\text{ave}}^{2/3}}\right)^2$$

$$= \left(\frac{(0.013)(6.1 \frac{\text{ft}}{\text{sec}})}{(1.49)(2.25 \text{ ft})^{2/3}}\right)^2$$

$$= 0.000961$$

From Eq. 19.90,

$$L = \frac{E_1 - E_2}{S - S_0} = \frac{4.607 \text{ ft} - 4.75 \text{ ft}}{0.000961 - 0.002}$$

$$= 138 \text{ ft}$$

### 33. HYDRAULIC JUMP

If water is introduced at high (supercritical) velocity to a section of slow-moving (subcritical) flow (as shown in Fig. 19.21), the velocity will be reduced rapidly over a short length of channel. The abrupt rise in the water surface is known as a *hydraulic jump*. The increase in depth is always from below the critical depth to above the critical depth.<sup>15</sup> The depths on either side of the hydraulic jump are known as *conjugate depths*. The conjugate depths and the relationship between them are as follows.

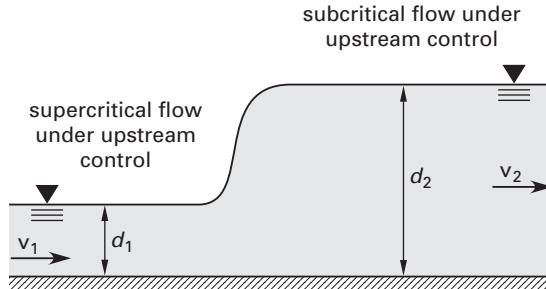

$$d_1 = -\frac{1}{2}d_2 + \sqrt{\frac{2v_2^2 d_2}{g} + \frac{d_2^2}{4}} \quad [\text{rectangular channels}] \quad 19.91$$

$$d_2 = -\frac{1}{2}d_1 + \sqrt{\frac{2v_1^2 d_1}{g} + \frac{d_1^2}{4}} \quad [\text{rectangular channels}] \quad 19.92$$

$$\frac{d_2}{d_1} = \frac{1}{2} \left( \sqrt{1 + 8(Fr_1)^2} - 1 \right) \quad [\text{rectangular channels}] \quad 19.93(a)$$

$$\frac{d_1}{d_2} = \frac{1}{2} \left( \sqrt{1 + 8(Fr_2)^2} - 1 \right) \quad [\text{rectangular channels}] \quad 19.93(b)$$

**Figure 19.21** Conjugate Depths

If the depths  $d_1$  and  $d_2$  are known, then the upstream velocity can be found from Eq. 19.94.

$$v_1^2 = \left(\frac{gd_2}{2d_1}\right)(d_1 + d_2) \quad [\text{rectangular channels}] \quad 19.94$$

Conjugate depths are not the same as alternate depths. Alternate depths are derived from the conservation of energy equation (i.e., a variation of the Bernoulli equation). Conjugate depths (calculated in Eq. 19.91 through Eq. 19.93) are derived from a conservation of momentum equation. Conjugate depths are calculated only when there has been an abrupt energy loss such as occurs in a hydraulic jump or drop.

<sup>15</sup>This provides a way of determining if a hydraulic jump can occur in a channel. If the original depth is above the critical depth, the flow is already subcritical. Therefore, a hydraulic jump cannot form. Only a hydraulic drop could occur.

Hydraulic jumps have practical applications in the design of stilling basins. Stilling basins are designed to intentionally reduce energy of flow through hydraulic jumps. In the case of a concrete apron at the bottom of a dam spillway, the apron friction is usually low, and the water velocity will decrease only gradually. However, supercritical velocities can be reduced to much slower velocities by having the flow cross a series of baffles on the channel bottom.

The specific energy lost in the jump is the energy lost per pound of water flowing.

$$\Delta E = \left( d_1 + \frac{v_1^2}{2g} \right) - \left( d_2 + \frac{v_2^2}{2g} \right) \approx \frac{(d_2 - d_1)^3}{4d_1 d_2} \quad 19.95$$

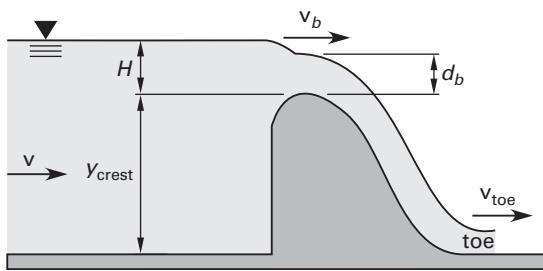

Evaluation of hydraulic jumps in stilling basins starts by determining the depth at the toe. The depth of flow at the toe of a spillway is found from an energy balance. Neglecting friction, the total energy at the toe equals the total upstream energy before the spillway. The total upstream energy before the spillway is

$$E_{\text{upstream}} = E_{\text{toe}} \quad 19.96$$

$$y_{\text{crest}} + H + \frac{v^2}{2g} = d_{\text{toe}} + \frac{v_{\text{toe}}^2}{2g} \quad 19.97$$

The upstream velocity,  $v$ , is the velocity before the spillway (which is essentially zero), not the velocity over the brink. If the brink depth is known, the velocity over the brink can be used with the continuity equation to calculate the upstream velocity, but the velocity over the brink should not be used with  $H$  to determine total energy since  $v_b \neq v$ . (See Fig. 19.22.)

**Figure 19.22** Total Energy Upstream of a Spillway

If water is drained quickly from the apron so that the tailwater depth is small or zero, no hydraulic jump will form. This is because the tailwater depth is already less than the critical depth.

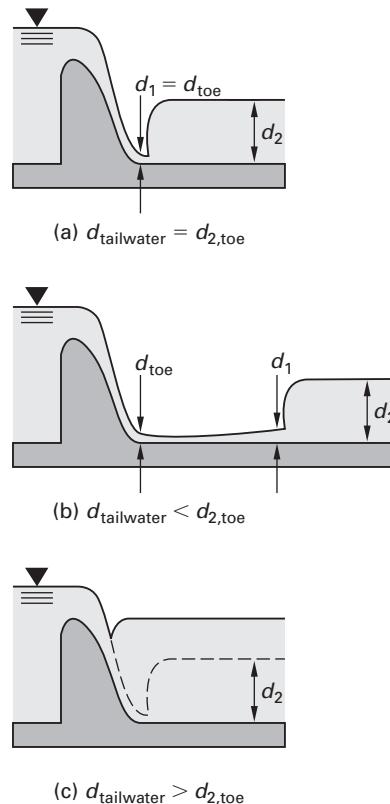

A hydraulic jump will form along the apron at the bottom of the spillway when the actual tailwater depth equals the conjugate depth  $d_2$  corresponding to the depth at the toe. That is, the jump is located at the toe when  $d_2 = d_{\text{tailwater}}$ , where  $d_2$  and  $d_1 = d_{\text{toe}}$  are conjugate depths. The tailwater and toe depths are implicitly the conjugate depths. This is shown in

Fig. 19.23(a) and is the proper condition for energy dissipation in a stilling basin.

When the actual tailwater depth is less than the conjugate depth  $d_2$  corresponding to  $d_{\text{toe}}$ , but still greater than the critical depth, flow will continue along the apron until the depth increases to conjugate depth  $d_1$  corresponding to the actual tailwater depth. This is shown in Fig. 19.23(b). A hydraulic jump will form at that point to increase the depth to the tailwater depth. (Another way of saying this is that the hydraulic jump moves downstream from the toe.) This is an undesirable condition, since the location of the jump is often inadequately protected from scour.

If the tailwater depth is greater than the conjugate depth corresponding to the depth at the toe, as in Fig. 19.23(c), the hydraulic jump may occur up on the spillway, or it may be completely submerged (i.e., it will not occur at all).

**Figure 19.23** Hydraulic Jump to Reach Tailwater Level

### Example 19.11

A hydraulic jump is produced at a point in a 10 ft (3 m) wide channel where the depth is 1 ft (0.3 m). The flow rate is 200 ft<sup>3</sup>/sec (5.7 m<sup>3</sup>/s). (a) What is the depth after the jump? (b) What is the total power dissipated?

*SI Solution*

(a) From Eq. 19.69,

$$v_1 = \frac{Q}{A} = \frac{5.7 \frac{\text{m}^3}{\text{s}}}{(3 \text{ m})(0.3 \text{ m})} = 6.33 \text{ m/s}$$

From Eq. 19.92,

$$\begin{aligned} d_2 &= -\frac{1}{2}d_1 + \sqrt{\frac{2v_1^2 d_1}{g} + \frac{d_1^2}{4}} \\ &= -\left(\frac{1}{2}\right)(0.3 \text{ m}) \\ &\quad + \sqrt{\frac{(2)\left(6.33 \frac{\text{m}}{\text{s}}\right)^2(0.3 \text{ m})}{9.81 \frac{\text{m}}{\text{s}^2}} + \frac{(0.3 \text{ m})^2}{4}} \\ &= 1.42 \text{ m} \end{aligned}$$

(b) The mass flow rate is

$$\dot{m} = \left(5.7 \frac{\text{m}^3}{\text{s}}\right) \left(1000 \frac{\text{kg}}{\text{m}^3}\right) = 5700 \text{ kg/s}$$

The velocity after the jump is

$$v_2 = \frac{Q}{A_2} = \frac{5.7 \frac{\text{m}^3}{\text{s}}}{(3 \text{ m})(1.42 \text{ m})} = 1.33 \text{ m/s}$$

From Eq. 19.95, the change in specific energy is

$$\begin{aligned} \Delta E &= \left(d_1 + \frac{v_1^2}{2g}\right) - \left(d_2 + \frac{v_2^2}{2g}\right) \\ &= \left(0.3 \text{ m} + \frac{\left(6.33 \frac{\text{m}}{\text{s}}\right)^2}{(2)(9.81 \frac{\text{m}}{\text{s}^2})}\right) \\ &\quad - \left(1.423 \text{ m} + \frac{\left(1.33 \frac{\text{m}}{\text{s}}\right)^2}{(2)(9.81 \frac{\text{m}}{\text{s}^2})}\right) \\ &= 0.83 \text{ m} \end{aligned}$$

The total power dissipated is

$$\begin{aligned} P &= \dot{m}g\Delta E \\ &= \left(5700 \frac{\text{kg}}{\text{s}}\right) \left(9.81 \frac{\text{m}}{\text{s}^2}\right) \left(\frac{0.83 \text{ m}}{1000 \frac{\text{W}}{\text{kW}}}\right) \\ &= 46.4 \text{ kW} \end{aligned}$$

*Customary U.S. Solution*

(a) From Eq. 19.69,

$$v_1 = \frac{Q}{A} = \frac{200 \frac{\text{ft}^3}{\text{sec}}}{(10 \text{ ft})(1 \text{ ft})} = 20 \text{ ft/sec}$$

From Eq. 19.92,

$$\begin{aligned} d_2 &= -\frac{1}{2}d_1 + \sqrt{\frac{2v_1^2 d_1}{g} + \frac{d_1^2}{4}} \\ &= -\left(\frac{1}{2}\right)(1 \text{ ft}) + \sqrt{\frac{(2)\left(20 \frac{\text{ft}}{\text{sec}}\right)^2(1 \text{ ft})}{32.2 \frac{\text{ft}}{\text{sec}^2}} + \frac{(1 \text{ ft})^2}{4}} \\ &= 4.51 \text{ ft} \end{aligned}$$

(b) The mass flow rate is

$$\dot{m} = \left(200 \frac{\text{ft}^3}{\text{sec}}\right) \left(62.4 \frac{\text{lbm}}{\text{ft}^3}\right) = 12,480 \text{ lbm/sec}$$

The velocity after the jump is

$$v_2 = \frac{Q}{A_2} = \frac{200 \frac{\text{ft}^3}{\text{sec}}}{(10 \text{ ft})(4.51 \text{ ft})} = 4.43 \text{ ft/sec}$$

From Eq. 19.95, the change in specific energy is

$$\begin{aligned} \Delta E &= \left(d_1 + \frac{v_1^2}{2g}\right) - \left(d_2 + \frac{v_2^2}{2g}\right) \\ &= \left(1 \text{ ft} + \frac{\left(20 \frac{\text{ft}}{\text{sec}}\right)^2}{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})}\right) \\ &\quad - \left(4.51 \text{ ft} + \frac{\left(4.43 \frac{\text{ft}}{\text{sec}}\right)^2}{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})}\right) \\ &= 2.4 \text{ ft} \end{aligned}$$

The total power dissipated is

$$\begin{aligned} P &= \frac{\dot{m}g\Delta E}{g_c} \\ &= \frac{\left(12,480 \frac{\text{lbm}}{\text{sec}}\right) \left(32.2 \frac{\text{ft}}{\text{sec}^2}\right) (2.4 \text{ ft})}{\left(32.2 \frac{\text{lbm-ft}}{\text{lbf-sec}^2}\right) \left(550 \frac{\text{ft-lbf}}{\text{hp-sec}}\right)} \\ &= 54.5 \text{ hp} \end{aligned}$$

### 34. LENGTH OF HYDRAULIC JUMP

For practical stilling basin design, it is helpful to have an estimate of the length of the hydraulic jump. Lengths of hydraulic jumps are difficult to measure because of the difficulty in defining the endpoints of the jumps. However, the length of the jump,  $L$ , varies within the limits of  $5 < L/d_2 < 6.5$ , in which  $d_2$  is the conjugate depth after the jump. Where greater accuracy is warranted, Table 19.6 can be used. This table correlates the length of the jump to the upstream Froude number.

**Table 19.6** Approximate Lengths of Hydraulic Jumps

Fr <sub>1</sub>	$L/d_2$
3	5.25
4	5.8
5	6.0
6	6.1
7	6.15
8	6.15

### 35. HYDRAULIC DROP

A *hydraulic drop* is the reverse of a hydraulic jump. If water is introduced at low (subcritical) velocity to a section of fast-moving (supercritical) flow, the velocity will be increased rapidly over a short length of channel. The abrupt drop in the water surface is known as a hydraulic drop. The decrease in depth is always from above the critical depth to below the critical depth.

Water flowing over a spillway and down a long, steep chute typically experiences a hydraulic drop, with critical depth occurring just before the brink. This is illustrated in Fig. 19.17 and Fig. 19.22.

The depths on either side of the hydraulic drop are the *conjugate depths*, which are determined from Eq. 19.91 and Eq. 19.92. The equations for calculating specific energy and power changes are the same for hydraulic jumps and drops.

### 36. ERODIBLE CHANNELS

Given an appropriate value of the Manning coefficient, the analysis of channels constructed of erodible materials is similar to that for concrete or pipe channels.

However, for design problems, maximum velocities and permissible side slopes must also be considered. The present state of knowledge is not sufficiently sophisticated to allow for precise designs. The usual uniform flow equations are insufficient because the stability of erodible channels is dependent on the properties of the channel material rather than on the hydraulics of flow. Two methods of design exist: (a) the tractive force method and (b) the simpler maximum permissible velocity method. Maximum velocities that should be used with erodible channels are given in Table 19.7.

**Table 19.7** Suggested Maximum Velocities

soil type or lining (earth; no vegetation)	maximum permissible velocities (ft/sec)		
	clear water	water carrying fine silts	water carrying sand and gravel
fine sand (noncolloidal)	1.5	2.5	1.5
sandy loam (noncolloidal)	1.7	2.5	2.0
silt loam (noncolloidal)	2.0	3.0	2.0
ordinary firm loam	2.5	3.5	2.2
volcanic ash	2.5	3.5	2.0
fine gravel	2.5	5.0	3.7
stiff clay (very colloidal)	3.7	5.0	3.0
graded, loam to cobbles (noncolloidal)	3.7	5.0	5.0
graded, silt to cobbles (colloidal)	4.0	5.5	5.0
alluvial silts (noncolloidal)	2.0	3.5	2.0
alluvial silts (colloidal)	3.7	5.0	3.0
coarse gravel (noncolloidal)	4.0	6.0	6.5
cobbles and shingles	5.0	5.5	6.5
shales and hard pans	6.0	6.0	5.0

(Multiply ft/sec by 0.3048 to obtain m/s.)

Source: Special Committee on Irrigation Research, ASCE, 1926.

The sides of the channel should not have a slope exceeding the natural angle of repose for the material used. Although there are other factors that determine the maximum permissible side slope, Table 19.8 lists some guidelines.

**Table 19.8** Recommended Side Slopes

type of channel	side slope (horizontal:vertical)
firm rock	vertical to $\frac{1}{4}:1$
concrete-lined stiff clay	$\frac{1}{2}:1$
fissured rock	$\frac{1}{2}:1$
firm earth with stone lining	1:1
firm earth, large channels	1:1
firm earth, small channels	$1\frac{1}{2}:1$
loose, sandy earth	2:1
sandy, porous loam	3:1

### 37. CULVERTS<sup>16</sup>

A *culvert* is a pipe that carries water under or through some feature (usually a road or highway) that would otherwise block the flow of water. For example, highways are often built at right angles to ravines draining hillsides and other watersheds. Culverts under the

<sup>16</sup>The methods of culvert flow analysis in this chapter are based on Bodhaine, G.L., 1968, *Measurement of Peak Discharge by Indirect Methods*, U.S. Geological Survey, *Techniques of Water Resources Investigations*, book 3, chapter A3.

highway keep the construction fill from blocking the natural runoff.

Culverts are classified according to which of their ends controls the discharge capacity: inlet control or outlet control. If water can flow through and out of the culvert faster than it can enter, the culvert is under *inlet control*. If water can flow into the culvert faster than it can flow through and out, the culvert is under *outlet control*. Culverts under inlet control will always flow partially full. Culverts under outlet control can flow either partially full or full.

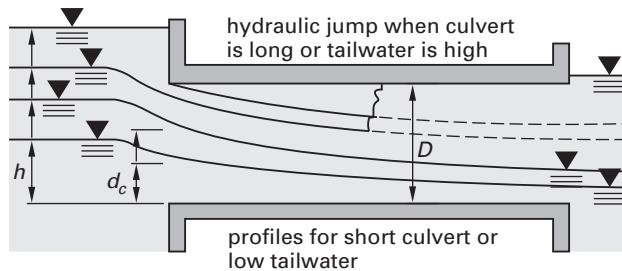

The culvert length is one of the most important factors in determining whether the culvert flows full. A culvert may be known as "hydraulically long" if it runs full and "hydraulically short" if it does not.<sup>17</sup>

All culvert design theory is closely dependent on energy conservation. However, due to the numerous variables involved, no single formula or procedure can be used to design a culvert. Culvert design is often an empirical, trial-and-error process. Figure 19.24 illustrates some of the important variables that affect culvert performance.

A culvert can operate with its entrance partially or totally submerged. Similarly, the exit can be partially or totally submerged, or it can have free outfall. The upstream head,  $h$ , is the water surface level above the lowest part of the culvert barrel, known as the *invert*.<sup>18</sup>

In Fig. 19.24, the three lowermost surface level profiles are of the type that would be produced with inlet control. Such a situation can occur if the culvert is short and the slope is steep. Flow at the entrance is critical as the water falls over the brink. Since critical flow occurs, the flow is choked and the inlet controls the flow rate. Downstream variations cannot be transmitted past the critical section.

**Figure 19.24** Flow Profiles in Culvert Design

If the tailwater covers the culvert exit completely (i.e., a submerged exit), the culvert will be full at that point, even though the inlet control forces the culvert to be only partially full at the inlet. The transition from partially full to totally full occurs in a hydraulic jump, the location of which depends on the flow resistance and

<sup>17</sup>Proper design of culvert entrances can reduce the importance of length on culvert filling.

<sup>18</sup>The highest part of the culvert barrel is known as the *soffit* or *crown*.

water levels. If the flow resistance is very high, or if the headwater and tailwater levels are high enough, the jump will occur close to or at the entrance.

If the flow in a culvert is full for its entire length, then the flow is under outlet control. The discharge will be a function of the differences in tailwater and headwater levels, as well as the flow resistance along the barrel length.

### 38. DETERMINING TYPE OF CULVERT FLOW

For convenience, culvert flow is classified into six different types on the basis of the type of control, the steepness of the barrel, the relative tailwater and headwater heights, and in some cases, the relationship between critical depth and culvert size. These parameters are quantified through the use of the ratios in Table 19.9.<sup>19</sup> The six types are illustrated in Fig. 19.25. Identification of the type of flow beyond the guidelines in Table 19.9 requires a trial-and-error procedure.

In the following cases, several variables appear repeatedly.  $C_d$  is the discharge coefficient, a function of the barrel inlet geometry. Orifice data can be used to approximate the discharge coefficient when specific information is unavailable.  $v_1$  is the average velocity of the water approaching the culvert entrance and is often insignificant. The velocity-head coefficient,  $\alpha$ , also called the *Coriolis coefficient*, accounts for a nonuniform distribution of velocities over the channel section. However, it represents only a second-order correction and is normally neglected (i.e., assumed equal to 1.0).  $d_c$  is the critical depth, which may not correspond to the actual depth of flow. (It must be calculated from the flow conditions.)  $h_f$  is the friction loss in the identified section. For culverts flowing full, the friction loss can be found in the usual manner developed for pipe flow: from the Darcy formula and the Moody friction factor chart. For partial flow, the Manning equation and its variations (e.g., Eq. 19.30) can also be used. The Manning equation is particularly useful since it eliminates the need for trial-and-error solutions. The friction head loss between sections 2 and 3, for example, can be calculated from Eq. 19.98.

$$h_{f,2-3} = \frac{LQ^2}{K_2 K_3} \quad 19.98$$

$$K = \left(\frac{1}{n}\right) R^{2/3} A \quad [\text{SI}] \quad 19.99(a)$$

$$K = \left(\frac{1.49}{n}\right) R^{2/3} A \quad [\text{U.S.}] \quad 19.99(b)$$

<sup>19</sup>The six cases presented here do not exhaust the various possibilities for entrance and exit control. Culvert design is complicated by this multiplicity of possible flows. Since only the easiest problems can be immediately categorized as one of the six cases, each situation needs to be carefully evaluated.

Figure 19.25 Culvert Flow Classifications

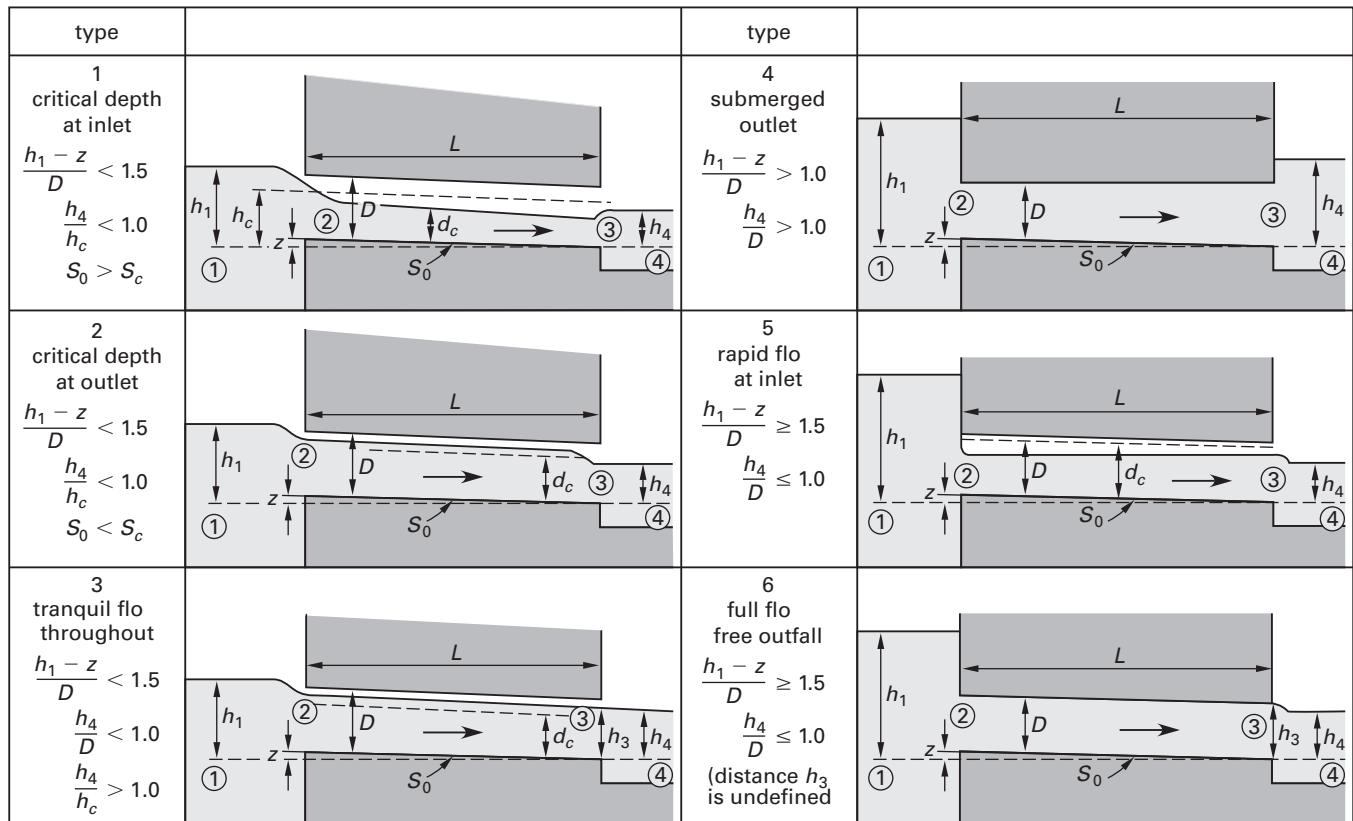

Table 19.9 Culvert Flow Classification Parameters

flow type	$\frac{h_1 - z}{D}$	$\frac{h_4}{h_c}$	$\frac{h_4}{D}$	culvert slope	barrel flow	location of control	kind of control
1	< 1.5	< 1.0	$\leq 1.0$	steep	partial	inlet	critical depth
2	< 1.5	< 1.0	$\leq 1.0$	mild	partial	outlet	critical depth
3	< 1.5	> 1.0	$\leq 1.0$	mild	partial	outlet	backwater
4	> 1.0		$\geq 1.0$	any	full	outlet	backwater
5	$\geq 1.5$		$\leq 1.0$	any	partial	inlet	entrance geometry
6	$\geq 1.5$		$\leq 1.0$	any	full	outlet	entrance and barrel geometry

The total hydraulic head available,  $H$ , (equal to  $h_1 - h_4$  in Fig. 19.25) is divided between the velocity head in the culvert, the entrance loss from Table 19.10 (if considered), and the friction.

$$H = \frac{v^2}{2g} + k_e \left( \frac{v^2}{2g} \right) + \frac{v^2 n^2 L}{R^{4/3}} \quad [\text{SI}] \quad 19.100(a)$$

$$H = \frac{v^2}{2g} + k_e \left( \frac{v^2}{2g} \right) + \frac{v^2 n^2 L}{2.21 R^{4/3}} \quad [\text{U.S.}] \quad 19.100(b)$$

Equation 19.100 can be solved directly for the velocity. Equation 19.101 is valid for culverts of any shape.

$$v = \sqrt{\frac{H}{\frac{1 + k_e}{2g} + \frac{n^2 L}{R^{4/3}}}} \quad [\text{SI}] \quad 19.101(a)$$

$$v = \sqrt{\frac{H}{\frac{1 + k_e}{2g} + \frac{n^2 L}{2.21 R^{4/3}}}} \quad [\text{U.S.}] \quad 19.101(b)$$

Table 19.10 Minor Entrance Loss Coefficients

$k_e$	condition of entrance
0.08	smooth, tapered
0.10	flush concrete groove
0.10	flush concrete bell
0.15	projecting concrete groove
0.15	projecting concrete bell
0.50	flush, square-edged
0.90	projecting, square-edged

## A. Type-1 Flow

Water passes through the critical depth near the culvert entrance, and the culvert flows partially full. The slope of the culvert barrel is greater than the critical slope, and the tailwater elevation is less than the elevation of the water surface at the control section.

The discharge is

$$Q = C_d A_c \sqrt{2g \left( h_1 - z + \frac{\alpha v_1^2}{2g} - d_c - h_{f,1-2} \right)} \quad 19.102$$

The area,  $A$ , used in the discharge equation is not the culvert area since the culvert does not flow full.  $A_c$  is the area in flow at the critical section.

## B. Type-2 Flow

As in type-1 flow, flow passes through the critical depth at the culvert outlet, and the barrel flows partially full. The slope of the culvert is less than critical, and the tailwater elevation does not exceed the elevation of the water surface at the control section.

$$Q = C_d A_c \sqrt{2g \left( h_1 + \frac{\alpha v_1^2}{2g} - d_c - h_{f,1-2} - h_{f,2-3} \right)} \quad 19.103$$

The area,  $A$ , used in the discharge equation is not the culvert area since the culvert does not flow full.  $A_c$  is the area in flow at the critical section.

## C. Type-3 Flow

When backwater is the controlling factor in culvert flow, the critical depth cannot occur. The upstream water-surface elevation for a given discharge is a function of the height of the tailwater. For type-3 flow, flow is subcritical for the entire length of the culvert, with the flow being partial. The outlet is not submerged, but the tailwater elevation does exceed the elevation of critical depth at the terminal section.

$$Q = C_d A_3 \sqrt{2g \left( h_1 + \frac{\alpha v_1^2}{2g} - h_3 - h_{f,1-2} - h_{f,2-3} \right)} \quad 19.104$$

The area,  $A$ , used in the discharge equation is not the culvert area since the culvert does not flow full.  $A_3$  is the area in flow at numbered section 3 (i.e., the exit).

## D. Type-4 Flow

As in type-3 flow, the backwater elevation is the controlling factor in this case. Critical depth cannot occur, and the upstream water surface elevation for a given discharge is a function of the tailwater elevation.

Discharge is independent of barrel slope. The culvert is submerged at both the headwater and the tailwater. No differentiation between low head and high head is made for this case. If the velocity head at section 1 (the entrance), the entrance friction loss, and the exit friction loss are neglected, the discharge can be calculated.  $A_o$  is the culvert area.

$$Q = C_d A_o \sqrt{2g \left( \frac{h_1 - h_4}{1 + \frac{29 C_d^2 n^2 L}{R^{4/3}}} \right)} \quad 19.105$$

The complicated term in the denominator corrects for friction. For rough estimates and for culverts less than 50 ft (15 m) long, the friction loss can be ignored.

$$Q = C_d A_o \sqrt{2g(h_1 - h_4)} \quad 19.106$$

## E. Type-5 Flow

Partially full flow under a high head is classified as type-5 flow. The flow pattern is similar to the flow downstream from a sluice gate, with rapid flow near the entrance. Usually, type-5 flow requires a relatively square entrance that causes contraction of the flow area to less than the culvert area. In addition, the barrel length, roughness, and bed slope must be sufficient to keep the velocity high throughout the culvert.

It is difficult to distinguish in advance between type-5 and type-6 flow. Within a range of the important parameters, either flow can occur.<sup>20</sup>  $A_o$  is the culvert area.

$$Q = C_d A_o \sqrt{2g(h_1 - z)} \quad 19.107$$

## F. Type-6 Flow

Type-6 flow, like type-5 flow, is considered a high-head flow. The culvert is full under pressure with free outfall. The discharge is

$$Q = C_d A_o \sqrt{2g(h_1 - h_3 - h_{f,2-3})} \quad 19.108$$

Equation 19.108 is inconvenient because  $h_3$  (the true piezometric head at the outfall) is difficult to evaluate without special graphical aids. The actual hydraulic head driving the culvert flow is a function of the Froude number. For conservative first approximations,  $h_3$  can be taken as the barrel diameter. This will give the minimum hydraulic head. In reality,  $h_3$  varies from somewhat less than half the barrel diameter to the full diameter.

<sup>20</sup>If the water surface ever touches the top of the culvert, the passage of air in the culvert will be prevented and the culvert will flow full everywhere. This is type-6 flow.

If  $h_3$  is taken as the barrel diameter, the total hydraulic head ( $H = h_1 - h_3$ ) will be split between the velocity head and friction. In that case, Eq. 19.101 can be used to calculate the velocity. The discharge is easily calculated from Eq. 19.109.<sup>21</sup>  $A_o$  is the culvert area.

$$Q = A_o v \quad 19.109$$

### Example 19.12

Size a square culvert with an entrance fluid level 5 ft above the barrel top and a free exit to operate with the following characteristics.

$$\text{slope} = 0.01$$

$$\text{length} = 250 \text{ ft}$$

$$\text{capacity} = 45 \text{ ft}^3/\text{sec}$$

$$n = 0.013$$

#### Solution

Since the  $h_1$  dimension is measured from the culvert invert, it is difficult to classify the type of flow at this point. However, either type 5 or type 6 is likely since the head is high.

*step 1:* Assume a trial culvert size. Select a square opening with 1 ft sides.

*step 2:* Calculate the flow assuming case 5 (entrance control). The entrance will act like an orifice.

$$A_o = (1 \text{ ft})(1 \text{ ft}) = 1 \text{ ft}^2$$

$$H = h_1 - z$$

$$\begin{aligned} &= (5 \text{ ft} + 1 \text{ ft} + (0.01)(250 \text{ ft})) \\ &\quad - (0.01)(250 \text{ ft}) \\ &= 6 \text{ ft} \end{aligned}$$

$C_d$  is approximately 0.62 for square-edged openings with separation from the wall. From Eq. 19.107,

$$\begin{aligned} Q &= C_d A_o \sqrt{2g(h_1 - z)} \\ &= (0.62)(1 \text{ ft}^2) \sqrt{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})(6 \text{ ft})} \\ &= 12.2 \text{ ft}^3/\text{sec} \end{aligned}$$

Since this size has insufficient capacity, try a larger culvert. Choose a square opening with 2 ft sides.

$$H = h_1 - z = 5 \text{ ft} + 2 \text{ ft} = 7 \text{ ft}$$

$$\begin{aligned} Q &= C_d A_o \sqrt{2g(h_1 - z)} \\ &= (0.62)(4 \text{ ft}^2) \sqrt{(2)(32.2 \frac{\text{ft}}{\text{sec}^2})(7 \text{ ft})} \\ &= 52.7 \text{ ft}^3/\text{sec} \end{aligned}$$

*step 3:* Begin checking the entrance control assumption by calculating the maximum hydraulic radius. The upper surface of the culvert is not wetted because the flow is entrance controlled. The hydraulic radius is maximum at the entrance.

$$\begin{aligned} R &= \frac{A_o}{P} \\ &= \frac{4 \text{ ft}^2}{2 \text{ ft} + 2 \text{ ft} + 2 \text{ ft}} \\ &= 0.667 \text{ ft} \end{aligned}$$

*step 4:* Calculate the velocity using the Manning equation for open channel flow. Since the hydraulic radius is maximum, the velocity will also be maximum.

$$\begin{aligned} v &= \left(\frac{1.49}{n}\right) R^{2/3} \sqrt{S} \\ &= \left(\frac{1.49}{0.013}\right) (0.667 \text{ ft})^{2/3} \sqrt{0.01} \\ &= 8.75 \text{ ft/sec} \end{aligned}$$

*step 5:* Calculate the normal depth,  $d_n$ .

$$\begin{aligned} d_n &= \frac{Q}{v w} = \frac{45 \frac{\text{ft}^3}{\text{sec}}}{(8.75 \frac{\text{ft}}{\text{sec}})(2 \text{ ft})} \\ &= 2.57 \text{ ft} \end{aligned}$$

Since the normal depth is greater than the culvert size, the culvert will flow full under pressure. (It was not necessary to calculate the critical depth since the flow is implicitly sub-critical.) The entrance control assumption was, therefore, not valid for this size culvert.<sup>22</sup> At this point, two things can be done: A larger culvert can be chosen if entrance control is desired, or the solution can continue by

<sup>21</sup>Equation 19.109 does not include the discharge coefficient. Velocity,  $v$ , when calculated from Eq. 19.101, is implicitly the velocity in the barrel.

<sup>22</sup>If the normal depth had been less than the barrel diameter, it would still be necessary to determine the critical depth of flow. If the normal depth was less than the critical depth, the entrance control assumption would have been valid.

checking to see if the culvert has the required capacity as a pressure conduit.

- step 6:* Check the capacity as a pressure conduit.  $H$  is the total available head.

$$\begin{aligned} H &= h_1 - h_3 \\ &= (5 \text{ ft} + 2 \text{ ft} + (0.01)(250 \text{ ft})) - 2 \text{ ft} \\ &= 7.5 \text{ ft} \end{aligned}$$

- step 7:* Since the pipe is flowing full, the hydraulic radius is

$$R = \frac{A}{P} = \frac{4 \text{ ft}^2}{8 \text{ ft}} = 0.5 \text{ ft}$$

- step 8:* Equation 19.101 can be used to calculate the flow velocity. Since the culvert has a square-edged entrance, a loss coefficient of  $k_e = 0.5$  is used. However, this does not greatly affect the velocity.

$$\begin{aligned} v &= \sqrt{\frac{H}{\frac{1+k_e}{2g} + \frac{n^2 L}{2.21 R^{4/3}}}} \\ &= \sqrt{\frac{7.5 \text{ ft}}{\frac{1+0.5}{(2)(32.2 \frac{\text{ft}}{\text{sec}})} + \frac{(0.013)^2 (250 \text{ ft})}{(2.21)(0.5 \text{ ft})^{4/3}}}} \\ &= 10.24 \text{ ft/sec} \end{aligned}$$

- step 9:* Check the capacity.

$$\begin{aligned} Q &= v A_o = \left(10.24 \frac{\text{ft}}{\text{sec}}\right) (4 \text{ ft}^2) \\ &= 40.96 \text{ ft}^3/\text{sec} \end{aligned}$$

The culvert size is not acceptable since its discharge under the maximum head does not have a capacity of  $45 \text{ ft}^3/\text{sec}$ .

- step 10:* Repeat from step 2, trying a larger-size culvert. With a 2.5 ft side, the following values are obtained.

$$\begin{aligned} A_o &= (2.5 \text{ ft})(2.5 \text{ ft}) = 6.25 \text{ ft}^2 \\ H &= 5 \text{ ft} + 2.5 \text{ ft} = 7.5 \text{ ft} \end{aligned}$$

$$\begin{aligned} Q &= (0.62)(6.25 \text{ ft}^2) \\ &\quad \times \sqrt{(2)\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)(7.5 \text{ ft})} \\ &= 85.2 \text{ ft}^3/\text{sec} \end{aligned}$$

$$\begin{aligned} R &= \frac{6.25 \text{ ft}^2}{7.5 \text{ ft}} = 0.833 \text{ ft} \\ v &= \left(\frac{1.49}{0.013}\right)(0.833 \text{ ft})^{2/3} \sqrt{0.01} \\ &= 10.15 \text{ ft/sec} \end{aligned}$$

$$\begin{aligned} d_n &= \frac{Q}{v w} = \frac{45 \frac{\text{ft}^3}{\text{sec}}}{\left(10.15 \frac{\text{ft}}{\text{sec}}\right)(2.5 \text{ ft})} \\ &= 1.77 \text{ ft} \end{aligned}$$

- step 11:* Calculate the critical depth. For rectangular channels, Eq. 19.75 can be used.

$$\begin{aligned} d_c &= \left(\frac{Q^2}{gw^2}\right)^{1/3} \\ &= \left(\frac{\left(45 \frac{\text{ft}^3}{\text{sec}}\right)^2}{\left(32.2 \frac{\text{ft}}{\text{sec}^2}\right)(2.5 \text{ ft})^2}\right)^{1/3} \\ &= 2.16 \text{ ft} \end{aligned}$$

Since the normal depth is less than the critical depth, the flow is supercritical. The entrance control assumption was correct for the culvert. The culvert has sufficient capacity to carry  $45 \text{ ft}^3/\text{sec}$ .

### 39. CULVERT DESIGN

Designing a culvert is somewhat easier than culvert analysis because of common restrictions placed on designers and the flexibility to change almost everything else. For example, culverts may be required to (a) never be more than 50% full (deep), (b) always be under inlet control, or (c) always operate with some minimum head (above the centerline or crown). In the absence of any specific guidelines, a culvert may be designed using the following procedure.

- step 1:* Determine the required flow rate.
- step 2:* Determine all water surface elevations, lengths, and other geometric characteristics.
- step 3:* Determine the material to be used for the culvert and its roughness.
- step 4:* Assume type 1 flow (inlet control).
- step 5:* Select a trial diameter.

- step 6:* Assume a reasonable slope.
- step 7:* Position the culvert entrance such that the ratio of headwater depth (inlet to water surface) to culvert diameter is 1:2 to 1:2.5.
- step 8:* Calculate the flow. Repeat step 5 through step 7 until the capacity is adequate.
- step 9:* Determine the location of the outlet. Check for outlet control. If the culvert is outlet controlled, repeat step 5 through step 7 using a different flow model.
- step 10:* Calculate the discharge velocity. Specify riprap, concrete, or other protection to prevent erosion at the outlet.

### 1. HYDROLOGIC CYCLE

The *hydrologic cycle* is the full “life cycle” of water. The cycle begins with *precipitation*, which encompasses all of the hydrometeorologic forms, including rain, snow, sleet,

and hail from a storm. Precipitation can (a) fall on vegetation and structures and evaporate back into the atmosphere, (b) be absorbed into the ground and either make its way to the water table or be absorbed by plants after which it evapotranspires back into the atmosphere, or (c) travel as surface water to a depression, watershed, or creek from which it either evaporates back into the atmosphere, infiltrates into the ground water system, or flows off in streams and rivers to an ocean or lakes. The cycle is completed when lake and ocean water evaporates into the atmosphere.

The *water balance equation* (*water budget equation*) is the application of conservation to the hydrologic cycle.

$$\begin{aligned} \text{total precipitation} &= \text{net change in surface water removed} \\ &\quad + \text{net change in ground water removed} \\ &\quad + \text{evapotranspiration} \\ &\quad + \text{interception evaporation} \\ &\quad + \text{net increase in surface water storage} \\ &\quad + \text{net increase in ground water storage} \end{aligned}$$

$$P = Q + E + \Delta S \quad 20.1$$

The total amount of water that is intercepted (and subsequently evaporates) and absorbed into ground water before runoff begins is known as the *initial abstraction*. Even after runoff begins, the soil continues to absorb some infiltrated water. Initial abstraction and infiltration do not contribute to surface runoff. Equation 20.1 can be restated as Eq. 20.2.

$$\begin{aligned} \text{total precipitation} &= \text{initial abstraction} + \text{infiltration} \\ &\quad + \text{surface runoff} \quad 20.2 \end{aligned}$$

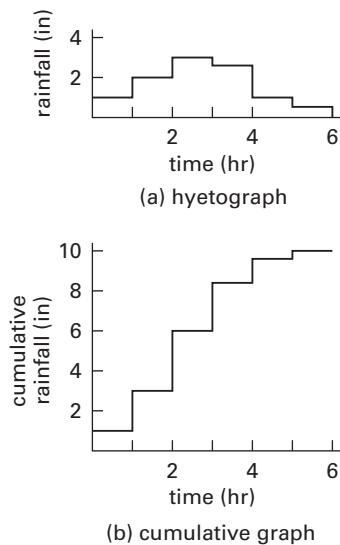

## 2. STORM CHARACTERISTICS

Storm rainfall characteristics include the duration, total volume, intensity, and areal distribution of a storm. Storms are also characterized by their recurrence intervals. (See Sec. 20.6.)

The duration of storms is measured in hours and days. The volume of rainfall is simply the total quantity of precipitation dropping on the watershed. Average rainfall intensity is the volume divided by the duration of the storm. Average rainfall can be considered to be generated by an equivalent theoretical storm that drops the same volume of water uniformly and constantly over the entire watershed area.

A *storm hyetograph* is the instantaneous rainfall intensity measured as a function of time, as shown in Fig. 20.1(a). Hyetographs are usually bar graphs showing constant rainfall intensities over short periods of time. Hyetograph data can be reformulated as a *cumulative rainfall curve*,

**Figure 20.1** Storm Hyetograph and Cumulative Rainfall Curves

as shown in Fig. 20.1(b). Cumulative rainfall curves are also known as *rainfall mass curves*.

## 3. PRECIPITATION DATA

Precipitation data on rainfall can be collected in a number of ways, but use of an open precipitation rain gauge is quite common. This type of gauge measures only the volume of rain collected between readings, usually 24 hr.

The *average precipitation* over a specific area can be found from station data in several ways.

*Method 1:* If the stations are uniformly distributed over a flat site, their precipitations can be averaged. This also requires that the individual precipitation records not vary too much from the mean.

*Method 2:* The *Thiessen method* calculates the average weighting station measurements by the area of the assumed watershed for each station. These assumed watershed areas are found by drawing dotted lines between all stations and bisecting these dotted lines with solid lines (which are extended outward until they connect with other solid lines). The solid lines will form a polygon whose area is the assumed watershed area.

*Method 3:* The *isohyetal method* requires plotting lines of constant precipitation (*isohyets*) and weighting the isohyet values by the areas enclosed by the lines. This method is the most accurate of the three methods, as long as there are enough observations to permit drawing of isohyets. Station data are used to draw isohyets, but they are not used in the calculation of average rainfall.

## 4. ESTIMATING UNKNOWN PRECIPITATION

If a precipitation measurement at a location is unknown, it may still be possible to estimate the value by one of the following procedures.

*Method 1:* Choose three stations close to and evenly spaced around the location with missing data. If the normal annual precipitations at the three sites do not vary more than 10% from the missing station's normal annual precipitation, the rainfall can be estimated as the arithmetic mean of the three neighboring stations' precipitations for the period in question.

*Method 2:* If the precipitation difference between locations is more than 10%, the *normal-ratio method* can be used. In Eq. 20.3,  $P_x$  is the precipitation at the missing station;  $N_x$  is the long-term normal precipitation at the missing station;  $P_A$ ,  $P_B$ , and  $P_C$  are the precipitations at known stations; and  $N_A$ ,  $N_B$ , and  $N_C$  are the long-term normal precipitations at the known stations.

$$P_x = \frac{1}{3} \left( \left( \frac{N_x}{N_A} \right) P_A + \left( \frac{N_x}{N_B} \right) P_B + \left( \frac{N_x}{N_C} \right) P_C \right) \quad 20.3$$

*Method 3:* Use data from stations in the four nearest quadrants (north, south, east, and west of the unknown station) and weight the data with the inverse squares of the distance between the stations. In Eq. 20.4,  $P_x$ ,  $P_A$ ,  $P_B$ ,  $P_C$ , and  $P_D$  are defined as in Method 2, and  $d_{A-x}$ ,  $d_{B-x}$ ,  $d_{C-x}$ , and  $d_{D-x}$  are the distances between stations A and  $x$ , B and  $x$ , and so on, respectively.

$$P_x = \frac{\frac{P_A}{d_{A-x}^2} + \frac{P_B}{d_{B-x}^2} + \frac{P_C}{d_{C-x}^2} + \frac{P_D}{d_{D-x}^2}}{\frac{1}{d_{A-x}^2} + \frac{1}{d_{B-x}^2} + \frac{1}{d_{C-x}^2} + \frac{1}{d_{D-x}^2}} \quad 20.4$$

## 5. TIME OF CONCENTRATION

*Time of concentration*,  $t_c$ , is defined as the time of travel from the hydraulically most remote (timewise) point in the watershed to the watershed outlet or other design point. For points (e.g., manholes) along storm drains being fed from a watershed, time of concentration is taken as the largest combination of overland flow time (sheet flow), swale or ditch flow (shallow concentrated flow), and storm drain, culvert, or channel time. It is unusual for time of concentration to be less than 0.1 hr (6 min) when using the Natural Resources Conservation Service (NRCS, previously known as the Soil Conservation Service (SCS)) method, or less than 10 min when using the rational method.

$$t_c = t_{\text{sheet}} + t_{\text{shallow}} + t_{\text{channel}} \quad 20.5$$

The NRCS specifies using the *Manning kinematic equation* (Overton and Meadows 1976 formulation) for calculating *sheet flow* travel time over distances less than 300 ft (100 m). In Eq. 20.6,  $n$  is the Manning roughness coefficient for sheet flow, as given in Table 20.1.  $P_2$  is the 2 yr, 24 hr rainfall in inches, and  $S$  is the slope of the hydraulic grade line in ft/ft.

$$t_{\text{sheet flow}} = \frac{0.007(nL_o)^{0.8}}{\sqrt{P_2} S^{0.4}_{\text{decimal}}} \quad 20.6$$

**Table 20.1** Manning Roughness Coefficient for Sheet Flow

surface	<i>n</i>
smooth surfaces (concrete, asphalt, gravel, or bare soil)	0.011
fallow (no residue cover)	0.05
cultivated soils	
residue cover $\leq 20\%$	0.06
residue cover $> 20\%$	0.17
grasses	
short prairie grass	0.15
dense grass <sup>a</sup>	0.24
Bermuda grass	0.41
range, natural	0.13
woods <sup>b</sup>	
light underbrush	0.40
dense underbrush	0.80

<sup>a</sup>This includes species such as weeping lovegrass, bluegrass, buffalo grass, blue grama grass, and native grass mixtures.

<sup>b</sup>When selecting a value of  $n$ , consider the cover to a height of about 0.1 ft (3 cm). This is the only part of the plant that will obstruct sheet flow.

Reprinted from *Urban Hydrology for Small Watersheds*, Technical Release TR-55, United States Department of Agriculture, Natural Resources Conservation Service, Table 3-1, after Engman (1986).

After about 300 ft (100 m), the flow usually becomes a shallow concentrated flow (swale, ditch flow). Travel time is calculated as  $L/v$ . Velocity can be found from the Manning equation if the flow geometry is well defined, but must be determined from other correlations, such as those specified by the NRCS in Eq. 20.7 and Eq. 20.8.

$$v_{\text{shallow,ft/sec}} = 16.1345\sqrt{S_{\text{decimal}}} \quad [\text{unpaved}] \quad 20.7$$

$$v_{\text{shallow,ft/sec}} = 20.3282\sqrt{S_{\text{decimal}}} \quad [\text{paved}] \quad 20.8$$

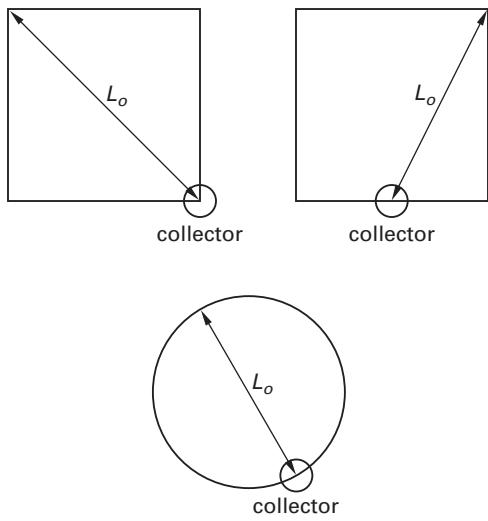

Storm drain (channel) time is found by dividing the storm drain length by the actual or an assumed channel velocity. Storm drain velocity is found from either the Manning or the Hazen-Williams equation. Since size and velocity are related, an iterative trial-and-error solution is generally required.<sup>1</sup>

There are a variety of methods available for estimating time of concentration. Early methods include Kirpich (1940), California Culverts Practice (1942), Hathaway (1945), and Izzard (1946). More recent methods include those from the Federal Aviation Administration, or FAA (1970), the kinematic wave formulas of Morgali (1965) and Aron (1973), the NRCS lag equation (1975), and NRCS average velocity charts (1975). Estimates of time of concentration from these methods can vary by as much as 100%. These differences carry over into estimates of peak flow, hence the need to carefully determine the validity of any method used.

<sup>1</sup>If the pipe or channel size is known, the velocity can be found from  $Q = Av$ . If the pipe size is not known, the area will have to be estimated. In that case, one might as well estimate velocity instead. 5 ft/sec (1.5 m/s) is a reasonable flow velocity for open channel flow. The minimum velocity for a *self-cleansing pipe* is 2 ft/sec (0.6 m/s).

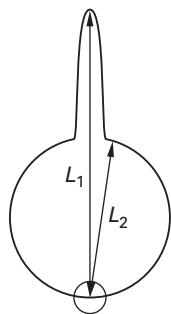

The distance  $L_o$  in the various equations that follow is the longest distance to the collection point, as shown in Fig. 20.2.

**Figure 20.2** Overland Flow Distances

For irregularly shaped drainage areas, it may be necessary to evaluate several alternative overland flow distances. For example, Fig. 20.3 shows a drainage area with a long tongue. Although the tongue area contributes little to the drainage area, it does lengthen the overland flow time. Depending on the intensity-duration-frequency curve, the longer overland flow time (resulting in a lower rainfall intensity) may offset the increase in area due to the tongue. Therefore, two runoffs need to be compared, one ignoring and the other including the tongue.

**Figure 20.3** Irregular Drainage Area

The *FAA formula*, Eq. 20.9, was developed from airfield drainage data collected by the Army Corps of Engineers. However, it has been widely used for urbanized areas.  $C$  is the rational method runoff coefficient. The slope  $S$  in Eq. 20.9 is in percent.  $L_o$  is in ft.

$$t_{c,\min} = \frac{1.8(1.1 - C)\sqrt{L_{o,ft}}}{S^{1/3}_{\text{percent}}} \quad 20.9$$

The *kinematic wave formula* is particularly accurate for uniform planar homogenous areas (e.g., paved areas such as parking lots and streets). It requires iteration, since both intensity and time of concentration are unknown. In Eq. 20.10,  $L_o$  is in ft,  $n$  is the *Manning overland roughness coefficient (retardance roughness coefficient)*,  $I$  is the intensity in in/hr, and  $S_{\text{decimal}}$  is the slope in ft/ft. Recommended values of  $n$  for this application are different than for open channel flow and are: smooth impervious surfaces, 0.011–0.014; smooth bare-packed soil, free of stones, 0.05; poor grass, moderately bare surface, 0.10; pasture or average grass cover, 0.20; and dense grass or forest, 0.40. Equation 20.10 is solved iteratively since the intensity depends on the time to concentration.

$$t_{c,\min} = \frac{0.94 L_{o,ft}^{0.6} n^{0.6}}{I_{\text{in/hr}}^{0.4} S_{\text{decimal,ft/ft}}^{0.3}} \quad 20.10$$

The NRCS *lag equation* was developed from observations of agricultural watersheds where overland flow paths are poorly defined and channel flow is absent. However, it has been adapted to small urban watersheds under 2000 ac. The equation performs reasonably well for areas that are completely paved, as well. Correction factors are used to account for channel improvement and impervious areas.  $L_o$  is in ft, CN is the NRCS runoff curve number,  $S_{\text{in}}$  is the potential maximum retention in the watershed after runoff begins in inches, and  $S_{\text{percent}}$  is the average slope in percent. The factor 1.67 converts the watershed lag time to the time of concentration. Since the formula overestimates time for mixed areas, different adjustment factors have been proposed. The NRCS lag equation performs poorly when channel flow is a significant part of the time of concentration.

$$\begin{aligned} t_{c,\min} &= 1.67 t_{\text{watershed lag time,min}} \\ &= \frac{(1.67) \left( 60 \frac{\text{min}}{\text{hr}} \right) L_{o,ft}^{0.8} (S_{\text{in}} + 1)^{0.7}}{1900 \sqrt{S_{\text{percent}}}} \\ &= \frac{(1.67) \left( 60 \frac{\text{min}}{\text{hr}} \right) L_{o,ft}^{0.8} \left( \frac{1000}{\text{CN}} - 9 \right)^{0.7}}{1900 \sqrt{S_{\text{percent}}}} \end{aligned} \quad 20.11$$

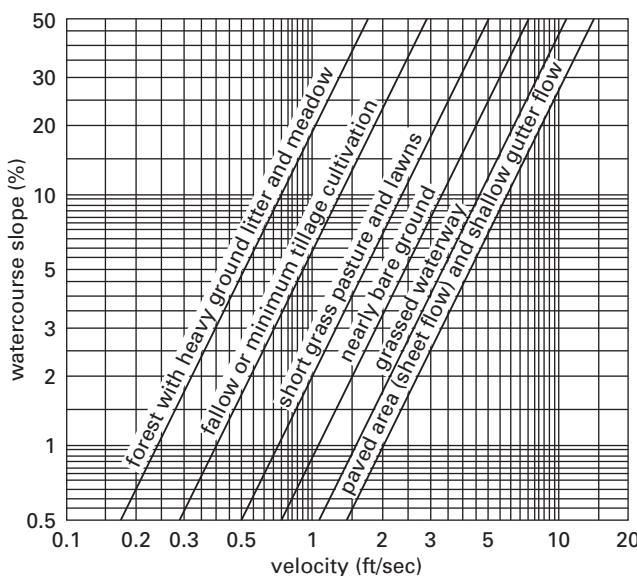

If the velocity of runoff water is known, the time of concentration can be easily determined. The NRCS has published charts of average velocity as functions of watercourse slope and surface cover. (See Fig. 20.4.) The charts are best suited for flow paths of at least several hundred feet (at least 70 m). The time of concentration is easily determined from these charts as

$$t_c = \frac{\sum L_{o,ft}}{v \left( 60 \frac{\text{sec}}{\text{min}} \right)} \quad 20.12$$

## 6. RAINFALL INTENSITY

Effective design of a surface feature depends on its geographical location and required degree of protection.

**Figure 20.4** NRCS Average Velocity Chart for Overland Flow Travel Time

Reprinted from NRCS TR-55-1975. TR-55-1986 contains a similar graph for shallow-concentrated flow over paved and unpaved surfaces, but it does not contain this particular graph.

Once the location of the feature is known, the *design storm* (or *design flood*) must be determined based on some probability of recurrence.

*Rainfall intensity* is the amount of precipitation per hour. The instantaneous intensity changes throughout the storm. However, it may be averaged over short time intervals or over the entire storm duration. Average intensity will be low for most storms, but it can be high for some. These high-intensity storms can be expected infrequently, say, every 20, 50, or 100 years. The average number of years between storms of a given intensity is known as the *frequency of occurrence* (*recurrence interval*, *return interval*, or *storm frequency*).

In general, the design storm may be specified by its recurrence interval (e.g., “100-year storm”), its annual probability of occurrence (e.g., “1% storm”), or a nickname (e.g., “century storm”). A 1% storm is a storm that would be exceeded in severity only once every hundred years on the average.

The average intensity of a storm over a time period  $t$  can be calculated from Eq. 20.13 (and similar correlations). (When using the rational method described in Sec. 20.15,  $t$  is the time of concentration.) In the United States, it is understood that the units of intensity calculated using Eq. 20.13 will be in in/hr.

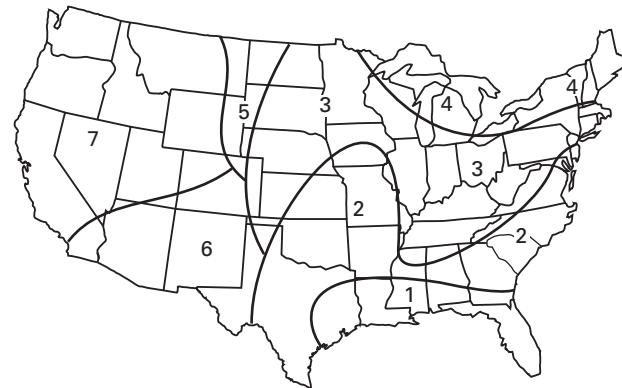

$$I = \frac{K' F^a}{(t + b)^c} \quad 20.13$$

$K'$ ,  $F$ ,  $a$ ,  $b$ , and  $c$  are constants that depend on the conditions, recurrence interval, and location of a storm. For many reasons, these constants may be unavailable.

The *Steel formula* is a simplification of Eq. 20.13. Steel formula rainfall regions are shown in Fig. 20.5.

$$I = \frac{K}{t_c + b} \quad 20.14$$

**Figure 20.5** Steel Formula Rainfall Regions

Values of the constants  $K$  and  $b$  in Eq. 20.14 are not difficult to obtain once the intensity-duration-frequency curve is established. Although a logarithmic transformation could be used to convert the data to straight-line form, an easier method exists. This method starts by taking the reciprocal of Eq. 20.14 and converting the equation to a straight line.

$$\begin{aligned} \frac{1}{I} &= \frac{t_c + b}{K} \\ &= \frac{t_c}{K} + \frac{b}{K} \\ &= C_1 t_c + C_2 \end{aligned} \quad 20.15$$

Once  $C_1$  and  $C_2$  have been found,  $K$  and  $b$  can be calculated.

$$K = \frac{1}{C_1} \quad 20.16$$

$$b = \frac{C_2}{C_1} \quad 20.17$$

Published values of  $K$  and  $b$  can be obtained from compilations, but these values are suitable only for very rough estimates. Table 20.2 is typical of some of this general data.

The total rainfall can be calculated from the average intensity and duration.

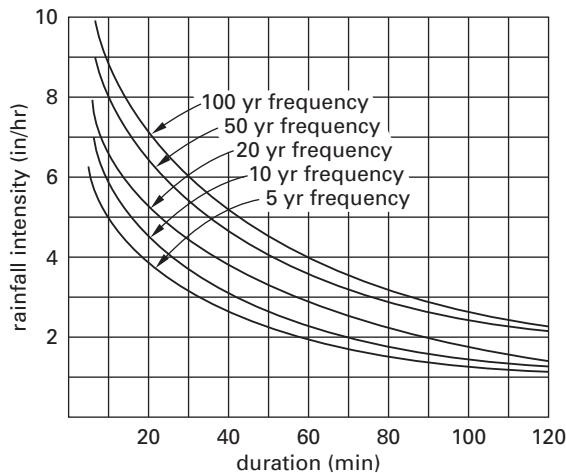

$$P = It \quad 20.18$$

Rainfall data can be compiled into *intensity-duration-frequency curves* (*IDF curves*) similar to those shown in Fig. 20.6.

**Table 20.2** Steel Formula Coefficients (for intensities of in/hr)

frequency in years	coefficients	region						
		1	2	3	4	5	6	7
2	<i>K</i>	206	140	106	70	70	68	32
	<i>b</i>	30	21	17	13	16	14	11
4	<i>K</i>	247	190	131	97	81	75	48
	<i>b</i>	29	25	19	16	13	12	12
10	<i>K</i>	300	230	170	111	111	122	60
	<i>b</i>	36	29	23	16	17	23	13
25	<i>K</i>	327	260	230	170	130	155	67
	<i>b</i>	33	32	30	27	17	26	10
50	<i>K</i>	315	350	250	187	187	160	65
	<i>b</i>	28	38	27	24	25	21	8
100	<i>K</i>	367	375	290	220	240	210	77
	<i>b</i>	33	36	31	28	29	26	10

(Multiply in/hr by 2.54 to obtain cm/h.)

**Figure 20.6** Typical Intensity-Duration-Frequency Curves**Example 20.1**

A storm has an intensity given by

$$I = \frac{100}{t_c + 10}$$

15 min are required for runoff from the farthest corner of a 5 ac watershed to reach a discharge culvert. What is the design intensity?

*Solution*

The intensity is

$$I = \frac{100}{t_c + 10} = \frac{100 \frac{\text{in-min}}{\text{hr}}}{15 \text{ min} + 10 \text{ min}} = 4 \text{ in/hr}$$

**7. FLOODS**

A *flood* occurs when more water arrives than can be drained away. When a watercourse (i.e., a creek or river) is too small to contain the flow, the water overflows the banks.

The flooding may be categorized as nuisance, damaging, or devastating. *Nuisance floods* result in inconveniences such as wet feet, tire spray, and soggy lawns. *Damaging floods* soak flooring, carpeting, and first-floor furniture. *Devastating floods* wash buildings, vehicles, and livestock downstream.

Although rain causes flooding, large storms do not always cause floods. The size of a flood depends not only on the amount of rainfall, but also on the conditions within the watershed before and during the storm. Runoff will occur only when the rain falls on a very wet watershed that is unable to absorb additional water, or when a very large amount of rain falls on a dry watershed faster than it can be absorbed.

Specific terms are sometimes used to designate the degree of protection required. For example, the *probable maximum flood* (PMF) is a hypothetical flood that can be expected to occur as a result of the most severe combination of critical meteorologic and hydrologic conditions possible within a region.

Designing for the *probable maximum precipitation* (PMP) or probable maximum flood is very conservative and usually uneconomical since the recurrence interval for these events exceeds 100 years and may even approach 1000 years. Designing for 100 year floods and floods with even lower recurrence intervals is more common. (100 year floods are not necessarily caused by 100 year storms.)

The *design flood* or *design basis flood* (DBF) depends on the site. It is the flood that is adopted as the basis for design of a particular project. The DBF is usually determined from economic considerations, or it is specified as part of the contract document.

The *standard flood* or *standard project flood* (SPF) is a flood that can be selected from the most severe combinations of meteorological and hydrological conditions reasonably characteristic of the region, excluding extremely rare combinations of events. SPF volumes are commonly 40–60% of the PMF volumes.

The probability that a flooding event in any given year will equal a design basis flood with a *recurrence interval frequency (return interval)* of *F* is

$$p\{F \text{ event in one year}\} = \frac{1}{F} \quad 20.19$$

The probability of an *F* event occurring in *n* years is

$$p\{F \text{ event in } n \text{ years}\} = 1 - \left(1 - \frac{1}{F}\right)^n \quad 20.20$$

Planning for a 1% flood has proven to be a good compromise between not doing enough and spending too much. Although the 1% flood is a common choice for the design basis flood, shorter recurrence intervals are often used, particularly in low-value areas such as cropland. For example, a 5 year value can be used in residential areas, a 10 year value in business sections, and a 15 year value for high-value districts where flooding will result in more extensive damage. The ultimate choice of recurrence interval, however, must be made on the basis of economic considerations and trade-offs.

### Example 20.2

A wastewater treatment plant has been designed to be in use for 40 years. What is the probability that a 1% flood will occur within the useful lifetime of the plant?

*Solution*

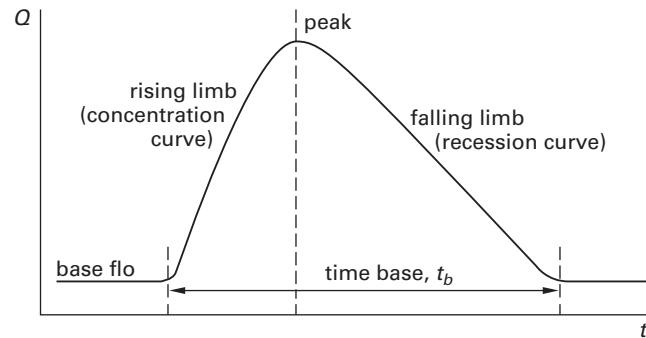

Use Eq. 20.20.

$$\begin{aligned} p\{F \text{ event in } n \text{ years}\} &= 1 - \left(1 - \frac{1}{F}\right)^n \\ p\{100 \text{ yr flood in 40 years}\} &= 1 - \left(1 - \frac{1}{100}\right)^{40} \\ &= 0.33 \quad (33\%) \end{aligned}$$

## 8. TOTAL SURFACE RUNOFF FROM STREAM HYDROGRAPH

After a rain, runoff and groundwater increases stream flow. A plot of the stream discharge versus time is known as a *hydrograph*. Hydrograph periods may be very short (e.g., hours) or very long (e.g., days, weeks, or months). A typical hydrograph is shown in Fig. 20.7. The *time base* is the length of time that the stream flow exceeds the original *base flow*. The flow rate increases on the *rising limb* (*concentration curve*) and decreases on the *falling limb* (*recession curve*).

**Figure 20.7** Stream Hydrograph

## 9. HYDROGRAPH SEPARATION

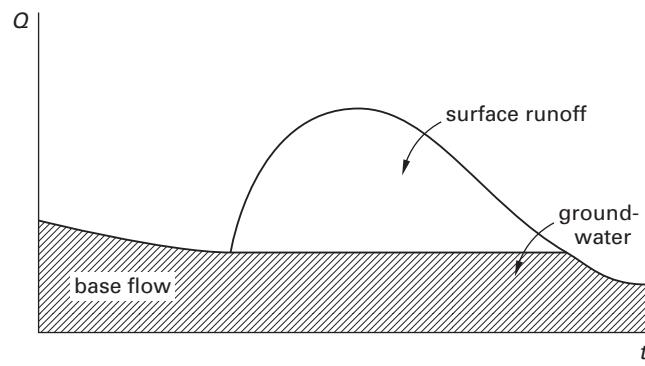

The stream discharge consists of both surface runoff and subsurface groundwater flows. A procedure known as

*hydrograph separation* or *hydrograph analysis* is used to separate runoff (*surface flow*, *net flow*, or *overland flow*) and groundwater (*subsurface flow*, *base flow*).<sup>2</sup>

There are several methods of separating groundwater from runoff. Most of the methods are somewhat arbitrary. Three methods that are easily carried out manually are presented here.

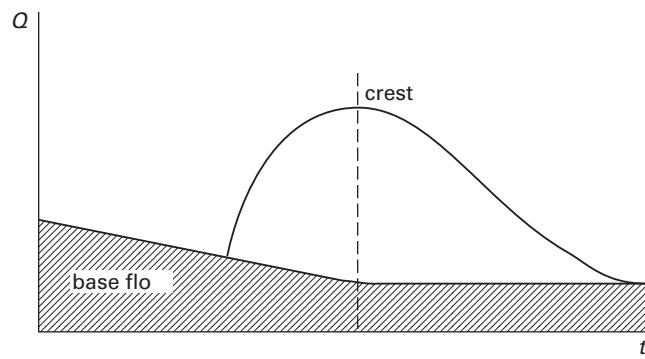

*Method 1:* In the *straight-line method*, a horizontal line is drawn from the start of the rising limb to the falling limb. All of the flow under the horizontal line is considered base flow. This assumption is not theoretically accurate, but the error can be small. This method is illustrated in Fig. 20.8.

**Figure 20.8** Straight-Line Method

*Method 2:* In the *fixed-base method*, shown in Fig. 20.9, the base flow existing before the storm is projected graphically down to a point directly under the peak of the hydrograph. Then, a straight line is used to connect the projection to the falling limb. The duration of the recession limb is determined by inspection, or it can be calculated from correlations with the drainage area.

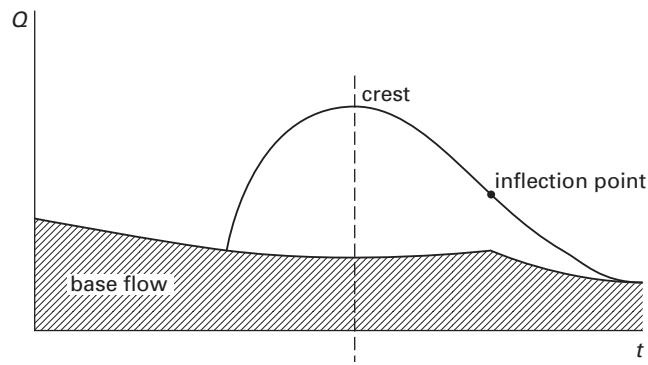

**Figure 20.9** Fixed-Base Method

<sup>2</sup>The total rain dropped by a storm is the *gross rain*. The rain that actually appears as immediate runoff can be called *surface runoff*, *overland flow*, *surface flow*, and *net rain*. The water that is absorbed by the soil and that does not contribute to the surface runoff can be called *base flow*, *groundwater*, *infiltration*, and *dry weather flow*.

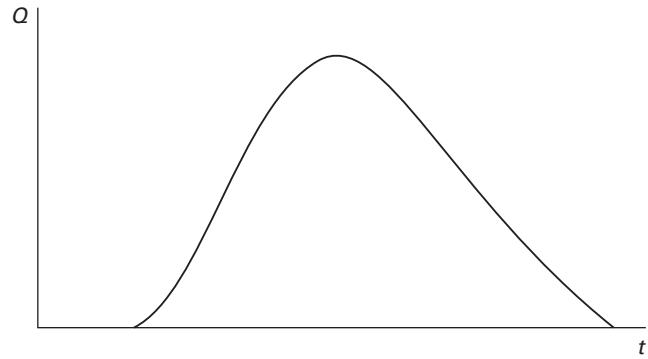

*Method 3:* The variable-slope method, as shown in Fig. 20.10, recognizes that the shape of the base flow curve before the storm will probably match the shape of the base flow curve after the storm. The groundwater curve after the storm is projected back under the hydrograph to a point under the inflection point of the falling limb. The separation line under the rising limb is drawn arbitrarily.

**Figure 20.10** Variable-Slope Method

Once the base flow is separated out, the hydrograph of surface runoff will have the approximate appearance of Fig. 20.11.

**Figure 20.11** Overland Flow Hydrograph

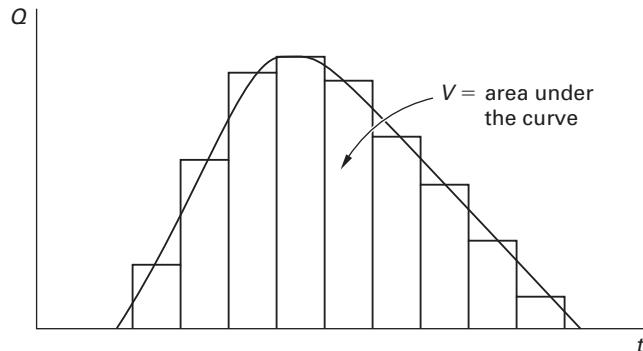

## 10. UNIT HYDROGRAPH

Once the overland flow hydrograph for a watershed has been developed, the total runoff (i.e., "excess rainfall") volume,  $V$ , from the storm can be found as the area under the curve. Although this can be found by integration, planimetry, or computer methods, it is often sufficiently accurate to approximate the hydrograph with a histogram and to sum the areas of the rectangles. (See Fig. 20.12.)

Since the area of the watershed is known, the average depth,  $P_{ave}$ , of the excess precipitation can be calculated. (Consistent units must be used in Eq. 20.21.)

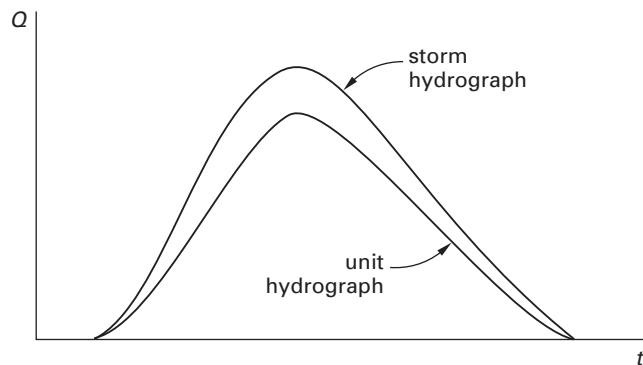

$$V = A_d P_{ave, \text{excess}} \quad 20.21$$

**Figure 20.12** Hydrograph Histogram

A *unit hydrograph* (UH) is developed by dividing every point on the overland flow hydrograph by the average excess precipitation,  $P_{ave, \text{excess}}$ . This is a hydrograph of a storm dropping 1 in (1 cm) of excess precipitation (runoff) evenly on the entire watershed. Units of the unit hydrograph are in/in (cm/cm). Figure 20.13 shows how a unit hydrograph compares to its surface runoff hydrograph.

**Figure 20.13** Unit Hydrograph

Once a unit hydrograph has been developed from historical data of a particular storm volume, it can be used for other storm volumes. Such application is based on several assumptions: (a) All storms in the watershed have the same duration, (b) the time base is constant for all storms, (c) the shape of the rainfall curve is the same for all storms, and (d) only the total amount of rainfall varies from storm to storm.

The hydrograph of a storm producing more or less than 1 in (1 cm) of rain is found by multiplying all ordinates on the unit hydrograph by the total precipitation of the storm.

A unit hydrograph can be used to predict the runoff for storms that have durations somewhat different than the storms used to develop the unit hydrograph. Generally, storm durations differing by up to  $\pm 25\%$  are considered to be equivalent.

**Example 20.3**

After a 2 hr storm, a station downstream from a 45 mi<sup>2</sup> (115 km<sup>2</sup>) drainage watershed records a peak discharge of 9400 ft<sup>3</sup>/sec (250 m<sup>3</sup>/s) and a total runoff of 3300 ac-ft (4 × 10<sup>6</sup> m<sup>3</sup>). (a) What is the unit hydrograph peak discharge? (b) What would be the peak runoff and design flood volume if a 2 hr storm dropped 2.5 in (6 cm) net precipitation?

*SI Solution*

(a) Use Eq. 20.21 to find the average precipitation for the drainage watershed.

$$\begin{aligned} P_{\text{ave}} &= \frac{V}{A_d} \\ &= \frac{4 \times 10^6 \text{ m}^3}{(115 \text{ km}^2) \left(1000 \frac{\text{m}}{\text{km}}\right)^2} \\ &= 0.0348 \text{ m} \quad (3.5 \text{ cm}) \end{aligned}$$

The ordinates for the unit hydrograph are found by dividing every point on the 3.5 cm hydrograph by 3.5 cm. Therefore, the peak discharge for the unit hydrograph is

$$\begin{aligned} Q_{p,\text{unit}} &= \frac{250 \frac{\text{m}^3}{\text{s}}}{3.5 \text{ cm}} \\ &= 71.4 \text{ m}^3/\text{s} \cdot \text{cm} \end{aligned}$$

(b) The hydrograph for a storm that is producing more than 1 cm of rain is found by multiplying the ordinates of the unit hydrograph by the total precipitation. For a 6 cm storm, the peak discharge is

$$\begin{aligned} Q_p &= \left(71.4 \frac{\text{m}^3}{\text{s} \cdot \text{cm}}\right)(6 \text{ cm}) \\ &= 428 \text{ m}^3/\text{s} \end{aligned}$$

To find the design flood volume, first use Eq. 20.21 to find the unit hydrograph total volume.

$$\begin{aligned} V &= A_d P \\ &= \frac{(115 \text{ km}^2) \left(1000 \frac{\text{m}}{\text{km}}\right)^2 \left(1 \frac{\text{cm}}{\text{cm}}\right)}{100 \frac{\text{cm}}{\text{m}}} \\ &= 1.15 \times 10^6 \text{ m}^3/\text{cm} \end{aligned}$$

The design flood volume for a 6 cm storm is

$$\begin{aligned} V &= (6 \text{ cm}) \left(1.15 \times 10^6 \frac{\text{m}^3}{\text{cm}}\right) \\ &= 6.9 \times 10^6 \text{ m}^3 \end{aligned}$$

*Customary U.S. Solution*

(a) Use Eq. 20.21 to find the average precipitation for the drainage watershed.

$$\begin{aligned} P_{\text{ave}} &= \frac{V}{A_d} \\ &= \frac{(3300 \text{ ac-ft}) \left(43,560 \frac{\text{ft}^2}{\text{ac}}\right) \left(12 \frac{\text{in}}{\text{ft}}\right)}{(45 \text{ mi}^2) \left(5280 \frac{\text{ft}}{\text{mi}}\right)^2} \\ &= 1.375 \text{ in} \end{aligned}$$

The ordinates for the unit hydrograph are found by dividing every point on the 1.375 in hydrograph by 1.375 in. Therefore, the peak discharge for the unit hydrograph is

$$\begin{aligned} Q_{p,\text{unit}} &= \frac{9400 \frac{\text{ft}^3}{\text{sec}}}{1.375 \text{ in}} \\ &= 6836 \text{ ft}^3/\text{sec-in} \end{aligned}$$

(b) The hydrograph for a storm that is producing more than 1 in of rain is found by multiplying the ordinates of the unit hydrograph by the total precipitation. For a 2.5 in storm, the peak discharge is

$$\begin{aligned} Q_p &= \left(6836 \frac{\text{ft}^3}{\text{sec-in}}\right)(2.5 \text{ in}) \\ &= 17,090 \text{ ft}^3/\text{sec} \end{aligned}$$

To find the design flood volume, first use Eq. 20.21 to find the unit hydrograph total volume.

$$\begin{aligned} V &= A_d P \\ &= (45 \text{ mi}^2) \left(\frac{640 \frac{\text{ac}}{\text{mi}^2}}{12 \frac{\text{in}}{\text{ft}}}\right) \left(1 \frac{\text{in}}{\text{in}}\right) \\ &= 2400 \text{ ac-ft/in} \end{aligned}$$

The design flood volume for a 2.5 in storm is

$$V = (2.5 \text{ in}) \left(2400 \frac{\text{ac-ft}}{\text{in}}\right) = 6000 \text{ ac-ft}$$

**Example 20.4**

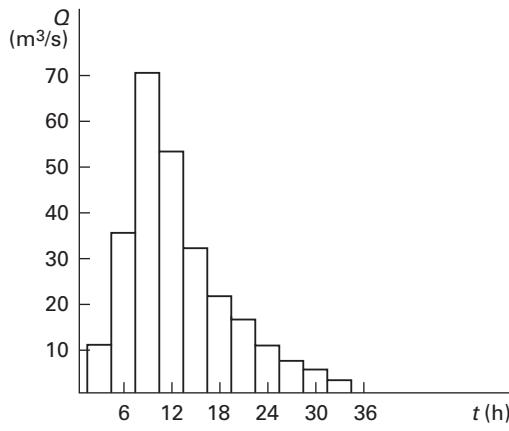

A 6 hr storm rains on a 25 mi<sup>2</sup> (65 km<sup>2</sup>) drainage watershed. Records from a stream gaging station draining the watershed are shown. (a) Construct the unit hydrograph for the 6 hr storm. (b) Find the runoff rate at t = 15 hr from a two-storm system if the first storm

drops 2 in (5 cm) starting at  $t = 0$  and the second storm drops 5 in (12 cm) starting at  $t = 12$  hr.

$t$ (hr)	$Q$ (ft <sup>3</sup> /sec)	$Q$ (m <sup>3</sup> /s)
0	0	0
3	400	10
6	1300	35
9	2500	70
12	1700	50
15	1200	35

21	600	15
24	400	10
27	300	10
30	200	5
33	100	3
36	0	0
totals	9500	263

#### SI Solution

(a) Plot the stream gaging data.

The total runoff is the total area under the curve, found by multiplying the average runoff by the rainfall interval. This is equivalent to summing the areas of each rectangle of the histogram. Each of the histogram bars is 3 hr “wide.”

$$V = \left( 263 \frac{\text{m}^3}{\text{s}} \right) (3 \text{ h}) \left( 3600 \frac{\text{s}}{\text{h}} \right)$$

$$= 2.84 \times 10^6 \text{ m}^3$$

The watershed drainage area is

$$A_d = (65 \text{ km}^2) \left( 1000 \frac{\text{m}}{\text{km}} \right)^2$$

$$= 65 \times 10^6 \text{ m}^2$$

The average precipitation is calculated from Eq. 20.21.

$$P = \frac{V}{A_d}$$

$$= \frac{(2.84 \times 10^6 \text{ m}^3)}{65 \times 10^6 \text{ m}^2}$$

$$= 4.37 \text{ cm}$$

The unit hydrograph has the same shape as the actual hydrograph with all ordinates reduced by a factor of 4.37.

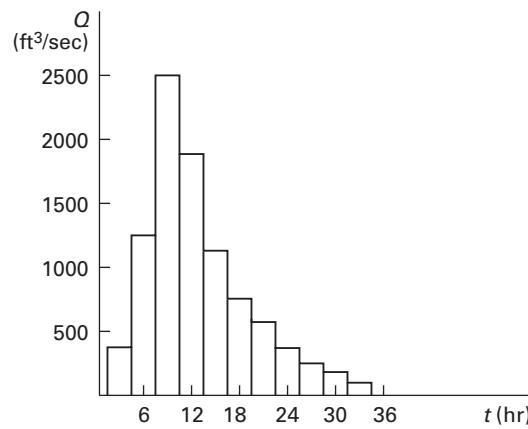

(b) To find the flow at 15 h, add the contributions from each storm. For the 5 cm storm, the contribution is the 15 h runoff multiplied by its scaling factors; for the 12 cm storm, the contribution is the 15 h – 12 h = 3 h runoff multiplied by its scaling factors.

$$Q = \frac{(5 \text{ cm}) \left( 35 \frac{\text{m}^3}{\text{s}} \right)}{4.37 \text{ cm}} + \frac{(12 \text{ cm}) \left( 10 \frac{\text{m}^3}{\text{s}} \right)}{4.37 \text{ cm}}$$

$$= 67.5 \text{ m}^3/\text{s}$$

#### Customary U.S. Solution

(a) Plot the stream gaging data.

The total runoff is the area under the curve, found by multiplying the average runoff by the rainfall interval. This is equivalent to summing the areas of each rectangle of the histogram. Each of the histogram bars is 3 hr “wide.”

$$V = \left( 9500 \frac{\text{ft}^3}{\text{sec}} \right) (3 \text{ hr}) \left( 3600 \frac{\text{sec}}{\text{hr}} \right)$$

$$= 1.026 \times 10^8 \text{ ft}^3$$

The watershed drainage area is

$$A_d = (25 \text{ mi}^2) \left( 5280 \frac{\text{ft}}{\text{mi}} \right)^2$$

$$= 6.97 \times 10^8 \text{ ft}^2$$

The average precipitation is calculated from Eq. 20.21.

$$\begin{aligned} P &= \frac{V}{A_d} \\ &= \frac{(1.026 \times 10^8 \text{ ft}^3) \left( 12 \frac{\text{in}}{\text{ft}} \right)}{6.97 \times 10^8 \text{ ft}^2} \\ &= 1.766 \text{ in} \end{aligned}$$

The unit hydrograph has the same shape as the actual hydrograph with all ordinates reduced by a factor of 1.766.

(b) To find the flow at  $t = 15$  hr, add the contributions from each storm. For the 2 in storm, the contribution is the 15 hr runoff multiplied by its scaling factors; for the 5 in storm, the contribution is the 15 hr – 12 hr = 3 hr runoff multiplied by its scaling factors.

$$\begin{aligned} Q &= \frac{(2 \text{ in}) \left( 1200 \frac{\text{ft}^3}{\text{sec}} \right)}{1.766 \text{ in}} + \frac{(5 \text{ in}) \left( 400 \frac{\text{ft}^3}{\text{sec}} \right)}{1.766 \text{ in}} \\ &= 2492 \text{ ft}^3/\text{sec} \end{aligned}$$

## 11. NRCS SYNTHETIC UNIT HYDROGRAPH

If a watershed is unmonitored such that no historical records are available to produce a unit hydrograph, the *synthetic hydrograph* can still be reasonably approximated. The process of developing a synthetic hydrograph is known as *hydrograph synthesis*.

Pioneering work was done in 1938 by Snyder, who based his analysis on Appalachian highland watersheds with areas between 10 mi<sup>2</sup> and 10,000 mi<sup>2</sup>. Snyder's work has been largely replaced by more sophisticated analyses, including the NRCS methods.

The NRCS developed a synthetic unit hydrograph based on the *curve number*, CN. The method was originally intended for use with rural watersheds up to 2000 ac, but it appears to be applicable for urban conditions up to 4000–5000 ac.

In order to draw the NRCS synthetic unit hydrograph, it is necessary to calculate the time to peak flow,  $t_p$ , and the peak discharge,  $Q_p$ . Provisions for calculating both of these parameters are included in the method.

$$t_p = 0.5t_R + t_1 \quad 20.22$$

$t_R$  in Eq. 20.22 is the storm duration (i.e., of the rainfall).  $t_1$  in Eq. 20.22 is the *lag time* (i.e., the time from the centroid of the rainfall distribution to the peak discharge). Lag time can be determined from correlations with geographical region and drainage area or calculated from Eq. 20.23. Although Eq. 20.23 was developed for natural watersheds, limited studies of urban watersheds indicate that it does not change significantly for urbanized watersheds.  $S$  in Eq. 20.23 is the

soil water storage capacity in inches, computed as a function of the curve number. (See Eq. 20.43.)

$$t_{1,\text{hr}} = \frac{L_{o,\text{ft}}^{0.8} (S+1)^{0.7}}{1900 \sqrt{S_{\text{percent}}}} \quad 20.23$$

The peak runoff is calculated as

$$Q_p = \frac{0.756 A_{d,\text{ac}}}{t_p} \quad 20.24$$

$$Q_p = \frac{484 A_{d,\text{mi}^2}}{t_p} \quad 20.25$$

$Q_p$  and  $t_p$  only contribute one point to the construction of the unit hydrograph. To construct the remainder, Table 20.3 must be used. Using time as the independent variable, selections of time (different from  $t_p$ ) are arbitrarily made, and the ratio  $t/t_p$  is calculated. The curve is then used to obtain the ratio of  $Q_t/Q_p$ .

## 12. NRCS SYNTHETIC UNIT TRIANGULAR HYDROGRAPH

The NRCS unit triangular hydrograph is shown in Fig. 20.14. It is found from the peak runoff, the time to peak, and the duration of runoff. Peak runoff,  $Q_p$ , is found from Eq. 20.24 or Eq. 20.25. Time to peak and duration are correlated with the time of concentration. These are generalizations that apply to specific storm and watershed types.

**Figure 20.14** NRCS Synthetic Unit Triangular Hydrograph

**Figure 20.15** Espey Watershed Conveyance Factor

Reprinted from *Recommended Hydrologic Procedures for Computing Urban Runoff from Small Watersheds in Pennsylvania*, Commonwealth of Pennsylvania, Fig. 6-3, 1982, Department of Environmental Resources.

Equation 20.26 can be used to estimate the time to peak.

$$t_p = 0.5t_R + t_1 \quad 20.26$$

$$t_1 \approx 0.6t_c \quad 20.27$$

Alternatively, the time to peak has been roughly correlated to the time of concentration.

$$t_p = 0.67t_c \quad 20.28$$

The total duration of the unit hydrograph is the sum of time to peak and length of recession limb, assumed to be  $1.67t_p$ .

$$t_b = t_p + t_{\text{recession}} = t_p + 1.67t_p = 2.67t_p \quad 20.29$$

## 13. ESPEY SYNTHETIC UNIT HYDROGRAPH

The *Espey method* calculates the time to peak ( $t_p$ , in min), peak discharge ( $Q_p$ , in  $\text{ft}^3/\text{sec}$ ), total hydrograph base ( $t_b$ , in min), and the hydrograph widths at 50% and 75% of the peak discharge rates ( $W_{50}$  and  $W_{75}$ , in min). These values depend on the watershed area ( $A$ , in  $\text{mi}^2$ ), main channel flow path length ( $L$ , in ft), slope ( $S$ , in  $\text{ft}/\text{ft}$ ), roughness, and percent imperviousness (Imp).  $\phi$  is a dimensionless watershed conveyance factor ( $0.6 < \phi < 1.3$ ) that depends on the percent imperviousness and weighted

main channel Manning roughness coefficient,  $n$ .  $\phi$  is found graphically from Fig. 20.15.

$$t_p = 3.1L^{0.23}S_{\text{decimal}}^{-0.25}(\text{Imp percent})^{-0.18}\phi^{1.57} \quad 20.30$$

$$Q_p = (31.62 \times 10^3)A^{0.96}t_p^{-1.07} \quad 20.31$$

$$t_b = (125.89 \times 10^3)AQ_p^{-0.95} \quad 20.32$$

$$W_{50} = (16.22 \times 10^3)A^{0.93}Q_p^{-0.92} \quad 20.33$$

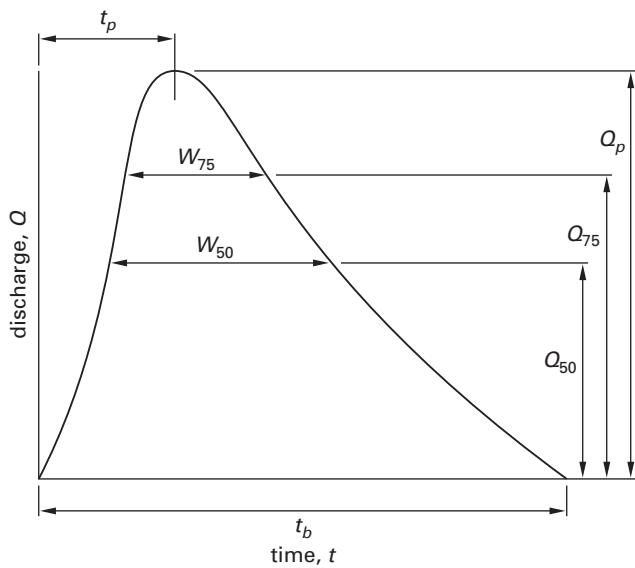

$$W_{75} = (3.24 \times 10^3)A^{0.79}Q_p^{-0.78} \quad 20.34$$

To use this method, the geometric slope,  $S$ , used in Eq. 20.30 is specifically calculated from Eq. 20.35.  $H$  is the difference in elevation of points A and B. Point A is the channel bottom a distance  $0.2L$  downstream from the upstream watershed boundary. Point B is the channel bottom at the downstream watershed boundary.

$$S_{\text{decimal}} = \frac{H}{0.8L} \quad 20.35$$

The unit hydrograph is drawn by manually “fitting” a smooth curve over the seven computed points. The widths of  $W_{50}$  and  $W_{75}$  are allocated in a 1:2 ratio to the rising and falling hydrograph limbs, respectively. After the curve is drawn, it is adjusted to be a unit hydrograph. The resulting curve is sometimes referred to as an *Espey 10-minute unit hydrograph*. (See Fig. 20.16.)

**Figure 20.16** Espey Synthetic Hydrograph

#### 14. HYDROGRAPH SYNTHESIS

If a storm's duration is not the same as, or close to, the hydrograph base length, the unit hydrograph cannot be used to predict runoff. For example, the runoff from a six hour storm cannot be predicted from a unit hydrograph derived from a two hour storm. However, the technique of hydrograph synthesis can be used to

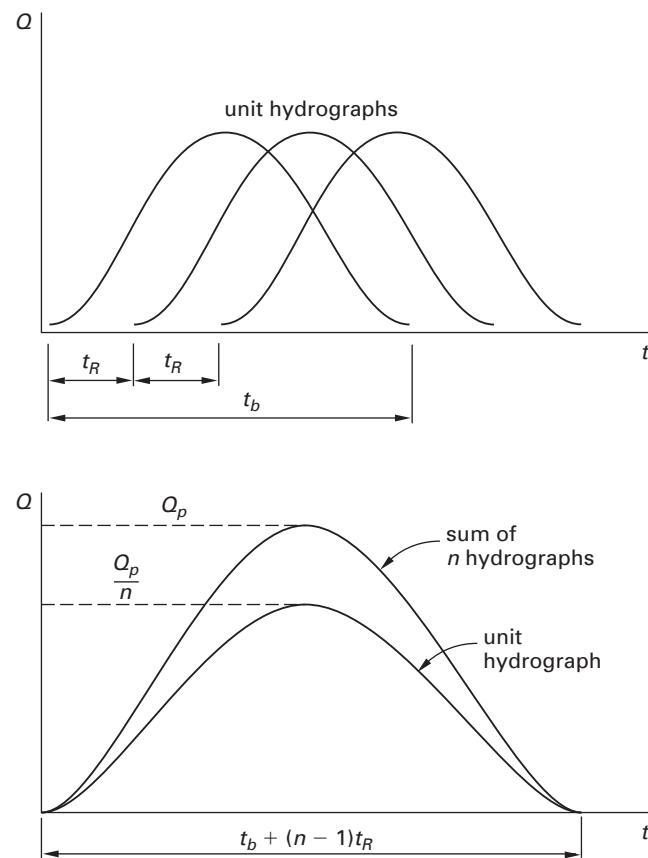

construct the hydrograph of the longer storm from the unit hydrograph of a shorter storm.

#### A. Lagging Storm Method

If a unit hydrograph for a storm of duration  $t_R$  is available, the *lagging storm method* can be used to construct the hydrograph of a storm whose duration is a whole multiple of  $t_R$ . (See Fig. 20.17.) For example, a six hour storm hydrograph can be constructed from a two hour unit hydrograph.

Let the whole multiple number be  $n$ . To construct the longer hydrograph, draw  $n$  unit hydrographs, each separated by time  $t_R$ . Then add the ordinates to obtain a hydrograph for an  $nt_R$  duration storm. Since the total rainfall from this new hydrograph is  $n$  inches (having been constructed from  $n$  unit hydrographs), the curve will have to be reduced (i.e., divided) by  $n$  everywhere to produce a unit hydrograph.

**Figure 20.17** Lagging Storm Method

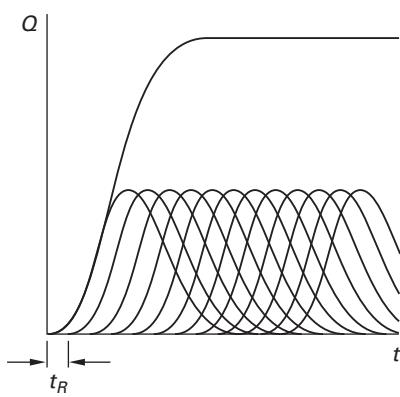

#### B. S-Curve Method

The *S-curve method* can be used to construct hydrographs from unit hydrographs with longer or shorter durations, even when the storm durations are not multiples. This method begins by adding the ordinates of

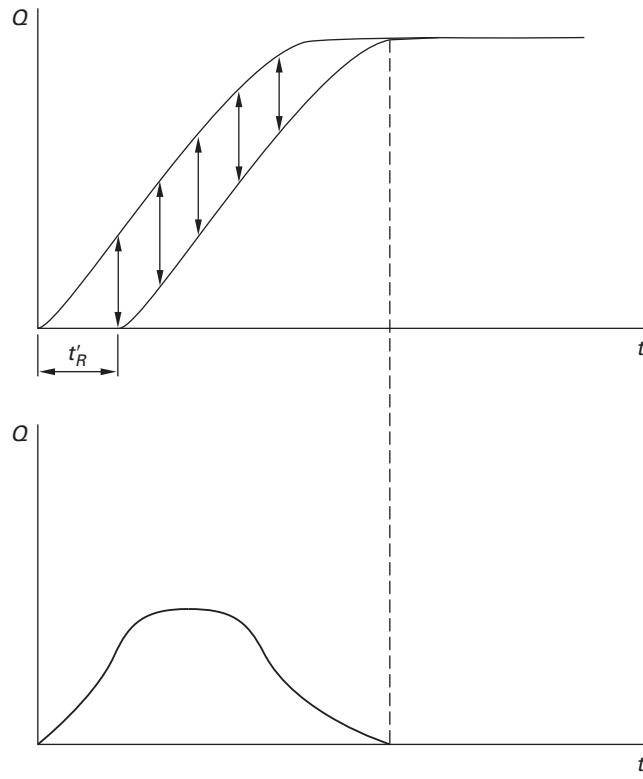

many unit hydrographs, each lagging the other by time  $t_R'$ , the duration of the storm that produced the unit hydrograph. After a sufficient number of lagging unit hydrographs have been added together, the accumulation will level off and remain constant. At that point, the lagging can be stopped. The resulting accumulation is known as an S-curve. (See Fig. 20.18.)

**Figure 20.18** Constructing the S-Curve

If two S-curves are drawn, one lagging the other by time  $t_R'$ , the area between the two curves represents a hydrograph area for a storm of duration  $t_R'$ . (See Fig. 20.19.) The differences between the two curves can be plotted and scaled to a unit hydrograph by multiplying by the ratio of  $t_R/t_R'$ .

**Figure 20.19** Using S-Curves to Construct a  $t'$  Hydrograph

## 15. PEAK RUNOFF FROM THE RATIONAL METHOD

Although total runoff volume is required for reservoir and dam design, the instantaneous peak runoff is needed to size culverts and storm drains.

The *rational formula* ("method," "equation," etc.), shown in Eq. 20.36, for peak discharge has been in widespread use in the United States since the early 1900s.<sup>3</sup> It is applicable to small areas (i.e., less than several hundred acres or so), but is seldom used for areas greater than 1–2 mi<sup>2</sup>. The intensity used in Eq. 20.36 depends on the time of concentration and the degree of protection desired (i.e., the recurrence interval).<sup>4</sup>

$$Q_p = CIA_d \quad 20.36$$

Since  $A_d$  is in acres,  $Q_p$  is in ac-in/hr. However,  $Q_p$  is taken as ft<sup>3</sup>/sec since the conversion factor between these two units is 1.008.

Typical values of  $C$  coefficients are found in App. 20.A. If more than one area contributes to the runoff, the coefficient is weighted by the areas.

Accurate values of the  $C$  coefficient depend not only on the surface cover and soil type, but also on the recurrence interval, antecedent moisture content, rainfall intensity, drainage area, slope, and fraction of imperviousness. These factors have been investigated and quantified by Rossmiller (1981), who correlated these effects with the NRCS curve number. The *Schaake, Geyer, and Knapp (1967) equation* developed at Johns Hopkins University was intended for use in urban areas, correlating the impervious fraction and slope.

$$C = 0.14 + 0.65(\text{Imp}_{\text{decimal}}) + 0.05S_{\text{percent}} \quad 20.37$$

The rational method assumes that rainfall occurs at a constant rate. If this is true, then the peak runoff will occur when the entire drainage area is contributing to surface runoff, which will occur at  $t_c$ . Other assumptions include (a) the recurrence interval of the peak flow is the same as for the design storm, (b) the runoff coefficient is constant, and (c) the rainfall is spatially uniform over the drainage area.

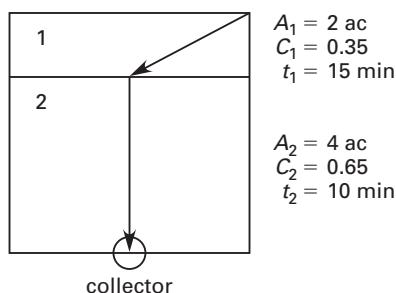

### Example 20.5

Two adjacent fields, as shown, contribute runoff to a collector whose capacity is to be determined. The storm

<sup>3</sup>In Great Britain, the rational equation is known as the *Lloyd-Davies equation*.

<sup>4</sup>When using intensity-duration-frequency curves to size storm sewers, culverts, and other channels, it is assumed that the frequencies and probabilities of flood damage and storms are identical. This is not generally true, but the assumption is usually made anyway.

intensity after 25 min is 3.9 in/hr. (a) Calculate the time to concentration. (b) Use the rational method to calculate the peak flow.

### Solution

(a) The overland flow time is given for both areas. The time for water from the farthest corner to reach the collector is

$$t_c = 15 \text{ min} + 10 \text{ min} = 25 \text{ min}$$

(b) The runoff coefficients are given for each area. Since the pipe carrying the total runoff needs to be sized, the coefficients are weighted by their respective contributing areas.

$$C = \frac{(2 \text{ ac})(0.35) + (4 \text{ ac})(0.65)}{2 \text{ ac} + 4 \text{ ac}} = 0.55$$

The intensity after 25 min was given as 3.9 in/hr.

The total area is  $4 \text{ ac} + 2 \text{ ac} = 6 \text{ ac}$ .

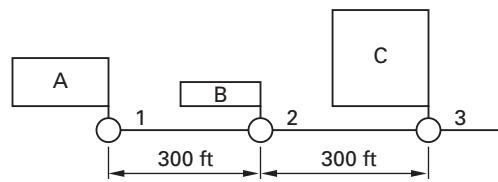

The peak flow is found from Eq. 20.36.

$$Q_p = CIA_d = (0.55) \left( 3.9 \frac{\text{in}}{\text{hr}} \right) (6 \text{ ac}) = 12.9 \text{ ac-in/hr} \quad (12.9 \text{ ft}^3/\text{sec})$$

### Example 20.6

Three watersheds contribute runoff to a storm drain. The watersheds have the following characteristics.

watershed	area (ac)	overland flow	
		time (min)	$C$
A	10	20	0.3
B	2	5	0.7
C	15	25	0.4

The instantaneous rainfall intensity (in/hr) for the area and specified storm frequency is

$$I = \frac{115}{t_c + 15}$$

The collector inlets are 300 ft apart. The pipe slope is 0.009. The Manning roughness coefficient is 0.015. Assume the flow velocity is 5 ft/sec in all sections. The storm duration is long enough to permit all three areas to contribute to the combined flow through section 3. (a) What should be the pipe size in section 2? (b) What is the maximum flow through section 3?

### Solution

The maximum flow occurs when the overland flow from both areas A and B have reached the second manhole. The time of concentration for area A is the time of concentration to the first manhole plus the travel time in pipe section 1.

$$t_c = 20 \text{ min} + \frac{300 \text{ ft}}{\left( 5 \frac{\text{ft}}{\text{sec}} \right) \left( 60 \frac{\text{sec}}{\text{min}} \right)} = 21 \text{ min}$$

The time of concentration for area B is 5 min. The pipe in section 2 should be sized for flow at 21 min.

$$I = \frac{115}{t_c + 15} = \frac{115 \frac{\text{in}-\text{hr}}{\text{hr}}}{21 \text{ min} + 15 \text{ min}} = 3.19 \text{ in/hr}$$

Use the sum of the  $CA$  values in Eq. 20.36.

$$\sum CA = (0.3)(10 \text{ ac}) + (0.7)(2 \text{ ac}) = 4.4 \text{ ac}$$

Use the rational formula, Eq. 20.36.

$$Q = \sum CA_d I = (4.4 \text{ ac}) \left( 3.19 \frac{\text{in}}{\text{hr}} \right) = 14.0 \text{ ac-in/hr} \quad (14.0 \text{ ft}^3/\text{sec})$$

This value of  $Q$  should be used to design section 2 of the pipe. From Eq. 19.16 and assuming the pipe is flowing full,

$$\begin{aligned} D &= 1.335 \left( \frac{nQ}{\sqrt{S_{\text{decimal}}}} \right)^{3/8} \\ &= (1.335) \left( \frac{(0.015) \left( 14.0 \frac{\text{ft}^3}{\text{sec}} \right)}{\sqrt{0.009}} \right)^{3/8} \\ &= 1.798 \text{ ft} \quad [\text{round to } 2.0 \text{ ft}] \end{aligned}$$

The maximum flow through section 3 occurs when the overland flow from plots A, B, and C reach the third manhole.

For plot A,

$$t_c = 20 \text{ min} + 1 \text{ min} + 1 \text{ min} = 22 \text{ min}$$

For plot B,

$$t_c = 5 \text{ min} + 1 \text{ min} = 6 \text{ min}$$

For plot C,

$$t_c = 25 \text{ min}$$

The maximum runoff will occur 25 min after the start of the storm.

$$\begin{aligned} I &= \frac{115}{t_c + 15} = \frac{115 \frac{\text{in-min}}{\text{hr}}}{25 \text{ min} + 15 \text{ min}} \\ &= 2.875 \text{ in/hr} \end{aligned}$$

The sum of the  $CA$  values is

$$\begin{aligned} \sum CA &= (0.3)(10 \text{ ac}) + (0.7)(2 \text{ ac}) + (0.4)(15 \text{ ac}) \\ &= 10.4 \text{ ac} \\ Q &= \sum CA_d I = (10.4 \text{ ac}) \left( 2.875 \frac{\text{in}}{\text{hr}} \right) \\ &= 29.9 \text{ ac-in/hr} \quad (29.9 \text{ ft}^3/\text{sec}) \end{aligned}$$

## 16. NRCS CURVE NUMBER

Several methods of calculating total and peak runoff have been developed over the years by the U.S. Natural Resources Conservation Service. These methods have generally been well correlated with actual experience, and the NRCS methods have become dominant in the United States.

The NRCS methods classify the land use and soil type by a single parameter called the *curve number*, CN. This method can be used for any size homogeneous watershed with a known percentage of imperviousness. If the watershed varies in soil type or in cover, it generally

should be divided into regions to be analyzed separately. A composite curve number can be calculated by weighting the curve number for each region by its area. Alternatively, the runoffs from each region can be calculated separately and added.

The NRCS method of using precipitation records and an assumed distribution of rainfall to construct a synthetic storm is based on several assumptions. First, a type II storm is assumed. Type I storms, which drop most of their precipitation early, are applicable to Hawaii, Alaska, and the coastal side of the Sierra Nevada and Cascade mountains in California, Oregon, and Washington. Type II distributions are typical of the rest of the United States, Puerto Rico, and the Virgin Islands.

This method assumes that initial abstraction (depression storage, evaporation, and interception losses) is equal to 20% of the storage capacity.

$$I_a = 0.2S \quad 20.38$$

For there to be any runoff at all, the gross rain must equal or exceed the initial abstraction.

$$P \geq I_a \quad 20.39$$

The storage capacity must be great enough to absorb the initial abstraction plus the infiltration.

$$S \geq I_a + F \quad 20.40$$

The following steps constitute the NRCS method.

*Step 1:* Classify the soil into a *hydrologic soil group* (HSG) according to its infiltration rate. Soil is classified into HSG A (low runoff potential) through D (high runoff potential).

*Group A:* High infiltration rates ( $> 0.30 \text{ in/hr}$  ( $0.76 \text{ cm/h}$ )) even if thoroughly saturated; chiefly deep sands and gravels with good drainage and high moisture transmission. In urbanized areas, this category includes sand, loamy sand, and sandy loam.

*Group B:* Moderate infiltration rates if thoroughly wetted ( $0.15$ – $0.30 \text{ in/hr}$  ( $0.38$ – $0.76 \text{ cm/h}$ )), moderate rates of moisture transmission, and consisting chiefly of coarse to moderately fine textures. In urbanized areas, this category includes silty loam and loam.

*Group C:* Slow infiltration rates if thoroughly wetted ( $0.05$ – $0.15 \text{ in/hr}$  ( $0.13$ – $0.38 \text{ cm/h}$ )), and slow moisture transmission; soils having moderately fine to fine textures or that impede the downward movement of water. In urbanized areas, this category includes sandy clay loam.

*Group D:* Very slow infiltration rates (less than  $0.05 \text{ in/hr}$  ( $0.13 \text{ cm/h}$ )) if thoroughly wetted, very slow water transmission, and consisting primarily of clay soils with high potential for swelling; soils with permanent high water tables;

or soils with an impervious layer near the surface. In urbanized areas, this category includes clay loam, silty clay loam, sandy clay, silty clay, and clay.

(Note that as a result of urbanization, the underlying soil may be disturbed or covered by a new layer. The original classification will no longer be applicable, and the "urbanized" soil HSGs are applicable.)

- step 2:* Determine the preexisting soil conditions. The soil condition is classified into *antecedent runoff conditions* (ARC) I through III.<sup>5</sup> Generally, "average" conditions (ARC II) are assumed.

*ARC I:* Dry soils, prior to or after plowing or cultivation, or after periods without rain.

*ARC II:* Typical conditions existing before maximum annual flood.

*ARC III:* Saturated soil due to heavy rainfall (or light rainfall with freezing temperatures) during 5 days prior to storm.

- step 3:* Classify *cover type* and hydrologic condition of the soil-cover complex. For pasture, range, row crops, arid, and semi-arid lands, the NRCS method includes additional tables to classify the cover and hydrologic conditions. In order to use these tables, it is necessary to characterize the surface coverage. The condition is "good" if it is lightly grazed or has plant cover over 75% or more of its area. The condition is "fair" if plant coverage is 50–75% or not heavily grazed. The condition is "poor" if the area is heavily grazed, has no mulch, or has plant cover over less than 50% of the area.

- step 4:* Use Table 20.4 or Table 20.5 to determine the *curve number*, CN, corresponding to the soil classification for ARC II.

- step 5:* If the soil is ARC I or ARC III, convert the curve number from step 4 by using Eq. 20.41 or Eq. 20.42 and rounding up.

$$CN_I = \frac{4.2 CN_{II}}{10 - 0.058 CN_{II}} \quad 20.41$$

$$CN_{III} = \frac{23 CN_{II}}{10 + 0.13 CN_{II}} \quad 20.42$$

- step 6:* If any significant fraction of the watershed is impervious (i.e., CN = 98 for pavement), or if the watershed consists of areas with different curve numbers, calculate the composite curve number by weighting by the runoff areas (same as weighting by the impervious and pervious fractions). If the watershed's impervious fraction is different from the value implicit in step 3's classification, or if the impervious area is not

<sup>5</sup>The *antecedent runoff condition* (ARC) may also be referred to as the *antecedent moisture condition* (AMC).

connected directly to a storm drainage system, then the NRCS method includes direct and graphical adjustments.

- step 7:* Estimate the time of concentration of the watershed.<sup>6</sup> (See Sec. 20.5.)
- step 8:* Determine the *gross (total) rainfall*, P, from the storm. (See Eq. 20.18.) To do this, it is necessary to assume the storm length and recurrence interval. It is a characteristic of the NRCS methods to use a 24 hr storm. Maps from the U.S. Weather Bureau can be used to read gross point rainfalls for storms with frequencies from 1 to 100 years.<sup>7</sup>
- step 9:* Multiply the gross rain point value from step 8 by a factor from Fig. 20.20 to make the gross rain representative of larger areas. This is the *areal rain*.
- step 10:* The NRCS method assumes that infiltration follows an exponential decay curve with time. Storage capacity of the soil (i.e., the potential maximum retention after runoff begins), S, is calculated from the curve number by using Eq. 20.43.

$$S_{in} = \frac{1000}{CN} - 10 \quad 20.43$$

- step 11:* Calculate the total runoff (net rain, precipitation excess, etc.), Q, in inches from the areal rain. Equation 20.44 subtracts losses from interception, storm period evaporation, depression storage, and infiltration from the *gross rain* to obtain the *net rain*. (Equation 20.44 can be derived from the water balance equation, Eq. 20.2.)

$$Q_{in} = \frac{(P_g - I_a)^2}{P_g - I_a + S} = \frac{(P_g - 0.2S)^2}{P_g + 0.8S} \quad 20.44$$

## 17. NRCS GRAPHICAL PEAK DISCHARGE METHOD

Two NRCS methods are available for calculating the peak discharge. When a full hydrograph is not needed, the so-called graphical method can be used. If a hydrograph is needed, the tabular method can be used.<sup>8</sup> The graphical method is applicable when (a) CN > 40, (b) 0.1 hr < t<sub>c</sub> < 10 hr, (c) the watershed is relatively homogeneous or uniformly mixed, (d) all streams have the same time of concentration, and (e) there is no interim storage along the stream path.

<sup>6</sup>The NRCS method uses T<sub>c</sub>, not t<sub>c</sub>, as the symbol for time of concentration.

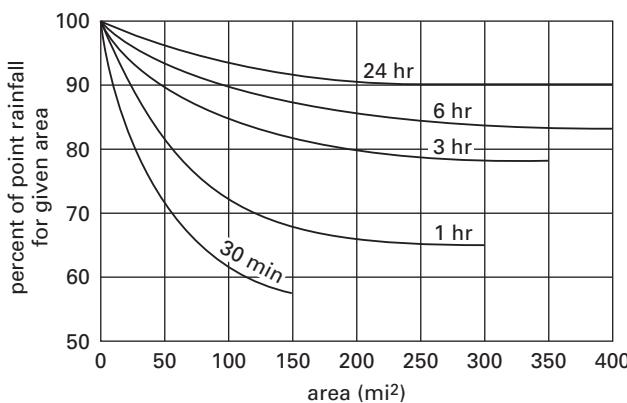

<sup>7</sup>Rainfall Frequency Atlas of the United States for Durations from 30 Minutes to 24 Hours and Return Periods from 1 to 100 Years (1961), U.S. Weather Bureau, Technical Paper 40.

<sup>8</sup>The graphical and tabular methods both rely on graphs and tables that are contained in TR-55. These graphs and tables are not included in this chapter. The NRCS tabular method is not described in this book.

**Table 20.4** Runoff Curve Numbers of Urban Areas (ARC II)

**Figure 20.20** Point to Areal Rain Conversion Factors

Equation 20.45 is the NRCS peak discharge equation.  $Q_p$  is the peak discharge ( $\text{ft}^3/\text{sec}$ ),  $q_u$  is the unit peak discharge (cubic feet per square mile per inch of runoff,  $\text{csm/in}$ ),  $A_{\text{mi}^2}$  is the drainage area in  $\text{mi}^2$ ,  $Q_{\text{inches}}$  is the runoff (in), and  $F_p$  is a pond and swamp adjustment factor.

$$Q_p = q_u A_{\text{mi}^2} Q_{\text{inches}} F_p \quad 20.45$$

The graphical method begins with obtaining the design for the 24 hr rainfall,  $P$ , for the area. Total runoff,  $Q$ , and the curve number, CN, are determined by the same method as in Sec. 20.16. Then, the initial abstraction,  $I_a$ , is obtained from Table 20.6, and the ratio  $I_a/P$  is calculated. Next, NRCS curves are entered with  $t_c$  and the  $I_a/P$  ratio to determine the runoff in cubic feet per square mile per inch of runoff ( $\text{csm/in}$ ). The appropriate pond and swamp adjustment factor is selected from the

<sup>a</sup>Crop residue cover applies only if residue is on at least 5% of the surface throughout the year.

<sup>b</sup>Hydrologic condition is based on a combination of factors that affect infiltration and runoff, including (a) density and canopy of vegetative areas, (b) amount of year-round cover, (c) amount of grass or close-seeded legumes in rotations, (d) percent of residue cover on the land surface (good ≥ 20%), and (e) degree of surface roughness.

Poor: Factors impair infiltration and tend to increase runoff.

Good: Factors encourage average and better-than-average infiltration and tend to decrease runoff.

Reprinted from *Urban Hydrology for Small Watersheds*, Technical Release TR-55, United States Department of Agriculture, Natural Resources Conservation Service, Table 2-b, 1986.

NRCS literature. ( $F_p=1$  if there are no ponds or swamps.)

## 18. RESERVOIR SIZING: MODIFIED RATIONAL METHOD

An effective method of preventing flooding is to store surface runoff temporarily. After the storm is over, the stored water can be gradually released. An *impounding*

*reservoir* (*retention watershed* or *detention watershed*) is a watershed used to store excess flow from a stream or river. The stored water is released when the stream flow drops below the minimum level that is needed to meet water demand. The *impoundment depth* is the design depth. Finding the impoundment depth is equivalent to finding the design storage capacity of the reservoir.

The purpose of a *reservoir sizing* (*reservoir yield*) analysis is to determine the proper size of a reservoir or dam,

**Table 20.6** Initial Abstraction Versus Curve Number

or to evaluate the ability of an existing reservoir to meet water demands.

The volume of a reservoir needed to hold streamflow from a storm is simply the total area of the hydrograph. Similarly, when comparing two storms, the incremental volume needed is simply the difference in the areas of their two hydrographs.

Poertner's 1974 *modified rational method*, as illustrated in Fig. 20.21, can be used to design detention storage facilities for small areas (up to 20 ac). A trapezoidal hydrograph is constructed with the peak flow calculated from the rational equation. The total hydrograph base (i.e., the total duration of surface runoff) is the storm duration plus the time to concentration. The durations of the rising and falling limbs are both taken as  $t_c$ .

To size a detention watershed using this method, a trapezoidal hydrograph is drawn for several storm durations greater than  $2t_c$  (e.g., 10, 15, 20, and 30 min). For each of the storm durations, the total rainfall is calculated as the hydrograph area. The difference between

**Figure 20.21** Modified Rational Method Hydrograph

the total rainfall and the total released water (calculated as the product of the allowable release rate and the storm duration) is the required storage capacity.

Detention watershed sizing for areas larger than 20 ac should be accomplished using full hydrograph methods in combination with reservoir routing.

## 19. RESERVOIR SIZING: NONSEQUENTIAL DROUGHT METHOD

The *nonsequential drought method* is somewhat complex, but it has the advantage of giving an estimate of the required reservoir size, rather than merely evaluating a trial size. In the absence of synthetic drought information, it is first necessary to develop intensity-duration-frequency curves from stream flow records.

*step 1:* Choose a duration. Usually, the first duration used will be 7 days, although choosing 15 days will not introduce too much error.

*step 2:* Search the stream flow records to find the smallest flow during the duration chosen. (The first time through, for example, find the smallest discharge totaled over any 7 days.) The days do not have to be sequential.

*step 3:* Continue searching the discharge records to find the next smallest discharge over the number of days in the period. Continue searching and finding the smallest discharges (which gradually increase) until all of the days in the record have been used up. Do not use the same day more than once.

*step 4:* Give the values of smallest discharge order numbers; that is, give  $M = 1$  to the smallest discharge,  $M = 2$  to the next smallest, etc.

*step 5:* For each observation, calculate the recurrence interval as

$$F = \frac{n_y}{M} \quad 20.46$$

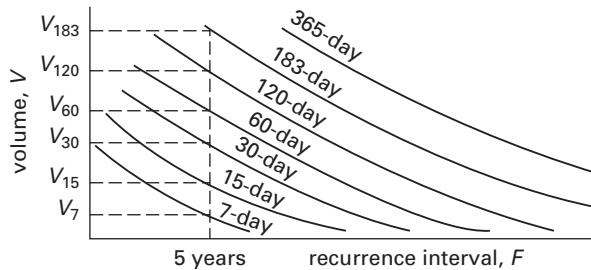

$n_y$  is the number of years of stream flow data that was searched to find the smallest discharges.

*step 6:* Plot the points as discharge on the  $y$ -axis versus  $F$  in years on the  $x$ -axis. Draw a reasonably continuous curve through the points.

*step 7:* Return to step 1 for the next duration. Repeat for all of the following durations: 7, 15, 30, 60, 120, 183, and 365 days.

A synthetic drought can be constructed for any recurrence interval. For example, in Fig. 20.22, a 5 year drought is being planned for, so the discharges  $V_7$ ,  $V_{15}$ ,  $V_{30}$ , ...,  $V_{365}$  are read from the appropriate curves for  $F = 5$  yr.

**Figure 20.22** Sample Family of Synthetic Inflow Curves

The next step is to plot the reservoir *mass diagram* (also known as a *Rippl diagram*). This is a plot of the cumulative net volume—a simultaneous plot of the cumulative demand (known as *draft*) and cumulative inflow. The mass diagram is used to graphically determine the reservoir storage requirements (i.e., size).

As long as the slopes of the cumulative demand and inflow lines are equal, the water reserve in the reservoir will not change. When the slope of the inflow is less than the slope of the demand, the inflow cannot by itself satisfy the community's water needs, and the reservoir is drawn down to make up the difference. A peak followed by a trough is, therefore, a drought condition.

If the reservoir is to be sized so that the community will not run dry during a drought, the required capacity is the maximum separation between two parallel lines (pseudo-demand lines with slopes equal to the demand rate) drawn tangent to a peak and a subsequent trough. If the mass diagram covers enough time so that multiple droughts are present, the largest separation between peaks and subsequent troughs represents the capacity.

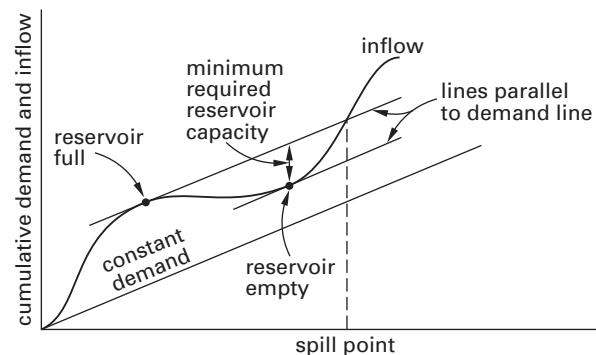

In order for the reservoir to supply enough water during a drought condition, the reservoir must be full prior to

the start of the drought. This fact is not represented when the mass diagram is drawn, hence the need to draw a pseudo-demand line parallel to the peak.

After a drought equal to the capacity of the reservoir, the reservoir will again be empty. At the trough, however, the reservoir begins to fill up again. When the cumulative excess exceeds the reservoir capacity, the reservoir will have to “spill” (i.e., release) water. This occurs when the cumulative inflow line crosses the prior peak's pseudo-demand line, as shown in Fig. 20.23.

A *flood-control dam* is built to keep water in and must be sized so that water is not spilled. The mass diagram can still be used, but the maximum separation between troughs and subsequent peaks (not peaks followed by troughs) is the required capacity.

**Figure 20.23** Reservoir Mass Diagram (*Rippl Diagram*)

## 20. RESERVOIR SIZING: RESERVOIR ROUTING

*Reservoir routing* is the process by which the outflow hydrograph (i.e., the outflow over time) of a reservoir is determined from the inflow hydrograph (i.e., the inflow over time), the initial storage, and other characteristics of the reservoir. The simplest method is to keep track of increments in inflow, storage, and outflow period by period in a tabular simulation. This is the basis of the *storage indication method*, which is basically a bookkeeping process. The validity of this method is dependent on choosing time increments that are as small as possible.

*step 1:* Determine the starting storage volume,  $V_n$ . If the starting volume is zero or considerably different from the average steady-state storage, a large number of iterations will be required before the simulation reaches its steady-state results. A convergence criterion should be determined before the simulation begins.

*step 2:* For the next iteration, determine the inflow, discharge, evaporation, and seepage. The starting

storage volume for the next iteration is found by solving Eq. 20.47.

$$V_{n+1} = V_n + (\text{inflow})_n - (\text{discharge})_n - (\text{seepage})_n - (\text{evaporation})_n \quad 20.47$$

Repeat step 2 as many times as necessary.

Loss due to seepage is generally very small compared to inflow and discharge, and it is often neglected. Reservoir evaporation can be estimated from analytical relationships or by evaluating data from *evaporation pans*. Pan data is extended to reservoir evaporation by the pan coefficient formula. In Eq. 20.48, the summation is taken over the number of days in the simulation period. Units of evaporation are typically in/day. The *pan coefficient*,  $K_p$ , is typically 0.7–0.8.

$$E_R = \sum K_p E_p \quad 20.48$$

Inflow can be taken from actual past history. However, since it is unlikely that history will repeat exactly, the next method is preferred.

## 21. RESERVOIR ROUTING: STOCHASTIC SIMULATION

The *stochastic simulation* method of reservoir routing is the same as tabular simulation except for the method of determining the inflow. This description uses a *Monte Carlo simulation* technique that is dependent on enough historical data to establish a cumulative inflow distribution. A Monte Carlo simulation is suitable if long periods are to be simulated. If short periods are to be simulated, the simulation should be performed several times and the results averaged.

*step 1:* Tabulate or otherwise determine a frequency distribution of inflow quantities.

*step 2:* Form a cumulative distribution of inflow quantities.

*step 3:* Multiply the cumulative  $x$ -axis (which runs from 0 to 1) by 100 or 1000, depending on the accuracy needed.

*step 4:* Generate random numbers between 0 and 100 (or 0 and 1000). Use of a random number table, such as App. 20.B, is adequate for hand simulation.

*step 5:* Locate the inflow quantity corresponding to the random number from the cumulative distribution  $x$ -axis.

### Example 20.7

A well-monitored stream has been observed for 50 years and has the following frequency distribution of total annual discharges.

discharge (units)	frequency (yr)	fraction of time
0 to 0.5	5	0.10
0.5 to 1.0	21	0.42
1.0 to 1.5	17	0.34
1.5 to 2.0	7	0.14

It is proposed that a dam be placed across the stream to create a reservoir with a capacity of 1.8 units. The reservoir is to support a town that will draw 1.2 units per year. Use stochastic simulation to simulate 10 yr of reservoir operation, assuming it is initially filled with 1.5 units.

*Solution*

*step 1:* The frequency distribution is given.

*steps 2 and 3:* Make a table to form the cumulative distribution with multiplied frequencies.

discharge	cumulative frequency	cumulative $\times 100$
0 to 0.5	0.10	10
0.5 to 1.0	0.52	52
1.0 to 1.5	0.86	86
1.5 to 2.0	1.00	100

*step 4:* From App. 20.B, choose 10 two-digit numbers. The starting point within the table is arbitrary, but the numbers must come sequentially from a row or column. Use the first row for this simulation.

78, 46, 68, 33, 26, 96, 58, 98, 87, 27

*step 5:* For the first year, the random number is 78. Since 78 is greater than 52 but less than 86, the inflow is in the 1.0–1.5 unit range. The midpoint of this range is taken as the inflow, which would be 1.25. The reservoir volume after the first year would be  $1.5 + 1.25 - 1.20 = 1.55$ . The remaining years can be similarly simulated.

year	starting volume	+ inflow	- usage	=	ending volume	+ spill
1	1.5	1.25	1.2		1.55	
2	1.55	0.75	1.2		1.1	
3	1.1	1.25	1.2		1.15	
4	1.15	0.75	1.2		0.7	
5	0.7	0.75	1.2		0.25	
6	0.25	1.75	1.2		0.8	
7	0.8	1.25	1.2		0.85	
8	0.85	1.75	1.2		1.4	
9	1.4	1.75	1.2		1.95	0.15
10	1.8	0.75	1.2		1.35	

No shortages are experienced; one spill is required.

## 22. STORMWATER/WATERSHED MANAGEMENT MODELING

*Flood routing* and *channel routing* are terms used to describe the passage of a flood or runoff wave through a complex system. Due to flow times, detention, and processing, the wave front appears at different points in a system at different times. The ability to simulate flood, channel, and reservoir routing is particularly useful when evaluating competing features (e.g., treatment, routing, storage options).

The interaction of stormwater features (e.g., watersheds, sewers and storm drains, detention watersheds, treatment facilities) during and after a storm is complex. In addition to continuity considerations, the interaction is affected by hydraulic considerations (e.g., the characteristics of the flow paths) and topography (e.g., the elevation changes from point to point).

Many computer programs have been developed to predict the performance of such complex systems. These simulation programs vary considerably in complexity, degree of hydraulic detail, length of simulation interval, and duration of simulation study. The Environmental Protection Agency (EPA) Stormwater Management Model is a well-known micro-scale model, particularly well-suited to areas with a high impervious fraction. The Army Corps of Engineers' STORM model is a macro-scale model. The NRCS TR-20 program is consistent with other NRCS methodology.

## 23. FLOOD CONTROL CHANNEL DESIGN

For many years, the traditional method of flood control was *channelization*, converting a natural stream to a uniform channel cross section. However, this method does not always work as intended and may fail at critical moments. Some of the reasons for reduced capacities are sedimentation, increased flow resistance, and inadequate maintenance.

The design of artificial channels is often based on clear-water hydraulics without sediment. However, the capacity of such channels is greatly affected by *sedimentation*. Silting and sedimentation can double or triple the Manning roughness coefficient. Every large flood carries appreciable amounts of bed load, significantly increasing the composite channel roughness. Also, when the channel is unlined, scour and erosion can significantly change the channel cross-sectional area.

To minimize cost and right-of-way requirements, shallow supercritical flow is often intended when the channel is designed. However, supercritical flow can occur only with low bed and side roughness. When the roughness increases during a flood, the flow shifts back to deeper, slower-moving subcritical flows.

Debris carried downstream by floodwaters can catch on bridge pilings and culverts, obstructing the flow. Actual flood profiles can resemble a staircase consisting of a series of backwater pools behind obstructed bridges, rather than a uniformly sloping surface. In such situations, the most effective flood control method may be replacement of bridges or improved emergency maintenance procedures to remove debris.

Vegetation and other debris that collects during dry periods in the flow channel reduces the flow capacity. Maintenance of channels to eliminate the vegetation is often haphazard.

Flood control channel design programs frequently emphasize "creek protection" and the long-term management of natural channels. Elements of such programs include (a) excavation of a low-flow channel within the natural channel, (b) periodic intervention to keep the channel clear, (c) establishment of a wide flood plain terrace along the channel banks, incorporating wetlands, vegetation, and public-access paths, and (d) planting riparian vegetation and trees along the terrace to slow bank erosion and provide a continuous corridor for wildlife.

**1. AQUIFERS**

*Underground water*, also known as *subsurface water*, is contained in saturated geological formations known as *aquifers*. Aquifers are divided into two zones by the water table surface. The *vadose zone* is above the elevation of the water table. Pores in the vadose zone may be either saturated, partially saturated, or empty. The *phreatic zone* is below the elevation of the water table. Pores are always saturated in the phreatic zone.

An aquifer whose water surface is at atmospheric pressure and that can rise or fall with changes in volume is a

*free aquifer*, also known as an *unconfined aquifer*. If a well is drilled into an unconfined aquifer, the water level in the well will correspond to the water table. Such a well is known as a *gravity well*.

An aquifer that is bounded on all extents is known as a *confined aquifer*. The water in confined aquifers may be under pressure. If a well is drilled into such an aquifer, the water in the well will rise to a height corresponding to the hydrostatic pressure. The *piezometric height* of the rise is

$$H = \frac{p}{\rho g} \quad [\text{SI}] \quad 21.1(a)$$

$$H = \frac{p}{\gamma} = \frac{p}{\rho} \times \frac{g_c}{g} \quad [\text{U.S.}] \quad 21.1(b)$$

If the confining pressure is high enough, the water will be expelled from the surface, and the source is known as an *artesian well*.

## 2. AQUIFER CHARACTERISTICS

*Soil moisture content (water content)*,  $w$ , can be determined by oven drying a sample of soil and measuring the change in mass.<sup>1</sup> The water content is the ratio of the mass of water to the mass of solids, expressed as a percentage. The water content can also be determined with a *tensiometer*, which measures the vapor pressure of the moisture in the soil.

$$w = \frac{m_w}{m_s} = \frac{m_t - m_s}{m_s} \quad 21.2$$

The *porosity*,  $n$ , of the aquifer is the percentage of void volume to total volume.<sup>2</sup>

$$n = \frac{V_v}{V_t} = \frac{V_t - V_s}{V_t} \quad 21.3$$

The *void ratio*,  $e$ , is

$$e = \frac{V_v}{V_s} = \frac{V_t - V_s}{V_s} \quad 21.4$$

Void ratio and porosity are related.

$$e = \frac{n}{1-n} \quad 21.5$$

Some pores and voids are dead ends or are too small to contribute to seepage. Only the *effective porosity*,  $n_e$ , 95–98% of the total porosity, contributes to groundwater flow.

The *hydraulic gradient*,  $i$ , is the change in hydraulic head over a particular distance. The hydraulic head at a point is determined as the piezometric head at observation wells.

$$i = \frac{\Delta H}{L} \quad 21.6$$

<sup>1</sup>It is common in civil engineering to use the term “weight” in place of mass. For example, the *water content* would be defined as the ratio of the weight of water to the weight of solids, expressed as a percentage.

<sup>2</sup>The symbol  $\theta$  is sometimes used for porosity.

## 3. PERMEABILITY

The flow of a liquid through a permeable medium is affected by both the fluid and the medium. The effects of the medium (independent of the fluid properties) are characterized by the *intrinsic permeability (specific permeability)*,  $k$ . Intrinsic permeability has dimensions of length squared. (See Table 21.1.) The *darcy* has been widely accepted as the unit of intrinsic permeability. One darcy is  $0.987 \times 10^{-8} \text{ cm}^2$ .

For studies involving the flow of water through an aquifer, effects of intrinsic permeability and the water are combined into the *hydraulic conductivity*, also known as the *coefficient of permeability* or simply the *permeability*,  $K$ . Hydraulic conductivity can be determined from a number of water-related tests.<sup>3</sup> It has units of volume per unit area per unit time, which is equivalent to length divided by time (i.e., units of velocity). Volume may be expressed as cubic feet and cubic meters, or gallons and liters.

$$K = \frac{k g \rho}{\mu} \quad [\text{SI}] \quad 21.7(a)$$

$$K = \frac{k \gamma}{\mu} \quad [\text{U.S.}] \quad 21.7(b)$$

For many years in the United States, hydraulic conductivity was specified in *Meinzer units* (gallons per day per square foot). To avoid confusion related to multiple definitions and ambiguities in these definitions, hydraulic conductivity is now often specified in units of ft/day (m/d).

The coefficient of permeability is proportional to the square of the mean particle diameter.

$$K = C D_{\text{mean}}^2 \quad 21.8$$

*Hazen's empirical formula* can be used to calculate an approximate coefficient of permeability for clean, uniform sands.  $D_{10}$  is the *effective size* in mm (i.e., the size for which 10% of the distribution is finer).

$$K_{\text{cm/s}} \approx C D_{10,\text{mm}}^2 \quad [0.1 \text{ mm} \leq D_{10,\text{mm}} \leq 3.0 \text{ mm}] \quad 21.9$$

The coefficient  $C$  is 0.4–0.8 for very fine sand (poorly sorted) or fine sand with appreciable fines; 0.8–1.2 for medium sand (well sorted) or coarse sand (poorly sorted); and 1.2–1.5 for coarse sand (well sorted and clean).

<sup>3</sup>Permeability can be determined from constant-head permeability tests (sands), falling-head permeability tests (fine sands and silts), consolidation tests (clays), and field tests of wells (in situ gravels and sands).

**Table 21.1** Typical Permeabilities

	$k$ (cm <sup>2</sup> )	$k$ (m <sup>2</sup> )	$k$ (darcys)	$K$ (cm/s)	$K$ (gal/day-ft <sup>2</sup> )
gravel	$10^{-5}$ to $10^{-3}$	$10^{-1}$ to 10	$10^3$ to $10^5$	0.5 to 50	$10^4$ to $10^6$
gravelly sand	$10^{-5}$	$10^{-1}$	$10^3$	0.5	$10^4$
clean sand	$10^{-6}$	$10^{-2}$	$10^2$	0.05	$10^3$
sandstone	$10^{-8}$	$10^{-3}$	10	0.005	$10^2$
dense shale or limestone	$10^{-9}$	$10^{-5}$	$10^{-1}$	0.000 05	1
granite or quartzite	$10^{-11}$	$10^{-7}$	$10^{-3}$	0.000 000 5	$10^{-2}$
clay	$10^{-11}$	$10^{-7}$	$10^{-3}$	0.000 000 5	$10^{-2}$

(Multiply gal/day-ft<sup>2</sup> by 0.1337 to obtain ft<sup>3</sup>/day-ft<sup>2</sup>.)(Multiply darcys by  $0.987 \times 10^{-8}$  to obtain cm<sup>2</sup>.)(Multiply darcys by  $0.987 \times 10^{-12}$  to obtain m<sup>2</sup>.)(Multiply cm<sup>2</sup> by  $10^{-4}$  to obtain m<sup>2</sup>.)(Multiply ft<sup>2</sup> by  $9.4135 \times 10^{10}$  to obtain darcys.)(Multiply m<sup>2</sup> by  $10^4$  to obtain cm<sup>2</sup>.)(Multiply gal/day-ft<sup>2</sup> by  $4.716 \times 10^{-5}$  to obtain cm/s.)

#### 4. DARCY'S LAW

Movement of groundwater through an aquifer is given by *Darcy's law*, Eq. 21.10.<sup>4</sup> The hydraulic gradient may be specified in either ft/ft (m/m) or ft/mi (m/km), depending on the units of area used.

$$Q = -KiA_{\text{gross}} = -v_e A_{\text{gross}} \quad 21.10$$

The *specific discharge* is the same as the *effective velocity*,  $v_e$ .

$$q = \frac{Q}{A_{\text{gross}}} = Ki = v_e \quad 21.11$$

Darcy's law is applicable only when the Reynolds number is less than 1. Significant deviations have been noted when the Reynolds number is even as high as 2. In Eq. 21.12,  $D_{\text{mean}}$  is the mean grain diameter.

$$Re = \frac{\rho q D_{\text{mean}}}{\mu} = \frac{q D_{\text{mean}}}{\nu} \quad 21.12$$

#### 5. TRANSMISSIVITY

*Transmissivity* (also known as the *coefficient of transmissivity*) is an index of the rate of groundwater movement. The transmissivity of flow from a saturated aquifer of thickness  $Y$  and width  $b$  is given by Eq. 21.13. The thickness,  $Y$ , of a confined aquifer is the difference in elevations

of the bottom and top of the saturated formation. For permeable soil, the thickness,  $Y$ , is the difference in elevations of the impermeable bottom and the water table.

$$T = KY \quad 21.13$$

Combining Eq. 21.10 and Eq. 21.13 gives

$$Q = bTi \quad 21.14$$

#### 6. SPECIFIC YIELD, RETENTION, AND CAPACITY

The dimensionless *storage constant (storage coefficient)*,  $S$ , of a confined aquifer is the change in aquifer water volume per unit surface area of the aquifer per unit change in head. That is, the storage constant is the amount of water that is removed from a column of the aquifer 1 ft<sup>2</sup> (1 m<sup>2</sup>) in plan area when the water table drops 1 ft (1 m). For unconfined aquifers, the storage coefficient is virtually the same as the specific yield. Various methods have been proposed for calculating the storage coefficient directly from properties of the rock and water. It can also be determined from unsteady flow analysis of wells. (See Sec. 21.12.)

The *specific yield*,  $S_y$ , is the water yielded when water-bearing material drains by gravity. It is the volume of water removed per unit area when a drawdown of one length unit is experienced. A time period may be given for different values of specific yield.

$$S_y = \frac{V_{\text{yielded}}}{V_{\text{total}}} \quad 21.15$$

<sup>4</sup>The negative sign in Darcy's law accounts for the fact that flow is in the direction of decreasing head. That is, the hydraulic gradient is negative in the direction of flow. The negative sign is omitted in the remainder of this chapter, or appropriate equations are rearranged to be positive.

The *specific retention* is the volume of water that, after being saturated, will remain in the aquifer against the pull of gravity.

$$S_r = \frac{V_{\text{retained}}}{V_{\text{total}}} = n - S_y \quad 21.16$$

The *specific capacity* of an aquifer is the discharge rate divided by the drawdown.

$$\text{specific capacity} = \frac{Q}{s} \quad 21.17$$

## 7. DISCHARGE VELOCITY AND SEEPAGE VELOCITY

The *pore velocity* (*linear velocity*, *flow front velocity*, and *seepage velocity*) is given by Eq. 21.18.<sup>5</sup>

$$v_{\text{pore}} = \frac{Q}{A_{\text{net}}} = \frac{Q}{nA_{\text{gross}}} = \frac{Q}{nbY} = \frac{Ki}{n} \quad 21.18$$

The gross cross-sectional area in flow depends on the aquifer dimensions. However, water can only flow through voids (pores) in the aquifer. If the gross cross-sectional area is known, it will be necessary to multiply by the porosity to reduce the area in flow. (The hydraulic conductivity is not affected.)

The *effective velocity* (also known as the *apparent velocity*, *Darcy velocity*, *Darcian velocity*, *Darcy flux*, *discharge velocity*, *specific discharge*, *superficial velocity*, *face velocity*, and *approach velocity*) through a porous medium is the velocity of flow averaged over the gross aquifer cross-sectional area.

$$v_e = nv_{\text{pore}} = \frac{Q}{A_{\text{gross}}} = \frac{Q}{bY} = Ki \quad 21.19$$

Contaminants introduced into an aquifer will migrate from place to place relative to the surface at the pore velocity given by Eq. 21.18. The effective velocity given in Eq. 21.19 should not be used to determine the overland time taken and distance moved by a contaminant.

## 8. FLOW DIRECTION

Flow direction will be from an area with a high piezometric head (as determined from observation wells) to an area of low piezometric head. Piezometric head is assumed to vary linearly between points of known head. Similarly, all points along a line joining two points with the same piezometric head can be considered to have the same head.

<sup>5</sup>Terms used to describe pore and effective velocities are not used consistently.

## 9. WELLS

Water in aquifers can be extracted from *gravity wells*. However, *monitor wells* may also be used to monitor the quality and quantity of water in an aquifer. *Relief wells* are used to dewater soil.

Wells may be dug, bored, driven, jetted, or drilled in a number of ways, depending on the aquifer material and the depth of the well. Wells deeper than 100 ft (30 m) are usually drilled. After construction, the well is *developed*, which includes the operations of removing any fine sand and mud. Production is *stimulated* by increasing the production rate. The fractures in the rock surrounding the well are increased in size by injecting high-pressure water or using similar operations.

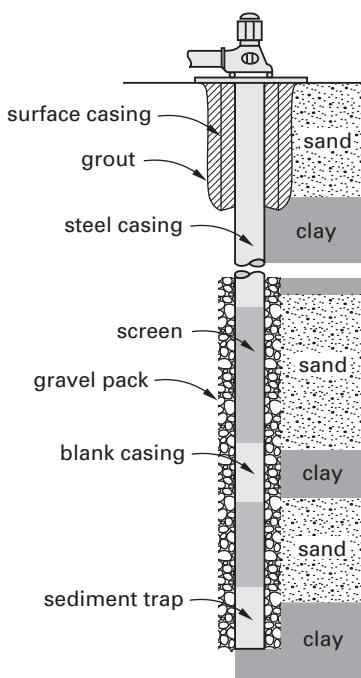

Well equipment is *sterilized* by use of chlorine or other disinfectants. The strength of any chlorine solution used to disinfect well equipment should not be less than 100 ppm by weight (i.e., 100 kg of chlorine per  $10^6$  kg of water). Calcium hypochlorite (which contains 65% available chlorine) and sodium hypochlorite (which contains 12.5% available chlorine) are commonly used for this purpose. The mass of any chlorine-supplying compound with fractional availability  $A$  required to produce  $V$  gallons of disinfectant with concentration  $C$  is

$$m_{\text{lbm}} = (8.33 \times 10^{-6}) V_{\text{gal}} \left( \frac{C_{\text{ppm}}}{A_{\text{decimal}}} \right) \quad 21.20$$

Figure 21.1 illustrates a typical water-supply well. Water is removed from the well through the *riser pipe* (*eductor pipe*). Water enters the well through a perforated or slotted casing known as the *screen*. The required *open area* depends on the flow rate and is limited by the maximum permissible entrance velocity that will not lift grains larger than a certain size. Table 21.2 recommends maximum flow velocities as functions of the grain diameter. A safety factor of 1.5–2.0 is also used to account for the fact that parts of the screen may become blocked. As a general rule, the openings should also be smaller than  $D_{50}$  (i.e., smaller than 50% of the screen material particles).

Screens do not necessarily extend the entire length of the well. The required screen length can be determined from the total amount of open area required and the open area per unit length of casing. For confined aquifers, screens are usually installed in the middle 70–80% of the well. For unconfined aquifers, screens are usually installed in the lower 30–40% of the well.

It is desirable to use screen openings as large as possible to reduce entrance friction losses. Larger openings can be tolerated if the well is surrounded by a *gravel pack* to prevent fine material from entering the well. Gravel packs are generally required in soils where the  $D_{90}$  size (i.e., the sieve size retaining 90% of the soil) is less than 0.01 in (0.25 mm) and when the well goes through layers of sand and clay.

**Figure 21.1** Typical Gravity Well**Table 21.2** Lifting Velocity of Water\*

grain diameter (mm)	maximum water velocity	
	(ft/sec)	(m/s)
0 to 0.25	0.10	0.030
0.25 to 0.50	0.22	0.066
0.50 to 1.00	0.33	0.10
1.00 to 2.00	0.56	0.17
2.00 to 4.00	2.60	0.78

(Multiply ft/sec by 0.3 to obtain m/s.)

\* spherical particles with specific gravity of 2.6

## 10. DESIGN OF GRAVEL SCREENS AND POROUS FILTERS

Gravel and other porous materials may be used as filters as long as their voids are smaller than the particles to be excluded. Actually, only the largest 15% of the particles need to be filtered out, since the agglomeration of these particles will themselves create even smaller openings, and so on.

In specifying the opening sizes for screens, perforated pipe, and fabric filters, the following criteria are in widespread use as the basis for filter design in sandy gravels.  $D_{15}$ , the interpolated grain size that passes 15%, is known as the *permeability protection limit*.  $D_{85}$  is known as the *piping predicting limit*.

$$D_{\text{opening,filter}} \leq D_{85,\text{soil}} \quad [\text{screen filters}] \quad 21.21$$

$$[\text{filtering criterion}]^6 \quad D_{15,\text{filter}} \leq 5D_{85,\text{soil}} \quad [\text{filter beds}] \quad 21.22$$

$$[\text{permeability criterion}]^7 \quad D_{15,\text{filter}} \leq 5D_{15,\text{soil}} \quad [\text{filter beds}] \quad 21.23$$

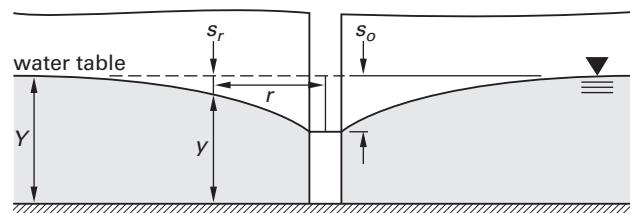

As stated in Sec. 21.9, the screen openings should also be smaller than  $D_{50}$  (i.e., smaller than 50% of the screen material particles).

The *coefficient of uniformity*,  $C_u$ , is used to determine whether the filter particles are properly graded. Only uniform materials ( $C_u < 2.5$ ) and well-graded materials ( $2.5 < C < 6$ ) are suitable for use as filters.

$$C_u = \frac{D_{60}}{D_{10}} \quad 21.24$$

## 11. WELL DRAWDOWN IN AQUIFERS

An aquifer with a well is shown in Fig. 21.2. Once pumping begins, the water table will be lowered in the vicinity of the well. The resulting water table surface is referred to as a *cone of depression*. The decrease in water level at some distance  $r$  from the well is known as the *drawdown*,  $s_r$ . The drawdown at the well is denoted as  $s_o$ .

**Figure 21.2** Well Drawdown in an Unconfined Aquifer

If the drawdown is small with respect to the aquifer phreatic zone thickness,  $Y$ , and the well completely penetrates the aquifer, the equilibrium (steady-state) well discharge is given by the *Dupuit equation*, Eq. 21.25. Equation 21.25 can only be used to determine the equilibrium flow rate a "long time" after pumping has begun.

$$Q = \frac{\pi K(y_1^2 - y_2^2)}{\ln \frac{r_1}{r_2}} \quad 21.25$$

In Eq. 21.25,  $y_1$  and  $y_2$  are the aquifer depths at radial distances  $r_1$  and  $r_2$ , respectively, from the well.  $y_1$  can also be taken as the original aquifer depth,  $Y$ , if  $r_1$  is the well's *radius of influence*, the distance at which the well has no effect on the water table level.

<sup>6</sup>Some authorities replace "5" with "9" for uniform soils.<sup>7</sup>Some authorities replace "5" with "4."

In very thick unconfined aquifers where the drawdown is negligible compared to the aquifer thickness, or in confined aquifers where there is no cone of depression at all,  $y_1 + y_2$  is essentially equal to  $2Y$ . Then, since  $y_2 - y_1 = s_1 - s_2$ ,  $y_2^2 - y_1^2 = (y_2 - y_1)(y_2 + y_1) = 2Y(s_1 - s_2)$ . Using this equality and Eq. 21.13, Eq. 21.25 can be written as

$$Q = \frac{2\pi T(s_2 - s_1)}{\ln \frac{r_1}{r_2}} \quad 21.26$$

For an artesian well fed by a confined aquifer of thickness  $Y$ , the discharge is given by the *Thiem equation*.

$$Q = \frac{2\pi KY(y_1 - y_2)}{\ln \frac{r_1}{r_2}} \quad 21.27$$

The rate (or amount in some period) of water that can be extracted without experiencing some undesirable result is known as the *safe yield*. Undesirable results include deteriorations in the water quality, large pump lifts, and infringement on the water rights of others. Extractions in excess of the safe yield are known as *overdrafts*.

### Example 21.1

A 9 in (25 cm) diameter well is pumped at the rate of 50 gal/min (0.2 m<sup>3</sup>/min). The aquifer is 100 ft (30 m) thick. After some time, the well sides cave in and are replaced with an 8 in (20 cm) diameter tube. The drawdown is 6 ft (2 m). The water table recovers its original thickness 2500 ft (750 m) from the well. What will be the steady flow from the new well?

*SI Solution*

$$r_1 = \frac{25 \text{ cm}}{2} = 12.5 \text{ cm} \quad (0.125 \text{ m})$$

$$y_1 = 30 \text{ m} - 2 \text{ m} = 28 \text{ m}$$

Rearrange Eq. 21.25 to determine hydraulic conductivity from the given information.

$$\begin{aligned} K &= \frac{Q \ln \frac{r_1}{r_2}}{\pi(y_1^2 - y_2^2)} \\ &= \frac{\left(0.2 \frac{\text{m}^3}{\text{min}}\right) \ln \frac{750 \text{ m}}{0.125 \text{ m}}}{\pi((30 \text{ m})^2 - (28 \text{ m})^2)} \\ &= 0.004774 \text{ m/min} \quad (0.007957 \text{ cm/s}) \end{aligned}$$

For the relined well,

$$r_2 = \frac{20 \text{ cm}}{2} = 10 \text{ cm} \quad (0.10 \text{ m})$$

Use Eq. 21.25 to solve for the new flow rate.

$$\begin{aligned} Q &= \frac{\pi K(y_1^2 - y_2^2)}{\ln \frac{r_1}{r_2}} \\ &= \pi \left(0.004774 \frac{\text{m}}{\text{min}}\right) \left(\frac{(30 \text{ m})^2 - (28 \text{ m})^2}{\ln \frac{750 \text{ m}}{0.10 \text{ m}}}\right) \\ &= 0.195 \text{ m}^3/\text{min} \end{aligned}$$

*Customary U.S. Solution*

$$\begin{aligned} r_1 &= \frac{9 \text{ in}}{(2)\left(12 \frac{\text{in}}{\text{ft}}\right)} = 0.375 \text{ ft} \\ y_1 &= 100 \text{ ft} - 6 \text{ ft} = 94 \text{ ft} \\ Q &= \left(50 \frac{\text{gal}}{\text{min}}\right) \left(0.002228 \frac{\text{ft}^3\text{-min}}{\text{sec-gal}}\right) \\ &= 0.1114 \text{ ft}^3/\text{sec} \end{aligned}$$

Rearrange Eq. 21.25 to find the hydraulic conductivity.

$$\begin{aligned} K &= \frac{Q \ln \frac{r_1}{r_2}}{\pi(y_1^2 - y_2^2)} \\ &= \frac{\left(50 \frac{\text{gal}}{\text{min}}\right) \left(1440 \frac{\text{min}}{\text{day}}\right) \ln \frac{2500 \text{ ft}}{0.375 \text{ ft}}}{\pi((100 \text{ ft})^2 - (94 \text{ ft})^2)} \\ &= 173.4 \text{ gal/day-ft}^2 \end{aligned}$$

For the relined well,

$$r_2 = \frac{8 \text{ in}}{(2)\left(12 \frac{\text{in}}{\text{ft}}\right)} = 0.333 \text{ ft}$$

Use Eq. 21.25 to solve for the new flow rate.

$$\begin{aligned} Q &= \frac{\pi K(y_1^2 - y_2^2)}{\ln \frac{r_1}{r_2}} \\ &= \frac{\pi \left(173.4 \frac{\text{gal}}{\text{day-ft}^2}\right) ((100 \text{ ft})^2 - (94 \text{ ft})^2)}{\ln \frac{2500 \text{ ft}}{0.333 \text{ ft}}} \\ &= 71,057 \text{ gal/day} \end{aligned}$$

## 12. UNSTEADY FLOW

When pumping first begins, the removed water also comes from the aquifer above the equilibrium cone of depression. Therefore, Eq. 21.26 cannot be used, and a nonequilibrium analysis is required.

Nonequilibrium solutions to well problems have been formulated in terms of dimensionless numbers. For small drawdowns compared with the initial thickness of the aquifer, the *Theis equation* for the drawdown at a distance  $r$  from the well and after pumping for time  $t$  is

$$\begin{aligned}s_{r,t} &= \left( \frac{Q}{4\pi K Y} \right) W(u) \\ &= \left( \frac{Q}{4\pi T} \right) W(u) \quad \begin{bmatrix} \text{consistent} \\ \text{units} \end{bmatrix}\end{aligned}\quad 21.28$$

$W(u)$  is a dimensionless *well function*. (See Table 21.3.) Though it is possible to obtain  $W(u)$  from  $u$ , extracting  $u$  from  $W(u)$  is more difficult. The relationship between  $u$  and  $W(u)$  is often given in tabular or graphical forms. In Eq. 21.30,  $S$  is the aquifer *storage constant*.

$$\begin{aligned}W(u) &= -0.577216 - \ln u + u - \frac{u^2}{(2)(2!)} \\ &\quad + \frac{u^3}{(3)(3!)} - \frac{u^4}{(4)(4!)} + \dots\end{aligned}\quad 21.29$$

$$u = \frac{r^2 S}{4 K Y t} = \frac{r^2 S}{4 T t} \quad \begin{bmatrix} \text{consistent} \\ \text{units} \end{bmatrix}\quad 21.30$$

Accordingly, for any two different times in the pumping cycle,

$$s_1 - s_2 = y_2 - y_1 = \left( \frac{Q}{4\pi K Y} \right) (W(u_1) - W(u_2))\quad 21.31$$

If  $u < 0.01$ , then *Jacob's equation* can be used.

$$s_{r,t} = \left( \frac{Q}{4\pi T} \right) \ln \frac{2.25 T t}{r^2 S}\quad 21.32$$

**Table 21.3** Well Function  $W(u)$  for Various Values of  $u$

Reprinted from L. K. Wenzel, "Methods for Determining Permeability of Water Bearing Materials with Special Reference to Discharging Well Methods," U.S. Geological Survey, 1942, Water-Supply Paper 887.

No fluid flows across streamlines, and a constant amount of fluid flows between any two streamlines.

Flow nets are constructed according to the following rules.

*Rule 21.1:* Streamlines enter and leave pervious surfaces perpendicular to those surfaces.

*Rule 21.2:* Streamlines approach the line of seepage (above which there is no hydrostatic pressure) asymptotically to (i.e., parallel but gradually approaching) that surface.

*Rule 21.3:* Streamlines are parallel to but cannot touch impervious surfaces that are streamlines.

*Rule 21.4:* Streamlines are parallel to the flow direction.

*Rule 21.5:* Equipotential lines are drawn perpendicular to streamlines such that the resulting cells are approximately square and the intersections are  $90^\circ$  angles. Theoretically, it should be possible to draw a perfect circle within each cell that touches all four boundaries, even though the cell is not actually square.

*Rule 21.6:* Equipotential lines enter and leave impervious surfaces perpendicular to those surfaces.

Many flow nets with differing degrees of detail can be drawn, and all will be more or less correct. Generally, three to five streamlines are sufficient for initial graphical evaluations. The size of the cells is determined by the number of intersecting streamlines and equipotential lines. As long as the rules are followed, the ratio of stream flow channels to equipotential drops will be approximately constant regardless of whether the grid is coarse or fine.

Figure 21.3 shows flow nets for several common cases. A careful study of the flow nets will help to clarify the rules and conventions previously listed.

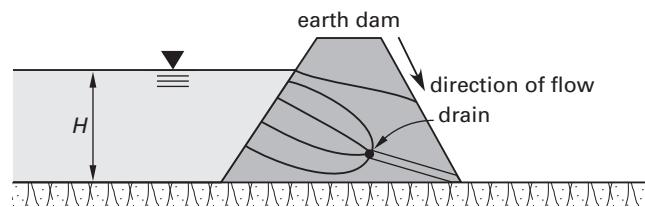

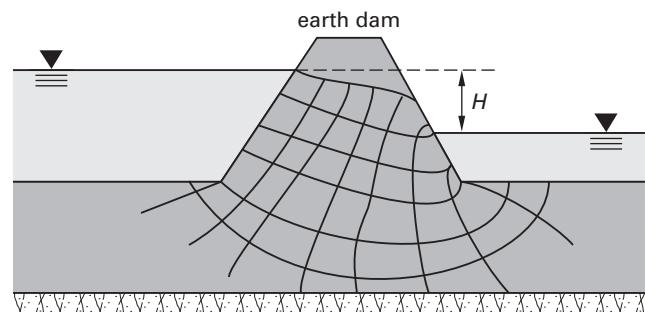

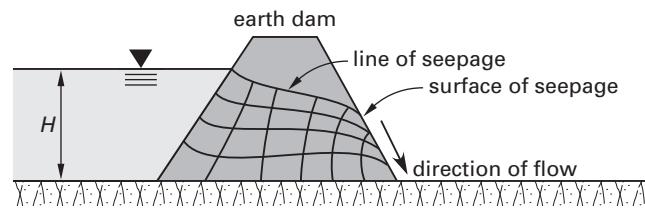

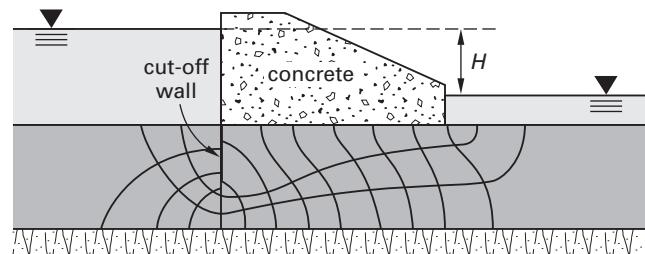

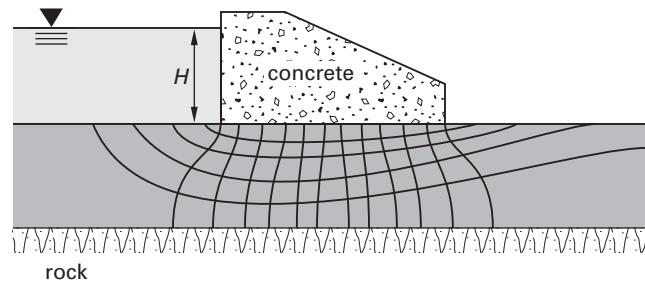

## 15. SEEPAGE FROM FLOW NETS

Once a flow net is drawn, it can be used to calculate the seepage. First, the number of flow channels,  $N_f$ , between the streamlines is counted. Then, the number of equipotential drops,  $N_p$ , between equipotential lines is counted. The total hydraulic head,  $H$ , is determined as a function of the water surface levels.

$$Q = KH \left( \frac{N_f}{N_p} \right) \quad [\text{per unit width}] \quad 21.33$$

$$H = H_1 - H_2 \quad 21.34$$

Figure 21.3 Typical Flow Nets

## 16. HYDROSTATIC PRESSURE ALONG FLOW PATH

The hydrostatic pressure at equipotential drop  $j$  (counting the last line on the downstream side as zero) in a flow net with a total of  $N_p$  equipotential drops is given

by Eq. 21.35. If the point being investigated is along the bottom of a dam or other structure, the hydrostatic pressure is referred to as *uplift pressure*. Since uplift due to velocity is negligible, all uplift is due to the neutral pore pressure. Therefore, *neutral pressure* is synonymous with uplift pressure.

$$p_u = \left( \frac{j}{N_p} \right) H g \rho_w \quad [\text{SI}] \quad 21.35(a)$$

$$p_u = \left( \frac{j}{N_p} \right) H \gamma_w \quad [\text{U.S.}] \quad 21.35(b)$$

If the point being investigated is located a distance  $z$  below the datum, then the pressure at the point is given by Eq. 21.36. If the point being investigated is above the datum,  $z$  is negative.

$$p_u = \left( \left( \frac{j}{N_p} \right) H + z \right) g \rho_w \quad [\text{SI}] \quad 21.36(a)$$

$$p_u = \left( \left( \frac{j}{N_p} \right) H + z \right) \gamma_w \quad [\text{U.S.}] \quad 21.36(b)$$

The actual *uplift force* on a surface of area  $A$  is given by Eq. 21.37.  $N$  is the *neutral stress coefficient*, defined as the fraction of the surface that is exposed to the hydrostatic pressure. For soil,  $N \approx 1$ . However, for fractured rock, concrete, porous limestone, or sandstone, it varies from 0.5–1.0. For impervious materials such as marble or granite, it can be as low as 0.1.

$$U = N p_u A \quad 21.37$$

As Table 21.1 indicates, some clay layers are impervious enough to prevent the passing of water. However, the hydrostatic uplift pressure below a clay layer can still be transmitted through the clay layer. The transfer geometry for thick layers is complex, making estimates of the amount of uplift force difficult. Upward forces on an impervious layer due to hydrostatic pressure below is known as *heave*. A factor of safety, FS, against heave of at least 1.5 is desirable.

$$(FS)_{\text{heave}} = \frac{\text{downward pressure}}{\text{uplift pressure}} \quad 21.38$$

## 17. INFILTRATION

Aquifers can be recharged (refilled) in a number of natural and artificial ways. The *Horton equation* gives a lower bound on the *infiltration capacity* (in inches (centimeters) of rainfall per unit time), which is the capacity of an aquifer to absorb water from a saturated source above as a function of time. When the rainfall supply exceeds the infiltration capacity, infiltration decreases exponentially over time. In Eq. 21.39,  $f_c$  is the final or

equilibrium capacity,  $f_0$  is the initial infiltration capacity, and  $f_t$  is the infiltration capacity at time  $t$ .  $k$  is an infiltration decay constant with dimensions of 1/hr determined from a *double-ring infiltration test*.

$$f_t = f_c + (f_0 - f_c) e^{-kt} \quad 21.39$$

The cumulative infiltration will not correspond to the increase in water table elevation due to the effects of porosity. However, the increase in water table elevation can be determined from a knowledge of the aquifer properties.

Infiltration rates for intermediate, silty soils are approximately 50% of those for sand. Clay infiltration rates are approximately 10% of those for sand. The actual infiltration rate at any time is equal (in the Horton model) to the smaller of the rainfall intensity,  $i(t)$ , and the instantaneous capacity.

$$f = i \quad [i \leq f_t] \quad 21.40$$

$$f = f_t \quad [i > f_t] \quad 21.41$$

The cumulative infiltration over time is

$$F_t = f_c t + \left( \frac{f_0 - f_c}{k} \right) (1 - e^{-kt}) \quad 21.42$$

The average infiltration rate is found by dividing Eq. 21.42 by the duration of infiltration.

$$\bar{f} = \frac{F_t}{t_{\text{infiltration}}} \quad 21.43$$

The depth of water stored in the layer,  $S$ , is equal to the total depth of infiltration,  $F_t$ , minus the depth of water that has leaked out the bottom of the layer. Except in very permeable soils (such as sand or gravel), water leaks out the bottom of the layer slowly. In that case, the water storage is

$$S = F_t - f_c t \quad 21.44$$

The maximum depth of water that the layer can store is

$$S_{\max} = \frac{f_0 - f_c}{k} \quad 21.45$$

Horton's equation assumes that the rate of precipitation,  $I$ , is greater than the infiltration rate,  $f_{\text{in}}$ , throughout the storm period. The overland flow,  $Q_{\text{overland}}$ , experienced when the rainfall rate is greater than the infiltration rate is

$$Q_{\text{overland}} = I - f_{\text{in}} \quad 21.46$$

The rate at which water is stored in the layer is equal to the infiltration rate minus the leakage outflow rate through the bottom of the layer.

$$\frac{dS}{dt} = f_{\text{in}} - f_{\text{out}} \quad 21.47$$

Equation 21.47 is easily solved for constant precipitation rates greater than the infiltration rate. If the precipitation rate is ever lower than the infiltration rate, the layer will lose water to lower levels, and Horton's theory must be modified. Rather than Eq. 21.47, finite difference techniques are used to calculate the infiltration rate and storage incrementally. The finite difference infiltration equation is given by Eq. 21.48. Of course, the infiltration can never exceed the rate of precipitation, no matter what the capacity.

$$S(t + \Delta t) = S(t) + \Delta t(f_{\text{in}} - f_c) \quad 21.48$$

### Example 21.2

A soil has the following characteristics

initial infiltration capacity ( $f_0$ ), 6.8 cm/h

equilibrium infiltration capacity ( $f_c$ ), 0.3 cm/h

infiltration decay constant ( $k$ ), 0.75 1/h

Calculate the (a) infiltration rate and (b) the total depth of infiltrated water after 3 hours of hard rain. (c) What is the maximum depth of water that the layer can store?

*Solution*

(a) Use Eq. 21.39 to calculate the infiltration rate.

$$\begin{aligned} f_t &= f_c + (f_0 - f_c)e^{-kt} \\ &= 0.3 \frac{\text{cm}}{\text{h}} + \left(6.8 \frac{\text{cm}}{\text{h}} - 0.3 \frac{\text{cm}}{\text{h}}\right) e^{-\left(0.75 \frac{1}{\text{h}}\right)(3 \text{ h})} \\ &= 0.985 \text{ cm/h} \end{aligned}$$

(b) Use Eq. 21.42 to calculate the total depth of infiltrated water.

$$\begin{aligned} F(t) &= f_c t + \left(\frac{f_0 - f_c}{k}\right)(1 - e^{-kt}) \\ &= \left(0.3 \frac{\text{cm}}{\text{h}}\right)(3 \text{ h}) \\ &\quad + \left(\frac{6.8 \frac{\text{cm}}{\text{h}} - 0.3 \frac{\text{cm}}{\text{h}}}{0.75 \frac{1}{\text{h}}}\right) \left(1 - e^{-\left(0.75 \frac{1}{\text{h}}\right)(3 \text{ h})}\right) \\ &= 8.65 \text{ cm} \end{aligned}$$

(c) The maximum storage is calculated from Eq. 21.45.

$$\begin{aligned} S_{\text{max}} &= \frac{f_0 - f_c}{k} = \frac{6.8 \frac{\text{cm}}{\text{h}} - 0.3 \frac{\text{cm}}{\text{h}}}{0.75 \frac{1}{\text{h}}} \\ &= 8.67 \text{ cm} \end{aligned}$$

## 1. ATOMIC STRUCTURE

An *element* is a substance that cannot be decomposed into simpler substances during ordinary chemical reactions.<sup>1</sup> An *atom* is the smallest subdivision of an element that can take part in a chemical reaction. A *molecule* is the smallest subdivision of an element or compound that can exist in a natural state.

The atomic nucleus consists of neutrons and protons, known as *nucleons*. The masses of neutrons and protons are essentially the same—one *atomic mass unit*, amu. One amu is exactly  $1/12$  of the mass of an atom of carbon-12, approximately equal to  $1.66 \times 10^{-27}$  kg.<sup>2</sup> The *relative atomic weight* or *atomic weight*,  $A$ , of an atom is approximately equal to the number of protons and neutrons in the nucleus.<sup>3</sup> (See App. 22.A.) The *atomic number*,  $Z$ , of an atom is equal to the number of protons in the nucleus.

The atomic number and atomic weight of an element  $E$  are written in symbolic form as  $_Z^A E$ ,  $E_Z^A$ , or  ${}^A_Z E$ . For example, carbon is the sixth element; radioactive carbon has an atomic mass of 14. Therefore, the symbol for carbon-14 is  $C_6^{14}$ . Since the atomic number is superfluous if the chemical symbol is given, the atomic number can be omitted (e.g.,  $C^{14}$ ).

## 2. ISOTOPES

Although an element can have only a single atomic number, atoms of that element can have different atomic weights. Many elements possess *isotopes*. The nuclei of isotopes differ from one another only in the number of neutrons. Isotopes behave the same way chemically.<sup>4</sup> Therefore, isotope separation must be done physically (e.g., by centrifugation or gaseous diffusion) rather than chemically.

Hydrogen has three isotopes.  $H_1^1$  is *normal hydrogen* with a single proton nucleus.  $H_1^2$  is known as *deuterium (heavy hydrogen)*, with a nucleus of a proton and neutron. (This nucleus is known as a *deuteron*.) Finally,  $H_1^3$  (*tritium*) has two neutrons in the nucleus. While normal hydrogen and deuterium are stable, tritium is radioactive. Many elements have more than one stable isotope. Tin, for example, has 10.

<sup>1</sup>Atoms of an element can be decomposed into subatomic particles in nuclear reactions.

<sup>2</sup>Until 1961, the atomic mass unit was defined as  $1/16$  of the mass of one atom of oxygen-16.

<sup>3</sup>The term *weight* is used even though all chemical calculations involve mass. The atomic weight of an atom includes the mass of the electrons. Published *chemical atomic weights* of elements are averages of all the atomic weights of stable isotopes, taking into consideration the relative abundances of the isotopes.

<sup>4</sup>There are slight differences, known as *isotope effects*, in the chemical behavior of isotopes. These effects usually influence only the rate of reaction, not the kind of reaction.

The *relative abundance*,  $x_i$ , of an isotope,  $i$ , is equal to the fraction of that isotope in a naturally occurring sample of the element. The *chemical atomic weight* is the weighted average of the isotope weights.

$$A_{\text{average}} = x_1 A_1 + x_2 A_2 + \dots \quad 22.1$$

## 3. PERIODIC TABLE

The *periodic table*, as shown in App. 22.B, is organized around the *periodic law*: The properties of the elements depend on the atomic structure and vary with the atomic number in a systematic way. Elements are arranged in order of increasing atomic numbers from left to right. Adjacent elements in horizontal rows differ decidedly in both physical and chemical properties. However, elements in the same column have similar properties. Graduations in properties, both physical and chemical, are most pronounced in the *periods* (i.e., the horizontal rows).

The vertical columns are known as *groups*, numbered in Roman numerals. Elements in a group are called *cogeners*. Each vertical group except 0 and VIII has A and B subgroups (*families*). The elements of a family resemble each other more than they resemble elements in the other family of the same group. Graduations in properties are definite but less pronounced in vertical families. The trend in any family is toward more *metallic properties* as the atomic weight increases.

*Metals* (elements at the left end of the periodic chart) have low electron affinities and electronegativities, are reducing agents, form positive ions, and have positive oxidation numbers. They have high electrical conductivities, luster, generally high melting points, ductility, and malleability.

*Nonmetals* (elements at the right end of the periodic chart) have high electron affinities and electronegativities, are oxidizing agents, form negative ions, and have negative oxidation numbers. They are poor electrical conductors, have little or no luster, and form brittle solids. Of the common nonmetals, fluorine has the highest electronic affinity and electronegativity, with oxygen having the next highest values.

The *metalloids* (e.g., boron, silicon, germanium, arsenic, antimony, tellurium, and polonium) have characteristics of both metals and nonmetals. Electrically, they are semiconductors.

The electron-attracting power of an atom is called its *electronegativity*. Metals have low electronegativities. Group VIIA elements (fluorine, chlorine, etc.) are most strongly electronegative. The alkali metals (Group IA) are the most weakly electronegative. Generally, the most *electronegative elements* are those at the right ends of the periods. Elements with low electronegativities are found at the beginning (i.e., left end) of the periods. Electronegativity decreases as you go down a group.

Elements in the periodic table are often categorized into the following groups.

- *actinides*: same as actinons
- *actinons*: elements 90–103<sup>5</sup>
- *alkali metals*: group IA
- *alkaline earth metals*: group IIA
- *halogens*: group VIIA
- *heavy metals*: metals near the center of the chart
- *inner transition elements*: same as transition metals
- *lanthanides*: same as lanthanons
- *lanthanons*: elements 58–71<sup>6</sup>
- *light metals*: elements in the first two groups
- *metals*: everything except the nonmetals
- *metalloids*: elements along the dark line in the chart separating metals and nonmetals
- *noble gases*: group 0
- *nonmetals*: elements 2, 5–10, 14–18, 33–36, 52–54, 85, and 86
- *rare earths*: same as lanthanons
- *transition elements*: same as transition metals
- *transition metals*: all B families and group VIII B<sup>7</sup>

#### 4. OXIDATION NUMBER

The *oxidation number* (*oxidation state*) is an electrical charge assigned by a set of prescribed rules. It is actually the charge assuming all bonding is ionic. The sum of the oxidation numbers equals the net charge. For monoatomic ions, the oxidation number is equal to the charge. The oxidation numbers of some common atoms and radicals are given in Table 22.1.

In covalent compounds, all of the bonding electrons are assigned to the ion with the greater electronegativity. For example, nonmetals are more electronegative than metals. Carbon is more electronegative than hydrogen.

For atoms in a free-state molecule, the oxidation number is zero. Hydrogen gas is a diatomic molecule, H<sub>2</sub>. Therefore, the oxidation number of the hydrogen molecule, H<sub>2</sub>, is zero. The same is true for the atoms in O<sub>2</sub>, N<sub>2</sub>, Cl<sub>2</sub>, and so on. Also, the sum of all the oxidation numbers of atoms in a neutral molecule is zero.

<sup>5</sup>The *actinons* resemble element 89, *actinium*. Therefore, element 89 is sometimes included as an actinon.

<sup>6</sup>The *lanthanons* resemble element 57, *lanthanum*. Therefore, element 57 is sometimes included as a lanthanon.

<sup>7</sup>The *transition metals* are elements whose electrons occupy the d sublevel. They can have various oxidation numbers, including +2, +3, +4, +6, and +7.

**Table 22.1** Oxidation Numbers of Selected Atoms and Charge Numbers of Radicals

name	symbol	oxidation or charge number
acetate	C <sub>2</sub> H <sub>3</sub> O <sub>2</sub>	-1
aluminum	Al	+3
ammonium	NH <sub>4</sub>	+1
barium	Ba	+2
borate	BO <sub>3</sub>	-3
boron	B	+3
bromine	Br	-1
calcium	Ca	+2
carbon	C	+4, -4
carbonate	CO <sub>3</sub>	-2
chlorate	ClO <sub>3</sub>	-1
chlorine	Cl	-1
chlorite	ClO <sub>2</sub>	-1
chromate	CrO <sub>4</sub>	-2
chromium	Cr	+2, +3, +6
copper	Cu	+1, +2
cyanide	CN	-1
dichromate	Cr <sub>2</sub> O <sub>7</sub>	-2
fluorine	F	-1
gold	Au	+1, +3
hydrogen	H	+1 (-1 in hydrides)
hydroxide	OH	-1
hypochlorite	ClO	-1
iron	Fe	+2, +3
lead	Pb	+2, +4
lithium	Li	+1
magnesium	Mg	+2
mercury	Hg	+1, +2
nickel	Ni	+2, +3
nitrate	NO <sub>3</sub>	-1
nitrite	NO <sub>2</sub>	-1
nitrogen	N	-3, +1, +2, +3, +4, +5
oxygen	O	-2 (-1 in peroxides)
perchlorate	ClO <sub>4</sub>	-1
permanganate	MnO <sub>4</sub>	-1
phosphate	PO <sub>4</sub>	-3
phosphorus	P	-3, +3, +5
potassium	K	+1
silicon	Si	+4, -4
silver	Ag	+1
sodium	Na	+1
sulfate	SO <sub>4</sub>	-2
sulfite	SO <sub>3</sub>	-2
sulfur	S	-2, +4, +6
tin	Sn	+2, +4
zinc	Zn	+2

Fluorine is the most electronegative element, and it has an oxidation number of -1. Oxygen is second only to fluorine in electronegativity. Usually, the oxidation number of oxygen is -2, except in peroxides, where it is -1, and when combined with fluorine, where it is +2. Hydrogen is usually +1, except in hydrides, where it is -1.

For a charged *radical* (a group of atoms that combine as a single unit), the net oxidation number is equal to the charge on the radical, known as the *charge number*.

### Example 22.1

What are the oxidation numbers of all the elements in the chlorate ( $\text{ClO}_3^{-1}$ ) and permanganate ( $\text{MnO}_4^{-1}$ ) ions?

*Solution*

For the chlorate ion, the oxygen is more electronegative than the chlorine. (Only fluorine is more electronegative than oxygen.) Therefore, the oxidation number of oxygen is  $-2$ . In order for the net oxidation number to be  $-1$ , the chlorine must have an oxidation number of  $+5$ .

For the permanganate ion, the oxygen is more electronegative than the manganese. Therefore, the oxidation number of oxygen is  $-2$ . For the net oxidation number to be  $-1$ , the manganese must have an oxidation number of  $+7$ .

## 5. FORMATION OF COMPOUNDS

Compounds form according to the *law of definite (constant) proportions*: A pure compound is always composed of the same elements combined in a definite proportion by mass. For example, common table salt is always  $\text{NaCl}$ . It is not sometimes  $\text{NaCl}$  and other times  $\text{Na}_2\text{Cl}$  or  $\text{NaCl}_3$  (which do not exist, in any case).

Furthermore, compounds form according to the *law of (simple) multiple proportions*: When two elements combine to form more than one compound, the masses of one element that combine with the same mass of the other are in the ratios of small integers.

In order to evaluate whether a compound formula is valid, it is necessary to know the *oxidation numbers* of the interacting atoms. Although some atoms have more than one possible oxidation number, most do not.

The sum of the oxidation numbers must be zero if a neutral compound is to form. For example,  $\text{H}_2\text{O}$  is a valid compound since the two hydrogen atoms have a total positive oxidation number of  $2 \times 1 = +2$ . The oxygen ion has an oxidation number of  $-2$ . These oxidation numbers sum to zero.

On the other hand,  $\text{NaCO}_3$  is not a valid compound formula. The sodium (Na) ion has an oxidation number of  $+1$ . However, the carbonate radical has a charge number of  $-2$ . The correct sodium carbonate molecule is  $\text{Na}_2\text{CO}_3$ .

## 6. NAMING COMPOUNDS

Combinations of elements are known as *compounds*. *Binary compounds* contain two elements; *ternary (tertiary) compounds* contain three elements. A *chemical formula* is a representation of the relative numbers of each element in the compound. For example, the formula

$\text{CaCl}_2$  shows that there are one calcium atom and two chlorine atoms in one molecule of calcium chloride.

Generally, the numbers of atoms are reduced to their lowest terms. However, there are exceptions. For example, acetylene is  $\text{C}_2\text{H}_2$ , and hydrogen peroxide is  $\text{H}_2\text{O}_2$ .

For binary compounds with a metallic element, the positive metallic element is listed first. The chemical name ends in the suffix “-ide.” For example,  $\text{NaCl}$  is sodium chloride. If the metal has two oxidation states, the suffix “-ous” is used for the lower state, and “-ic” is used for the higher state. Alternatively, the element name can be used with the oxidation number written in Roman numerals. For example,

$\text{FeCl}_2$ : ferrous chloride, or iron (II) chloride

$\text{FeCl}_3$ : ferric chloride, or iron (III) chloride

For binary compounds formed between two nonmetals, the more positive element is listed first. The number of atoms of each element is specified by the prefixes “di-” (2), “tri-” (3), “tetra-” (4), and “penta-” (5), and so on. For example,

$\text{N}_2\text{O}_5$ : dinitrogen pentoxide

*Binary acids* start with the prefix “hydro-,” list the name of the nonmetallic element, and end with the suffix “-ic.” For example,

$\text{HCl}$ : hydrochloric acid

Ternary compounds generally consist of an element and a radical. The positive part is listed first in the formula. *Ternary acids* (also known as *oxyacids*) usually contain hydrogen, a nonmetal, and oxygen, and can be grouped into families with different numbers of oxygen atoms. The most common acid in a family (i.e., the root acid) has the name of the nonmetal and the suffix “-ic.” The acid with one more oxygen atom than the root is given the prefix “per-” and the suffix “-ic.” The acid containing one less oxygen atom than the root is given the ending “-ous.” The acid containing two less oxygen atoms than the root is given the prefix “hypo-” and the suffix “-ous.”

For example,

$\text{HClO}$ : hypochlorous acid

$\text{HClO}_2$ : chlorous acid

$\text{HClO}_3$ : chloric acid (the root)

$\text{HClO}_4$ : perchloric acid

A list of chemical names, along with their common names and formulas, is provided in App. 22.E.

## 7. MOLES AND AVOGADRO'S LAW

The *mole* is a measure of the quantity of an element or compound. Specifically, a mole of an element will have a mass equal to the element's atomic (or molecular) weight. The three main types of moles are based on

mass being measured in grams, kilograms, and pounds. Obviously, a gram-based mole of carbon (12.0 grams) is not the same quantity as a pound-based mole of carbon (12.0 pounds). Although “mol” is understood in SI countries to mean a gram-mole, the term *mole* is ambiguous, and the units mol (gmol), kmol (kgmol), or lbmol must be specified.<sup>8</sup>

One gram-mole of any substance has the same number of particles (atoms, molecules, ions, electrons, etc.),  $6.022 \times 10^{23}$ , *Avogadro’s number*,  $N_A$ . A pound-mole contains approximately 454 times the number of particles in a gram-mole.

*Avogadro’s law (hypothesis)* holds that equal volumes of all gases at the same temperature and pressure contain equal numbers of gas molecules. Specifically, at standard scientific conditions (1.0 atm and 0°C), one gram-mole of any gas contains  $6.022 \times 10^{23}$  molecules and occupies 22.4 L. A pound-mole occupies 454 times that volume, 359 ft<sup>3</sup>.

“Molar” is used as an adjective when describing properties of a mole. For example, a *molar volume* is the volume of a mole.

### Example 22.2

How many electrons are in 0.01 g of gold? ( $A = 196.97$ ;  $Z = 79$ .)

*Solution*

The number of gram-moles of gold present is

$$n = \frac{m}{\text{MW}} = \frac{0.01 \text{ g}}{196.97 \frac{\text{g}}{\text{mol}}} = 5.077 \times 10^{-5} \text{ mol}$$

The number of gold nuclei is

$$\begin{aligned} N &= nN_A = (5.077 \times 10^{-5} \text{ mol}) \left( 6.022 \times 10^{23} \frac{\text{nuclei}}{\text{mol}} \right) \\ &= 3.057 \times 10^{19} \text{ nuclei} \end{aligned}$$

Since the atomic number is 79, there are 79 protons and 79 electrons in each gold atom. The number of electrons is

$$N_{\text{electrons}} = (3.057 \times 10^{19})(79) = 2.42 \times 10^{21}$$

## 8. FORMULA AND MOLECULAR WEIGHTS

The *formula weight*, FW, of a molecule (compound) is the sum of the atomic weights of all elements in the molecule. The *molecular weight*, MW, is generally the same as the formula weight. The units of molecular weight are g/mol, kg/kmol, or lbm/lbmol. However,

<sup>8</sup>There are also variations on the presentation of these units, such as g mol, gmole, g-mole, kmole, kg-mol, lb-mole, pound-mole, and p-mole. In most cases, the intent is clear.

units are sometimes omitted because weights are relative. For example,

An *ultimate analysis* (which determines how much of each element is present in a compound) will not necessarily determine the molecular formula. It will determine only the formula weight based on the relative proportions of each element. Therefore, except for hydrated molecules and other linked structures, the molecular weight will be an integer multiple of the formula weight.

For example, an ultimate analysis of hydrogen peroxide ( $\text{H}_2\text{O}_2$ ) will show that the compound has one oxygen atom for each hydrogen atom. In this case, the formula would be assumed to be HO and the formula weight would be approximately 17, although the actual molecular weight is 34.

For *hydrated molecules* (e.g.,  $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ ), the mass of the *water of hydration* (also known as the *water of crystallization*) is included in the formula and in the molecular weight.

## 9. EQUIVALENT WEIGHT

The *equivalent weight*, EW (i.e., an *equivalent*), is the amount of substance (in grams) that supplies one gram-mole (i.e.,  $6.022 \times 10^{23}$ ) of reacting units. For acid-base reactions, an acid equivalent supplies one gram-mole of  $\text{H}^+$  ions. A base equivalent supplies one gram-mole of  $\text{OH}^-$  ions. In oxidation-reduction reactions, an equivalent of a substance gains or loses a gram-mole of electrons. Similarly, in electrolysis reactions an equivalent weight is the weight of substance that either receives or donates one gram-mole of electrons at an electrode.

The equivalent weight can be calculated as the molecular weight divided by the change in oxidation number experienced by a compound in a chemical reaction. A compound can have several equivalent weights.

$$\text{EW} = \frac{\text{MW}}{\Delta \text{ oxidation number}} \quad 22.2$$

### Example 22.3

What are the equivalent weights of the following compounds?

(a) Al in the reaction

(b)  $\text{H}_2\text{SO}_4$  in the reaction

(c) NaOH in the reaction

*Solution*

(a) The atomic weight of aluminum is approximately 27. Since the change in the oxidation number is 3, the equivalent weight is  $27/3 = 9$ .

(b) The molecular weight of sulfuric acid is approximately 98. Since the acid changes from a neutral molecule to ions with two charges each, the equivalent weight is  $98/2 = 49$ .

(c) Sodium hydroxide has a molecular weight of approximately 40. The originally neutral molecule goes to a singly charged state. Therefore, the equivalent weight is  $40/1 = 40$ .

## 10. GRAVIMETRIC FRACTION

The *gravimetric fraction*,  $x_i$ , of an element  $i$  in a compound is the fraction by weight  $m$  of that element in the compound. The gravimetric fraction is found from an *ultimate analysis* (also known as a *gravimetric analysis*) of the compound.

$$x_i = \frac{m_i}{m_1 + m_2 + \dots + m_i + \dots + m_n} = \frac{m_i}{m_t} \quad 22.3$$

The *percentage composition* is the gravimetric fraction converted to percentage.

$$\% \text{ composition} = x_i \times 100\% \quad 22.4$$

If the gravimetric fractions are known for all elements in a compound, the *combining weights* of each element can be calculated. (The term *weight* is used even though mass is the traditional unit of measurement.)

$$m_i = x_i m_t \quad 22.5$$

## 11. EMPIRICAL FORMULA DEVELOPMENT

It is relatively simple to determine the *empirical formula* of a compound from the atomic and combining weights of elements in the compound. The empirical formula gives the relative number of atoms (i.e., the formula weight is calculated from the empirical formula).

*step 1:* Divide the gravimetric fractions (or percentage compositions) by the atomic weight of each respective element.

*step 2:* Determine the smallest ratio from step 1.

*step 3:* Divide all of the ratios from step 1 by the smallest ratio.

*step 4:* Write the chemical formula using the results from step 3 as the numbers of atoms. Multiply through as required to obtain all integer numbers of atoms.

## Example 22.4

A clear liquid is analyzed, and the following gravimetric percentage compositions are recorded: carbon, 37.5%; hydrogen, 12.5%; oxygen, 50%. What is the chemical formula for the liquid?

*Solution*

*step 1:* Divide the percentage compositions by the atomic weights.

$$\text{C: } \frac{37.5}{12} = 3.125$$

$$\text{H: } \frac{12.5}{1} = 12.5$$

$$\text{O: } \frac{50}{16} = 3.125$$

*step 2:* The smallest ratio is 3.125.

*step 3:* Divide all ratios by 3.125.

$$\text{C: } \frac{3.125}{3.125} = 1$$

$$\text{H: } \frac{12.5}{3.125} = 4$$

$$\text{O: } \frac{3.125}{3.125} = 1$$

*step 4:* The empirical formula is CH<sub>4</sub>O.

If it had been known that the liquid behaved as though it contained a hydroxyl (OH) radical, the formula would have been written as CH<sub>3</sub>OH. This is recognized as methyl alcohol.

## 12. CHEMICAL REACTIONS

During chemical reactions, bonds between atoms are broken and new bonds are usually formed. The starting substances are known as *reactants*; the ending substances are known as *products*. In a chemical reaction, reactants are either converted to simpler products or synthesized into more complex compounds. There are four common types of reactions.

- *direct combination* (or *synthesis*): This is the simplest type of reaction where two elements or compounds combine directly to form a compound.

- *decomposition* (or *analysis*): Bonds within a compound are disrupted by heat or other energy to produce simpler compounds or elements.

- *single displacement* (or *replacement*<sup>9</sup>): This type of reaction has one element and one compound as reactants.

- *double displacement* (or *replacement*): These are reactions with two compounds as reactants and two compounds as products.

### 13. BALANCING CHEMICAL EQUATIONS

The coefficients in front of element and compound symbols in chemical reaction equations are the numbers of molecules or moles taking part in the reaction. (For gaseous reactants and products, the coefficients also represent the numbers of volumes. This is a direct result of Avogadro's hypothesis that equal numbers of molecules in the gas phase occupy equal volumes under the same conditions.)<sup>10</sup>

Since atoms cannot be changed in a normal chemical reaction (i.e., mass is conserved), the numbers of each element must match on both sides of the equation. When the numbers of each element match, the equation is said to be "balanced." The total atomic weights on both sides of the equation will be equal when the equation is balanced.

Balancing simple chemical equations is largely a matter of deductive trial and error. More complex reactions require use of oxidation numbers.

#### Example 22.5

Balance the following reaction equation.

#### Solution

As written, the reaction is not balanced. For example, there is one aluminum on the left, but there are two on the right. The starting element in the balancing procedure is chosen somewhat arbitrarily.

*step 1:* Since there are two aluminums on the right, multiply Al by 2.

<sup>9</sup>Another name for replacement is *metathesis*.

<sup>10</sup>When water is part of the reaction, the interpretation that the coefficients are volumes is valid only if the reaction takes place at a high enough temperature to vaporize the water.

*step 2:* Since there are three sulfate radicals ( $\text{SO}_4$ ) on the right, multiply  $\text{H}_2\text{SO}_4$  by 3.

*step 3:* Now there are six hydrogens on the left, so multiply  $\text{H}_2$  by 3 to balance the equation.

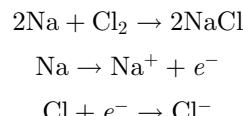

### 14. OXIDATION-REDUCTION REACTIONS

*Oxidation-reduction reactions* (also known as *redox reactions*) involve the transfer of electrons from one element or compound to another. Specifically, one reactant is oxidized, and the other reactant is reduced.

In *oxidation*, a substance's oxidation state increases, the substance loses electrons, and the substance becomes less negative. Oxidation occurs at the anode (positive terminal) in electrolytic reactions.

In *reduction*, a substance's oxidation state decreases, the substance gains electrons, and the substance becomes more negative. Reduction occurs at the cathode (negative terminal) in electrolytic reactions.

Whenever oxidation occurs in a chemical reaction, reduction must also occur. For example, consider the formation of sodium chloride from sodium and chlorine. This reaction is a combination of oxidation of sodium and reduction of chlorine. Notice that the electron released during oxidation is used up in the reduction reaction.

The substance (chlorine in the example) that causes oxidation to occur is called the *oxidizing agent* and is itself reduced (i.e., becomes more negative) in the process. The substance (sodium in the example) that causes reduction to occur is called the *reducing agent* and is itself oxidized (i.e., becomes less negative) in the process.

#### Example 22.6

The balanced equation for a reaction between nitric acid and hydrogen sulfide is

- What is oxidized?
- What is reduced?
- What is the oxidizing agent?
- What is the reducing agent?

**Solution**

First, recognize that the nitric acid exists as dissociated positive and negative ions, not as molecules of  $\text{HNO}_3$ . (Otherwise, the entire molecule might be chosen as one of the agents.)

It is clear that the nitrogen is split out of the nitrate ion. Since the nitrate radical ( $\text{NO}_3^-$ ) has a net charge number of  $-1$ , and the oxidation number of oxygen is (usually)  $-2$ , the nitrogen must have an initial oxidation number of  $+5$ .

In the  $\text{NO}$  molecule, the oxygen is still at  $-2$ , but the nitrogen has changed to  $+2$ .

In the  $\text{H}_2\text{S}$  molecule, the oxidation number of hydrogen is  $+1$ , so the sulfur has an oxidation number of  $-2$ . As a product in the free state, sulfur has an oxidation number of  $0$ .

- (a) The sulfur becomes less negative. Sulfur is oxidized.
- (b) The nitrogen becomes more negative (i.e., less positive). Nitrogen is reduced.
- (c) The oxidizing agent is the nitrate radical,  $\text{NO}_3^-$ , since it contains nitrogen which decreases in oxidation state. (Notice that  $\text{HNO}_3$  is not the oxidizing agent, because the molecule has dissociated.)
- (d) The reducing agent is  $\text{H}_2\text{S}$  since it contains sulfur, which increases in oxidation number. ( $\text{H}_2\text{S}$  essentially does not dissociate. Therefore, the entire molecule is chosen as the reducing agent, rather than just  $\text{S}^{-2}$ .)

## 15. BALANCING OXIDATION-REDUCTION REACTIONS

The total number of electrons lost during oxidation must equal the total number of electrons gained during reduction. This is the main principle used in balancing redox reactions. Although there are several formal methods of applying this principle, balancing an oxidation-reduction equation remains somewhat intuitive and iterative.<sup>11</sup>

The *oxidation number change method* of balancing consists of the following steps.

*step 1:* Write an unbalanced equation that includes all reactants and products.

*step 2:* Assign oxidation numbers to each atom in the unbalanced equation.

*step 3:* Note which atoms change oxidation numbers, and calculate the amount of change for each atom. (When more than one atom of an element

that changes oxidation number is present in a formula, calculate the change in oxidation number for that atom per formula unit.)

*step 4:* Balance the equation so that the number of electrons gained equals the number lost.

*step 5:* Balance (by inspection) the remainder of the chemical equation as required.

### Example 22.7

How many  $\text{AgNO}_3$  molecules are formed per  $\text{NO}$  molecule in the reaction of silver and nitric acid?

#### *Solution*

The unbalanced reaction is written with constants  $c_i$  to represent the unknown coefficients.

The oxidation number of Ag as a reactant is zero. The oxidation number of Ag in  $\text{AgNO}_3$  is  $+1$ . Therefore, silver has become less negative (more positive) and has been oxidized through the loss of one electron.

The N in  $\text{HNO}_3$  has an oxidation number of  $+5$ . The N in  $\text{NO}$  has an oxidation number of  $+2$ . The nitrogen has become more negative (less positive) and has been reduced through the gain of three electrons.

Since three electrons are required for every  $\text{NO}$  molecule formed, it is necessary that  $c_3 = 3c_4$ .

## 16. STOICHIOMETRIC REACTIONS

*Stoichiometry* is the study of the proportions in which elements and compounds react and are formed. A *stoichiometric reaction* (also known as a *perfect reaction* or an *ideal reaction*) is one in which just the right amounts of reactants are present. After the reaction stops, there are no unused reactants.

Stoichiometric problems are known as *weight and proportion problems* because their solutions use simple ratios to determine the masses of reactants required to produce given masses of products, or vice versa. The procedure for solving these problems is essentially the same regardless of the reaction.

*step 1:* Write and balance the chemical equation.

*step 2:* Determine the atomic (molecular) weight of each element (compound) in the equation.

*step 3:* Multiply the atomic (molecular) weights by their respective coefficients and write the products under the formulas.

<sup>11</sup>The *ion-electron method* of balancing is not presented in this book.

- step 4:* Write the given mass data under the weights determined in step 3.
- step 5:* Fill in the missing information by calculating simple ratios.

### Example 22.8

Caustic soda ( $\text{NaOH}$ ) is made from sodium carbonate ( $\text{Na}_2\text{CO}_3$ ) and slaked lime ( $\text{Ca}(\text{OH})_2$ ) according to the given reaction. How many kilograms of caustic soda can be made from 2000 kg of sodium carbonate?

*Solution*

$\text{Na}_2\text{CO}_3$	+	$\text{Ca}(\text{OH})_2$	$\rightarrow$	2 $\text{NaOH}$	+	$\text{CaCO}_3$
molecular weights	106	74		$2 \times 40$	100	
given data	2000 kg			$m$ kg		

The simple ratio used is

$$\frac{\text{NaOH}}{\text{Na}_2\text{CO}_3} = \frac{80}{106} = \frac{m}{2000 \text{ kg}}$$

Solving for the unknown mass,  $m = 1509 \text{ kg}$ .

## 17. NONSTOICHIOMETRIC REACTIONS

In many cases, it is not realistic to assume a stoichiometric reaction because an excess of one or more reactants is necessary to assure that all of the remaining reactants take part in the reaction. Combustion is an example where the stoichiometric assumption is, more often than not, invalid. Excess air is generally needed to ensure that all of the fuel is burned.

With nonstoichiometric reactions, the reactant that is used up first is called the *limiting reactant*. The amount of product will be dependent on (limited by) the limiting reactant.

The *theoretical yield* or *ideal yield* of a product is the maximum mass of product per unit mass of limiting reactant that can be obtained from a given reaction if the reaction goes to completion. The *percentage yield* is a measure of the efficiency of the actual reaction.

$$\text{percentage yield} = \frac{\text{actual yield} \times 100\%}{\text{theoretical yield}} \quad 22.6$$

## 18. SOLUTIONS OF GASES IN LIQUIDS

When a liquid is exposed to a gas, a small amount of the gas will dissolve in the liquid. Diffusion alone is sufficient for this to occur; bubbling or collecting the gas

over a liquid is not necessary. Given enough time, at equilibrium, the concentration of the gas will reach a maximum known as the *saturation concentration*.

Due to the large amount of liquid compared to the small amount of dissolved gas, a liquid exposed to multiple gases will eventually become saturated by all of the gases; the presence of one gas does not affect the solubility of another gas.

The characteristics of a solution of one or more gases in a liquid is predicted by *Henry's law*. In one formulation specifically applicable to liquids exposed to mixtures of gases, Henry's law states that, at equilibrium, the partial pressure,  $p_i$ , of a gas in a mixture will be proportional to the gas mole fraction,  $x_i$ , of that dissolved gas in solution.

In Eq. 22.7, Henry's law constant,  $H$ , has units of pressure, typically reported in the literature in atmospheres (same as atm/mole fraction). (See Table 22.2.)

$$p_i = H_i x_i \quad 22.7$$

**Table 22.2** Approximate Values of Henry's Law Constant (solutions of gases in water)

gas	Henry's law constant, $H$ (atm) (Multiply all values by $10^3$ )	20°C	30°C
CO	53.6	62.0	
$\text{CO}_2$	1.42	1.86	
$\text{H}_2\text{S}$	48.3	60.9	
$\text{N}_2$	80.4	92.4	
NO	26.4	31.0	
$\text{O}_2$	40.1	47.5	
$\text{SO}_2$	0.014	0.016	

Adapted from *Scrubber Systems Operational Review* (APTI Course SI:412C), Second Edition, Lesson 11: Design Review of Absorbers Used for Gaseous Pollutants, 1998, North Carolina State University for the U.S. Environmental Protection Agency.

Since, for mixtures of ideal gases, the mole fraction,  $x_i$ , volumetric fraction,  $B_i$ , and partial pressure fraction,  $p_i/p_{\text{total}}$ , all have the same numerical values, these measures can all be integrated into Henry's law.

Henry's law is stated in several incompatible formulations, and the corresponding equations and Henry's law constants are compatible only with their own formulations. Also, a variety of variables are used for Henry's law constant, including  $H$ ,  $k_H$ ,  $K_H$ , and so on. The context and units of the Henry's law constant must be used to determine Henry's law.

equation	typical units of Henry's law constant	Henry's law statement (at equilibrium)
$p_i = H_i x_i$	$H$ : pressure (atm)	Partial pressure is proportional to mole fraction.
$p_i = k_{H(p/C),i} C_i$	$k_{H(p/C),i}$ : pressure divided by concentration (atm·L/mol; atm·L/mg)	
$p_i = \frac{C_i}{k_{H(C/p),i}}$	$k_{H(C/p)}$ : concentration divided by pressure (mol/atm·L; mg/atm·L)	Partial pressure is proportional to concentration. <sup>*</sup>
$C_{i,gas} = \alpha_i C_{i,liquid}$	$\alpha$ : dimensionless ( $L_{gas}/L_{liquid}$ )	Concentration in the gas mixture is proportional to concentration in the liquid solution.

\*The statements of Henry's law are the same. However, the values of Henry's law constants are inverses.

The dimensionless form of the Henry's law constant is also known as the *absorption coefficient*, *coefficient of absorption*, and *solubility coefficient*. It represents the volume of a gas at a specific temperature and pressure that can be dissolved in a unit volume of liquid.

Typical units are L/L (dimensionless). Approximate values for gases in water at 1 atm and 20°C are: CO, 0.023; CO<sub>2</sub>, 0.88; He, 0.009; H<sub>2</sub>, 0.017; H<sub>2</sub>S, 2.62; N<sub>2</sub>, 0.015; NH<sub>3</sub>, 710; O<sub>2</sub>, 0.028.

The amount of gas dissolved in a liquid varies with the temperature of the liquid and the concentration of dissolved salts in the liquid. Generally, the solubility of gases in liquids decreases with increasing temperature.

Appendix 22.E lists the saturation values of dissolved oxygen in water at various temperatures and for various amounts of chloride ion (also referred to as *salinity*).

### Example 22.9

At 20°C and 1 atm, 1 L of water can absorb 0.043 g of oxygen and 0.017 g of nitrogen. Atmospheric air is 20.9% oxygen by volume, and the remainder is assumed to be nitrogen. What masses of oxygen and nitrogen will be absorbed by 1 L of water exposed to 20°C air at 1 atm?

### Solution

Since partial pressure is volumetrically weighted,

$$m_{\text{oxygen}} = (0.209) \left( 0.043 \frac{\text{g}}{\text{L}} \right) \\ = 0.009 \text{ g/L}$$

$$m_{\text{nitrogen}} = (1.000 - 0.209) \left( 0.017 \frac{\text{g}}{\text{L}} \right) \\ = 0.0134 \text{ g/L}$$

### Example 22.10

At an elevation of 4000 ft, the barometric pressure is 660 mm Hg. What is the dissolved oxygen concentration of 18°C water with a 800 mg/L chloride concentration at that elevation?

### Solution

From App. 22.D, oxygen's saturation concentration for 18°C water corrected for a 800 mg/L chloride concentration is

$$C_s = 9.54 \frac{\text{mg}}{\text{L}} - \left( \frac{800 \frac{\text{mg}}{\text{L}}}{100 \frac{\text{mg}}{\text{L}}} \right) \left( 0.009 \frac{\text{mg}}{\text{L}} \right) \\ = 9.468 \text{ mg/L}$$

Use the App. 22.D footnote to correct for the barometric pressure.

$$C'_s = \left( 9.468 \frac{\text{mg}}{\text{L}} \right) \left( \frac{660 \text{ mm} - 16 \text{ mm}}{760 \text{ mm} - 16 \text{ mm}} \right) \\ = 8.20 \text{ mg/L}$$

## 19. PROPERTIES OF SOLUTIONS

There are very few convenient ways of predicting the properties of nonreacting, nonvolatile organic and aqueous solutions (acids, brines, alcohol mixtures, coolants, etc.) from the individual properties of the components.

Volumes of two nonreacting organic liquids (e.g., acetone and chloroform) in a mixture are essentially additive. The volume change upon mixing will seldom be more than a few tenths of a percent. The volume change in aqueous solutions is often slightly greater, but is still limited to a few percent (e.g., 3% for some solutions of methanol and water). Therefore, the specific gravity (density, specific weight, etc.) can be considered to be a volumetric weighting of the individual specific gravities.

Most other fluid properties of aqueous solutions, such as viscosity, compressibility, surface tension, and vapor pressure, must be measured.

## 20. SOLUTIONS OF SOLIDS IN LIQUIDS

When a solid is added to a liquid, the solid is known as the *solute*, and the liquid is known as the *solvent*.<sup>12</sup> If the dispersion of the solute throughout the solvent is at the molecular level, the mixture is known as a *solution*. If the solute particles are larger than molecules, the mixture is known as a *suspension*.<sup>13</sup>

In some solutions, the solvent and solute molecules bond loosely together. This loose bonding is known as *solvation*. If water is the solvent, the bonding process is also known as *aquation* or *hydration*.

The solubility of most solids in liquid solvents usually increases with increasing temperature. Pressure has very little effect on the solubility of solids in liquids.

When the solvent has absorbed as much solute as it can, it is a *saturated solution*.<sup>14</sup> Adding more solute to an already saturated solution will cause the excess solute to settle to the bottom of the container, a process known as *precipitation*. Other changes (in temperature, concentration, etc.) can be made to cause precipitation from saturated and unsaturated solutions. Precipitation in a chemical reaction is indicated by a downward arrow (i.e., “↓”). For example, the precipitation of silver chloride from an aqueous solution of silver nitrate ( $\text{AgNO}_3$ ) and potassium chloride (KCl) would be written as

## 21. UNITS OF CONCENTRATION

Several units of concentration are commonly used to express solution strengths.

*F*— *formality*: The number of gram formula weights (i.e., molecular weights in grams) per liter of solution.

*m*— *molality*: The number of gram-moles of solute per 1000 grams of solvent. A “molal” solution contains 1 gram-mole per 1000 grams of solvent.

*M*— *molarity*: The number of gram-moles of solute per liter of solution. A “molar” (i.e., 1 M) solution contains 1 gram-mole per liter of solution. Molarity is related to normality as shown in Eq. 22.8.

$$N = M \times \Delta \text{ oxidation number} \quad 22.8$$

*N*— *normality*: The number of gram equivalent weights of solute per liter of solution. A solution is “normal” (i.e., 1 N) if there is exactly one gram equivalent weight per liter of solution.

<sup>12</sup>The term *solvent* is often associated with volatile liquids, but the term is more general than that. (A *volatile liquid* evaporates rapidly and readily at normal temperatures.) Water is the solvent in aqueous solutions.

<sup>13</sup>An *emulsion* is not a mixture of a solid in a liquid. It is a mixture of two immiscible liquids.

<sup>14</sup>Under certain circumstances, a *supersaturated solution* can exist for a limited amount of time.

*x*— *mole fraction*: The number of moles of solute divided by the number of moles of solvent and all solutes.

*meq/L*— *milligram equivalent weights of solute per liter of solution*: calculated by multiplying normality by 1000 or dividing concentration in mg/L by equivalent weight.

*mg/L*— *milligrams per liter*: The number of milligrams of solute per liter of solution. Same as ppm for solutions of water.

*ppm*— *parts per million*: The number of pounds (or grams) of solute per million pounds (or grams) of solution. Same as mg/L for solutions of water.

*ppb*— *parts per billion*: The number of pounds (or grams) of solute per billion ( $10^9$ ) pounds (or grams) of solution. Same as  $\mu\text{g}/\text{L}$  for solutions of water.

For compounds whose molecules do not dissociate in solution (e.g., table sugar), there is no difference between molarity and formality. There is a difference, however, for compounds that dissociate into ions (e.g., table salt). Consider a solution derived from 1 gmol of magnesium nitrate  $\text{Mg}(\text{NO}_3)_2$  in enough water to bring the volume to 1 L. The formality is 1 F (i.e., the solution is 1 formal). However, 3 moles of ions will be produced: 1 mole of  $\text{Mg}^{++}$  ions and 2 moles of  $\text{NO}_3^-$  ions. Therefore, molarity is 1 M for the magnesium ion and 2 M for the nitrate ion.

The use of formality avoids the ambiguity in specifying concentrations for ionic solutions. Also, the use of formality avoids the problem of determining a molecular weight when there are no discernible molecules (e.g., as in a crystalline solid such as NaCl). Unfortunately, the distinction between molarity and formality is not always made, and molarity may be used as if it were formality.

### Example 22.11

A solution is made by dissolving 0.353 g of  $\text{Al}_2(\text{SO}_4)_3$  in 730 g of water. If ionization is 100%, what is the concentration expressed as normality, molarity, and mg/L?

*Solution*

The molecular weight of  $\text{Al}_2(\text{SO}_4)_3$  is

$$\begin{aligned} \text{MW} &= (2)\left(26.98 \frac{\text{g}}{\text{mol}}\right) + (3)\left(32.06 \frac{\text{g}}{\text{mol}}\right) \\ &\quad + (4)(3)\left(16 \frac{\text{g}}{\text{mol}}\right) \\ &= 342.14 \text{ g/mol} \end{aligned}$$

Either the aluminum or sulfate ion can be used to determine the net charge transfer (i.e., the oxidation number). Since each aluminum ion has a charge of 3, and since there are two aluminum ions in the molecule, the oxidation number is  $(3)(2) = 6$ .

The equivalent weight is

$$\text{EW} = \frac{\text{MW}}{\text{oxidation number}} = \frac{342.14 \frac{\text{g}}{\text{mol}}}{6} = 57.02 \text{ g/mol}$$

The number of gram equivalent weights used is

$$\frac{0.353 \text{ g}}{57.02 \frac{\text{g}}{\text{mol}}} = 6.19 \times 10^{-3} \text{ GEW}$$

The volume of solution (same as the solvent volume if the small amount of solute is neglected) is 0.73 L.

The normality is

$$N = \frac{6.19 \times 10^{-3} \text{ GEW}}{0.73 \text{ L}} = 8.48 \times 10^{-3}$$

The number of moles of solute used is

$$\frac{0.353 \text{ g}}{342.14 \frac{\text{g}}{\text{mol}}} = 1.03 \times 10^{-3} \text{ mol}$$

The molarity is

$$M = \frac{1.03 \times 10^{-3} \text{ mol}}{0.73 \text{ L}} = 1.41 \times 10^{-3} \text{ mol/L}$$

The concentration is

$$C = \frac{m}{V} = \frac{(0.353 \text{ g}) \left( 1000 \frac{\text{mg}}{\text{g}} \right)}{0.73 \text{ L}} = 483.6 \text{ mg/L}$$

## 22. pH AND pOH

A standard measure of the strength of an acid or base is the number of hydrogen or hydroxide ions in a liter of solution. Since these are very small numbers, a logarithmic scale is used.

$$\text{pH} = -\log_{10}[\text{H}^+] = \log_{10} \frac{1}{[\text{H}^+]} \quad 22.9$$

$$\text{pOH} = -\log_{10}[\text{OH}^-] = \log_{10} \frac{1}{[\text{OH}^-]} \quad 22.10$$

The quantities  $[\text{H}^+]$  and  $[\text{OH}^-]$  in square brackets are the *ionic concentrations* in moles of ions per liter. The number of moles can be calculated from Avogadro's law by dividing the actual number of ions per liter by  $6.022 \times 10^{23}$ . Alternatively, for a partially ionized compound in a solution of known molarity,  $M$ , the ionic concentration is

$$[\text{ion}] = XM \quad 22.11$$

A *neutral solution* has a pH of 7. Solutions with a pH below 7 are acidic; the smaller the pH, the more acidic the solution. Solutions with a pH above 7 are basic.

The relationship between pH and pOH is

$$\text{pH} + \text{pOH} = 14 \quad 22.12$$

## Example 22.12

A 4.2% ionized 0.01M ammonia solution is prepared from ammonium hydroxide ( $\text{NH}_4\text{OH}$ ). Calculate the pH, pOH, and concentrations of  $[\text{H}^+]$  and  $[\text{OH}^-]$ .

*Solution*

From Eq. 22.11,

$$\begin{aligned} [\text{OH}^-] &= XM = (0.042)(0.01) \\ &= 4.2 \times 10^{-4} \text{ mol/L} \end{aligned}$$

From Eq. 22.10,

$$\begin{aligned} \text{pOH} &= -\log [\text{OH}^-] = -\log(4.2 \times 10^{-4}) \\ &= 3.38 \end{aligned}$$

From Eq. 22.12,

$$\begin{aligned} \text{pH} &= 14 - \text{pOH} = 14 - 3.38 \\ &= 10.62 \end{aligned}$$

The  $[\text{H}^+]$  ionic concentration can be extracted from the definition of pH.

$$\begin{aligned} [\text{H}^+] &= 10^{-\text{pH}} = 10^{-10.62} \\ &= 2.4 \times 10^{-11} \text{ mol/L} \end{aligned}$$

## 23. BUFFERS

A *buffer solution* resists changes in acidity and maintains a relatively constant pH when a small amount of an acid or base is added to it. Buffers are usually combinations of weak acids and their salts. A buffer is most effective when the acid and salt concentrations are equal.

## 24. NEUTRALIZATION

Acids and bases neutralize each other to form water.

Assuming 100% ionization of the solute, the volumes,  $V$ , required for complete neutralization can be calculated from the normalities,  $N$ , or the molarities,  $M$ .

$$V_b N_b = V_a N_a \quad 22.13$$

$$V_b M_b \Delta_{b,\text{charge}} = V_a M_a \Delta_{a,\text{charge}} \quad 22.14$$

## 25. REVERSIBLE REACTIONS

*Reversible reactions* are capable of going in either direction and do so to varying degrees (depending on the concentrations and temperature) simultaneously. These reactions are characterized by the simultaneous presence of all reactants and all products. For example, the chemical equation for the exothermic formation of ammonia from nitrogen and hydrogen is

At *chemical equilibrium*, reactants and products are both present. Concentrations of the reactants and products do not change after equilibrium is reached.

## 26. LE CHATELIER'S PRINCIPLE

*Le Châtelier's principle* predicts the direction in which a reversible reaction initially at equilibrium will go when some condition (e.g., temperature, pressure, concentration) is “stressed” (i.e., changed). The principle says that when an equilibrium state is stressed by a change, a new equilibrium is formed that reduces that stress.

Consider the formation of ammonia from nitrogen and hydrogen. (See Sec. 22.25.) When the reaction proceeds in the forward direction, energy in the form of heat is released and the temperature increases. If the reaction proceeds in the reverse direction, heat is absorbed and the temperature decreases. If the system is stressed by increasing the temperature, the reaction will proceed in the reverse direction because that direction absorbs heat and reduces the temperature.

For reactions that involve gases, the reaction equation coefficients can be interpreted as volumes. In the nitrogen-hydrogen reaction, four volumes combine to form two volumes. If the equilibrium system is stressed by increasing the pressure, then the forward reaction will occur because this direction reduces the volume and pressure.<sup>15</sup>

If the concentration of any participating substance is increased, the reaction proceeds in a direction away from the substance with the increase in concentration. (For example, an increase in the concentration of the reactants shifts the equilibrium to the right, increasing the amount of products formed.)

The *common ion effect* is a special case of Le Châtelier's principle. If a salt containing a common ion is added to a solution of a weak acid, almost all of the salt will dissociate, adding large quantities of the common ion to the solution. Ionization of the acid will be greatly suppressed, a consequence of the need to have an unchanged equilibrium constant.

<sup>15</sup>The exception to this rule is the addition of an inert or nonparticipating gas to a gaseous equilibrium system. Although there is an increase in total pressure, the position of the equilibrium is not affected.

## 27. IRREVERSIBLE REACTION KINETICS

The rate at which a compound is formed or used up in an irreversible (one-way) reaction is known as the *rate of reaction*, *speed of reaction*, *reaction velocity*, and so on. The rate, *v*, is the change in concentration per unit time, usually measured in mol/L·s.

$$v = \frac{\text{change in concentration}}{\text{time}} \quad 22.15$$

According to the *law of mass action*, the rate of reaction varies with the concentrations of the reactants and products. Specifically, the rate is proportional to the molar concentrations (i.e., the molarities). The rate of the formation or conversion of substance A is represented in various forms, such as  $r_A$ ,  $dA/dt$ , and  $d[A]/dt$ , where the variable A or [A] can represent either the mass or the concentration of substance A. Substance A can be either a pure element or a compound.

The rate of reaction is generally not affected by pressure, but it does depend on five other factors.

- *type of substances in the reaction:* Some substances are more reactive than others.
- *exposed surface area:* The rate of reaction is proportional to the amount of contact between the reactants.
- *concentrations:* The rate of reaction increases with increases in concentration.
- *temperature:* The rate of reaction approximately doubles with every 10°C increase in temperature.
- *catalysts:* If a catalyst is present, the rate of reaction increases. However, the equilibrium point is not changed. (A catalyst is a substance that increases the reaction rate without being consumed in the reaction.)

## 28. ORDER OF THE REACTION

The *order of the reaction* is the total number of reacting molecules in or before the slowest step in the process.<sup>16</sup> The order must be determined experimentally. However, for an irreversible elementary reaction, the order is usually assumed from the stoichiometric reaction equation as the sum of the combining coefficients for the reactants.<sup>17,18</sup> For example, for the reaction

<sup>16</sup>This definition is valid for elementary reactions. For complex reactions, the order is an empirical number that need not be an integer.

<sup>17</sup>The overall order of the reaction is the sum of the orders with respect to the individual reactants. For example, in the reaction  $2\text{NO} + \text{O}_2 \rightarrow 2\text{NO}_2$ , the reaction is second order with respect to NO, first order with respect to  $\text{O}_2$ , and third order overall.

<sup>18</sup>In practice, the order of the reaction must be known, given, or determined experimentally. It is not always equal to the sum of the combining coefficients for the reactants. For example, in the reaction  $\text{H}_2 + \text{I}_2 \rightarrow 2\text{HI}$ , the overall order of the reaction is indeed 2, as expected. However, in the reaction  $\text{H}_2 + \text{Br}_2 \rightarrow 2\text{HBr}$ , the overall order is found experimentally to be 3/2, even though the two reactions have the same stoichiometry, and despite the similarities of iodine and bromine.

**Table 22.3** Reaction Rates and Half-Life Equations

reaction	order	rate equation	integrated forms
$A \rightarrow B$	zero	$\frac{d[A]}{dt} = -k_0$	$[A] = [A]_0 - k_0 t$ $t_{1/2} = \frac{[A]_0}{2k_0}$
$A \rightarrow B$	first	$\frac{d[A]}{dt} = -k_1[A]$	$\ln \frac{[A]}{[A]_0} = -k_1 t$ $t_{1/2} = \frac{1}{k_1} \ln 2$
$A + A \rightarrow P$	second, type I	$\frac{d[A]}{dt} = -k_2[A]^2$	$\frac{1}{[A]} - \frac{1}{[A]_0} = k_2 t$ $t_{1/2} = \frac{1}{k_2[A]_0}$
$aA + bB \rightarrow P$	second, type II	$\frac{d[A]}{dt} = -k_2[A][B]$	$\ln \frac{[A]_0 - [B]}{[B]_0 - \left(\frac{b}{a}\right)[X]} = \ln \frac{[A]}{[B]}$ $= \left(\frac{b[A]_0 - a[B]_0}{a}\right)k_2 t + \ln \frac{[A]_0}{[B]_0}$ $t_{1/2} = \left(\frac{a}{k_2(b[A]_0 - a[B]_0)}\right) \ln \left(\frac{a[B]_0}{2a[B]_0 - b[A]_0}\right)$

$mA + nB \rightarrow pC$ , the overall order of the forward reaction is assumed to be  $m + n$ .

Many reactions (e.g., dissolving metals in acid or the evaporation of condensed materials) have *zero-order reaction rates*. These reactions do not depend on the concentrations or temperature at all, but rather, are affected by other factors such as the availability of reactive surfaces or the absorption of radiation. The formation (conversion) rate of a compound in a zero-order reaction is constant. That is,  $dA/dt = -k_0$ .  $k_0$  is known as the *reaction rate constant*. (The subscript “0” refers to the zero-order.) Since the concentration (amount) of the substance decreases with time,  $dA/dt$  is negative. Since the negative sign is explicit in rate equations, the reaction rate constant is generally reported as a positive number.

Once a reaction rate equation is known, it can be integrated to obtain an expression for the concentration (mass) of the substance at various times. The time for half of the substance to be formed (or converted) is the *half-life*,  $t_{1/2}$ . Table 22.3 contains reaction rate equations and half-life equations for various types of low-order reactions.

### Example 22.13

Nitrogen pentoxide decomposes according to the following first-order reaction.

At a particular temperature, the decomposition of nitrogen pentoxide is 85% complete after 11 min. What is the reaction rate constant?

### Solution

The reaction is given as first order. Use the integrated reaction rate equation from Table 22.3. Since the decomposition reaction is 85% complete, the surviving fraction is 15% (0.15).

$$\begin{aligned} \ln \frac{[A]}{[A]_0} &= k_1 t \\ \ln(0.15) &= k_1(11 \text{ min}) \\ k_1 &= -0.172 \text{ 1/min} \quad (0.172 \text{ 1/min}) \end{aligned}$$

(The rate constant is reported as a positive number.)

## 29. REVERSIBLE REACTION KINETICS

Consider the following reversible reaction.

In Eq. 22.17 and Eq. 22.18, the *reaction rate constants* are  $k_{\text{forward}}$  and  $k_{\text{reverse}}$ . The order of the forward reaction is  $a + b$ ; the order of the reverse reaction is  $c + d$ .

$$v_{\text{forward}} = k_{\text{forward}}[A]^a[B]^b \quad 22.17$$

$$v_{\text{reverse}} = k_{\text{reverse}}[C]^c[D]^d \quad 22.18$$

At equilibrium, the forward and reverse speeds of reaction are equal.

$$v_{\text{forward}} = v_{\text{reverse}}|_{\text{equilibrium}} \quad 22.19$$

### 30. EQUILIBRIUM CONSTANT

For reversible reactions, the *equilibrium constant*,  $K$ , is proportional to the ratio of the reverse rate of reaction to the forward rate of reaction.<sup>19</sup> Except for catalysis, the equilibrium constant depends on the same factors affecting the reaction rate. For the complex reversible reaction given by Eq. 22.16, the equilibrium constant is given by the *law of mass action*.

$$K = \frac{[C]^c[D]^d}{[A]^a[B]^b} = \frac{k_{\text{forward}}}{k_{\text{reverse}}} \quad 22.20$$

If any of the reactants or products are in pure solid or pure liquid phases, their concentrations are omitted from the calculation of the equilibrium constant. For example, in weak aqueous solutions, the concentration of water,  $\text{H}_2\text{O}$ , is very large and essentially constant; therefore, that concentration is omitted.

For gaseous reactants and products, the concentrations (i.e., the numbers of atoms) will be proportional to the partial pressures. Therefore, an equilibrium constant can be calculated directly from the partial pressures and is given the symbol  $K_p$ . For example, for the formation of ammonia gas from nitrogen and hydrogen, the equilibrium constant is

$$K_p = \frac{[p_{\text{NH}_3}]^2}{[p_{\text{N}_2}][p_{\text{H}_2}]^3} \quad 22.21$$

$K$  and  $K_p$  are not numerically the same, but they are related by Eq. 22.22.  $\Delta n$  is the number of moles of products minus the number of moles of reactants.

$$K_p = K(R^* T)^{\Delta n} \quad 22.22$$

#### Example 22.14

A particularly weak solution of acetic acid ( $\text{HC}_2\text{H}_3\text{O}_2$ ) in water has the ionic concentrations (in mol/L) given. What is the equilibrium constant?

$$[\text{HC}_2\text{H}_3\text{O}_2] = 0.09866$$

$$[\text{H}_2\text{O}] = 55.5555$$

$$[\text{H}_3\text{O}^+] = 0.00134$$

$$[\text{C}_2\text{H}_3\text{O}_2^-] = 0.00134$$

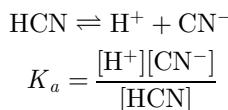

#### Solution

The concentration of the water molecules is not included in the calculation of the equilibrium or ionization constant. Therefore, the equilibrium constant is

$$K = K_a = \frac{[\text{H}_3\text{O}^+][\text{C}_2\text{H}_3\text{O}_2^-]}{[\text{HC}_2\text{H}_3\text{O}_2]} = \frac{(0.00134)(0.00134)}{0.09866} \\ = 1.82 \times 10^{-5}$$

### 31. IONIZATION CONSTANT

The equilibrium constant for a weak solution is essentially constant and is known as the *ionization constant* (also known as a *dissociation constant*). (See Table 22.4 and App. 22.F.) For weak acids, the symbol  $K_a$  and name *acid constant* are used. (See App. 22.G.) For weak bases, the symbol  $K_b$  and the name *base constant* are used. (See App. 22.H.) For example, for the ionization of hydrocyanic acid,

Pure water is itself a very weak electrolyte and ionizes only slightly.

At equilibrium, the ionic concentrations are equal.

$$[\text{H}_3\text{O}^+] = 10^{-7}$$

$$[\text{OH}^-] = 10^{-7}$$

From Eq. 22.20, the ionization constant (*ion product*) for pure water is

$$K_w = K_{a,\text{water}} = [\text{H}_3\text{O}^+][\text{OH}^-] = (10^{-7})(10^{-7}) \\ = 10^{-14} \quad 22.24$$

If the molarity,  $M$ , and *fraction of ionization*,  $X$ , are known, the ionization constant can be calculated from Eq. 22.25.

$$K_{\text{ionization}} = \frac{MX^2}{1-X} \quad [K_a \text{ or } K_b] \quad 22.25$$

The reciprocal of the ionization constant is the *stability constant* (*overall stability constant*), also known as the *formation constant*. Stability constants are used to describe complex ions that dissociate readily.

#### Example 22.15

A 0.1 molar (0.1 M) acetic acid solution is 1.34% ionized. Find the (a) hydrogen ion concentration, (b) acetate ion concentration, (c) un-ionized acid concentration, and (d) ionization constant.

<sup>19</sup>The symbols  $K_c$  (in molarity units) and  $K_{\text{eq}}$  are occasionally used for the equilibrium constant.

**Table 22.4** Approximate Ionization Constants of Common Water Supply Chemicals

substance	0°C	5°C	10°C	15°C	20°C	25°C
Ca(OH) <sub>2</sub>						$3.74 \times 10^{-3}$
HClO	$2.0 \times 10^{-8}$	$2.3 \times 10^{-8}$	$2.6 \times 10^{-8}$	$3.0 \times 10^{-8}$	$3.3 \times 10^{-8}$	$3.7 \times 10^{-8}$
HC <sub>2</sub> H <sub>3</sub> O <sub>2</sub>	$1.67 \times 10^{-5}$	$1.70 \times 10^{-5}$	$1.73 \times 10^{-5}$	$1.75 \times 10^{-5}$	$1.75 \times 10^{-5}$	$1.75 \times 10^{-5}$
HBrO					$\approx 2 \times 10^{-9}$	
H <sub>2</sub> CO <sub>3</sub> ( $K_1$ )	$2.6 \times 10^{-7}$	$3.04 \times 10^{-7}$	$3.44 \times 10^{-7}$	$3.81 \times 10^{-7}$	$4.16 \times 10^{-7}$	$4.45 \times 10^{-7}$
HClO <sub>2</sub>					$\approx 1.1 \times 10^{-2}$	
NH <sub>3</sub>	$1.37 \times 10^{-5}$	$1.48 \times 10^{-5}$	$1.57 \times 10^{-5}$	$1.65 \times 10^{-5}$	$1.71 \times 10^{-5}$	$1.77 \times 10^{-5}$
NH <sub>4</sub> OH						$1.79 \times 10^{-5}$
water *	14.9435	14.7338	14.5346	14.3463	14.1669	13.9965

\*  $-\log_{10}K$  given

### Solution

(a) From Eq. 22.11, the hydrogen (hydronium) ion concentration is

$$\begin{aligned} [\text{H}_3\text{O}^+] &= XM = (0.0134)(0.1) \\ &= 0.00134 \text{ mol/L} \end{aligned}$$

(b) Since every hydronium ion has a corresponding acetate ion, the acetate and hydronium ion concentrations are the same.

$$[\text{C}_2\text{H}_3\text{O}_2^-] = [\text{H}_3\text{O}^+] = 0.00134 \text{ mol/L}$$

(c) The concentration of un-ionized acid can be derived from Eq. 22.11.

$$\begin{aligned} [\text{HC}_2\text{H}_3\text{O}_2] &= (1 - X)M = (1 - 0.0134)(0.1) \\ &= 0.09866 \text{ mol/L} \end{aligned}$$

(d) The ionization constant is calculated from Eq. 22.25.

$$\begin{aligned} K_a &= \frac{MX^2}{1 - X} = \frac{(0.1)(0.0134)^2}{1 - 0.0134} \\ &= 1.82 \times 10^{-5} \end{aligned}$$

### Example 22.16

The ionization constant for acetic acid is  $1.82 \times 10^{-5}$ . What is the hydrogen ion concentration for a 0.2 M solution?

### Solution

From Eq. 22.25,

$$\begin{aligned} K_a &= \frac{MX^2}{1 - X} \\ 1.82 \times 10^{-5} &= \frac{0.2X^2}{1 - X} \end{aligned}$$

Since acetic acid is a weak acid,  $X$  is known to be small. Therefore, the computational effort can be reduced by assuming that  $1 - X \approx 1$ .

$$\begin{aligned} 1.82 \times 10^{-5} &= 0.2X^2 \\ X &= 9.54 \times 10^{-3} \end{aligned}$$

From Eq. 22.11, the concentration of the hydrogen ion is

$$\begin{aligned} [\text{H}_3\text{O}^+] &= XM = (9.54 \times 10^{-3})(0.2) \\ &= 1.9 \times 10^{-3} \text{ mol/L} \end{aligned}$$

### Example 22.17

The ionization constant for acetic acid (HC<sub>2</sub>H<sub>3</sub>O<sub>2</sub>) is  $1.82 \times 10^{-5}$ . What is the hydrogen ion concentration of a solution with 0.1 mol of 80% ionized ammonium acetate (NH<sub>4</sub>C<sub>2</sub>H<sub>3</sub>O<sub>2</sub>) in one liter of 0.1 M acetic acid?

### Solution

The acetate ion (C<sub>2</sub>H<sub>3</sub>O<sub>2</sub><sup>-</sup>) is a common ion, since it is supplied by both the acetic acid and the ammonium acetate. Both sources contribute to the ionic concentration. However, the ammonium acetate's contribution dominates. Since the acid dissociates into an equal number of hydrogen and acetate ions,

$$\begin{aligned} [\text{C}_2\text{H}_3\text{O}_2^-]_{\text{total}} &= [\text{C}_2\text{H}_3\text{O}_2^-]_{\text{acid}} \\ &\quad + [\text{C}_2\text{H}_3\text{O}_2^-]_{\text{ammonium acetate}} \\ &= [\text{H}_3\text{O}^+] + (0.8)(0.1) \\ &\approx (0.8)(0.1) = 0.08 \end{aligned}$$

As a result of the common ion effect and Le Châtelier's law, the acid's dissociation is essentially suppressed by the addition of the ammonium acetate. The concentration of un-ionized acid is

$$\begin{aligned} [\text{HC}_2\text{H}_3\text{O}_2] &= 0.1 - [\text{H}_3\text{O}^+] \\ &\approx 0.1 \end{aligned}$$

The ionization constant is unaffected by the number of sources of the acetate ion.

$$K_a = \frac{[\text{H}_3\text{O}^+][\text{C}_2\text{H}_3\text{O}_2^-]}{[\text{HC}_2\text{H}_3\text{O}_2]}$$

$$1.82 \times 10^{-5} = \frac{[\text{H}_3\text{O}^+](0.08)}{0.1}$$

$$[\text{H}_3\text{O}^+] = 2.3 \times 10^{-5} \text{ mol/L}$$

## 32. IONIZATION CONSTANTS FOR POLYPROTIC ACIDS

A *polyprotic acid* has as many ionization constants as it has acidic hydrogen atoms. For oxyacids (see Sec. 22.6), each successive ionization constant is approximately  $10^5$  times smaller than the preceding one. For example, phosphoric acid ( $\text{H}_3\text{PO}_4$ ) has three ionization constants.

$$K_1 = 7.1 \times 10^{-3} \quad (\text{H}_3\text{PO}_4)$$

$$K_2 = 6.3 \times 10^{-8} \quad (\text{H}_2\text{PO}_4^-)$$

$$K_3 = 4.4 \times 10^{-13} \quad (\text{HPO}_4^{2-})$$

## 33. SOLUBILITY PRODUCT

When an ionic solid is dissolved in a solvent, it dissociates. For example, consider the ionization of silver chloride in water.

If the equilibrium constant is calculated, the terms for pure solids and liquids (in this case,  $[\text{AgCl}]$  and  $[\text{H}_2\text{O}]$ ) are omitted. Therefore, the *solubility product*,  $K_{\text{sp}}$ , consists only of the ionic concentrations. As with the general case of ionization constants, the solubility product for slightly soluble solutes is essentially constant at a standard value. (See App. 22.F.)

$$K_{\text{sp}} = [\text{Ag}^+][\text{Cl}^-] \quad 22.26$$

When the product of terms exceeds the standard value of the solubility product, solute will precipitate out until the product of the remaining ion concentrations attains the standard value. If the product is less than the standard value, the solution is not saturated.

The solubility products of nonhydrolyzing compounds are relatively easy to calculate. (Example 22.18 demonstrates a method.) Such is the case for chromates ( $\text{CrO}_4^{2-}$ ), halides ( $\text{F}^-$ ,  $\text{Cl}^-$ ,  $\text{Br}^-$ ,  $\text{I}^-$ ), sulfates ( $\text{SO}_4^{2-}$ ), and iodates ( $\text{IO}_3^-$ ). However, compounds that hydrolyze (i.e., combine with water molecules) must be treated

differently. The method used in Ex. 22.18 cannot be used for hydrolyzing compounds. Appendix 22.F lists some common solubility products.

### Example 22.18

At a particular temperature, it takes 0.038 grams of lead sulfate ( $\text{PbSO}_4$ , molecular weight = 303.25) per liter of water to prepare a saturated solution. What is the solubility product of lead sulfate if all of the lead sulfate ionizes?

*Solution*

Sulfates are not one of the hydrolyzing ions. Therefore, the solubility product can be calculated from the concentrations.

Since one liter of water has a mass of 1 kg, the number of moles of lead sulfate dissolved per saturated liter of solution is

$$n = \frac{m}{\text{MW}} = \frac{0.038 \text{ g}}{303.25 \frac{\text{g}}{\text{mol}}} = 1.25 \times 10^{-4} \text{ mol}$$

Lead sulfate ionizes according to the following reaction.

Since all of the lead sulfate ionizes, the number of moles of each ion is the same as the number of moles of lead sulfate. Therefore,

$$K_{\text{sp}} = [\text{Pb}^{2+}][\text{SO}_4^{2-}] = (1.25 \times 10^{-4})(1.25 \times 10^{-4}) \\ = 1.56 \times 10^{-8}$$

## 34. ENTHALPY OF FORMATION

*Enthalpy*,  $H$ , is the useful energy that a substance possesses by virtue of its temperature, pressure, and phase.<sup>20</sup> The *enthalpy of formation (heat of formation)*,  $\Delta H_f$ , of a compound is the energy absorbed during the formation of 1 gmol of the compound from the elements in their free, standard states.<sup>21</sup> The enthalpy of formation is assigned a value of zero for elements in their free states at 25°C and 1 atm. This is the so-called *standard state* for enthalpies of formation.

Table 22.5 contains enthalpies of formation for some common elements and compounds. The enthalpy of formation depends on the temperature and phase of the compound. A standard temperature of 25°C is used in most tables of enthalpies of formation.<sup>22</sup> Compounds are solid (*s*) unless indicated to be gaseous (*g*) or liquid (*l*). Some aqueous (*aq*) values are also encountered.

<sup>20</sup>The older term *heat* is rarely encountered today.

<sup>21</sup>The symbol  $H$  is used to denote molar enthalpies. The symbol  $h$  is used for specific enthalpies (i.e., enthalpy per kilogram or per pound).

<sup>22</sup>It is possible to correct the enthalpies of formation to account for other reaction temperatures.

**Table 22.5** Standard Enthalpies of Formation (at 25°C)

element/compound	$\Delta H_f$ (kcal/mol)
Al (s)	0.00

(Multiply kcal/mol by 4.184 to obtain kJ/mol.)

(Multiply kcal/mol by 1800/MW to obtain Btu/lbm.)

### 35. ENTHALPY OF REACTION

The *enthalpy of reaction* (*heat of reaction*),  $\Delta H_r$ , is the energy absorbed during a chemical reaction under constant volume conditions. It is found by summing the enthalpies of formation of all products and subtracting the sum of enthalpies of formation of all reactants. This is

essentially a restatement of the energy conservation principle and is known as *Hess' law of energy summation*.

$$\Delta H_r = \sum_{\text{products}} \Delta H_f - \sum_{\text{reactants}} \Delta H_f \quad 22.27$$

Reactions that give off energy (i.e., have negative enthalpies of reaction) are known as *exothermic reactions*. Many (but not all) exothermic reactions begin spontaneously. On the other hand, *endothermic reactions* absorb energy and require thermal or electrical energy to begin.

### Example 22.19

Using enthalpies of formation, calculate the heat of stoichiometric combustion (standardized to 25°C) of gaseous methane (CH<sub>4</sub>) and oxygen.

*Solution*

The balanced chemical equation for the stoichiometric combustion of methane is

The enthalpy of formation of oxygen gas (its free-state configuration) is zero. Using enthalpies of formation from Table 22.5 in Eq. 22.27, the enthalpy of reaction per mole of methane is

$$\begin{aligned}\Delta H_r &= 2\Delta H_{f,\text{H}_2\text{O}} + \Delta H_{f,\text{CO}_2} - \Delta H_{f,\text{CH}_4} - 2\Delta H_{f,\text{O}_2} \\ &= (2)\left(-57.80 \frac{\text{kcal}}{\text{mol}}\right) + \left(-94.05 \frac{\text{kcal}}{\text{mol}}\right) \\ &\quad - \left(-17.90 \frac{\text{kcal}}{\text{mol}}\right) - (2)(0) \\ &= -191.75 \text{ kcal/mol CH}_4 \quad [\text{exothermic}]\end{aligned}$$

Using the footnote of Table 22.5, this value can be converted to Btu/lbm. The molecular weight of methane is

$$\begin{aligned}\text{MW}_{\text{CH}_4} &= 12 + (4)(1) = 16 \\ \text{higher heating value} &= \frac{\left(191.75 \frac{\text{kcal}}{\text{mol}}\right) \left(1800 \frac{\text{Btu-mol}}{\text{lbm-kcal}}\right)}{16} \\ &= 21,572 \text{ Btu/lbm}\end{aligned}$$

### 36. GALVANIC ACTION

*Galvanic action* (*galvanic corrosion* or *two-metal corrosion*) results from the difference in oxidation potentials of metallic ions. The greater the difference in oxidation potentials, the greater will be the galvanic action. If two metals with different oxidation potentials are placed in an electrolytic medium (e.g., seawater), a galvanic cell will be created. The metal with the higher potential (i.e., the more “active” metal) will act as an anode and will corrode. The metal with the lower potential (the more “noble” metal), being the cathode, will be unchanged. In

one extreme type of intergranular corrosion known as *exfoliation*, open endgrains separate into layers.

Metals are often classified according to their positions in the *galvanic series* listed in Table 22.6. As would be expected, the metals in this series are in approximately the same order as their half-cell potentials. However, alloys and proprietary metals are also included in the series.

**Table 22.6** Galvanic Series in Seawater (top to bottom anodic (sacrificial, active) to cathodic (noble, passive))

magnesium
zinc
Alclad 3S
cadmium
2024 aluminum alloy
low-carbon steel
cast iron
stainless steels (active)

silver
stainless steels (passive)
Monel metal
Hastelloy C
titanium
graphite
gold

Precautionary measures can be taken to inhibit or reduce galvanic action when use of dissimilar metals is unavoidable.

- Use dissimilar metals that are close neighbors in the galvanic series.
- Use *sacrificial anodes*. In marine saltwater applications, sacrificial zinc plates can be used.
- Use protective coatings, oxides, platings, or inert spacers to reduce the access of corrosive environments to the metals.<sup>23</sup>

<sup>23</sup>While cadmium, nickel, chromium, and zinc are often used as protective deposits on steel, porosities in the surfaces can act as small galvanic cells, resulting in invisible subsurface corrosion.

### 37. CORROSION

*Corrosion* is an undesirable degradation of a material resulting from a chemical or physical reaction with the environment. Conditions within the crystalline structure can accentuate or retard corrosion. Corrosion rates are reported in units of mils per year (mpy) and micrometers per year ( $\mu\text{m}/\text{y}$ ). (A *mil* is a thousandth of an inch.)

Uniform rusting of steel and oxidation of aluminum over entire exposed surfaces are examples of *uniform attack corrosion*. Uniform attack is usually prevented by the use of paint, plating, and other protective coatings.

Some metals are particularly sensitive to *intergranular corrosion*, IGC—selective or localized attack at metal-grain boundaries. For example, the  $\text{Cr}_2\text{O}_3$  oxide film on stainless steel contains numerous imperfections at grain boundaries, and these boundaries can be attacked and enlarged by chlorides.

Intergranular corrosion may occur after a metal has been heated, in which case it may be known as *weld decay*. In the case of type 304 austenitic stainless steels, heating to 930–1300°F (500–700°C) in a welding process causes chromium carbides to precipitate out, reducing the corrosion resistance.<sup>24</sup> Reheating to 1830–2010°F (1000–1100°C) followed by rapid cooling will redissolve the chromium carbides and restore corrosion resistance.

*Pitting* is a localized perforation on the surface. It can occur even where there is little or no other visible damage. Chlorides and other halogens in the presence of water (e.g., HF and HCl) foster pitting in passive alloys, especially in stainless steels and aluminum alloys.

*Concentration-cell corrosion* (also known as *crevice corrosion* and *intergranular attack*, IGA) occurs when a metal is in contact with different electrolyte concentrations. It usually occurs in crevices, between two assembled parts, under riveted joints, or where there are scale and surface deposits that create stagnant areas in a corrosive medium.

*Erosion corrosion* is the deterioration of metals buffeted by the entrained solids in a corrosive medium.

*Selective leaching* is the dealloying process in which one of the alloy ingredients is removed from the solid solution. This occurs because the lost ingredient has a lower corrosion resistance than the remaining ingredient. *Dezincification* is the classic case where zinc is selectively destroyed in brass. Other examples include the dealloying of nickel from copper-nickel alloys, iron from steel, and aluminum from copper-aluminum alloys.

<sup>24</sup>Austenitic stainless steels are the 300 series. They consist of chromium nickel alloys with up to 8% nickel. They are not hardenable by heat treatment, are nonmagnetic, and offer the greatest resistance to corrosion. *Martensitic stainless steels* are hardenable and magnetic. *Ferritic stainless steels* are magnetic and not hardenable.

*Hydrogen damage* occurs when hydrogen gas diffuses through and decarburizes steel (i.e., reacts with carbon to form methane). *Hydrogen embrittlement* (also known as *caustic embrittlement*) is hydrogen damage from hydrogen produced by caustic corrosion.

When subjected to sustained surface tensile stresses (including low residual stresses from manufacturing) in corrosive environments, certain metals exhibit catastrophic *stress corrosion cracking*, SCC. When the stresses are cyclic, *corrosion fatigue* failures can occur well below normal fatigue lives.

Stress corrosion occurs because the more highly stressed grains (at the crack tip) are slightly more anodic than neighboring grains with lower stresses. Although intergranular cracking (at grain boundaries) is more common, corrosion cracking may be *intergranular* (between the grains), *transgranular* (through the grains), or a combination of the two, depending on the alloy. Cracks propagate, often with extensive branching, until failure occurs.

The precautionary measures that can be taken to inhibit or eliminate stress corrosion are as follows.

- Avoid using metals that are susceptible to stress corrosion in corrosive environments. These include austenitic stainless steels without heat treatment in seawater; certain tempers of the aluminum alloys 2124, 2219, 7049, and 7075 in seawater; and copper alloys exposed to ammonia.
- Protect open-grain surfaces from the environment. For example, press-fitted parts in drilled holes can be assembled with wet zinc chromate paste. Also, weldable aluminum can be “buttered” with pure aluminum rod.
- Stress-relieve by annealing heat treatment after welding or cold working.

*Fretting corrosion* occurs when two highly loaded members have a common surface (known as a *faying surface*) at which rubbing and sliding take place. The phenomenon is a combination of wear and chemical corrosion. Metals that depend on a film of surface oxide for protection, such as aluminum and stainless steel, are especially susceptible.

Fretting corrosion can be reduced by the following methods.

- Lubricate the faying surfaces.
- Seal the faying surfaces.
- Reduce vibration and movement.

*Cavitation* is the formation and sudden collapse of minute bubbles of vapor in liquids. It is caused by a combination of reduced pressure and increased velocity in the fluid. In effect, very small amounts of the fluid vaporize (i.e., boil) and almost immediately condense. The repeated collapse of the bubbles hammers and work-hardens the surface.

When the surface work-hardens, it becomes brittle. Small amounts of the surface flake away, and the surface becomes pitted. This is known as *cavitation corrosion*. Eventually, the entire piece may work-harden and become brittle, leading to structural failure.

## 38. WATER SUPPLY CHEMISTRY

Most municipal water supply composition data are not given in units of molarity, normality, molality, and so on. Rather, the most common measure of solution strength is the *CaCO<sub>3</sub> equivalent*. With this method, substances are reported in milligrams per liter (mg/L, same as parts per million, ppm) “as CaCO<sub>3</sub>,” even when CaCO<sub>3</sub> is unrelated to the substance or reaction that produced the substance.

Actual gravimetric amounts of a substance can be converted to amounts as CaCO<sub>3</sub> by use of the conversion factors in App. 22.C. These factors are easily derived from stoichiometric principles.

The reason for converting all substance quantities to amounts as CaCO<sub>3</sub> is to simplify calculations for non-technical personnel. Equal CaCO<sub>3</sub> amounts constitute stoichiometric reaction quantities. For example, 100 mg/L as CaCO<sub>3</sub> of sodium ion (Na<sup>+</sup>) will react with 100 mg/L as CaCO<sub>3</sub> of chloride ion (Cl<sup>-</sup>) to produce 100 mg/L as CaCO<sub>3</sub> of salt (NaCl), even though the gravimetric quantities differ and CaCO<sub>3</sub> is not part of the reaction.

### Example 22.20

Lime is added to water to remove carbon dioxide gas.

If water contains 5 mg/L of CO<sub>2</sub>, how much lime is required for its removal?

*Solution*

From App. 22.C, the factor that converts CO<sub>2</sub> as substance to CO<sub>2</sub> as CaCO<sub>3</sub> is 2.27.

$$\begin{aligned} \text{CO}_2 \text{ as CaCO}_3 \text{ equivalent} &= (2.27) \left( 5 \frac{\text{mg}}{\text{L}} \right) \\ &= 11.35 \text{ mg/L as CaCO}_3 \end{aligned}$$

Therefore, the CaCO<sub>3</sub> equivalent of lime required will also be 11.35 mg/L.

From App. 22.C again, the factor that converts lime as CaCO<sub>3</sub> to lime as substance is (1/1.35).

$$\begin{aligned} \text{Ca}(\text{OH})_2 \text{ substance} &= \frac{11.35 \frac{\text{mg}}{\text{L}}}{1.35} \\ &= 8.41 \text{ mg/L as substance} \end{aligned}$$

This problem could also have been solved stoichiometrically.

### 39. ACIDITY AND ALKALINITY IN MUNICIPAL WATER SUPPLIES

*Acidity* is a measure of acids in solutions. Acidity in surface water (e.g., lakes and streams) is caused by formation of *carbonic acid* ( $\text{H}_2\text{CO}_3$ ) from carbon dioxide in the air.<sup>25</sup> Acidity in water is typically given in terms of the  $\text{CaCO}_3$  equivalent.

*Alkalinity* is a measure of the amount of negative (basic) ions in the water. Specifically,  $\text{OH}^-$ ,  $\text{CO}_3^{--}$ , and  $\text{HCO}_3^-$  all contribute to alkalinity.<sup>26</sup> The measure of alkalinity is the sum of concentrations of each of the substances measured as  $\text{CaCO}_3$ .

Alkalinity and acidity of a titrated sample are determined from color changes in indicators added to the titrant.

#### Example 22.21

Water from a city well is analyzed and is found to contain 20 mg/L as substance of  $\text{HCO}_3^-$  and 40 mg/L as substance of  $\text{CO}_3^{--}$ . What is the alkalinity of this water as  $\text{CaCO}_3$ ?

*Solution*

From App. 22.C, the factors converting  $\text{HCO}_3^-$  and  $\text{CO}_3^{--}$  ions to  $\text{CaCO}_3$  equivalents are 0.82 and 1.67, respectively.

$$\begin{aligned} \text{alkalinity} &= (0.82)(20 \frac{\text{mg}}{\text{L}}) + (1.67)(40 \frac{\text{mg}}{\text{L}}) \\ &= 83.2 \text{ mg/L as CaCO}_3 \end{aligned}$$

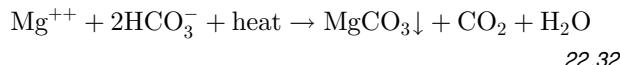

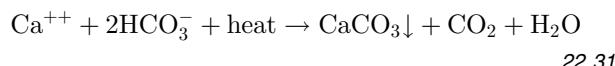

### 40. WATER HARDNESS

*Water hardness* is caused by multivalent (doubly charged, triply charged, etc., but not singly charged) positive metallic ions such as calcium, magnesium, iron, and manganese. (Iron and manganese are not as common, however.) Hardness reacts with soap to reduce its cleansing effectiveness and to form scum on the water surface and a ring around the bathtub.

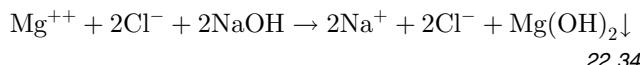

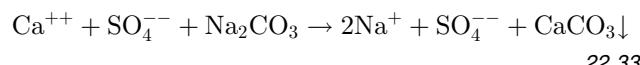

<sup>25</sup>Carbonic acid is very aggressive and must be neutralized to eliminate the cause of water pipe corrosion. If the pH of water is greater than 4.5, carbonic acid ionizes to form bicarbonate. (See Eq. 22.29.) If the pH is greater than 8.3, carbonate ions form that cause water hardness by combining with calcium. (See Eq. 22.30.)

<sup>26</sup>Other ions, such as  $\text{NO}_3^-$ , also contribute to alkalinity, but their presence is rare. If detected, they should be included in the calculation of alkalinity.

Water containing bicarbonate ( $\text{HCO}_3^-$ ) ions can be heated to precipitate carbonate molecules.<sup>27</sup> This hardness is known as *temporary hardness* or *carbonate hardness*.<sup>28</sup>

Remaining hardness due to sulfates, chlorides, and nitrates is known as *permanent hardness* or *noncarbonate hardness* because it cannot be removed by heating. The amount of permanent hardness can be determined numerically by causing precipitation, drying, and then weighing the precipitate.

*Total hardness* is the sum of temporary and permanent hardnesses, both expressed in mg/L as  $\text{CaCO}_3$ .

### 41. COMPARISON OF ALKALINITY AND HARDNESS

Hardness measures the presence of positive, multivalent ions in the water supply. Alkalinity measures the presence of negative (basic) ions such as hydrates, carbonates, and bicarbonates. Since positive and negative ions coexist, an alkaline water can also be hard.

If certain assumptions are made, it is possible to draw conclusions about the water composition from the hardness and alkalinity. For example, if the effects of  $\text{Fe}^{++2}$  and  $\text{OH}^-$  are neglected, the following rules apply. (All concentrations are measured as  $\text{CaCO}_3$ .)

- *hardness = alkalinity*: There is no noncarbonate hardness. There are no  $\text{SO}_4^-$ ,  $\text{Cl}^-$ , or  $\text{NO}_3^-$  ions present.
- *hardness > alkalinity*: Noncarbonate hardness is present.
- *hardness < alkalinity*: All hardness is carbonate hardness. The extra  $\text{HCO}_3^-$  comes from other sources (e.g.,  $\text{NaHCO}_3$ ).

Titration with indicator solutions is used to determine the alkalinity. The *phenolphthalein alkalinity* (or “P reading” in mg/L as  $\text{CaCO}_3$ ) measures hydrate alkalinity and half of the carbonate alkalinity. The *methyl*

<sup>27</sup>Hard water forms scale when heated. This scale, if it forms in pipes, eventually restricts water flow. Even in small quantities, the scale insulates boiler tubes. Therefore, water used in steam-producing equipment must be essentially hardness-free.

<sup>28</sup>The hardness is known as *carbonate hardness* even though it is caused by *bicarbonate* ions, not carbonate ions.

orange alkalinity (or “M reading” in mg/L as CaCO<sub>3</sub>) measures the total alkalinity (including the phenolphthalein alkalinity). Table 22.7 can be used to interpret these tests.<sup>29</sup>

**Table 22.7 Interpretation of Alkalinity Tests**

case	hydrate as CaCO <sub>3</sub>	carbonate as CaCO <sub>3</sub>	bicarbonate as CaCO <sub>3</sub>
P = 0	0	0	M
0 < P < $\frac{M}{2}$	0	2P	M - 2P
$P = \frac{M}{2}$	0	2P	0
$\frac{M}{2} < P < M$	2P - M	2(M - P)	0
P = M	M	0	0

## 42. WATER SOFTENING WITH LIME

Water softening can be accomplished with lime and soda ash to precipitate calcium and magnesium ions from the solution. Lime treatment has the added benefits of disinfection, iron removal, and clarification. Practical limits of *precipitation softening* are 30 mg/L of CaCO<sub>3</sub> and 10 mg/L of Mg(OH)<sub>2</sub> (as CaCO<sub>3</sub>) because of intrinsic solubilities. Water treated by this method usually leaves the softening apparatus with a hardness between 50 mg/L and 80 mg/L as CaCO<sub>3</sub>.

## 43. WATER SOFTENING BY ION EXCHANGE

In the *ion exchange process* (also known as *zeolite process* or *base exchange method*), water is passed through a filter bed of exchange material. This exchange material is known as *zeolite*. Ions in the insoluble exchange material are displaced by ions in the water.

The processed water will have a zero hardness. However, if there is no need for water with zero hardness (as in municipal water supply systems), some water can be bypassed around the unit.

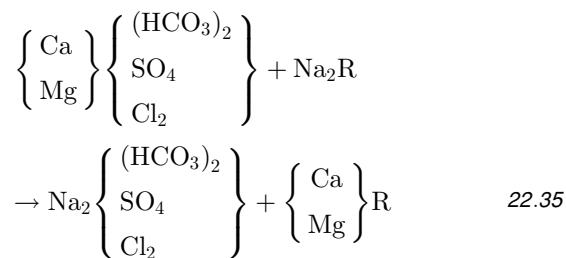

There are three types of ion exchange materials. *Green-sand* (*glauconite*) is a natural substance that is mined and treated with manganese dioxide. *Siliceous-gel zeolite* is an artificial solid used in small volume deionizer columns. *Polystyrene resins* are also synthetic and dominate the softening field.

The earliest synthetic zeolites were gelular *ion exchange resins* using a three-dimensional copolymer (e.g., styrene-divinylbenzene). Porosity through the continuous-phase gel was near zero, and dry contact surface areas of 500 ft<sup>2</sup>/lbm (0.1 m<sup>2</sup>/g) or less were common.

<sup>29</sup>The titration may be affected by the presence of silica and phosphates, which also contribute to alkalinity. The effect is small, but the titration may not be a completely accurate measure of carbonates and bicarbonates.

*Macroreticular synthetic resins* are discontinuous, three-dimensional copolymer beads in a rigid-sponge type formation. Each bead is made up of thousands of microspheres of the gel resin. Porosity is increased, and dry contact surface areas are approximately 270,000 ft<sup>2</sup>/lbm to 320,000 ft<sup>2</sup>/lbm (55 m<sup>2</sup>/g to 65 m<sup>2</sup>/g).

During operation, the calcium and magnesium ions are removed according to the following reaction in which R represents the zeolite anion. The resulting sodium compounds are soluble.

Typical saturation capacities of synthetic resins are 1.0 meq/mL to 1.5 meq/mL for anion exchange resins and 1.7 meq/mL to 1.9 meq/mL for cation exchange resins. However, working capacities are more realistic measures. Working capacities are approximately 10 kilograins/ft<sup>3</sup> to 15 kilograins/ft<sup>3</sup> (23 kg/m<sup>3</sup> to 35 kg/m<sup>3</sup>) before regeneration.

Flow rates through the bed are typically 1 gpm/ft<sup>3</sup> to 6 gpm/ft<sup>3</sup> (2 L/s·m<sup>3</sup> to 13 L/s·m<sup>3</sup>) of resin volume. The flow rate in terms of gpm/ft<sup>2</sup> (L/s·m<sup>2</sup>) across the exposed surface will depend on the geometry of the bed, but values of 3 gpm/ft<sup>2</sup> to 15 gpm/ft<sup>2</sup> (2 L/s·m<sup>2</sup> to 10 L/s·m<sup>2</sup>) are typical.<sup>30</sup>

### Example 22.22

A municipal plant processes water with a total initial hardness of 200 mg/L. The designed discharge hardness is 50 mg/L. If an ion exchange unit is used, what is the bypass factor?

*Solution*

The water passing through the ion exchange unit is reduced to zero hardness. If x is the water fraction bypassed around the zeolite bed,

$$(1-x)\left(0 \frac{\text{mg}}{\text{L}}\right) + x\left(200 \frac{\text{mg}}{\text{L}}\right) = 50 \frac{\text{mg}}{\text{L}}$$

$$x = 0.25$$

<sup>30</sup>Much higher values, up to 15 gpm/ft<sup>3</sup> to 20 gpm/ft<sup>3</sup> or 40 gpm/ft<sup>2</sup> to 50 gpm/ft<sup>2</sup> (33 L/s·m<sup>3</sup> to 45 L/s·m<sup>3</sup> or 27 L/s·m<sup>2</sup> to 34 L/s·m<sup>2</sup>), may occur in certain types of units and at certain times (e.g., start-up and leak conditions).

## 44. REGENERATION OF ION EXCHANGE RESINS

Ion exchange material has a finite capacity for ion removal. When the zeolite is saturated or has reached some other prescribed limit, it must be regenerated (rejuvenated).

Standard ion exchange units are regenerated when the alkalinity of their effluent increases to the *set point*. Most condensate polishing units that also collect crud are operated to a *pressure-drop endpoint*. The pressure drop through the ion exchange unit is primarily dependent on the amount of crud collected. When the pressure drop reaches a set point, the resin is regenerated.

Regeneration of synthetic ion exchange resins is accomplished by passing a *regenerating solution* over/through the resin. Although regeneration can occur in the ion exchange unit itself, external regeneration is common. This involves removing the bed contents hydraulically, backwashing to separate the components (for mixed beds), regenerating the bed components separately, washing, then recombining and transferring the bed components back into service.

Common regeneration compounds are NaCl (for water hardness removal units), H<sub>2</sub>SO<sub>4</sub> (for cation exchange resins), and NaOH (for anion exchange resins). The amount of regeneration solution depends on the resin's degree of saturation. A rule of thumb is to expect to use 6 lbm to 10 lbm of regeneration compound per cubic foot of resin (100 kg to 160 kg per cubic meter). Alternatively, dosage of the regeneration compound may be specified in terms of hardness removed (e.g., 0.4 lbm of salt per 1000 grains of hardness removed). These rates are applicable to deionization plants for boiler make-up water. For condensate polishing, saturation levels of 10 lbm/ft<sup>3</sup> to 25 lbm/ft<sup>3</sup> (160 kg/m<sup>3</sup> to 400 kg/m<sup>3</sup>) are used.

## 45. CHARACTERISTICS OF BOILER FEEDWATER

Water that is converted to steam in a boiler is known as *feedwater*. Water that is added to replace losses is known as *make-up water*. The purity of the feedwater returned to the boiler (after condensing) depends on the purity of the make-up water, since impurities continually build up. *Blowdown* is the intentional periodic release of some of the feedwater in order to remove chemicals whose concentrations have built up over time.

Water impurities cause *scaling* (which reduces fluid flow and heat transfer rates) and corrosion (which reduces strength). Deposits from calcium, magnesium, and silica compounds are particularly troublesome.<sup>31</sup> As feedwater impurity increases, deposits from copper, iron, and nickel oxides (corrosion products from pipe and equipment) become more problematic.

<sup>31</sup>Silica is most troubling because silicate deposits cannot be removed by chemical means. They must be removed mechanically.

Water can also contain dissolved oxygen, nitrogen, and carbon dioxide. The nitrogen is inert and does not need to be considered. However, both the oxygen and carbon dioxide need to be removed. High-temperature dissolved oxygen readily attacks pipe and boiler metal. Most of the oxygen in make-up water is removed by heating the water. Although the solubility of oxygen in water decreases with temperature, water at high pressures can hold large amounts of oxygen. Hydrazine (N<sub>2</sub>H<sub>4</sub>) and sodium sulfite (Na<sub>2</sub>SO<sub>3</sub>) are used for *oxygen scavenging*.<sup>32</sup> Because sodium sulfite forms sodium sulfate at high pressures, only hydrazine should be used above 1500 psi to 1800 psi (10.3 MPa to 12.4 MPa).

Carbon dioxide combines with water to form *carbonic acid*. In power plants, this is more likely found in condenser return lines than elsewhere. Acidity of the condensate is reduced by *neutralizing amines* such as morpholine, cyclohexylamine, ethanolamine (the tetra-sodium salt of ethylenediamine tetra-acetic acid, also known as Na<sub>4</sub>EDTA), and diethylaminoethanol.

Most types of corrosion are greatly reduced when the pH is within the range of 9 to 10. Below this range, corrosion and deposits of sulfates, carbonates, and silicates become a major problem. For this reason, boilers are often shut down when the pH drops below 8.

*Filming amines (polar amines)* such as octadecylamine do not neutralize acidity or raise pH. They form a non-wettable layer which protects surfaces from corrosive compounds. Filming and neutralizing amines are often used in conjunction, though they are injected at different locations in the system.

Other purity requirements depend on the boiler equipment, and in particular, the steam pressure. Also, specific locations within the system can tolerate different concentrations.<sup>33</sup> The following guidelines apply to boilers operating in the 900 psig to 2500 psig (6.2 MPa to 17.3 MPa) range.<sup>34</sup>

- All water feedwater entering the boiler should be free from dissolved oxygen, carbon dioxide, suspended solids, and hardness.
- pH of water entering the boiler should be in the range of 8.5 to 9.0. pH of water in the boiler should be in the range of 10.8 to 11.5.
- Silica in boiler water should be limited to 5 ppm (as CaCO<sub>3</sub>) at 900 psig (6.2 MPa), with a gradual reduction to 1 ppm (as CaCO<sub>3</sub>) at 2500 psig (17.3 MPa).

<sup>32</sup>8 ppm of sodium nitrate react with 1 ppm of oxygen. To achieve a complete reaction, an excess of 2 ppm to 3 ppm of sodium nitrate is required. Hydrazine reacts on a one-to-one basis and is commonly available as a 35% solution. Therefore, approximately 3 ppm of solution is required per ppm of oxygen.

<sup>33</sup>For example, silica in the boiler feedwater may be limited to 1 ppm to 5 ppm, but the silica content in steam should be limited to 0.01 ppm to 0.03 ppm.

<sup>34</sup>Tolerable concentrations at cold start-up can be as much as 5 to 100 times higher.

## 46. MONITORING OF BOILER FEEDWATER QUALITY

Water chemistry of boiler feedwater is monitored through continuous *inline sampling* and periodic *grab sampling*. Water impurities are expressed in milligrams per liter (mg/L), parts per million (ppm), parts per billion (ppb), unit equivalents per million (epm), and milliequivalents per milliliter (meq/mL).<sup>35,36</sup> ppm and ppb can be “as CaCO<sub>3</sub>” equivalents or “as substance.” Electrical conductivity (a measure of total dissolved solids) is measured in microsiemens<sup>37</sup> (μS) or ppm.

Water quality is maintained by monitoring pH, electrical resistivity silica, and hardness (calcium, magnesium, and bicarbonates), the primary corrosion species (sulfates, chlorides, and sodium), dissolved gases (primarily oxygen), and the concentrations of buffering chemicals (e.g., phosphate, hydrazine, or AVT).

Continuous monitoring of ionic concentrations is complicated by a process known as *hideout*, in which a chemical species (e.g., *crevice salts*) disappears by precipitation or adsorption during low-flow and high heat transfer. Upon cooling (as during a shutdown), the hideout chemicals reappear.

## 47. PRODUCTION AND REGENERATION OF BOILER FEEDWATER

The processes used to treat raw water for use in power-generating plants depend on the incoming water quality. Depending on need, filters may be used to remove solids, softeners or exchange units may remove permanent (sulfate) hardness, and activated carbon may remove organics.

Bicarbonate hardness is converted to sludge when the water is boiled, is removed during blowdown, and does not need to be chemically removed. However, a strong *dispersant (sludge conditioner)* must be added to prevent scale formation.<sup>38</sup> Alternatively, the calcium salts can be converted to sludges of phosphate salts by adding phosphates. Prior to the 1970s, *caustic phosphate treatments* using sodium phosphate, SP, in the form of Na<sub>3</sub>PO<sub>4</sub>, NaHPO<sub>4</sub>, and NaH<sub>2</sub>PO<sub>4</sub>, were the most common method used to treat low-pressure boiler feedwater

<sup>35</sup>Milligrams per liter (mg/L) is essentially the same as parts per million (ppm). The older units of grains per gallon are still occasionally encountered. 1 *grain* equals 1/7000th of a pound. Multiply grains per gallon (gpg) by 17.1 to get ppm. Unit equivalents per million are derived by dividing the concentration in ppm by the equivalent weight. Equivalent weight is the molecular weight divided by the valence or oxidation number.

<sup>36</sup>Use the following relationship to convert meq/mL to ppm.

$$\text{ppm} = (1000) \left( \frac{\text{meq}}{\text{mL}} \right) (\text{equivalent weight})$$

$$= \frac{(1000) \left( \frac{\text{meq}}{\text{mL}} \right) (\text{formula weight})}{\text{valence}}$$

<sup>37</sup>Microsiemens were previously known as “micromhos,” where “ohms” is spelled backward to indicate its inverse.

<sup>38</sup>Typical sludge conditioner dispersants are natural organics (lignins, tannins, and starches) and synthetics (sodium polyacrylate, sodium polymethacrylate, sulfonated polystyrene, and maleic anhydride).

with high solids. Sodium phosphate converts impurities and buffers pH.

However, magnesium phosphate is a sticky sludge, and using phosphates may cause more problems than not using them. Also, with higher pressures and temperatures, pipe wall *wasting* becomes problematic.<sup>39</sup> Therefore, many modern plants now use an *all-volatile treatment*, AVT, also known as a *zero-solids treatment*. Early AVTs used ammonia (NH<sub>3</sub>) for pH control, but ammonia causes *denting* in systems that operate without blowdown.<sup>40</sup>

*Chelant AVTs* do not add any solid chemicals to the boiler. They work by keeping calcium and magnesium in solution. The compounds are removed through continuous blowdown.<sup>41</sup> Chelant treatments can be used in boilers up to approximately 1500 psi (10.3 MPa) but require high-purity (low-solids) feedwater.<sup>42</sup>

Subsequent advances in corrosion protection have been based on use of stainless steel or titanium-tubed condensers, condensate polishing, and even better AVT formulations. Supplementing ammonia-AVTs are volatile amines, chelants, and boric acid treatments. Boric acid effectively combats denting, intergranular attack, and intergranular stress corrosion cracking.

Water that is processed through an ion-exchange unit is known as *deionized water*. Deionized water is “hungry” for minerals and picks up contamination as it passes through the power plant. When the operating pressure is 1500 psig (10.3 MPa) or higher, condensed steam cannot be reused without additional demineralization.<sup>43</sup> *Demineralization* is not generally needed for lower-pressure units, but some *condensate polishing* is still necessary.

In low-pressure plants, condensate polishing may consist of passing the water through a filter (of sand, anthracite, or pre-coat cellulose), a strong-acid cation unit, and a mixed-bed unit. The filter removes gross particles (referred to as *crud*), the strong-acid unit removes the dissolved iron, and the mixed-bed unit polishes the condensate.<sup>44</sup>

In modern high-pressure plants, the filtration step is often omitted, and crud removal occurs in the strong-acid unit. Furthermore, if the mixed-bed unit is made large enough or the cation component is increased, the strong-acid unit can also be omitted. A mixed-bed unit operating by itself is known as a *naked mixed-bed unit*. Demineralization of condensed steam is commonly accomplished with naked mixed beds.

<sup>39</sup>*Wasting* is a term used in the power-generating industry to describe the process of general pipe wall thinning.

<sup>40</sup>*Denting* is the constricting of the intersection between tubes and support plates in boilers due to a buildup of corrosion.

<sup>41</sup>AVTs work in a completely different way than phosphates. It is not necessary to use phosphates and AVTs simultaneously.

<sup>42</sup>If the feedwater becomes contaminated, a supplementary phosphate treatment will be required.

<sup>43</sup>The term *deionization* refers to the process that produces makeup water. *Demineralization* refers to the process used to prepare condensed steam for reuse.

<sup>44</sup>*Crud* is primarily iron-corrosion products ranging from dissolved to particulate matter.

# 23 Organic Chemistry

1. Introduction to Organic Chemistry .....	23-1
2. Functional Groups .....	23-1
3. Families of Organic Compounds .....	23-1
4. Symbolic Representation .....	23-1
5. Formation of Organic Compounds .....	23-2

## 1. INTRODUCTION TO ORGANIC CHEMISTRY

Organic chemistry deals with the formation and reaction of compounds of carbon, many of which are produced by living organisms. Organic compounds typically have one or more of the following characteristics.

- They are insoluble in water.<sup>1</sup>
- They are soluble in concentrated acids.
- They are relatively non-ionizing.
- They are unstable at high temperatures.

The method of naming organic compounds was standardized in 1930 at the International Union Chemistry meeting in Belgium. Names conforming to the established guidelines are known as *IUC names* or *IUPAC names*.<sup>2</sup>

## 2. FUNCTIONAL GROUPS

Certain combinations (groups) of atoms occur repeatedly in organic compounds and remain intact during reactions. Such combinations are called *functional groups* or *moieties*.<sup>3</sup> For example, the radical OH<sup>-</sup> is known as a *hydroxyl group*. Table 23.1 contains some common functional groups. In this table and others similar to it, the symbols R and R' usually denote an attached hydrogen atom or other hydrocarbon chain of any length. They may also denote some other group of atoms.

<sup>1</sup>This is especially true for hydrocarbons. However, many organic compounds containing oxygen are water soluble. The sugar family is an example of water-soluble compounds.

<sup>2</sup>IUPAC stands for *International Union of Pure and Applied Chemistry*.

<sup>3</sup>Although “moiety” is often used synonymously with “functional group,” there is a subtle difference. When a functional group combines into a compound, its moiety may gain/lose an atom from/to its combinant. Therefore, moieties differ from their original functional groups by one or more atoms.

**Table 23.1** Selected Functional Groups

name	standard symbol	formula	number of single bonding sites
aldehyde		CHO	1
alkyl	[R]	C <sub>n</sub> H <sub>2n+1</sub>	1
alkoxy	[RO]	C <sub>n</sub> H <sub>2n+1</sub> O	1
amine			
(amino, n = 2)		NH <sub>n</sub>	3 - n [n = 0,1,2]
aryl			
(benzene ring)	[Ar]	C <sub>6</sub> H <sub>5</sub>	1
carbinol		COH	3
carbonyl (keto)	[CO]	CO	2
carboxyl		COOH	1
ester		COO	1
ether		O	2
halogen (halide)	[X]	Cl, Br, I, or F	1
hydroxyl		OH	1
nitrile		CN	1
nitro		NO <sub>2</sub>	1

## 3. FAMILIES OF ORGANIC COMPOUNDS

For convenience, organic compounds are categorized into families, or *chemical classes*. “R” is an abbreviation for the word “radical,” though it is unrelated to ionic radicals. Compounds within each family have similar structures, being based on similar combinations of groups. For example, all compounds in the alcohol family have the structure [R]-OH, where [R] is any alkyl group and -OH is the hydroxyl group.

Families of compounds can be further subdivided into subfamilies. For example, the hydrocarbons are classified into alkanes (single carbon-carbon bond), alkenes (double carbon-carbon bond), and alkynes (triple carbon-carbon bond).<sup>4</sup>

Table 23.2 contains some common organic families, and Table 23.3 gives synthesis routes for various classes of organic compounds.

## 4. SYMBOLIC REPRESENTATION

The nature and structure of organic groups and families cannot be explained fully without showing the types of

<sup>4</sup>Hydrocarbons with two double carbon-carbon bonds are known as *dienes*.

bonds between the elements. Figure 23.1 illustrates the symbolic representation of some of the functional groups and families, and Fig. 23.2 illustrates reactions between organic compounds.

## 5. FORMATION OF ORGANIC COMPOUNDS

There are usually many ways of producing an organic compound. The types of reactions contained in this

section deal only with the interactions between the organic families. The following processes are referred to.

- *oxidation*: replacement of a hydrogen atom with a hydroxyl group
- *reduction*: replacement of a hydroxyl group with a hydrogen atom
- *hydrolysis*: addition of one or more water molecules
- *dehydration*: removal of one or more water molecules

**Table 23.2 Families (Chemical Classes) of Organic Compounds**

family (chemical class)	structure <sup>a</sup>	example
organic acids		
carboxylic acids	[R]-COOH	acetic acid ((CH <sub>3</sub> )COOH)
fatty acids	[Ar]-COOH	benzoic acid (C <sub>6</sub> H <sub>5</sub> COOH)
alcohols		
aliphatic	[R]-OH	methanol (CH <sub>3</sub> OH)
aromatic	[Ar]-[R]-OH	benzyl alcohol (C <sub>6</sub> H <sub>5</sub> CH <sub>2</sub> OH)
aldehydes	[R]-CHO	formaldehyde (HCHO)
alkyl halides		
(haloalkanes)	[R]-[X]	chloromethane (CH <sub>3</sub> Cl)
amides	[R]-CO-NH <sub>n</sub>	β-methylbutyramide (C <sub>4</sub> H <sub>9</sub> CONH <sub>2</sub> )
amines	[R] <sub>3-n</sub> -NH <sub>n</sub>	methylamine (CH <sub>3</sub> NH <sub>2</sub> )
	[Ar] <sub>3-n</sub> -NH <sub>n</sub>	aniline (C <sub>6</sub> H <sub>5</sub> NH <sub>2</sub> )
primary amines	<i>n</i> = 2	
secondary amines	<i>n</i> = 1	
tertiary amines	<i>n</i> = 0	
amino acids	CH-[R]-(NH <sub>2</sub> )COOH	glycine (CH <sub>2</sub> (NH <sub>2</sub> )COOH)
anhydrides	[R]-CO-O-CO-[R']	acetic anhydride (CH <sub>3</sub> CO) <sub>2</sub> O
arenes (aromatics)	ArH = C <sub>n</sub> H <sub>2n-6</sub>	benzene (C <sub>6</sub> H <sub>6</sub> )
aryl halides	[AR]-[X]	fluorobenzene (C <sub>6</sub> H <sub>5</sub> F)
carbohydrates	C <sub>x</sub> (H <sub>2</sub> O) <sub>y</sub>	dextrose (C <sub>6</sub> H <sub>12</sub> O <sub>6</sub> )
sugars		
polysaccharides		
esters	[R]-COO-[R']	methyl acetate (CH <sub>3</sub> COOCH <sub>3</sub> )
ethers	[R]-O-[R]	diethyl ether (C <sub>2</sub> H <sub>5</sub> OC <sub>2</sub> H <sub>5</sub> )
	[Ar]-O-[R]	methyl phenyl ether (CH <sub>3</sub> OC <sub>6</sub> H <sub>5</sub> )
glycols	[Ar]-O-[Ar]	diphenyl ether (C <sub>6</sub> H <sub>5</sub> OC <sub>6</sub> H <sub>5</sub> )
hydrocarbons	C <sub>n</sub> H <sub>2n</sub> (OH) <sub>2</sub>	ethylene glycol (C <sub>2</sub> H <sub>4</sub> (OH) <sub>2</sub> )
alkanes (single bonds) <sup>b</sup>	RH = C <sub>n</sub> H <sub>2n+2</sub>	octane (C <sub>8</sub> H <sub>18</sub> )
saturated hydrocarbons		
cycloalkanes (cycloparaffins)		
alkenes (double bonds between two carbons) <sup>c</sup>	C <sub>n</sub> H <sub>2n</sub>	cyclohexane (C <sub>6</sub> H <sub>12</sub> )
unsaturated hydrocarbons	C <sub>n</sub> H <sub>2n</sub>	ethylene (C <sub>2</sub> H <sub>4</sub> )
cycloalkenes		
alkynes (triple bonds between two carbons)	C <sub>n</sub> H <sub>2n-2</sub>	cyclohexene (C <sub>6</sub> H <sub>10</sub> )
unsaturated hydrocarbons	C <sub>n</sub> H <sub>2n-2</sub>	acetylene (C <sub>2</sub> H <sub>2</sub> )
ketones	[R]-[CO]-[R]	
nitriles	[R]-CN	acetone ((CH <sub>3</sub> ) <sub>2</sub> CO)
phenols	[Ar]-OH	acetonitrile (CH <sub>3</sub> CN)
		phenol (C <sub>6</sub> H <sub>5</sub> OH)

<sup>a</sup>See Table 23.1 for definitions of [R], [Ar], [X], and [CO].

<sup>b</sup>Alkanes are also known as the *paraffin series* and *methane series*.

<sup>c</sup>Alkenes are also known as the *olefin series*.

## 1. HYDROCARBONS

With the exception of sulfur and related compounds, most fuels are hydrocarbons. Hydrocarbons are further categorized into subfamilies such as *alkynes* ( $C_nH_{2n-2}$ , such as acetylene  $C_2H_2$ ), *alkenes* ( $C_nH_{2n}$ , such as ethylene  $C_2H_4$ ), and *alkanes* ( $C_nH_{2n+2}$ , such as octane  $C_8H_{18}$ ). The alkynes and alkenes are referred to as *unsaturated hydrocarbons*, while the alkanes are referred to as *saturated hydrocarbons*. The alkanes are also known as the *paraffin series* and *methane series*. The alkenes are subdivided into the chain-structured *olefin series* and the ring-structured *naphthalene series*. *Aromatic hydrocarbons* ( $C_nH_{2n-6}$ , such as benzene  $C_6H_6$ ) constitute another subfamily. Names for common hydrocarbon compounds are listed in App. 24.A.

**Table 24.1** Approximate Specific Heats (at Constant Pressure) of Gases ( $c_p$  in Btu/lbm·°R; at 1 atm)

gas	temperature (°R)							
	500	1000	1500	2000	2500	3000	4000	5000
air	0.240	0.249	0.264	0.277	0.286	0.294	0.302	—
carbon dioxide	0.196	0.251	0.282	0.302	0.314	0.322	0.332	0.339
carbon monoxide	0.248	0.257	0.274	0.288	0.298	0.304	0.312	0.316

water vapor	0.444	0.475	0.519	0.566	0.609	0.645	0.696	0.729

(Multiply Btu/lbm·°R by 4.187 to obtain kJ/kg·K.)

## 2. CRACKING OF HYDROCARBONS

*Cracking* is the process of splitting hydrocarbon molecules into smaller molecules. For example, alkane molecules crack into a smaller member of the alkane subfamily and a member of the alkene subfamily. Cracking is used to obtain lighter hydrocarbons (such as those in gasoline) from heavy hydrocarbons (e.g., crude oil).

Cracking can proceed under the influence of high temperatures (*thermal cracking*) or catalysts (*catalytic cracking* or “cat cracking”). Since (from Le Châtelier’s principle) cracking at high pressure favors recombination, catalytic cracking is performed at pressures near atmospheric. Catalytic cracking produces gasolines with better antiknock properties than does thermal cracking.

## 3. FUEL ANALYSIS

Fuel analyses are reported as either percentages by weight (for liquid and solid fuels) or percentages by volume (for gaseous fuels). Percentages by weight are known as *gravimetric analyses*, while percentages by volume are known as *volumetric analyses*. An *ultimate analysis* is a type of gravimetric analysis in which the constituents are reported by atomic species rather than by compound. In an ultimate analysis, combined hydrogen from moisture in the fuel is added to hydrogen from the combustive compounds. (See Sec. 24.6.)

A *proximate analysis* (not “approximate”) gives the gravimetric fraction of moisture, volatile matter, fixed carbon, and ash. Sulfur may be combined with the ash or may be specified separately.

A *combustible analysis* considers only the combustible components, disregarding moisture and ash.

Compositions of gaseous fuels are typically given as volumetric fractions of each component. For gas A in a mixture, its *volumetric fraction*,  $B_A$ ; *mole fraction*,  $x_A$ , and *partial pressure ratio*,  $p_A/p_t$ , are all the same. This means the same value can be used with Dalton’s and Henry’s laws.

A volumetric fraction can be converted to a gravimetric fraction by multiplying by the molecular weight and

then dividing by the sum of the products of all the volumetric fractions and molecular weights.

## 4. WEIGHTING OF THERMODYNAMIC PROPERTIES

Many gaseous fuels (and all gaseous combustion products) are mixtures of different compounds. Some thermodynamic properties of mixtures are gravimetrically weighted, while others are volumetrically weighted. Specific heat, specific gas constant, enthalpy, internal energy, and entropy are gravimetrically weighted. For gases, molecular weight, density, and all molar properties are volumetrically weighted.<sup>1</sup>

When a compound experiences a large temperature change, the thermodynamic properties should be evaluated at the average temperature. Table 24.1 can be used to find the specific heat of gases at various temperatures.

## 5. STANDARD CONDITIONS

Many gaseous fuel properties are specified per unit volume. The phrases “standard cubic foot” (SCF) and “normal cubic meters” (nm or Nm<sup>3</sup>) are incorporated into the designations of volumes and flow rates. These volumes are “standard” or “normal” because they are based on standard conditions. Unfortunately, there are numerous definitions of *standard temperature and pressure* (*standard conditions, STP*). For nearly a century, the natural gas and oil industries in North America and the Organization of the Petroleum Exporting Countries (OPEC) defined standard conditions as 14.73 psia and 60°F (15.56°C; 288.71K). The *international standard metric conditions* for natural gas and similar fuels are 288.15K (59.00°F; 15.00°C) and 101.325 kPa. Some gas flows related to environmental engineering are based on standard conditions of either 15°C or 20°C and 101.325 kPa. These are different from the standard conditions used for scientific work, historically 32.00°F and 14.696 psia (0°C and 101.325 kPa) but now transitioning to 0°C and

<sup>1</sup>For gases, molar properties include molar specific heats, enthalpy per mole, and internal energy per mole.

100.00 kPa, and the various temperatures, usually 20°C or 25°C, used to tabulate standard enthalpies of formation and reaction of components. Clearly, it is essential to know the “standard” conditions onto which any gaseous fuel flows are referred.

Some combustion equipment (e.g., particulate collectors) operates within a narrow range of temperatures and pressures. These conditions are referred to as *normal temperature and pressure* (NTP).

## 6. MOISTURE

If an ultimate analysis of a solid or liquid fuel is given, all of the oxygen is assumed to be in the form of free water.<sup>2</sup> The amount of hydrogen combined as free water is assumed to be one-eighth of the oxygen weight.<sup>3</sup> All remaining hydrogen, known as the *available hydrogen*, is assumed to be combustible. (Also, see Sec. 24.35.)

$$G_{\text{H,combined}} = \frac{G_O}{8} \quad 24.1$$

$$G_{\text{H,available}} = G_{\text{H,total}} - \frac{G_O}{8} \quad 24.2$$

Moisture in fuel is undesirable because it increases fuel weight (transportation costs) and decreases available combustion heat.<sup>4</sup> For coal, the “*bed*” moisture level refers to the moisture level when the coal is mined. The terms *dry* and *as fired* are often used in commercial coal specifications. The “*as fired*” condition corresponds to a specific moisture content when placed in the furnace. The “*as fired*” heating value should be used, since the moisture actually decreases the useful combustion energy. The approximate relationship between the two heating values is given by Eq. 24.3, where *M* is the moisture content from a proximate analysis.<sup>5</sup>

$$\text{HV}_{\text{as fired}} = \text{HV}_{\text{dry}}(1 - M) \quad 24.3$$

## 7. ASH AND MINERAL MATTER

*Mineral matter* is the noncombustible material in a fuel. *Ash* is the residue remaining after combustion. Ash may contain some combustible carbon as well as the original mineral matter. The two terms (“mineral matter” and “ash”) are often used interchangeably when reporting fuel analyses.

<sup>2</sup>This assumes that none of the oxygen is in the form of carbonates.

<sup>3</sup>The value of one-eighth follows directly from the combustion reaction of hydrogen and oxygen.

<sup>4</sup>A moisture content up to 5% is reported to be beneficial in some mechanically fired boilers. The moisture content contributes to lower temperatures, protecting grates from slag formation and sintering.

<sup>5</sup>Equation 24.3 corrects for the portion of the as-fired coal that isn’t combustible, but it neglects other moisture-related losses. Section 24.35 and Sec. 24.37 contain more rigorous discussions.

Ash may also be categorized according to where it is recovered. Dry and wet *bottom ashes* are recovered from *ash pits*. However, as little as 10% of the total ash content may be recovered in the ash pit. *Fly ash* is carried out of the boiler by the flue gas. Fly ash can be deposited on walls and heat transfer surfaces. It will be discharged from the stack if not captured. *Economizer ash* and *air heater ash* are recovered from the devices the ashes are named after.

The finely powdered ash that covers combustion grates protects them from high temperatures.<sup>6</sup> If the ash has a low (i.e., below 2200°F; 1200°C) fusion temperature (melting point), it may form *clinkers* in the furnace and/or *slag* in other high-temperature areas. In extreme cases, it can adhere to the surfaces. Ashes with high melting (fusion) temperatures (i.e., above 2600°F; 1430°C) are known as *refractory ashes*. The *T<sub>250</sub> temperature* is used as an index of slagging tendencies of an ash. This is the temperature at which the slag becomes molten with a viscosity of 250 poise. Slagging will be experienced when the *T<sub>250</sub>* temperature is exceeded.

The actual melting point depends on the ash composition. Ash is primarily a mixture of silica (SiO<sub>2</sub>), alumina (Al<sub>2</sub>O<sub>3</sub>), and ferric oxide (Fe<sub>2</sub>O<sub>3</sub>).<sup>7</sup> The relative proportions of each will determine the melting point, with lower melting points resulting from high amounts of ferric oxide and calcium oxide. The melting points of pure alumina and pure silica are in the 2700–2800°F (1480–1540°C) range.

*Coal ash* is either of a bituminous type or lignite type. Bituminous-type ash (from midwestern and eastern coals) contains more ferric oxide than lime and magnesia. Lignite-type ash (from western coals) contains more lime and magnesia than ferric oxide.

## 8. SULFUR

Several forms of sulfur are present in coal and fuel oils. *Pyritic sulfur* (FeS<sub>2</sub>) is the primary form. *Organic sulfur* is combined with hydrogen and carbon in other compounds. *Sulfate sulfur* is iron sulfate and gypsum (CaSO<sub>4</sub>·2H<sub>2</sub>O). Sulfur in elemental, organic, and pyritic forms oxidizes to sulfur dioxide. *Sulfur trioxide* can be formed under certain conditions. Sulfur trioxide combines with water to form sulfuric acid and is a major source of boiler/stack corrosion and acid rain.

<sup>6</sup>Some boiler manufacturers rely on the thermal protection the ash provides. For example, coal burned in cyclone boilers should have a minimum ash content of 7% to cover and protect the cyclone barrel tubes. Boiler wear and ash carryover will increase with lower ash contents.

<sup>7</sup>Calcium oxide (CaO), magnesium oxide (“magnesia,” MgO), titanium oxide (“titania,” TiO<sub>2</sub>), ferrous oxide (FeO), and alkalies (Na<sub>2</sub>O and K<sub>2</sub>O) may be present in smaller amounts.

## 9. WOOD

Wood is not an industrial fuel, though it may be used in small quantities in developing countries. Most woods have higher heating values around 8300 Btu/lbm (19 MJ/kg), with specific values depending on the species and moisture content.

## 10. WASTE FUELS

*Waste fuels* are increasingly being used as fuels in industrial boilers and furnaces. Such fuels include digester and landfill gases, waste process gases, flammable waste liquids, and volatile organic compounds (VOCs) such as benzene, toluene, xylene, ethanol, and methane. Other waste fuels include oil shale, tar sands, green wood, seed and rice hulls, biomass refuse, peat, tire shavings, and shingle/roofing waste.

The term *refuse-derived fuels* (RDF) is used to describe fuel produced from municipal waste. After separation (removal of glass, plastics, metals, corrugated cardboard, etc.), the waste is merely pushed into the combustion chamber. If the waste is to be burned elsewhere, it is compressed and baled.

The heating value of RDF depends on the moisture content and fraction of combustible material. For RDFs derived from typical municipal wastes, the heating value ranges from 3000 Btu/lbm to 6000 Btu/lbm (7 MJ/kg to 14 MJ/kg). Higher ranges (such as 7500–8500 Btu/lbm (17.5–19.8 MJ/kg)) can be obtained by careful selection of ingredients. Pelletized RDF (containing some coal and a limestone binder) with heating values around 8000 Btu/lbm (18.6 MJ/kg) can be used as a supplemental fuel in coal-fired units.

Scrap tires are an attractive fuel source due to their high heating values, which range from 12,000 Btu/lbm to 16,000 Btu/lbm (28 MJ/kg to 37 MJ/kg). To be compatible with existing coal-loading equipment, tires are chipped or shredded to 1 in (25 mm) size. Tires in this form are known as *tire-derived fuel* (TDF). Metal (from tire reinforcement) may or may not be present.

TDF has been shown to be capable of supplying up to 90% of a steam-generating plant's total Btu input without any deterioration in particulate emissions, pollutants, and stack opacity. In fact, compared with some low-quality coals (e.g., lignite), TDF is far superior: about 2.5 times the heating value and about 2.5 times less sulfur per Btu.

## 11. INCINERATION

Many toxic wastes are incinerated rather than “burned.” Incineration and combustion are not the same. *Incineration* is the term used to describe a disposal process that uses combustion to render wastes ineffective (non-harmful, nontoxic, etc.). Wastes and combustible fuel are combined in a furnace, and the heat of combustion

destroys the waste.<sup>8</sup> Wastes may themselves be combustible, though they may not be self-sustaining if the moisture content is too high.

Wastes destined for industrial incineration are usually classified by composition and heating value. The Incinerator Institute of America published broad classifications to categorize incinerator waste in 1968. Although the compositions of many wastes, particularly municipal, have changed since then, these categories remain in use. For example, biological and pathological waste is referred to as “type 4 waste.” Incinerated wastes are categorized into seven types. Type 0 is *trash* (highly combustible paper and wood, with 10% or less moisture); type 1 is *rubbish* (combustible waste with up to 25% moisture); type 2 is *refuse* (a mixture of rubbish and garbage, with up to 50% moisture); type 3 is *garbage* (residential waste with up to 70% moisture); type 4 is animal solids and pathological wastes (85% moisture); type 5 is industrial process wastes in gaseous, liquid, and semiliquid form; and type 6 is industrial process wastes in solid and semisolid form requiring incineration in hearth, retort, or grate burning equipment.

## 12. COAL

Coal consists of volatile matter, fixed carbon, moisture, noncombustible mineral matter (“ash”), and sulfur. *Volatile matter* is driven off as a vapor when the coal is heated, and it is directly responsible for flame size. *Fixed carbon* is the combustible portion of the solid remaining after the volatile matter is driven off. Moisture is present in the coal as free water and (for some mineral compounds) as water of hydration. Sulfur, an undesirable component, contributes to heat content.

Coals are categorized into anthracitic, bituminous, and lignitic types. *Anthracite coal* is clean, dense, and hard. It is comparatively difficult to ignite but burns uniformly and smokelessly with a short flame. *Bituminous coal* varies in composition, but generally has a higher volatile content than anthracite, starts easily, and burns freely with a long flame. Smoke and soot are possible if bituminous coal is improperly fired. *Lignite coal* is a coal of woody structure, is very high in moisture, and has a low heating value. It normally ignites slowly due to its moisture, breaks apart when burning, and burns with little smoke or soot.

Coal is burned efficiently in a particular furnace only if it is uniform in size. Screen sizes are used to grade coal, but descriptive terms can also be used.<sup>9</sup> *Run-of-mine coal*, ROM, is coal as mined. *Lump coal* is in the 1–6 in (25–150 mm) range. *Nut coal* is smaller, followed by even smaller *pea coal screenings*, and *fines* (dust).

<sup>8</sup>Rotary kilns can accept waste in many forms. They are “workhorse” incinerators.

<sup>9</sup>The problem with descriptive terms is that one company's “pea coal” may be as small as 1/4 in (6 mm), while another's may start at 1/2 in (13 mm).

### 13. LOW-SULFUR COAL

Switching to low-sulfur coal is a way to meet sulfur emission standards. Western and eastern low-sulfur coals have different properties.<sup>10,11</sup> Eastern low-sulfur coals are generally low-impact coals (that is, few changes need to be made to the power plant when switching to them). Western coals are generally high-impact coals. Properties of typical high- and low-sulfur fuels are shown in Table 24.2.

The lower sulfur content results in less boiler corrosion. However, of all the coal variables, the different ash characteristics are the most significant with regard to the steam generator components. The slagging and fouling tendencies are prime concerns.

**Table 24.2** Typical Properties of High- and Low-Sulfur Coals\*

property	high-sulfur	low-sulfur	
		eastern	western
higher heating value, Btu/lbm (MJ/kg)	10,500 (24.4)	13,400 (31.2)	8000 (18.6)
moisture content, %	11.7	6.9	30.4
ash content, %	11.8	4.5	6.4
sulfur content, %	3.2	0.7	0.5
slag melting temperature, °F (°C)	2400 (1320)	2900 (1590)	2900 (1590)

(Multiply Btu/lbm by 2.326 to obtain kJ/kg.)

\* All properties are "as received."

### 14. CLEAN COAL TECHNOLOGIES

A lot of effort has been put into developing technologies that will reduce acid rain, pollution and air toxics (NO<sub>x</sub> and SO<sub>2</sub>), and carbon dioxide emissions. These technologies are loosely labeled as *clean coal technologies* (CCTs). Whether or not these technologies can be retrofitted into an existing plant or designed into a new plant depends on the economics of the process.

With *coal cleaning*, coal is ground to ultrafine sizes to remove sulfur and ash-bearing minerals.<sup>12</sup> However, finely ground coal creates problems in handling, storage, and dust production. The risk of fire and explosion increases. Different approaches to reducing the problems associated with transporting and storing finely ground coal include the use of dust suppression chemicals, pelletizing, transportation of coal in liquid slurry form, and pelletizing followed by reslurrying. Some of these technologies may not be suitable for retrofit into existing installations.

<sup>10</sup>In the United States, low-sulfur coals predominately come from the western United States ("western subbituminous"), although some come from the east ("eastern bituminous").

<sup>11</sup>Some parameters dependent on coal type are coal preparation, firing rate, ash volume and handling, slagging, corrosion rates, dust collection and suppression, and fire and explosion prevention.

<sup>12</sup>80% or more of *micronized coal* is 44 microns or less in size.

With *coal upgrading*, moisture is thermally removed from low-rank coal (e.g., lignite or subbituminous coal). With some technologies, sulfur and ash are also removed when the coal is upgraded.

Reduction in sulfur dioxide emissions is the goal of *SO<sub>2</sub> control* technologies. These technologies include conventional use of lime and limestone in *flue gas desulfurization* (FGD) systems, *furnace sorbent-injection* (FSI), and *duct sorbent-injection*. Advanced scrubbing is included in FGD technologies.

Redesigned burners and injectors and adjustment of the flame zone are typical types of *NO<sub>x</sub> control*. Use of secondary air, injection of ammonia or urea, and selective catalytic reduction (SCR) are also effective in NO<sub>x</sub> reduction.

*Fluidized-bed combustion* (FBC) reduces NO<sub>x</sub> emissions by reducing combustion temperatures to around 1500°F (815°C). FBC is also effective in removing up to 90% of the SO<sub>2</sub>. *Atmospheric FBC* operates at atmospheric pressure, but higher thermal efficiencies are achieved in *pressurized FBC* units operating at pressures up to 10 atm.

*Integrated gasification/combined cycle* (IGCC) processes are able to remove 99% of all sulfur while reducing NO<sub>x</sub> to well below current emission standards. *Synthetic gas* (*syngas*) is derived from coal. Syngas has a lower heating value than natural gas, but it can be used to drive gas turbines in combined cycles or as a reactant in the production of other liquid fuels.

### 15. COKE

*Coke*, typically used in blast furnaces, is produced by heating coal in the absence of oxygen. The heavy hydrocarbons crack (i.e., the hydrogen is driven off), leaving only a carbonaceous residue containing ash and sulfur. Coke burns smokelessly. *Breeze* is coke smaller than 5/8 in (16 mm). It is not suitable for use in blast furnaces, but steam boilers can be adapted to use it. *Char* is produced from coal in a 900°F (500°C) carbonization process. The volatile matter is removed, but there is little cracking. The process is used to solidify tars, bitumens, and some gases.

### 16. LIQUID FUELS

Liquid fuels are lighter hydrocarbon products refined from crude petroleum oil. They include liquefied petroleum gas (LPG), gasoline, kerosene, jet fuel, diesel fuels, and heating oils. JP-4 ("jet propellant") is a 50-50 blend of kerosene and gasoline. JP-8 and Jet A are kerosene-like fuels for aircraft gas turbine engines. Important characteristics of a liquid fuel are its composition, ignition temperature, flash point,<sup>13</sup> viscosity, and heating value.

<sup>13</sup>This is different from the *flash point* that is the temperature at which fuel oils generate enough vapor to sustain ignition in the presence of spark or flame.

**Table 24.3** Typical Properties of Common Commercial Fuels

	butane	no. 1 diesel	no. 2 diesel	ethanol	gasoline	JP-4	methanol	propane
chemical formula	C <sub>4</sub> H <sub>10</sub>	—	—	C <sub>2</sub> H <sub>5</sub> OH	—	—	CH <sub>3</sub> OH	C <sub>3</sub> H <sub>8</sub>
molecular weight	58.12	≈ 170	≈ 184	46.07	≈ 126	—	32.04	44.09
heating value								
higher, Btu/lbm	21,240	19,240	19,110	12,800	20,260	—	9838	21,646
lower, Btu/lbm	19,620	18,250	18,000	11,500	18,900	18,400	8639	19,916
lower, Btu/gal	102,400	133,332	138,110	76,152	116,485	123,400	60,050	81,855
latent heat of vaporization, Btu/lbm		115	105	361	142	—	511 (20°C)	147
specific gravity*	2.01	0.876	0.920	0.794	0.68–0.74	0.8017	0.793	1.55

(Multiply Btu/lbm by 2.326 to obtain kJ/kg.)

(Multiply Btu/gal by 0.2786 to obtain MJ/m<sup>3</sup>.)

\*Specific gravities of propane and butane are with respect to air.

## 17. FUEL OILS

In the United States, fuel oils are categorized into grades 1 through 6 according to their viscosities.<sup>14</sup> Viscosity is the major factor in determining firing rate and the need for preheating for pumping or atomizing prior to burning. Grades 1 and 2 can be easily pumped at ambient temperatures. In the United States, the heaviest fuel oil used is grade 6, also known as *Bunker C oil*.<sup>15,16</sup> Fuel oils are also classified according to their viscosities as *distillate oils* (lighter) and *residual fuel oils* (heavier).

Like coal, fuel oils contain sulfur and ash that may cause pollution, slagging on the hot end of the boiler, and corrosion in the cold end. Table 24.3 lists typical properties of common commercial fuels, while Table 24.4 lists typical properties of fuel oils.

**Table 24.4** Typical Properties of Fuel Oils<sup>a</sup>

grade	specific gravity	heating value	
		(MBtu/gal) <sup>b</sup>	(GJ/m <sup>3</sup> )
1	0.805	134	37.3
2	0.850	139	38.6
4	0.903	145	40.4
5	0.933	148	41.2
6	0.965	151	41.9

(Multiply MBtu/gal by 0.2786 to obtain GJ/m<sup>3</sup>.)<sup>a</sup>Actual values will vary depending on composition.<sup>b</sup>One MBtu equals one thousand Btus.

## 18. GASOLINE

*Gasoline* is not a pure compound. It is a mixture of various hydrocarbons blended to give a desired

<sup>14</sup>Grade 3 became obsolete in 1948. Grade 5 is also subdivided into light and heavy categories.

<sup>15</sup>120°F (48°C) is the optimum temperature for pumping no. 6 fuel oil. At that temperature, no. 6 oil has a viscosity of approximately 3000 SSU. Further heating is necessary to lower the viscosity to 150–350 SSU for atomizing.

<sup>16</sup>To avoid *coking* of oil, heating coils in contact with oil should not be hotter than 240°F (116°C).

flammability, volatility, heating value, and octane rating. There is an infinite number of blends that can be used to produce gasoline.

Gasoline's heating value depends only slightly on composition. Within a variation of 1½%, the heating value can be taken as 20,200 Btu/lbm (47.0 MJ/kg) for regular gasoline and as 20,300 Btu/lbm (47.2 MJ/kg) for high-octane aviation fuel.

Since gasoline is a mixture of hydrocarbons, different fractions will evaporate at different temperatures. The *volatility* is the percentage of the fuel that evaporates by a given temperature. Typical volatility specifications call for 10% or greater at 167°F (75°C), 50% at 221°F (105°C), and 90% at 275°F (135°C). Low volatility causes difficulty in starting and poor engine performance at low temperatures.

The *octane number* (ON) is a measure of *knock resistance*. It is based on comparison, performed in a standardized one-cylinder engine, with the burning of iso-octane and *n*-heptane. *n*-heptane, C<sub>7</sub>H<sub>16</sub>, is rated zero and produces violent knocking. Iso-octane, C<sub>8</sub>H<sub>18</sub>, is rated 100 and produces relatively knock-free operation. The percentage blend by volume of these fuels that matches the performance of the gasoline is the octane rating. The *research octane number* (RON) is a measure of the fuel's anti-knock characteristics while idling; the *motor octane number* (MON) applies to high-speed, high-acceleration operations. The octane rating reported for commercial gasoline is an average of the two.

Gasolines with octanes greater than 100 (including aviation gasoline) are rated by their performance number. The *performance number* (PN) of gasoline containing antiknock compounds (e.g., tetraethyl lead, TEL, used in aviation gasoline) is related to the octane number.

$$\text{ON} = 100 + \frac{\text{PN} - 100}{3} \quad 24.4$$

**Table 24.5** Typical Properties of Common Oxygenates

	ethanol	MTBE <sup>a</sup>	TAME	ETBE	TAEE
specific gravity	0.794	0.744	0.740	0.770	0.791
octane <sup>b</sup>	115	110	112	105	100
heating value, MBtu/gal <sup>c</sup>	76.2	93.6			
Reid vapor pressure, psig <sup>d</sup>	18	8	15–4	3–4	2
percent oxygen by weight	34.73	18.15	15.66	15.66	13.8
volumetric percent needed to achieve gasoline					
2.7% oxygen by weight	7.8	15.1	17.2	17.2	19.4
2.0% oxygen by weight	5.6	11.0	12.4	12.7	13.0

(Multiply MBtu/gal by 0.2786 to obtain MJ/m<sup>3</sup>.)<sup>a</sup>MTBE is water soluble and does not degrade. It imparts a foul taste to water and is a possible carcinogen. It has been legislatively banned in most states, including California.<sup>b</sup>Octane is equal to (1/2)(MON + RON).<sup>c</sup>One MBtu equals one thousand Btus.<sup>d</sup>The Reid vapor pressure is the vapor pressure when heated to 100°F (38°C). This may also be referred to as the “blending vapor pressure.”

## 19. OXYGENATED GASOLINE

In parts of the United States, gasoline is “oxygenated” during the cold winter months. This has led to use of the term “winterized gasoline.” The addition of *oxygenates* raises the combustion temperature, reducing carbon monoxide and unburned hydrocarbons.<sup>17</sup> Common oxygenates used in *reformulated gasoline* (RFG) include methyl tertiary-butyl ether (MTBE) and ethanol. Methanol, ethyl tertiary-butyl ether (ETBE), tertiary-amyl methyl ether (TAME), and tertiary-amyl ethyl ether (TAEE), may also be used. (See Table 24.5.) Oxygenates are added to bring the minimum oxygen level to 2–3% by weight.<sup>18</sup>

## 20. DIESEL FUEL

Properties and specifications for various grades of diesel fuel oil are similar to specifications for fuel oils. Grade 1-D (“D” for diesel) is a light distillate oil for high-speed engines in service requiring frequent speed and load changes. Grade 2-D is a distillate of lower volatility for engines in industrial and heavy mobile service. Grade 4-D is for use in medium speed engines under sustained loads.

Diesel oils are specified by a *cetane number*, which is a measure of the ignition quality (ignition delay) of a fuel. A cetane number of approximately 30 is required for satisfactory operation of low-speed diesel engines.

<sup>17</sup>Oxygenation may not be successful in reducing carbon dioxide. Since the heating value of the oxygenates is lower, fuel consumption of oxygenated fuels is higher. On a per-gallon (per-liter) basis, oxygenation reduces carbon dioxide. On a per-mile (per-kilometer) basis, however, oxygenation appears to increase carbon dioxide. In any case, claims of CO<sub>2</sub> reduction are highly controversial, as the CO<sub>2</sub> footprint required to plant, harvest, dispose of decaying roots, stalks, and leaves (i.e., silage), and refine alcohol is generally ignored.

<sup>18</sup>Other restrictions on gasoline during the winter months intended to reduce pollution may include maximum percentages of benzene and total aromatics and limits on Reid vapor pressure, as well as specifications covering volatile organic compounds, nitric oxide (NO<sub>x</sub>), and toxins.

High-speed engines, such as those used in cars, require a cetane number of 45 or more. Like the octane number for gasoline, the cetane number is determined by comparison with standard fuels. Cetane, C<sub>16</sub>H<sub>34</sub>, has a cetane number of 100. *n*-methyl-naphthalene, C<sub>11</sub>H<sub>10</sub>, has a cetane number of zero. The cetane number can be increased by use of such additives as amyl nitrate, ethyl nitrate, and ether.

A diesel fuel’s *pour point* number refers to its viscosity. A fuel with a pour point of 10°F (−12°C) will flow freely above that temperature. A fuel with a high pour point will thicken in cold temperatures.

The *cloud point* refers to the temperature at which wax crystals cloud the fuel at lower temperatures. The cloud point should be 20°F (−7°C) or higher. Below that temperature, the engine will not run well.

## 21. ALCOHOL

Both methanol and ethanol can be used in internal combustion engines. *Methanol* (*methyl alcohol*) is produced from natural gas and coal, although it can also be produced from wood and organic debris. *Ethanol* (*ethyl alcohol, grain alcohol*) is distilled from grain, sugarcane, potatoes, and other agricultural products containing various amounts of sugars, starches, and cellulose.

Although methanol generally works as well as ethanol, only ethanol can be produced in large quantities from inexpensive agricultural products and by-products.

Alcohol is water soluble. The concentration of alcohol is measured by its *proof*, where 200 proof is pure alcohol. (180 proof is 90% alcohol and 10% water.)

*Gasohol* is a mixture of approximately 90% gasoline and 10% alcohol (generally ethanol).<sup>19</sup> Alcohol’s heating value is less than gasoline’s, so fuel consumption (per distance traveled) is higher with gasohol. Also, since

<sup>19</sup>In fact, oxygenated gasoline may use more than 10% alcohol.

alcohol absorbs moisture more readily than gasoline, corrosion of fuel tanks becomes problematic. In some engines, significantly higher percentages of alcohol may require such modifications as including larger carburetor jets, timing advances, heaters for preheating fuel in cold weather, tank lining to prevent rusting, and alcohol-resistant gaskets.

Mixtures of gasoline and alcohol can be designated by the first letter and the fraction of the alcohol. E10 is a mixture of 10% ethanol and 90% gasoline. M85 is a blend of 85% methanol and 15% gasoline.

Alcohol is a poor substitute for diesel fuel because alcohol's cetane number is low—from −20 to +8. Straight injection of alcohol results in poor performance and heavy knocking.

## 22. GASEOUS FUELS

Various gaseous fuels are used as energy sources, but most applications are limited to natural gas and *liquefied petroleum gases* (LPGs) (i.e., propane, butane, and mixtures of the two).<sup>20,21</sup> *Natural gas* is a mixture of methane (between 55% and 95%), higher hydrocarbons (primarily ethane), and other noncombustible gases. Typical heating values for natural gas range from 950 Btu/ft<sup>3</sup> to 1100 Btu/ft<sup>3</sup> (35 MJ/m<sup>3</sup> to 41 MJ/m<sup>3</sup>).

The production of *synthetic gas* (*syngas*) through coal gasification may be applicable to large power generating plants. The cost of gasification, though justifiable to reduce sulfur and other pollutants, is too high for syngas to become a widespread substitute for natural gas.

## 23. IGNITION TEMPERATURE

The *ignition temperature* (*autoignition temperature*) is the minimum temperature at which combustion can be sustained. It is the temperature at which more heat is generated by the combustion reaction than is lost to the surroundings, after which combustion becomes self-sustaining. For coal, the minimum ignition temperature varies from around 800°F (425°C) for bituminous varieties to 900–1100°F (480–590°C) for anthracite. For sulfur and charcoal, the ignition temperatures are approximately 470°F (240°C) and 650°F (340°C), respectively.

For gaseous fuels, the ignition temperature depends on the air/fuel ratio, temperature, pressure, and length of

<sup>20</sup>A number of *manufactured gases* are of practical (and historical) interest in specific industries, including *coke-oven gas*, *blast-furnace gas*, *water gas*, *producer gas*, and *town gas*. However, these gases are not now in widespread use.

<sup>21</sup>At atmospheric pressure, propane boils at −44°F (−42°C), while butane boils at 31°F (−0.5°C).

time the source of heat is applied. Ignition can be instantaneous or delayed, depending on the temperature. Generalizations can be made for any gas, but the generalized temperatures will be meaningless without specifying all of these factors.

## 24. ATMOSPHERIC AIR

It is important to make a distinction between "air" and "oxygen." Atmospheric air is a mixture of oxygen, nitrogen, and small amounts of carbon dioxide, water vapor, argon, and other inert ("rare") gases. For the purpose of combustion calculations, all constituents except oxygen are grouped with nitrogen. (See Table 24.6.) It is necessary to supply 4.32 (i.e., 1/0.2315) masses of air to obtain one mass of oxygen. Similarly, it is necessary to supply 4.773 volumes of air to obtain one volume of oxygen. The average molecular weight of air is 28.97, and its specific gas constant is 53.35 ft-lbf/lbm·°R (287.03 J/kg·K).

**Table 24.6** Composition of Dry Air<sup>a</sup>

component	percent by weight	percent by volume
oxygen	23.15	20.95
nitrogen/inerts	76.85	79.05
ratio of nitrogen to oxygen	3.320	3.773 <sup>b</sup>
ratio of air to oxygen	4.320	4.773

<sup>a</sup>Inert gases and CO<sub>2</sub> are included as N<sub>2</sub>.

<sup>b</sup>The value is also reported by various sources as 3.76, 3.78, and 3.784.

## 25. COMBUSTION REACTIONS

A limited number of elements appear in combustion reactions. Carbon, hydrogen, sulfur, hydrocarbons, and oxygen are the reactants. Carbon dioxide and water vapor are the main products, with carbon monoxide, sulfur dioxide, and sulfur trioxide occurring in lesser amounts. Nitrogen and excess oxygen emerge hotter but unchanged from the stack.

Combustion reactions occur according to the normal chemical reaction principles. Balancing combustion reactions is usually easiest if carbon is balanced first, followed by hydrogen and then by oxygen. When a gaseous fuel has several combustible gases, the volumetric fuel composition can be used as coefficients in the chemical equation.

Table 24.7 lists ideal combustion reactions. These reactions do not include any nitrogen or water vapor that are present in the combustion air.

**Table 24.7** Ideal Combustion Reactions

fuel	formula	reaction equation (excluding nitrogen)
carbon (to CO)	C	$2\text{C} + \text{O}_2 \rightarrow 2\text{CO}$
carbon (to $\text{CO}_2$ )	C	$\text{C} + \text{O}_2 \rightarrow \text{CO}_2$
sulfur (to $\text{SO}_2$ )	S	$\text{S} + \text{O}_2 \rightarrow \text{SO}_2$
sulfur (to $\text{SO}_3$ )	S	$2\text{S} + 3\text{O}_2 \rightarrow 2\text{SO}_3$
carbon monoxide	CO	$2\text{CO} + \text{O}_2 \rightarrow 2\text{CO}_2$
methane	$\text{CH}_4$	$\text{CH}_4 + 2\text{O}_2 \rightarrow \text{CO}_2 + 2\text{H}_2\text{O}$
acetylene	$\text{C}_2\text{H}_2$	$2\text{C}_2\text{H}_2 + 5\text{O}_2 \rightarrow 4\text{CO}_2 + 2\text{H}_2\text{O}$
ethylene	$\text{C}_2\text{H}_4$	$\text{C}_2\text{H}_4 + 3\text{O}_2 \rightarrow 2\text{CO}_2 + 2\text{H}_2\text{O}$
ethane	$\text{C}_2\text{H}_6$	$2\text{C}_2\text{H}_6 + 7\text{O}_2 \rightarrow 4\text{CO}_2 + 6\text{H}_2\text{O}$
hydrogen	$\text{H}_2$	$2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$
hydrogen sulfide	$\text{H}_2\text{S}$	$2\text{H}_2\text{S} + 3\text{O}_2 \rightarrow 2\text{H}_2\text{O} + 2\text{SO}_2$

paraffin series	$\text{C}_n\text{H}_{2n+2}$	$2\text{C}_n\text{H}_{2n+2} + (3n+1)\text{O}_2 \rightarrow 2n\text{CO}_2 + (2n+2)\text{H}_2\text{O}$

(Multiply oxygen volumes by 3.773 to get nitrogen volumes.)

**Example 24.1**

A gaseous fuel is 20% hydrogen and 80% methane by volume. What stoichiometric volume of oxygen is required to burn 120 volumes of fuel at the same conditions?

*Solution*

Write the unbalanced combustion reaction.

Use the volumetric analysis as coefficients of the fuel.

Balance the carbons.

Balance the hydrogens.

Balance the oxygens.

For gaseous components, the coefficients correspond to the volumes. Since one ( $0.2 + 0.8$ ) volume of fuel requires 1.7 volumes of oxygen, the required oxygen is

$$(1.7)(120 \text{ volumes of fuel}) = 204 \text{ volumes of oxygen}$$

**26. STOICHIOMETRIC REACTIONS**

*Stoichiometric quantities (ideal quantities)* are the exact quantities of reactants that are needed to complete a combustion reaction without any reactants left over. Table 24.7 contains some of the more common chemical reactions. Stoichiometric volumes and masses can always be determined from the balanced chemical reaction equation. Table 24.8 can be used to quickly determine stoichiometric amounts for some fuels.

**27. STOICHIOMETRIC AIR**

*Stoichiometric air (ideal air)* is the air necessary to provide the exact amount of oxygen for complete combustion of a fuel. Stoichiometric air includes atmospheric nitrogen. For each volume of oxygen, 3.773 volumes of nitrogen pass unchanged through the reaction.<sup>22</sup>

Stoichiometric air can be stated in units of mass (pounds or kilograms of air) for solid and liquid fuels, and in units of volume (cubic feet or cubic meters of air) for gaseous fuels. When stated in terms of mass, the stoichiometric ratio of air to fuel masses is known as the ideal *air/fuel ratio*,  $R_{a/f}$ .

$$R_{a/f,\text{ideal}} = \frac{m_{\text{air,ideal}}}{m_{\text{fuel}}} \quad 24.5$$

The ideal air/fuel ratio can be determined from the combustion reaction equation. It can also be determined by adding the oxygen and nitrogen amounts listed in Table 24.8.

For fuels whose ultimate analysis is known, the approximate stoichiometric air (oxygen and nitrogen) requirement in pounds of air per pound of fuel (kilograms of air per kilogram of fuel) can be quickly

<sup>22</sup>The only major change in the nitrogen gas is its increase in temperature. Dissociation of nitrogen and formation of nitrogen compounds can occur but are essentially insignificant.

**Table 24.8** Consolidated Combustion Data<sup>a,b,c,d</sup>

(Multiply lbm/ft<sup>3</sup> by 0.06243 to obtain kg/m<sup>3</sup>.)<sup>a</sup>Rounding of molecular weights and air composition may introduce slight inconsistencies in the table values. This table is based on atomic weights with at least four significant digits, a ratio of 3.773 volumes of nitrogen per volume of oxygen, and 379.5 ft<sup>3</sup> per mole at 1 atm and 60°F.<sup>b</sup>Volumes per unit mass are at 1 atm and 60°F (16°C). To obtain volumes at other temperatures, multiply by  $(T_F + 460)/(520 + (T_C + 273))^{289}$ .<sup>c</sup>The volume of water applies only when the combustion products are at such high temperatures that all of the water is in vapor form.<sup>d</sup>This table can be used directly determine some SI ratios. For kg/kg ratios, the values are the same as lbm/lbm. For L/L or m<sup>3</sup>/m<sup>3</sup>, use ft<sup>3</sup>/ft<sup>3</sup>. For mol/mol, use mole/mole. For mixed units (e.g., ft<sup>3</sup>/lbm), conversions are required.<sup>e</sup>Sulfur is not used in gaseous form.

calculated by using Eq. 24.6.<sup>23</sup> All oxygen in the fuel is assumed to be free moisture. All of the reported oxygen is assumed to be locked up in the form of water. Any free oxygen (i.e., oxygen dissolved in liquid fuels) is subtracted from the oxygen requirements.

$$R_{a/f,\text{ideal}} = 34.5 \left( \frac{G_C}{3} + G_H - \frac{G_O}{8} + \frac{G_S}{8} \right) \quad [ \text{solid and liquid fuels} ] \quad 24.6$$

For fuels consisting of a mixture of gases, Eq. 24.7 and the constant  $J_i$  from Table 24.9 can be used to quickly determine the stoichiometric air requirements.

$$R_{a/f,\text{ideal}} = \sum G_i J_i \quad [ \text{gaseous fuels} ] \quad 24.7$$

For fuels consisting of a mixture of gases, the air/fuel ratio can also be expressed in volumes of air per volume of fuel using values of  $K_i$  from Table 24.9.

$$\text{volumetric air/fuel ratio} = \sum B_i K_i \quad [ \text{gaseous fuels} ] \quad 24.8$$

**Table 24.9** Approximate Air/Fuel Ratio Coefficients for Components of Natural Gas\*

fuel component	$J$ (gravimetric)	$K$ (volumetric)
acetylene, C <sub>2</sub> H <sub>2</sub>	13.25	11.945
butane, C <sub>4</sub> H <sub>10</sub>	15.43	31.06
carbon monoxide, CO	2.463	2.389
ethane, C <sub>2</sub> H <sub>6</sub>	16.06	16.723
ethylene, C <sub>2</sub> H <sub>4</sub>	14.76	14.33
hydrogen, H <sub>2</sub>	34.23	2.389
hydrogen sulfide, H <sub>2</sub> S	6.074	7.167
methane, CH <sub>4</sub>	17.20	9.556
oxygen, O <sub>2</sub>	-4.320	-4.773
propane, C <sub>3</sub> H <sub>8</sub>	15.65	23.89

\*Rounding of molecular weights and air composition may introduce slight inconsistencies in the table values. This table is based on atomic weights with at least four significant digits and a ratio of 3.773 volumes of nitrogen per volume of oxygen.

### Example 24.2

Use Table 24.8 to determine the theoretical volume of 90°F (32°C) air required to burn 1 volume of 60°F (16°C) carbon monoxide to carbon dioxide.

*Solution*

From Table 24.8, 0.5 volumes of oxygen are required to burn 1 volume of carbon monoxide to carbon dioxide.

<sup>23</sup>This is a "compromise" equation. Variations in the atomic weights will affect the coefficients slightly. The coefficient 34.5 is reported as 34.43 in some older books. 34.5 is the exact value needed for carbon and hydrogen, which constitute the bulk of the fuel. 34.43 is the correct value for sulfur, but the error is small and is disregarded in this equation.

1.887 volumes of nitrogen accompany the oxygen. The total amount of air at the temperature of the fuel is  $0.5 + 1.887 = 2.387$  volumes.

This volume will expand at the higher temperature. The volume at the higher temperature is

$$\begin{aligned} V_2 &= \frac{T_2 V_1}{T_1} \\ &= \frac{(90^\circ\text{F} + 460^\circ)(2.387 \text{ volumes})}{60^\circ\text{F} + 460^\circ} \\ &= 2.53 \text{ volumes} \end{aligned}$$

### Example 24.3

How much air is required for the ideal combustion of (a) coal with an ultimate analysis of 93.5% carbon, 2.6% hydrogen, 2.3% oxygen, 0.9% nitrogen, and 0.7% sulfur; (b) fuel oil with a gravimetric analysis of 84% carbon, 15.3% hydrogen, 0.4% nitrogen, and 0.3% sulfur; and (c) natural gas with a volumetric analysis of 86.92% methane, 7.95% ethane, 2.81% nitrogen, 2.16% propane, and 0.16% butane?

*Solution*

(a) Use Eq. 24.6.

$$\begin{aligned} R_{a/f,\text{ideal}} &= 34.5 \left( \frac{G_C}{3} + G_H - \frac{G_O}{8} + \frac{G_S}{8} \right) \\ &= (34.5) \left( \frac{0.935}{3} + 0.026 - \frac{0.023}{8} + \frac{0.007}{8} \right) \\ &= 11.58 \text{ lbm/lbm (kg/kg)} \end{aligned}$$

(b) Use Eq. 24.6.

$$\begin{aligned} R_{a/f,\text{ideal}} &= 34.5 \left( \frac{G_C}{3} + G_H + \frac{G_S}{8} \right) \\ &= (34.5) \left( \frac{0.84}{3} + 0.153 + \frac{0.003}{8} \right) \\ &= 14.95 \text{ lbm/lbm (kg/kg)} \end{aligned}$$

(c) Use Eq. 24.8 and the coefficients from Table 24.9.

$$\begin{aligned} \text{volumetric air/fuel ratio} &= \sum B_i K_i \\ &= (0.8692) \left( 9.556 \frac{\text{ft}^3}{\text{ft}^3} \right) \\ &\quad + (0.0795) \left( 16.723 \frac{\text{ft}^3}{\text{ft}^3} \right) \\ &\quad + (0.0216) \left( 23.89 \frac{\text{ft}^3}{\text{ft}^3} \right) \\ &\quad + (0.0016) \left( 31.06 \frac{\text{ft}^3}{\text{ft}^3} \right) \\ &= 10.20 \text{ ft}^3/\text{ft}^3 (\text{m}^3/\text{m}^3) \end{aligned}$$

## 28. INCOMPLETE COMBUSTION

*Incomplete combustion* occurs when there is insufficient oxygen to burn all of the hydrogen, carbon, and sulfur in the fuel. Without enough available oxygen, carbon burns to carbon monoxide.<sup>24</sup> Carbon monoxide in the flue gas indicates incomplete and inefficient combustion. Incomplete combustion is caused by cold furnaces, low combustion temperatures, poor air supply, smothering from improperly vented stacks, and insufficient mixing of air and fuel.

## 29. SMOKE

The amount of smoke can be used as an indicator of combustion completeness. Smoky combustion may indicate improper air/fuel ratio, insufficient draft, leaks, insufficient preheat, or misadjustment of the fuel system.

Smoke measurements are made in a variety of ways, with the standards depending on the equipment used. Photoelectric sensors in the stack are used to continuously monitor smoke. The *smoke spot number* (SSN) and ASTM smoke scale are used with continuous stack monitors. For coal-fired furnaces, the maximum desirable smoke number is SSN 4. For grade 2 fuel oil, the SSN should be less than 1; for grade 4, SSN 4; for grades 5L, 5H, and low-sulfur residual fuels, SSN 3; for grade 6, SSN 4.

The *Ringelmann scale* is a subjective method in which the smoke density is visually compared to five standardized white-black grids. Ringelmann chart no. 0 is solid white; chart no. 5 is solid black. Ringelmann chart no. 1, which is 20% black, is the preferred (and required) operating point for most power plants.

## 30. FLUE GAS ANALYSIS

Combustion products that pass through a furnace's exhaust system are known as *flue gases (stack gases)*. Flue gases are almost all nitrogen.<sup>25</sup> Nitrogen oxides are not present in large enough amounts to be included separately in combustion reactions.

The actual composition of flue gases can be obtained in a number of ways, including by modern electronic detectors, less expensive "length-of-stain" detectors, and direct sampling with an Orsat-type apparatus.

The antiquated *Orsat apparatus* determines the volumetric percentages of CO<sub>2</sub>, CO, O<sub>2</sub>, and N<sub>2</sub> in a flue gas. The sampled flue gas passes through a series of chemical compounds. The first compound absorbs only CO<sub>2</sub>, the next only O<sub>2</sub>, and the third only CO. The unabsorbed gas is assumed to be N<sub>2</sub> and is found by subtracting the volumetric percentages of all other components from 100%. An Orsat analysis is a dry analysis; the percentage

<sup>24</sup>Toxic alcohols, ketones, and aldehydes may also be formed during incomplete combustion.

<sup>25</sup>This assumption is helpful in making quick determinations of the thermodynamic properties of flue gases.

of water vapor is not usually determined. A wet volumetric analysis (needed to compute the dew-point temperature) can be derived if the volume of water vapor is added to the Orsat volumes.

The Orsat procedure is now rarely used, although the term "Orsat" may be generally used to refer to any flue gas analyzer. Modern electronic analyzers can determine free oxygen (and other gases) independently of the other gases.

## 31. ACTUAL AND EXCESS AIR

*Complete combustion* occurs when all of the fuel is burned. Usually, *excess air* is required to achieve complete combustion. Excess air is expressed as a percentage of the theoretical air requirements. Different fuel types burn more efficiently with different amounts of excess air. Coal-fired boilers need approximately 30–35% excess air, oil-based units need about 15%, and natural gas burners need about 10%.

The actual air/fuel ratio for dry, solid fuels with no unburned carbon can be estimated from the volumetric flue gas analysis and the gravimetric fractions of carbon and sulfur in the fuel.

$$R_{a/f,\text{actual}} = \frac{m_{\text{air,actual}}}{m_{\text{fuel}}} = \frac{3.04B_{\text{N}_2} \left( G_{\text{C}} + \frac{G_{\text{S}}}{1.833} \right)}{B_{\text{CO}_2} + B_{\text{CO}}} \quad 24.9$$

Too much free oxygen or too little carbon dioxide in the flue gas are indicative of excess air. Because the relationship between oxygen and excess air is relatively insensitive to fuel composition, oxygen measurements are replacing standard carbon dioxide measurements in determining combustion efficiency.<sup>26</sup> The relationship between excess air and the volumetric fraction of oxygen in the flue gas is given in Table 24.10.

**Table 24.10** Approximate Volumetric Percentage of Oxygen in Stack Gas

fuel*	excess air						
	0%	1%	5%	10%	20%	50%	100%
fuel oils,							
no. 2–6	0	0.22	1.06	2.02	3.69	7.29	10.8
natural gas	0	0.25	1.18	2.23	4.04	7.83	11.4
propane	0	0.23	1.08	2.06	3.75	7.38	10.9
							14.2
							14.7
							14.3

\*Values for coal are only marginally lower than the values for fuel oils.

Reducing the air/fuel ratio will have several outcomes. (a) The furnace temperature will increase due to a reduction in cooling air. (b) The flue gas will decrease

<sup>26</sup>The relationship between excess air required and CO<sub>2</sub> is much more dependent on fuel type (e.g., liquid) and furnace design.

in quantity. (c) The heat loss will decrease. (d) The furnace efficiency will increase. (e) Pollutants will (usually) decrease.

With a properly adjusted furnace and good mixing, the flue gas will contain no carbon monoxide, and the amount of carbon dioxide will be maximized. The stoichiometric amount of carbon dioxide in the flue gas is known as the *ultimate CO<sub>2</sub>* and is the theoretical maximum level of carbon dioxide. The air/fuel mixture should be adjusted until the maximum level of carbon dioxide is attained.

#### Example 24.4

Propane (C<sub>3</sub>H<sub>8</sub>) is burned completely with 20% excess air. What is the volumetric fraction of carbon dioxide in the flue gas?

*Solution*

From Table 24.7, the balanced chemical reaction equation is

With 20% excess air, the oxygen volume is (1.2)(5) = 6.

From Table 24.6, there are 3.773 volumes of nitrogen for every volume of oxygen.

$$(3.773)(6) = 22.6$$

For gases, the coefficients can be interpreted as volumes. The volumetric fraction of carbon dioxide is

$$\begin{aligned} B_{\text{CO}_2} &= \frac{3}{3 + 4 + 1 + 22.6} \\ &= 0.0980 \quad (9.8\%) \end{aligned}$$

### 32. CALCULATIONS BASED ON FLUE GAS ANALYSIS

Equation 24.10 gives the approximate percentage (by volume) of actual excess air.

$$\begin{aligned} \text{actual excess air} &= \frac{(\text{B}_{\text{O}_2} - 0.5\text{B}_{\text{CO}})}{0.264\text{B}_{\text{N}_2} - \text{B}_{\text{O}_2} + 0.5\text{B}_{\text{CO}}} \times 100\% \\ &\quad 24.10 \end{aligned}$$

The ultimate CO<sub>2</sub> (i.e., the maximum theoretical carbon dioxide) can be determined from Eq. 24.11.

$$\text{ultimate CO}_2 = \frac{\text{B}_{\text{CO}_2,\text{actual}}}{1 - 4.773\text{B}_{\text{O}_2,\text{actual}}} \times 100\% \quad 24.11$$

The mass ratio of dry flue gases to solid fuel is given by Eq. 24.12.

$$\frac{\text{mass of flue gas}}{\text{mass of solid fuel}} = \frac{(11\text{B}_{\text{CO}_2} + 8\text{B}_{\text{O}_2} + 7(\text{B}_{\text{CO}} + \text{B}_{\text{N}_2}))}{3(\text{B}_{\text{CO}_2} + \text{B}_{\text{CO}})} \quad 24.12$$

#### Example 24.5

A sulfur-free coal has a proximate analysis of 75% carbon. The volumetric analysis of the flue gas is 80.2% nitrogen, 12.6% carbon dioxide, 6.2% oxygen, and 1.0% carbon monoxide. Calculate the (a) actual air/fuel ratio, (b) percentage excess air, (c) ultimate carbon dioxide, and (d) mass of flue gas per mass of fuel.

*Solution*

(a) Use Eq. 24.9.

$$\begin{aligned} R_{a/f,\text{actual}} &= \frac{3.04\text{B}_{\text{N}_2}\text{G}_C}{\text{B}_{\text{CO}_2} + \text{B}_{\text{CO}}} \\ &= \frac{(3.04)(0.802)(0.75)}{0.126 + 0.01} \\ &= 13.4 \text{ lbm air/lbm fuel (kg air/kg fuel)} \end{aligned}$$

(b) Use Eq. 24.10.

$$\begin{aligned} \text{actual excess air} &= \frac{\text{B}_{\text{O}_2} - 0.5\text{B}_{\text{CO}}}{0.264\text{B}_{\text{N}_2} - \text{B}_{\text{O}_2} + 0.5\text{B}_{\text{CO}}} \times 100\% \\ &= \frac{0.062 - (0.5)(0.01)}{(0.264)(0.802)} \times 100\% \\ &\quad - 0.062 + (0.5)(0.01) \\ &= 36.8\% \text{ by volume} \end{aligned}$$

(c) Use Eq. 24.11.

$$\begin{aligned} \text{ultimate CO}_2 &= \frac{\text{B}_{\text{CO}_2,\text{actual}}}{1 - 4.773\text{B}_{\text{O}_2,\text{actual}}} \times 100\% \\ &= \frac{0.126}{1 - (4.773)(0.062)} \times 100\% \\ &= 17.9\% \text{ by volume} \end{aligned}$$

(d) Use Eq. 24.12.

$$\begin{aligned} & (11B_{\text{CO}_2} + 8B_{\text{O}_2} + 7(B_{\text{CO}} + B_{\text{N}_2})) \\ \frac{\text{mass of flue gas}}{\text{mass of solid fuel}} &= \frac{\times \left( G_{\text{C}} + \frac{G_{\text{S}}}{1.833} \right)}{3(B_{\text{CO}_2} + B_{\text{CO}})} \\ &= \frac{\left( (11)(0.126) + (8)(0.062) \right) (0.75)}{(3)(0.126 + 0.01)} \\ &= 13.9 \text{ lbm flue gas/lbm fuel} \\ &\quad (\text{kg flue gas/kg fuel}) \end{aligned}$$

### 33. TEMPERATURE OF FLUE GAS

The temperature of the gas at the furnace outlet—before the gas reaches any other equipment—should be approximately 550°F (300°C). Overly low temperatures mean there is too much excess air. Overly high temperatures—above 750°F (400°C)—mean that heat is being wasted to the atmosphere and indicate other problems (ineffective heat transfer surfaces, overfiring, defective combustion chamber, etc.).

The *net stack temperature* is the difference between the stack and local environment temperatures. The net stack temperature should be as low as possible without causing corrosion of the low end.

### 34. DEW POINT OF FLUE GAS MOISTURE

The *dew point* is the temperature at which the water vapor in the flue gas begins to condense in a constant pressure process. To avoid condensation and corrosion in the stack, the temperature of the flue gases must be above the dew point. When there is no sulfur in the fuel, the dew point is typically around 100°F (40°C). The presence of sulfur in virtually any quantity increases the actual dew point to approximately 300°F (150°C).<sup>27</sup>

*Dalton's law* predicts the dew point of moisture in the flue gas. The partial pressure of the water vapor depends on the mole fraction (i.e., the volumetric fraction) of water vapor. The higher the water vapor pressure, the higher the dew point. Air entering a furnace can also contribute to moisture in the flue gas. This moisture should be added to the water vapor from combustion when calculating the mole fraction.

$$\frac{\text{water vapor}}{\text{partial pressure}} = \frac{(\text{water vapor mole fraction})}{\times (\text{flue gas pressure})}$$

24.13

<sup>27</sup>The theoretical dew point is even higher—up to 350–400°F (175–200°C). For complex reasons, the theoretical value is not attained.

Once the water vapor's partial pressure is known, the dew point can be found from steam tables as the saturation temperature corresponding to the partial pressure.

### 35. HEAT OF COMBUSTION

The *heating value* of a fuel can be determined experimentally in a *bomb calorimeter*, or it can be estimated from the fuel's chemical analysis. The *higher heating value* (HHV), or *gross heating value*, of a fuel includes the heat of vaporization (condensation) of the water vapor formed from the combustion of hydrogen in the fuel. The *lower heating value* (LHV), or *net heating value*, assumes that all the products of combustion remain gaseous. The LHV is generally the value to use in calculations of thermal energy generated, since the heat of vaporization is not recovered within the furnace.

Traditionally, heating values have been reported on an HHV basis for coal-fired systems but on an LHV basis for natural gas-fired combustion turbines. There is an 11% difference between HHV and LHV thermal efficiencies for gas-fired systems and a 4% difference for coal-fired systems, approximately.

The HHV can be calculated from the LHV if the enthalpy of vaporization,  $h_{fg}$ , is known at the pressure of the water vapor.<sup>28</sup> In Eq. 24.14,  $m_{\text{water}}$  is the mass of water produced per unit (lbm, mole, m<sup>3</sup>, etc.) of fuel.

$$\text{HHV} = \text{LHV} + m_{\text{water}} h_{fg} \quad 24.14$$

As presented in Sec. 24.6, only the hydrogen that is not locked up with oxygen in the form of water is combustible. This is known as the *available hydrogen*. The correct percentage of combustible hydrogen,  $G_{\text{H,available}}$ , is calculated from the hydrogen and oxygen fraction. Equation 24.15 (same as Eq. 24.2) assumes that all of the oxygen is present in the form of water.

$$G_{\text{H,available}} = G_{\text{H,total}} - \frac{G_{\text{O}}}{8} \quad 24.15$$

*Dulong's formula* calculates the higher heating value of coals and coke with a 2–3% accuracy range for moisture contents below approximately 10%.<sup>29</sup> The gravimetric or volumetric analysis percentages for each combustible element (including sulfur) are multiplied by the heating

<sup>28</sup>For the purpose of initial studies, the heat of vaporization is usually assumed to be 1040 Btu/lbm (2.42 MJ/kg). This corresponds to a partial pressure of approximately 1 psia (7 kPa) and a dew point of 100°F (40°C).

<sup>29</sup>The coefficients in Eq. 24.16 are slightly different from the coefficients originally proposed by Dulong. Equation 24.16 reflects currently accepted heating values that were unavailable when Dulong developed his formula. Equation 24.16 makes these assumptions: (1) None of the oxygen is in carbonate form. (2) There is no free oxygen. (3) The hydrogen and carbon are not combined as hydrocarbons. (4) Carbon is amorphous, not graphitic. (5) Sulfur is not in sulfate form. (6) Sulfur burns to sulfur dioxide.

value per unit (mass or volume) from App. 24.A and summed.

$$\text{HHV}_{\text{MJ/kg}} = 32.78G_C + 141.8 \left( G_H - \frac{G_O}{8} \right) + 9.264G_S \quad [\text{SI}] \quad 24.16(a)$$

$$\text{HHV}_{\text{Btu/lbm}} = 14,093G_C + 60,958 \left( G_H - \frac{G_O}{8} \right) + 3983G_S \quad [\text{U.S.}] \quad 24.16(b)$$

The higher heating value of gasoline can be approximated from the Baumé specific gravity,  ${}^{\circ}\text{Be}$ .

$$\text{HHV}_{\text{gasoline,MJ/kg}} = 42.61 + 0.093({}^{\circ}\text{Be} - 10) \quad [\text{SI}] \quad 24.17(a)$$

$$\text{HHV}_{\text{gasoline,Btu/lbm}} = 18,320 + 40({}^{\circ}\text{Be} - 10) \quad [\text{U.S.}] \quad 24.17(b)$$

The heating value of petroleum oils (including diesel fuel) can also be approximately determined from the oil's specific gravity. The values derived by using Eq. 24.18 may not exactly agree with values for specific oils because the equation does not account for refining methods and sulfur content. Equation 24.18 was originally intended for combustion at constant volume, as in a gasoline engine. However, variations in heating values for different oils are very small; therefore, Eq. 24.18 is widely used as an approximation for all types of combustion, including constant pressure combustion in industrial boilers.

$$\text{HHV}_{\text{fuel oil,MJ/kg}} = 51.92 - 8.792(\text{SG})^2 \quad [\text{SI}] \quad 24.18(a)$$

$$\text{HHV}_{\text{fuel oil,Btu/lbm}} = 22,320 - 3780(\text{SG})^2 \quad [\text{U.S.}] \quad 24.18(b)$$

### Example 24.6

A coal has an ultimate analysis of 93.9% carbon, 2.1% hydrogen, 2.3% oxygen, 0.3% nitrogen, and 1.4% ash. What are its (a) higher and (b) lower heating values in Btu/lbm?

*Solution*

(a) The noncombustible ash, oxygen, and nitrogen do not contribute to heating value. Some of the hydrogen is in the form of water. From Eq. 24.2, the available hydrogen fraction is

$$\begin{aligned} G_{\text{H,available}} &= G_{\text{H,total}} - \frac{G_O}{8} \\ &= 2.1\% - \frac{2.3\%}{8} \\ &= 1.8\% \end{aligned}$$

From App. 24.A, the higher heating values of carbon and hydrogen are 14,093 Btu/lbm and 60,958 Btu/lbm, respectively. From Eq. 24.16, the total heating value per pound of coal is

$$\begin{aligned} \text{HHV} &= 14,093G_C + 60,958G_{\text{H,available}} \\ &= \left( 14,093 \frac{\text{Btu}}{\text{lbm}} \right)(0.939) \\ &\quad + \left( 60,958 \frac{\text{Btu}}{\text{lbm}} \right)(0.018) \\ &= 14,331 \text{ Btu/lbm} \end{aligned}$$

(b) All of the combustible hydrogen forms water vapor. The mass of water produced is equal to the hydrogen mass plus eight times as much oxygen.

$$\begin{aligned} m_w &= m_H + m_{\text{O}_2} = m_{\text{H,available}} + 8m_{\text{H,available}} \\ &= 0.018 + (8)(0.018) \\ &= 0.162 \text{ lbm water/lbm coal} \end{aligned}$$

Assume that the partial pressure of the water vapor is approximately 1 psia (7 kPa). Then, from steam tables, the heat of condensation will be 1040 Btu/lbm. From Eq. 24.14, the lower heating value is approximately

$$\begin{aligned} \text{LHV} &= \text{HHV} - m_w h_{fg} \\ &= 14,331 \frac{\text{Btu}}{\text{lbm}} - \left( 0.162 \frac{\text{lbm}}{\text{lbm}} \right) \left( 1040 \frac{\text{Btu}}{\text{lbm}} \right) \\ &= 14,163 \text{ Btu/lbm} \end{aligned}$$

Alternatively, the lower heating value of the coal can be calculated from Eq. 24.16 by substituting the lower (net) hydrogen heating value from App. 24.A, 51,623 Btu/lbm, for the gross heating value of 60,598 Btu/lbm. This yields 14,167 Btu/lbm.

### 36. MAXIMUM THEORETICAL COMBUSTION (FLAME) TEMPERATURE

It can be assumed that the maximum theoretical increase in flue gas temperature will occur if all of the combustion energy is absorbed adiabatically by the smallest possible quantity of combustion products. This provides a method of estimating the *maximum theoretical combustion temperature*, also sometimes called the *maximum flame temperature* or *adiabatic flame temperature*.<sup>30</sup>

In Eq. 24.19, the mass of the products is the sum of the fuel, oxygen, and nitrogen masses for stoichiometric combustion. The mean specific heat is a gravimetrically

<sup>30</sup>Flame temperature is limited by the dissociation of common reaction products ( $\text{CO}_2$ ,  $\text{N}_2$ , etc.). At high enough temperatures (3400–3800°F; 1880–2090°C), the endothermic dissociation process reabsorbs combustion heat and the temperature stops increasing. The temperature at which this occurs is known as the *dissociation temperature (maximum flame temperature)*. This definition of flame temperature is not a function of heating values and flow rates.

weighted average of the values of  $c_p$  for all combustion gases. (Since nitrogen comprises the majority of the combustion gases, the mixture's specific heat will be approximately that of nitrogen.) The heat of combustion can be found either from the lower heating value, LHV, or from a difference in air enthalpies across the furnace.

$$T_{\max} = T_i + \frac{\text{LHV}}{m_{\text{products}} c_{p,\text{mean}}} \quad 24.19$$

Due to thermal losses, incomplete combustion, and excess air, actual flame temperatures are always lower than the theoretical temperature. Most fuels produce flame temperatures in the range of 3350–3800°F (1850–2100°C).

### 37. COMBUSTION LOSSES

A portion of the combustion energy is lost in heating the dry flue gases,  $q_1$ .<sup>31</sup> This is known as *dry flue gas loss*. In Eq. 24.20,  $m_{\text{flue gas}}$  is the mass of dry flue gas per unit mass of fuel. It can be estimated from Eq. 24.12. Although the full temperature difference is used, the specific heat should be evaluated at the average temperature of the flue gas. For quick estimates, the dry flue gas can be assumed to be pure nitrogen.

$$q_1 = m_{\text{flue gas}} c_p (T_{\text{flue gas}} - T_{\text{incoming air}}) \quad 24.20$$

Heat is lost in vaporizing the water formed during the combustion of hydrogen. In Eq. 24.21,  $m_{\text{vapor}}$  is the mass of vapor per pound of fuel.  $G_H$  is the gravimetric fraction of hydrogen in the fuel. The coefficient 8.94 is essentially  $8 + 1 = 9$  and converts the gravimetric mass of hydrogen to gravimetric mass of water formed.  $h_g$  is the enthalpy of superheated steam at the flue gas temperature and the partial pressure of the water vapor.  $h_f$  is the enthalpy of saturated liquid at the air's entrance temperature.

$$q_2 = m_{\text{vapor}} (h_g - h_f) = 8.94 G_H (h_g - h_f) \quad 24.21$$

Heat is lost when it is absorbed by moisture originally in the combustion air (and by free moisture in the fuel, if any). In Eq. 24.22,  $m_{\text{combustion air}}$  is the mass of combustion air per pound of fuel.  $\omega$  is the humidity ratio.  $h'_g$  is the enthalpy of superheated steam at the air's entrance temperature and partial pressure of the water vapor.

$$\begin{aligned} q_3 &= m_{\text{atmospheric water vapor}} (h_g - h'_g) \\ &= \omega m_{\text{combustion air}} (h_g - h'_g) \end{aligned} \quad 24.22$$

<sup>31</sup>The abbreviation “dfg” for dry flue gas is peculiar to the combustion industry. It may not be recognized outside of that field.

When carbon monoxide appears in the flue gas, potential energy is lost in incomplete combustion. The higher heating value of carbon monoxide in combustion to CO<sub>2</sub> is 4347 Btu/lbm (9.72 MJ/kg).<sup>32</sup>

$$q_4 = \frac{2.334 \text{HHV}_{\text{CO}} G_C B_{\text{CO}}}{B_{\text{CO}_2} + B_{\text{CO}}} \quad 24.23$$

For solid fuels, energy is lost in unburned carbon in the ash. (Some carbon may be carried away in the flue gas, as well.) This is known as *combustible loss* or *unburned fuel loss*. In Eq. 24.24,  $m_{\text{ash}}$  is the mass of ash produced per pound of fuel consumed.  $G_{\text{C,ash}}$  is the gravimetric fraction of carbon in the ash. The heating value of carbon is 14,093 Btu/lbm (32.8 MJ/kg).

$$q_5 = \text{HHV}_{\text{C}} m_{\text{ash}} G_{\text{C,ash}} \quad 24.24$$

Energy is also lost through radiation from the exterior boiler surfaces. This can be calculated if enough information is known. The *radiation loss* is fairly insensitive to different firing rates, and once calculated it can be considered constant for different conditions.

Other conditions where energy can be lost include air leaks, poor pulverizer operation, excessive blowdown, steam leaks, missing or loose insulation, and excessive soot-blower operation. Losses due to these sources must be evaluated on a case-by-case basis. The term *manufacturer's margin* is used to describe an accumulation of various unaccounted-for losses, which can include incomplete combustion to CO, energy loss in ash, instrument errors, energy carried away by atomizing steam, sulfation and calcination reactions in fluidized bed combustion boilers, and loss due to periodic blowdown. It can be 0.25–1.5% of all energy inputs, depending on the type of combustor/boiler.

### 38. COMBUSTION EFFICIENCY

The *combustion efficiency* (also referred to as *boiler efficiency*, *furnace efficiency*, and *thermal efficiency*) is the overall thermal efficiency of the combustion reaction. Furnace/boilers for all fuels (e.g., coal, oil, and gas) with air heaters and economizers have 75–85% efficiency ranges, with all modern installation trending to the higher end of the range.

In Eq. 24.25,  $m_{\text{steam}}$  is the mass of steam produced per pound of fuel burned. The useful heat may also be determined from the boiler rating. One *boiler*

<sup>32</sup>2.334 is the ratio of the molecular weight of carbon monoxide (28.01) to carbon (12), which is necessary to convert the higher heating value of carbon monoxide from a mass of CO to a mass of C. The product 2.334HHV<sub>CO</sub> is often stated as 10,160 Btu/lbm (23.63 MJ/kg), although the actual calculated value is somewhat less. Other values such as 10,150 Btu/lbm (23.61 MJ/kg) and 10,190 Btu/lbm (23.70 MJ/kg) are encountered.

horsepower equals approximately 33,475 Btu/hr (9.8106 kW).<sup>33</sup>

$$\eta = \frac{\text{useful heat extracted}}{\text{heating value}}$$

$$= \frac{m_{\text{steam}}(h_{\text{steam}} - h_{\text{feedwater}})}{\text{HHV}} \quad 24.25$$

Calculating the efficiency by subtracting all known losses is known as the *loss method*. Minor sources of thermal energy, such as the entering air and feedwater, are essentially disregarded.

$$\eta = \frac{\text{HHV} - q_1 - q_2 - q_3 - q_4 - q_5 - \text{radiation}}{\text{HHV}} \quad 24.26$$

$$= \frac{\text{LHV} - q_1 - q_4 - q_5 - \text{radiation}}{\text{HHV}}$$

Combustion efficiency can be improved by decreasing either the temperature or the volume of the flue gas or both. Since the latent heat of moisture is a loss, and since the amount of moisture generated corresponds to the hydrogen content of the fuel, a minimum efficiency loss due to moisture formation cannot be eliminated. This minimum loss is approximately 13% for natural gas, 8% for oil, and 6% for coal.

<sup>33</sup>Boiler horsepower is sometimes equated with a gross heating rate of 44,633 Btu/hr (13.08 kW). However, this is the total incoming heating value assuming a standardized 75% combustion efficiency.

### 1. CATIONS AND ANIONS IN NEUTRAL SOLUTIONS

Equivalency concepts provide a useful check on the accuracy of water analyses. For the water to be electrically neutral, the sum of anion equivalents must equal the sum of cation equivalents.

Concentrations of dissolved compounds in water are usually expressed in mg/L, not equivalents. (See Sec. 22.18.) However, anionic and cationic substances

can be converted to their equivalent concentrations in milliequivalents per liter (meq/L) by dividing their concentrations in mg/L by their equivalent weights. Appendix 22.B is useful for this purpose.

Since water is an excellent solvent, it will contain the ions of the inorganic compounds to which it is exposed. A chemical analysis listing these ions does not explicitly determine the compounds from which the ions originated. Several graphical methods, such as bar graphs and Piper (Hill) trilinear diagrams, can be used for this purpose. The bar graph, also known as a *milliequivalent per liter bar chart*, is constructed by listing the cations (positive ions) in the sequence of calcium (Ca<sup>++</sup>), magnesium (Mg<sup>++</sup>), sodium (Na<sup>+</sup>), and potassium (K<sup>+</sup>), and pairing them with the anions (negative ions) in the sequence of carbonate (CO<sub>3</sub><sup>2-</sup>), bicarbonate (HCO<sub>3</sub><sup>-</sup>), sulfate (SO<sub>4</sub><sup>2-</sup>), and chloride (Cl<sup>-</sup>). A bar chart, such as the one shown in Ex. 25.1, can be used to deduce the hypothetical combinations of positive and negative ions that would have resulted in the given water analysis.

#### Example 25.1

A water analysis reveals the following ionic components in solution: Ca<sup>++</sup>, 29.0 mg/L; Mg<sup>++</sup>, 16.4 mg/L; Na<sup>+</sup>, 23.0 mg/L; K<sup>+</sup>, 17.5 mg/L; HCO<sub>3</sub><sup>-</sup>, 171 mg/L; SO<sub>4</sub><sup>2-</sup>, 36.0 mg/L; Cl<sup>-</sup>, 24.0 mg/L. Verify that the analysis is reasonably accurate. Draw the milliequivalent per liter bar chart.

#### Solution

Use the equivalent weights in App. 22.B to complete the following table.

compound	concentration (mg/L)	equivalent weight (g/mol)	equivalent (meq/L)
<i>cations</i>			
Ca <sup>++</sup>	29.0	20.0	1.45
Mg <sup>++</sup>	16.4	12.2	1.34
Na <sup>+</sup>	23.0	23.0	1.00
K <sup>+</sup>	17.5	39.1	0.44
		total	4.23
<i>anions</i>			
HCO <sub>3</sub> <sup>-</sup>	171.0	61.0	2.80
SO <sub>4</sub> <sup>2-</sup>	36.0	48.0	0.75
Cl <sup>-</sup>	24.0	35.5	0.68
		total	4.23

The sums of the cation equivalents and anion equivalents are equal. The analysis is presumed to be reasonably accurate.

	1.45	2.79	3.79	4.23
Ca <sup>++</sup>	Mg <sup>++</sup>	Na <sup>+</sup>	K <sup>+</sup>	
HCO <sub>3</sub> <sup>-</sup>		SO <sub>4</sub> <sup>2-</sup>	Cl <sup>-</sup>	
	2.80	3.55	4.23	

## 2. ACIDITY

Acidity is a measure of acids in solution. Acidity in surface water is caused by formation of carbonic acid (H<sub>2</sub>CO<sub>3</sub>) from carbon dioxide in the air. (See Eq. 25.1.) Carbonic acid is aggressive and must be neutralized to eliminate a cause of water pipe corrosion. If the pH of water is greater than 4.5, carbonic acid ionizes to form bicarbonate. (See Eq. 25.2.) If the pH is greater than 8.3, carbonate ions form. (See Eq. 25.3.)

Measurement of acidity is done by titration with a standard basic measuring solution. Acidity, *A*, in water is typically given in terms of the CaCO<sub>3</sub> equivalent that would neutralize the acid. The constant 50 000 used in Eq. 25.4 is the product of the equivalent weight of CaCO<sub>3</sub> (50 g) and 1000 mg/g.

$$A_{\text{mg/L as CaCO}_3} = \frac{V_{\text{titrant,mL}} N_{\text{titrant}} (50\,000)}{V_{\text{sample,mL}}} \quad 25.4$$

The standard titration procedure for determining acidity measures the amount of titrant needed to raise the pH to 3.7 plus the amount needed to raise the pH to 8.3. The total of these two is used in Eq. 25.4. Most water samples, unless grossly polluted with industrial wastes, will exist at a pH greater than 3.7, so the titration will be a one-step process.

## 3. ALKALINITY

Alkalinity is a measure of the ability of a water to neutralize acids (i.e., to absorb hydrogen ions without significant pH change). The principal alkaline ions are OH<sup>-</sup>, CO<sub>3</sub><sup>2-</sup>, and HCO<sub>3</sub><sup>-</sup>. Other radicals, such as NO<sub>3</sub><sup>-</sup>, also contribute to alkalinity, but their presence is rare. The measure of alkalinity is the sum of concentrations of each of the substances measured as equivalent CaCO<sub>3</sub>.

The standard titration method for determining alkalinity measures the amount of acidic titrant needed to lower the pH to 8.3 plus the amount needed to lower the pH to 4.5. Therefore, alkalinity, *M*, is the sum of all titratable base concentrations down to a pH of 4.5. The

constant 50 000 in Eq. 25.5 is the product of the equivalent weight of CaCO<sub>3</sub> (50 g) and 1000 mg/g.

$$M_{\text{mg/L as CaCO}_3} = \frac{V_{\text{titrant,mL}} N_{\text{titrant}} (50\,000)}{V_{\text{sample,mL}}} \quad 25.5$$

## Example 25.2

Water from a city well is analyzed and found to contain 20 mg/L as substance of HCO<sub>3</sub><sup>-</sup> and 40 mg/L as substance of CO<sub>3</sub><sup>2-</sup>. What is the alkalinity of the water expressed as CaCO<sub>3</sub>?

*Solution*

From App. 22.B, the equivalent weight of HCO<sub>3</sub><sup>-</sup> is 61 g/mol, the equivalent weight of CO<sub>3</sub><sup>2-</sup> is 30 g/mol, and the equivalent weight of CaCO<sub>3</sub> is 50 g/mol.

$$\begin{aligned} M_{\text{mg/L of CaCO}_3} &= \left(20 \frac{\text{mg}}{\text{L}}\right) \left(\frac{50 \frac{\text{g}}{\text{mol}}}{61 \frac{\text{g}}{\text{mol}}}\right) \\ &\quad + \left(40 \frac{\text{mg}}{\text{L}}\right) \left(\frac{50 \frac{\text{g}}{\text{mol}}}{30 \frac{\text{g}}{\text{mol}}}\right) \\ &= 83.1 \text{ mg/L as CaCO}_3 \end{aligned}$$

## 4. INDICATOR SOLUTIONS

End points for acidity and alkalinity titrations are determined by color changes in indicator dyes that are pH sensitive. Several commonly used indicators are listed in Table 25.1.

**Table 25.1** Indicator Solutions Commonly Used in Water Chemistry

indicator	titration	end point pH	color change
bromophenol blue	acidity	3.7	yellow to blue
phenolphthalein	acidity	8.3	colorless to red-violet
phenolphthalein	alkalinity	8.3	red-violet to colorless
mixed brom cresol/ green-methyl red	alkalinity	4.5	grayish to orange-red

Depending on pH, alkaline samples can contain hydroxide alone, hydroxide and carbonate, carbonate alone, carbonate and bicarbonate, or bicarbonate alone. Samples containing hydroxide or hydroxide and carbonate have a high pH, usually greater than 10. If the titration is complete at the phenolphthalein end point (i.e., the mixed brom cresol green-methyl red indicator does not change color), the alkalinity is hydroxide alone. Samples containing carbonate and

bicarbonate alkalinity have a pH greater than 8.3, and the titration to the phenolphthalein end point represents stoichiometrically one-half of the carbonate alkalinity. If the volume of phenolphthalein titrant equals the volume of titrant needed to reach the mixed bromocresol green-methyl red end point, all of the alkalinity is in the form of carbonate.

If abbreviations of  $P$  for the measured phenolphthalein alkalinity and  $M$  for the total alkalinity are used, the following relationships define the possible alkalinity states of the sample. In sequence, the relationships can be used to determine the actual state of a sample.

- (state I) hydroxide =  $P = M$
- (state II) hydroxide =  $2P - M$  and  
carbonate =  $2(M - P)$
- (state III) carbonate =  $2P = M$
- (state IV) carbonate =  $2P$  and  
bicarbonate =  $M - 2P$
- (state V) bicarbonate =  $M$

### Example 25.3

A 100 mL sample is titrated for alkalinity by using 0.02 N sulfuric acid solution. To reach the phenolphthalein end point requires 3.0 mL of the acid solution, and an additional 12.0 mL is added to reach the mixed bromocresol green-methyl red end point. Calculate the (a) phenolphthalein alkalinity and (b) total alkalinity. (c) What are the ionic forms of alkalinity present?

*Solution*

(a) Use Eq. 25.5.

$$\begin{aligned} P &= \frac{V_{\text{titrant,mL}} N_{\text{titrant}} (50000)}{V_{\text{sample,mL}}} \\ &= \frac{(3.0 \text{ mL}) \left( 0.02 \frac{\text{gEW}}{\text{L}} \right) \left( 50000 \frac{\text{mg}}{\text{gEW}} \right)}{100 \text{ mL}} \\ &= 30 \text{ mg/L (as CaCO}_3 \text{)} \end{aligned}$$

(b) Use Eq. 25.5.

$$\begin{aligned} M &= \frac{V_{\text{titrant,mL}} N_{\text{titrant}} (50000)}{V_{\text{sample,mL}}} \\ &= \frac{(3.0 \text{ mL} + 12.0 \text{ mL})}{100 \text{ mL}} \times \left( 0.02 \frac{\text{gEW}}{\text{L}} \right) \left( 50000 \frac{\text{mg}}{\text{gEW}} \right) \\ &= 150 \text{ mg/L (as CaCO}_3 \text{)} \end{aligned}$$

(c) Test the state relationships in sequence.

(I) hydroxide =  $P = M$ :

$$30 \text{ mg/L} \neq 150 \text{ mg/L}$$

(invalid:  $P \neq M$ )

(II) hydroxide =  $2P - M$ :

$$\begin{aligned} (2) \left( 30 \frac{\text{mg}}{\text{L}} \right) - 150 \frac{\text{mg}}{\text{L}} \\ = -90 \text{ mg/L} \end{aligned}$$

(invalid: negative value)

(III) carbonate =  $2P = M$ :

$$(2) \left( 30 \frac{\text{mg}}{\text{L}} \right) \neq 150 \text{ mg/L}$$

(invalid:  $2P \neq M$ )

(IV) carbonate =  $2P$ :

$$\begin{aligned} (2) \left( 30 \frac{\text{mg}}{\text{L}} \right) &= 60 \text{ mg/L} \\ \text{bicarbonate} &= M - 2P \\ 150 \frac{\text{mg}}{\text{L}} - (2) \left( 30 \frac{\text{mg}}{\text{L}} \right) &= 90 \text{ mg/L} \end{aligned}$$

The process ends at (IV) since a valid answer is obtained. It is not necessary to check relationship (V), as (IV) gives consistent results. The alkalinity is composed of 60 mg/L as  $\text{CaCO}_3$  of carbonate and 90 mg/L as  $\text{CaCO}_3$  of bicarbonate.

## 5. HARDNESS

*Hardness* in natural water is caused by the presence of polyvalent (but not singly charged) metallic cations. Principal cations causing hardness in water and the major anions associated with them are presented in Table 25.2. Because the most prevalent of these species are the divalent cations of calcium and magnesium, total hardness is typically defined as the sum of the concentration of these two elements and is expressed in terms of milligrams per liter as  $\text{CaCO}_3$ . (Hardness is occasionally expressed in units of *grains per gallon*, where 7000 grains are equal to a pound.)

**Table 25.2** Principal Cations and Anions Indicating Hardness

cations	anions
$\text{Ca}^{++}$	$\text{HCO}_3^-$
$\text{Mg}^{++}$	$\text{SO}_4^{--}$
$\text{Sr}^{++}$	$\text{Cl}^-$
$\text{Fe}^{++}$	$\text{NO}_3^-$
$\text{Mn}^{++}$	$\text{SiO}_3^{--}$

*Carbonate hardness* is caused by cations from the dissolution of calcium or magnesium carbonate and bicarbonate in the water. Carbonate hardness is hardness that is chemically equivalent to alkalinity, where most of the alkalinity in natural water is caused by the bicarbonate and carbonate ions.

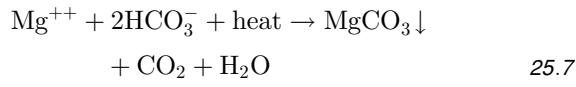

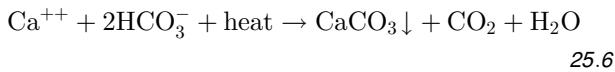

*Noncarbonate hardness* is caused by cations from calcium (i.e., calcium hardness) and magnesium (i.e., magnesium hardness) compounds of sulfate, chloride, or silicate that are dissolved in the water. Noncarbonate hardness is equal to the total hardness minus the carbonate hardness.

Hardness can be classified as shown in Table 25.3. Although high values of hardness do not present a health risk, they have an impact on the aesthetic acceptability of water for domestic use. (Hardness reacts with soap to reduce its cleansing effectiveness and to form scum on the water surface.) Where feasible, carbonate hardness in potable water should be reduced to the 25–40 mg/L range and total hardness reduced to the 50–75 mg/L range.

**Table 25.3** Relationship of Hardness Concentration to Classification

hardness (mg/L as CaCO <sub>3</sub> )	classification
0 to 60	soft
61 to 120	moderately hard
121 to 180	hard
181 to 350	very hard
> 350	saline; brackish

Water containing bicarbonate (HCO<sub>3</sub><sup>-</sup>) can be heated to precipitate carbonate (CO<sub>3</sub><sup>2-</sup>) as a *scale*. Water used in steam-producing equipment (e.g., boilers) must be essentially hardness-free to avoid deposit of scale.

*Noncarbonate hardness*, also called *permanent hardness*, cannot be removed by heating. It can be removed by precipitation softening processes (typically the lime-soda ash process) or by ion exchange processes using resins selective for ions causing hardness.

Hardness is measured in the laboratory by titrating the sample using a standardized solution of ethylenediaminetetraacetic acid (EDTA) and an indicator dye such as Eriochrome Black T. The sample is titrated at a pH of approximately 10 until the dye color changes from red to blue. The standardized solution of EDTA is usually prepared such that 1 mL of EDTA is equivalent to 1 mg/L of hardness, but Eq. 25.8 can be used to determine hardness with any strength EDTA solution.

$$H_{\text{mg/L as CaCO}_3} = \frac{V_{\text{titrant,mL}}(\text{CaCO}_3 \text{ equivalent of EDTA})(1000)}{V_{\text{sample,mL}}} \quad 25.8$$

#### Example 25.4

A water sample contains sodium (Na<sup>+</sup>, 15 mg/L), magnesium (Mg<sup>++</sup>, 70 mg/L), and calcium (Ca<sup>++</sup>, 40 mg/L). What is the hardness?

#### Solution

Sodium is singly charged, so it does not contribute to hardness. The necessary approximate equivalent weights are found in App. 22.B.

$$\begin{aligned} \text{Mg: } &12.2 \text{ g/mol} \\ \text{Ca: } &20.0 \text{ g/mol} \\ \text{CaCO}_3: &50 \text{ g/mol} \end{aligned}$$

The equivalent hardness is

$$\begin{aligned} H &= \left(70 \frac{\text{mg}}{\text{L}}\right) \left(\frac{50 \frac{\text{g}}{\text{mol}}}{12.2 \frac{\text{g}}{\text{mol}}}\right) + \left(40 \frac{\text{mg}}{\text{L}}\right) \left(\frac{50 \frac{\text{g}}{\text{mol}}}{20 \frac{\text{g}}{\text{mol}}}\right) \\ &= 387 \text{ mg/L (as CaCO}_3\text{)} \end{aligned}$$

#### Example 25.5

A 75 mL water sample was titrated using 8.1 mL of an EDTA solution formulated such that 1 mL of EDTA is equivalent to 0.8 mg/L of CaCO<sub>3</sub>. What is the hardness of the sample, measured in terms of mg/L of CaCO<sub>3</sub>?

#### Solution

Use Eq. 25.8.

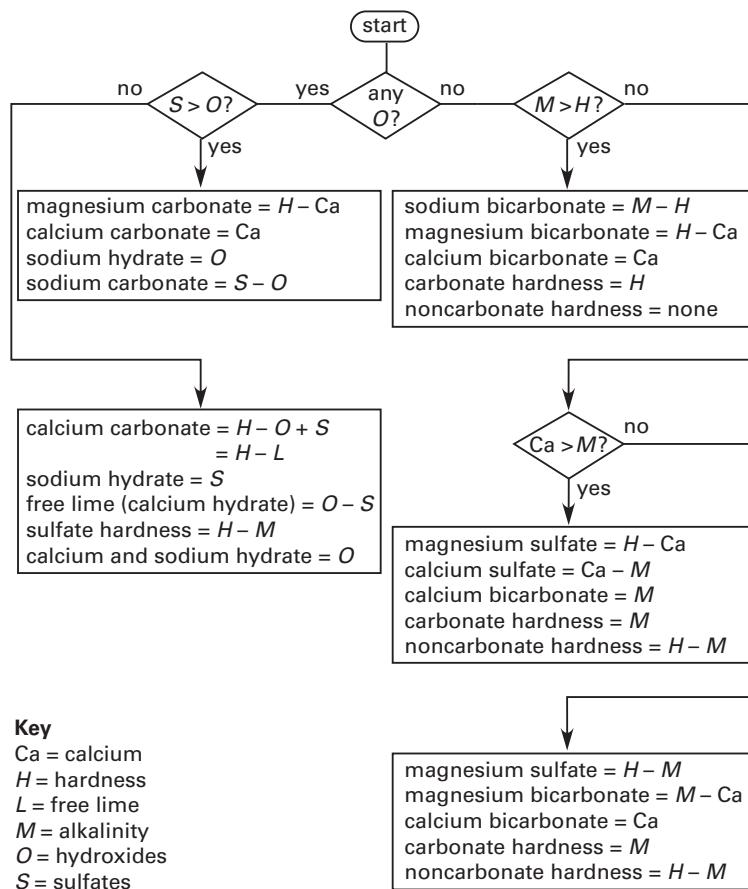

$$\begin{aligned} H &= \frac{V_{\text{titrant,mL}}(\text{CaCO}_3 \text{ equivalent of EDTA})(1000)}{V_{\text{sample,mL}}} \\ &= \frac{(8.1 \text{ mL})\left(0.8 \frac{\text{gEW}}{\text{L}}\right)\left(1000 \frac{\text{mg}}{\text{gEW}}\right)}{75 \text{ mL}} \\ &= 86.4 \text{ mg/L (as CaCO}_3\text{)} \end{aligned}$$

## 6. HARDNESS AND ALKALINITY

Hardness is caused by multi-positive ions. Alkalinity is caused by negative ions. Both positive and negative ions are present simultaneously. Therefore, an alkaline water can also be hard.

With some assumptions and minimal information about the water composition, it is possible to determine the ions in the water from the hardness and alkalinity. For example, Fe<sup>++</sup> is an unlikely ion in most water supplies, and it is often neglected. Figure 25.1 can be used to quickly deduce the compounds in the water from hardness and alkalinity.

If hardness and alkalinity (both as CaCO<sub>3</sub>) are the same and there are no monovalent cations, then there are no SO<sub>4</sub><sup>2-</sup>, Cl<sup>-</sup>, or NO<sub>3</sub><sup>-</sup> ions present. That is, there is no noncarbonate (permanent) hardness. If hardness is greater than the alkalinity, however, then noncarbonate hardness is present, and the carbonate (temporary) hardness is equal to the alkalinity. If hardness is less than the alkalinity, then all hardness is carbonate hardness, and the extra HCO<sub>3</sub><sup>-</sup> comes from other sources (such as NaHCO<sub>3</sub>).

**Figure 25.1** Hardness and Alkalinity<sup>a,b</sup><sup>a</sup>All concentrations are expressed as  $\text{CaCO}_3$ .<sup>b</sup>Not for use when other ionic species are present in significant quantities**Example 25.6**

A water sample analysis results in the following: alkalinity, 220 mg/L; hardness, 180 mg/L;  $\text{Ca}^{++}$ , 140 mg/L;  $\text{OH}^-$ , insignificant. All concentrations are expressed as  $\text{CaCO}_3$ . (a) What is the noncarbonate hardness? (b) What is the  $\text{Mg}^{++}$  content in mg/L as substance?

*Solution*

(a) Use Fig. 25.1 with  $M > H$  (alkalinity greater than hardness).

$$[\text{NaHCO}_3] = M - H = 220 \frac{\text{mg}}{\text{L}} - 180 \frac{\text{mg}}{\text{L}} \\ = 40 \text{ mg/L (as } \text{CaCO}_3\text{)}$$

$$[\text{Mg}(\text{HCO}_3)_2] = H - \text{Ca} = 180 \frac{\text{mg}}{\text{L}} - 140 \frac{\text{mg}}{\text{L}} \\ = 40 \text{ mg/L (as } \text{CaCO}_3\text{)}$$

$$[\text{Ca}(\text{HCO}_3)_2] = \text{Ca} = 140 \text{ mg/L (as } \text{CaCO}_3\text{)}$$

$$\text{carbonate hardness} = H = 180 \text{ mg/L (as } \text{CaCO}_3\text{)}$$

$$\text{noncarbonate hardness} = 0$$

(b) The  $\text{Mg}^{++}$  ion content as  $\text{CaCO}_3$  is equal to the  $\text{Mg}(\text{HCO}_3)_2$  content as  $\text{CaCO}_3$ . Use App. 22.B to convert  $\text{CaCO}_3$  equivalents to amounts as substance. To convert  $\text{Mg}^{++}$  as  $\text{CaCO}_3$  to  $\text{Mg}^{++}$  as substance, use a factor of 4.1.

$$\text{Mg}^{++} = \frac{40 \frac{\text{mg}}{\text{L}}}{4.1} = 9.8 \text{ mg/L (as substance)}$$

**7. NATIONAL PRIMARY DRINKING WATER STANDARDS**

Following passage of the Safe Drinking Water Act in the United States, the Environmental Protection Agency (EPA) established minimum primary drinking water standards. These standards set limits on the amount of various substances in drinking water. Every public water supply serving at least 15 service connections or 25 or more people must ensure that its water meets these minimum standards.

Accordingly, the EPA has established the National Primary Drinking Water Standards, outlined in App. 25.A, and the National Secondary Drinking Water Standards. The primary standards establish *maximum contaminant levels* (MCL) and *maximum contaminant level goals* (MCLG) for materials that are known or suspected health hazards. The MCL is the enforceable level that the water supplier must not exceed, while the MCLG is an unenforceable health goal equal to the maximum level of a contaminant that is not expected to cause any adverse health effects over a lifetime of exposure.

## 8. NATIONAL SECONDARY DRINKING WATER STANDARDS

The national secondary drinking water standards, outlined in Table 25.4, are not designed to protect public health. Instead, they are intended to protect “public welfare” by providing helpful guidelines regarding the taste, odor, color, and other aesthetic aspects of drinking water.

**Table 25.4** National Secondary Drinking Water Standards (Code of Federal Regulations (CFR) Title 40, Ch. I, Part 143)

contaminant	suggested levels	effects
aluminum	0.05–0.2 mg/L	discoloration of water
chloride	250 mg/L	salty taste and pipe corrosion
color	15 color units	visible tint
copper	1.0 mg/L	metallic taste and staining
corrosivity	noncorrosive	taste, staining, and corrosion
fluoride	2.0 mg/L	dental fluorosis
foaming agents	0.5 mg/L	froth, odor, and bitter taste
iron	0.3 mg/L	taste, staining, and sediment
manganese	0.05 mg/L	taste and staining
odor	3 TON*	“rotten egg,” musty, and chemical odor
pH	6.5–8.5	low pH—metallic taste and corrosion high pH—slippery feel, soda taste, and deposits
silver	0.1 mg/L	discoloration of skin and graying of eyes
sulfate	250 mg/L	salty taste and laxative effect
total dissolved solids (TDS)	500 mg/L	taste, corrosivity, and soap interference
zinc	5 mg/L	metallic taste

\*threshold odor number

## 9. IRON

Even at low concentrations, iron is objectionable because it stains porcelain bathroom fixtures, causes a brown color in laundered clothing, and can be tasted. Typically, iron is a problem in groundwater pumped

from anaerobic aquifers in contact with iron compounds. Soluble ferrous ions can be formed under these conditions, which, when exposed to atmospheric air at the surface or to dissolved oxygen in the water system, are oxidized to the insoluble ferric state, causing the color and staining problems mentioned. Iron determinations are made through colorimetric (i.e., wet titration) analysis.

## 10. MANGANESE

Manganese ions are similar in formation, effect, and measurement to iron ions.

## 11. FLUORIDE

Natural fluoride is found in groundwaters as a result of dissolution from geologic formations. Surface waters generally contain much smaller concentrations of fluoride. An absence or low concentration of ingested fluoride causes the formation of tooth enamel less resistant to decay, resulting in a high incidence of dental cavities in children’s teeth. Excessive concentration of fluoride causes *fluorosis*, a brownish discoloration of dental enamel. The MCL of 4.0 mg/L established by the EPA is to prevent unsightly fluorosis.

Communities with water supplies deficient in natural fluoride may chemically add fluoride during the treatment process. Since water consumption is influenced by climate, the recommended optimum concentrations listed in Table 25.5 are based on the annual average of the maximum air temperatures based on a minimum of five years of records.

**Table 25.5** Recommended Optimum Concentrations of Fluoride in Drinking Water

average air temperature range (°F (°C))	recommended optimum concentration (mg/L)
53.7 (12.0) and below	1.2
53.8 to 58.3 (12.1–14.6)	1.1
58.4 to 63.8 (14.7–17.6)	1.0
63.9 to 70.6 (17.7–21.4)	0.9
70.7 to 79.2 (21.5–26.2)	0.8
79.3 to 90.5 (26.3–32.5)	0.7

Compounds commonly used as fluoride sources in water treatment are listed in Table 25.6.

**Table 25.6** Fluoridation Chemicals

compound	formula	percentage F <sup>-</sup> ion (%)
sodium fluoride	NaF	45
sodium silicofluoride	Na <sub>2</sub> SiF <sub>6</sub>	61
hydrofluosilicic acid	H <sub>2</sub> SiF <sub>6</sub>	79
ammonium silicofluoride*	(NH <sub>4</sub> ) <sub>2</sub> SiF <sub>6</sub>	64

\*used in conjunction with chlorine disinfection where it is desired to maintain a chloramine residual in the distribution system

**Example 25.7**

A liquid feeder adds a 4.0% saturated sodium fluoride solution to a water supply, increasing the fluoride concentration from the natural fluoride level of 0.4 mg/L to 1.0 mg/L. The commercial NaF powder used to prepare the NaF solution contains 45% fluoride by weight. (a) How many pounds (kilograms) of NaF are required per million gallons (liters) treated? (b) What volume of 4% NaF solution is used per million gallons (liters)?

*SI Solution*

$$m_{\text{NaF}} = \frac{(1.0 \frac{\text{mg}}{\text{L}} - 0.4 \frac{\text{mg}}{\text{L}})(10^6 \frac{\text{L}}{\text{ML}})}{(0.45)(10^6 \frac{\text{mg}}{\text{kg}})}$$

$$= 1.33 \text{ kg/ML} \quad (\text{kg per million liters})$$

(b) One liter of water has a mass of one kilogram ( $10^6$  mg). Therefore, a 4% NaF solution contains 40 000 mg NaF per liter. The concentration needs to be increased from 0.4 mg/L to 1.0 mg/L.

$$(40000 \frac{\text{mg}}{\text{L}})(0.45) = 18000 \text{ mg/L}$$

$$V = \frac{(1.0 \times 10^6 \frac{\text{L}}{\text{ML}}) \times (1.0 \frac{\text{mg}}{\text{L}} - 0.4 \frac{\text{mg}}{\text{L}})}{18000 \frac{\text{mg}}{\text{L}}}$$

$$= 33.3 \text{ L/ML}$$

*Customary U.S. Solution*

$$m_{\text{NaF}} = \left( \frac{1.0 \frac{\text{mg}}{\text{L}} - 0.4 \frac{\text{mg}}{\text{L}}}{0.45} \right) \left( 8.345 \frac{\text{lbf-MG}}{\text{mg-MG}} \right)$$

$$= 11.1 \text{ lbm/MG} \quad (\text{lbf per million gallons})$$

(b) A 4% NaF solution contains 40,000 mg NaF per liter. The concentration needs to be increased from 0.4 mg/L to 1.0 mg/L.

$$(40,000 \frac{\text{mg}}{\text{L}})(0.45) = 18,000 \text{ mg/L}$$

$$V = \frac{(1.0 \times 10^6 \frac{\text{gal}}{\text{MG}}) \times (1.0 \frac{\text{mg}}{\text{L}} - 0.4 \frac{\text{mg}}{\text{L}})}{18,000 \frac{\text{mg}}{\text{L}}}$$

$$= 33.3 \text{ gal/MG}$$

**12. PHOSPHORUS**

Phosphate content is more of a concern in wastewater treatment than in supply water, although phosphorus can enter water supplies in large amounts from runoff. Excessive phosphate discharge contributes to aquatic plant (phytoplankton, algae, and macrophytes) growth and subsequent *eutrophication*. (Eutrophication is an “over-fertilization” of receiving waters.)

Phosphorus is of considerable interest in the management of lakes and reservoirs because phosphorus is a nutrient that has a major effect on aquatic plant growth. Algae normally have a phosphorus content of 0.1–1% of dry weight. The molar N:P ratio for ideal algae growth is 16:1.

Phosphorus exists in several forms in aquatic environments. Soluble phosphorus occurs as *orthophosphate*, as condensed *polyphosphates* (from detergents), and as various organic species. Orthophosphates ( $\text{H}_2\text{PO}_4^-$ ,  $\text{HPO}_4^{2-}$ , and  $\text{PO}_4^{3-}$ ) and polyphosphates (such as  $\text{Na}_3(\text{PO}_3)_6$ ) result from the use of synthetic detergents (*syndets*). A sizable fraction of the soluble phosphorus is in the organic form, originating from the decay or excretion of nucleic acids and algal storage products. *Particulate phosphorus* occurs in the organic form as a part of living organisms and detritus as well as in the inorganic form of minerals such as apatite.

Phosphorus is normally measured by colorimetric or digestion methods. The results are reported in terms of mg/L of phosphorus (e.g., “mg/L of P” or “mg/L of total P”), although the tests actually measure the concentration of orthophosphate. The concentration of a particular compound is found by multiplying the concentration as P by the molecular weight of the compound and dividing by the atomic weight of phosphorus (30.97).

$$[\text{X}] = \frac{[\text{P}](\text{MW}_x)}{30.97} \quad 25.9$$

A substantial amount of the phosphorus that enters lakes is probably not available to aquatic plants. Bioavailable compounds include orthophosphates, polyphosphates, most soluble organic phosphorus, and a portion of the particulate fraction. Studies have indicated that bioavailable phosphorus generally does not exceed 60% of the total phosphorus.

In aquatic systems, phosphorus does not enter into any redox reactions, nor are any common species volatile. Therefore, lakes retain a significant portion of the entering phosphorus. The main mechanism for retaining phosphorus is simple sedimentation of particles containing the phosphorus. Particulate phosphorus can originate from the watershed (*allochthonous material*) or can be formed within the lake (*autochthonous material*).

A large fraction of the phosphorus that enters a lake is recycled, and much of the recycling occurs at the sediment-water interface. Recycling of phosphorus is

linked to iron and manganese recycling. Soluble phosphorus in the water column is removed by adsorption onto iron and manganese hydroxides, which precipitate under aerobic conditions. However, when the *hypolimnion* (i.e., the lower part of the lake that is essentially stagnant) becomes anaerobic, the iron (or manganese) is reduced, freeing up phosphorus. This is consistent with a fairly general observation that phosphorus release rates are nearly an order of magnitude higher under anaerobic conditions than under aerobic conditions.

Factors that control phosphorus recycling rates are not well understood, although it is clear that oxygen status, phosphorus speciation, temperature, and pH are important variables. Phosphorus release from sediments is usually considered to be constant (usually less than 1 mg/m<sup>2</sup>-day under aerobic conditions).

In addition to direct regeneration from sediments, *macrophytes* (large aquatic plants) often play a significant role in phosphorus recycling. Macrophytes with highly developed root systems derive most of their phosphorus from the sediments. Regeneration to the water column can occur by excretion or through decay, effectively “pumping” phosphorus from the sediments. The internal loading generated by recycling is particularly important in shallow, eutrophic lakes. In several cases where phosphorus inputs have been reduced to control algal blooms, regeneration of phosphorus from phosphorus-rich sediments has slowed the rate of recovery.

### 13. NITROGEN

Compounds containing nitrogen are not abundant in virgin surface waters. However, nitrogen can reach large concentrations in ground waters that have been contaminated with barnyard runoff or that have percolated through heavily fertilized fields. Sources of surface water contamination include agricultural runoff and discharge from sewage treatment facilities.

Of greatest interest, in order of decreasing oxidation state, are nitrates ( $\text{NO}_3^-$ ), nitrites ( $\text{NO}_2^-$ ), ammonia ( $\text{NH}_3$ ), and organic nitrogen. These three compounds are reported as *total nitrogen*, TN, with units of “mg/L of N” or “mg/L of total N.” The concentration of a particular compound is found by multiplying the concentration as N by the molecular weight of the compound and dividing by the atomic weight of nitrogen (14.01).

$$[\text{X}] = \frac{[\text{N}](\text{MW}_X)}{14.01} \quad 25.10$$

Excessive amounts of nitrate in water can contribute to the illness in infants known as *methemoglobinemia* (“blue baby” syndrome). As with phosphorus, nitrogen stimulates aquatic plant growth.

Un-ionized ammonia is a colorless gas at standard temperature and pressure. A pungent odor is detectable at levels above 50 mg/L. Ammonia is very soluble in water at low pH.

Ammonia levels in zero-salinity surface water increase with increasing pH and temperature (see Table 25.7). At low pH and temperature, ammonia combines with water to produce ammonium ( $\text{NH}_4^+$ ) and hydroxide ( $\text{OH}^-$ ) ions. The ammonium ion is nontoxic to aquatic life and not of great concern. The un-ionized ammonia ( $\text{NH}_3$ ), however, can easily cross cell membranes and have a toxic effect on a wide variety of fish. The EPA has established the criteria for fresh and saltwater fish that depend on temperature, pH, species, and averaging period.

**Table 25.7** Percentage of Total Ammonia Present in Toxic, Un-ionized Form

temp (°F (°C))	pH									
	6.0	6.5	7.0	7.5	8.0	8.5	9.0	9.5	10.0	
41 (5)	0.013	0.040	0.12	0.39	1.2	3.8	11	28	56	
50 (10)	0.019	0.059	0.19	0.59	1.8	5.6	16	37	65	
59 (15)	0.027	0.087	0.27	0.86	2.7	8.0	21	46	73	
68 (20)	0.040	0.13	0.40	1.2	3.8	11	28	56	80	
77 (25)	0.057	0.18	0.57	1.8	5.4	15	36	64	85	
86 (30)	0.080	0.25	0.80	2.5	7.5	20	45	72	89	

Ammonia is usually measured by a distillation and titration technique or with an ammonia-selective electrode. The results are reported as ammonia nitrogen. Nitrites are measured by a colorimetric method. The results are reported as nitrite nitrogen. Nitrates are measured by ultraviolet spectrophotometry, selective electrode, or reduction methods. The results are reported as nitrate nitrogen. Organic nitrogen is determined by a digestion process that identifies organic and ammonia nitrogen combined. Organic nitrogen is found by subtracting the ammonia nitrogen value from the digestion results.

### 14. COLOR

Color in water is caused by substances in solution, known as *true color*, and by substances in suspension, mostly organics, known as *apparent* or *organic color*. Iron, copper, manganese, and industrial wastes all can cause color. Color is aesthetically undesirable, and it stains fabrics and porcelain bathroom fixtures.

Water color is determined by comparison with standard platinum/cobalt solutions or by spectrophotometric methods. The standard color scales range from 0 (clear) to 70. Water samples with more intense color can be evaluated using a dilution technique.

### 15. TURBIDITY

*Turbidity* is a measure of the light-transmitting properties of water and is comprised of suspended and colloidal material. Turbidity is expressed in *nephelometric turbidity units* (NTU). Viruses and bacteria become attached to these particles, where they can

be protected from the bactericidal and viricidal effects of chlorine, ozone, and other disinfecting agents. The organic material included in turbidity has also been identified as a potential precursor to carcinogenic disinfection by-products.

Turbidity in excess of 5 NTU is noticeable by visual observation. Turbidity in a typical clear lake is approximately 25 NTU, and muddy water exceeds 100 NTU. Turbidity is measured using an electronic instrument called a nephelometer, which detects light scattered by the particles when a focused light beam is shown through the sample.

## 16. SOLIDS

Solids present in a sample of water can be classified in several ways.

- *total solids* (TS): Total solids are the material residue left in the vessel after the evaporation of the sample at 103–105°C. Total solids include total suspended solids and total dissolved solids.
- *total suspended solids* (TSS): The material retained on a standard glass-fiber filter disk is defined as the suspended solids in a sample. The filter is weighed before filtration, dried at 103–105°C, and weighed again. The gain in weight is the amount of suspended solids. Suspended solids can also be categorized into *volatile suspended solids* (VSS) and *fixed suspended solids* (FSS).
- *total dissolved solids* (TDS): These solids are in solution and pass through the pores of the standard glass-fiber filter. Dissolved solids are determined by passing the sample through a filter, collecting the filtrate in a weighed drying dish, and evaporating the liquid at 180°C. The gain in weight represents the dissolved solids. Dissolved solids can be categorized into *volatile dissolved solids* (VDS) and *fixed dissolved solids* (FDS).
- *total volatile solids* (TVS): The residue from one of the previous determinations is ignited to constant weight in an electric muffle furnace at 550°C. The loss in weight during the ignition process represents the volatile solids.
- *total fixed solids* (TFS): The weight of solids that remain after the ignition used to determine volatile solids represents the fixed solids.
- *settleable solids*: The volume (mL/L) of settleable solids is measured by allowing a sample to settle for one hour in a graduated conical container (*Imhoff cone*).

The following relationships exist.

$$TS = TSS + TDS = TVS + TFS \quad 25.11$$

$$TSS = VSS + FSS \quad 25.12$$

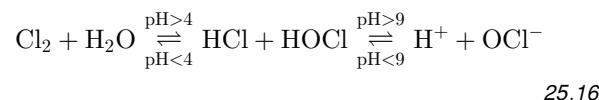

$TDS = VDS + FDS$	25.13
$TVS = VSS + VDS$	25.14
$TFS = FSS + FDS$	25.15

Waters with high concentrations of suspended solids are classified as *turbid waters*. Waters with high concentrations of dissolved solids often can be tasted. Therefore, a limit of 500 mg/L has been established in the National Secondary Drinking Water Standards for dissolved solids.

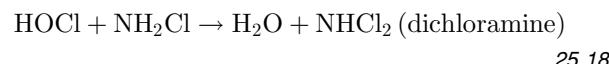

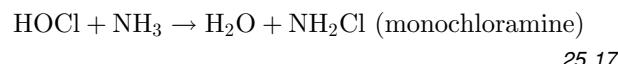

## 17. CHLORINE AND CHLORAMINES

Chlorine is the most common disinfectant used in water treatment. It is a strong oxidizer that deactivates microorganisms. Its oxidizing capability also makes it useful in removing soluble iron and manganese ions.

Chlorine gas in water forms *hydrochloric* and *hypochlorous acids*. At a pH greater than 9, hypochlorous acid dissociates to hydrogen and hypochlorite ions, as shown in Eq. 25.16.

Free chlorine, hypochlorous acid, and hypochlorite ions left in water after treatment are known as *free chlorine residuals*. Hypochlorous acid reacts with ammonia (if it is present) to form *chloramines*. Chloramines are known as *combined residuals*. Chloramines are more stable than free residuals, but their disinfecting ability is less.

Free and combined residual chlorine can be determined by color comparison, by titration, and with chlorine-sensitive electrodes. Color comparison is the most common field method.

## 18. HALOGENATED COMPOUNDS

Halogenated compounds have become a subject of concern in the treatment of water due to their potential as carcinogens. The use of chlorine as a disinfectant in water treatment generates these compounds by reacting with organic substances in the water. (For this reason there are circumstances under which chlorine may not be the most appropriate disinfectant.)

The organic substances, called *precursors*, are not in themselves harmful, but the chlorinated end products, known by the term *disinfection by-products* (DBPs)

raise serious health concerns. Typical precursors are decay by-products such as humic and fulvic acids. Several of the DBPs contain bromine, which is found in low concentrations in most surface waters and can also occur as an impurity in commercial chlorine gas.

The DBPs can take a variety of forms depending on the precursors present, the concentration of free chlorine, the contact time, the pH, and the temperature. The most common ones are the trihalomethanes (THMs), haloacetic acids (HAAs), dihaloacetonitriles (DHANs), and various trichlorophenol isomers.

## 19. TRIHALOMETHANES

Only four trihalomethane (THM) compounds are normally found in chlorinated waters.

$\text{CHCl}_3$	trichloromethane (chloroform)
$\text{CHBrCl}_2$	bromodichloromethane
$\text{CHBr}_2\text{Cl}$	dibromochloromethane
$\text{CHBr}_3$	tribromomethane (bromoform)

Trihalomethanes are regulated by the EPA under the National Primary Drinking Water Standards. Standards for total *haloacetic acids* (referred to as "HAA5" in consideration of the five compounds identified) have also been established.

## 20. HALOACETIC ACIDS

The haloacetic acids (HAAs) exist in tri-, di-, and mono-forms, abbreviated as THAAs, DHAAs, and MHAAs. All of the haloacetic acids are toxic and are suspected or proven carcinogens. Maximum concentration limits for HAAs are listed in App. 25.A.

$\text{C}_2\text{HCl}_3\text{O}_2$	trichloroacetic acid	(TCAA)
$\text{C}_2\text{HBrCl}_2\text{O}_2$	bromodichloroacetic acid	(BDCAA)
$\text{C}_2\text{HBr}_2\text{ClO}_2$	dibromochloroacetic acid	(DBCAA)
$\text{C}_2\text{HBr}_3\text{O}_2$	tribromoacetic acid	(TBAA)
$\text{C}_2\text{H}_2\text{Cl}_2\text{O}_2$	dichloroacetic acid	(DCAA)
$\text{C}_2\text{H}_2\text{BrClO}_2$	bromochloroacetic acid	(BCAA)
$\text{C}_2\text{H}_2\text{Br}_2\text{O}_2$	dibromoacetic acid	(DBAA)
$\text{C}_2\text{H}_3\text{ClO}_2$	monochloroacetic acid	(MCAA)
$\text{C}_2\text{H}_3\text{BrO}_2$	monobromoacetic acid	(MBAA)

## 21. DIHALOACETONITRILES

The dihaloacetonitriles (DHANs) are formed when acetonitrile (methyl cyanide:  $\text{C}_2\text{H}_3\text{N}$  (structurally  $\text{H}_3\text{CCN}$ )) is exposed to chlorine. All are toxic and suspected carcinogens. Maximum concentration limits have not been established by the EPA for DHANs.

$\text{C}_2\text{HCl}_2\text{N}$	dichloroacetonitrile	(DCAN)
$\text{C}_2\text{HBrClN}$	bromochloroacetonitrile	(BCAN)
$\text{C}_2\text{HBr}_2\text{N}$	dibromoacetonitrile	(DBAN)

## 22. TRICHLOROPHENOL

Trichlorophenol can exist in six isomeric forms, with varying potential toxicities. As with all halogenated organics, they are potential carcinogens.

2,3,4-trichlorophenol	
2,3,5-trichlorophenol	
2,3,6-trichlorophenol	
2,4,5-trichlorophenol	irritant
2,4,6-trichlorophenol	fungicide, bactericide
3,4,5-trichlorophenol	

## 23. AVOIDANCE OF DISINFECTION BY-PRODUCTS IN DRINKING WATER

Reduction of DBPs can best be achieved by avoiding their production in the first place. The best strategy dictates using source water with few or no organic precursors.

Often source water choices are limited, necessitating tailoring treatment processes to produce the desired result. This entails removing the precursors prior to the application of chlorine, applying chlorine at certain points in the treatment process that minimize production of DBPs, using disinfectants that do not produce significant DBPs, or a combination of these techniques.

Removal of precursors is achieved by preventing growth of vegetative material (algae, plankton, etc.) in the source water and by collecting source water at various depths to avoid concentrations of precursors. Oxidizers such as potassium permanganate and chlorine dioxide can often reduce the concentration of the precursors without forming the DBPs. Use of activated carbon, pH-adjustment processes or dechlorination can reduce the impact of chlorination.

Chlorine application should be delayed if possible until after the flocculation, coagulation, settling, and filtration processes have been completed. In this manner, turbidity and common precursors will be reduced. If it is necessary to chlorinate early to facilitate treatment processes, chlorination can be followed by dechlorination to reduce contact time. Granular activated carbon has been used to some extent to remove DBPs after they form, but the carbon needs frequent regeneration.

Alternative disinfectants include ozone, chloramines, chlorine dioxide, iodine, bromine, potassium permanganate, hydrogen peroxide, and ultraviolet radiation. Ozone and chloramines, singularly or together, are often used for control of THMs. However, ozone creates other DBPs, including aldehydes, hydrogen peroxide, carboxylic acids, ketones, and phenols. When ozone is used as the primary disinfectant, a secondary disinfectant such as chlorine or chloramine must be used to provide an active residual that can be measured within the distribution system.

## 24. SALINITY IN IRRIGATION WATER

Crop yield is affected greatly by *salinity*. Plants can only transpire pure water. Therefore, the primary effect of high salinity on crop productivity is the inability of plants to compete with ions in the soil solution for water. The higher the salinity, the less water is available to plants, even though the soil is saturated. The specific sensitivity to salinity depends greatly on the crop, type of soil, and salinity depth.

Salinity can be characterized in several ways, including ionic concentrations and electrical conductivity. When salinity is characterized by relative portions of various ions, the deleterious effects are referred to as *salinity hazard*, *sodium hazard*, *boron hazard*, and *bicarbonate hazard*.

The *soluble sodium percent (percent sodium content)*, SSP, is defined by Eq. 25.20, where the concentrations are expressed in meq/L. Water quality for irrigation is roughly classified based on the SSP according to: < 20%, excellent; 20–40%, good; 20–60% permissible; 60–80% doubtful; and > 80%, unsuitable.

$$\text{SSP} = \frac{[\text{Na}^+] \times 100\%}{[\text{Ca}^{++}] + [\text{Mg}^{++}] + [\text{Na}^+] + [\text{K}^+]} \quad 25.20$$

In waters with high concentrations of bicarbonate ions, calcium and magnesium may precipitate out as the water in the soil becomes more concentrated. As a result, the relative proportion of sodium in the form of sodium carbonate increases. The *relative proportion of*

*sodium carbonate*, RSC, is defined by Eq. 25.21, where all of the concentrations are expressed as meq/L. The U.S. Department of Agriculture categorizes water according to its RSC as good (< 1.5 meq/L), doubtful (1.5–2.5 meq/L), and unsuitable (> 2.5 meq/L).

$$\text{RSC} = ([\text{HCO}_3^-] + [\text{CO}_3^{--}]) - ([\text{Ca}^{++}] + [\text{Mg}^{++}]) \quad 25.21$$

Percent sodium and RSC are based on chemical species, but not on reactions with the soil itself. A better measure of the sodium hazard for irrigation is the *sodium adsorption ratio*, SAR. SAR is an indicator of the amount of sodium in the water relative to calcium and magnesium. Sodium hazard is low with SAR < 9. For SAR 10–17, hazard is medium, and soil amendments (e.g., gypsum) and leaching may be required. Water with SAR 18–25 has a high sodium hazard and cannot be used continuously. An SAR in excess of 25 represents unsuitable water.

$$\text{SAR} = \frac{[\text{Na}^+]}{\sqrt{\frac{[\text{Ca}^{++}] + [\text{Mg}^{++}]}{2}}} \quad 25.22$$

Salinity, like total dissolved solids, is also commonly categorized by electrical conductivity (EC) and reported in dS/m.<sup>1,2</sup> Water is classified according to EC as excellent (< 0.25 dS/m), good (0.25–0.75 dS/m), permissible (0.75–2.0 dS/m), doubtful (2.0–3.0 dS/m), and unsuitable (> 3.0 dS/m).

<sup>1</sup>The subscripts w, iw, or e may be used (e.g., EC<sub>w</sub>) to indicate water, irrigation water, or saturated soil extract.

<sup>2</sup>Decisiemens per meter, dS/m, is numerically the same as mS/cm. The siemens, S, is equivalent to the obsolete mho unit.

**1. WATER TREATMENT PLANT LOCATION**

The location chosen for a water treatment plant is influenced by many factors. The most common factors include availability of resources such as (a) local water, (b) power, and (c) sewerage services; economic factors such as (d) land cost and (e) annual taxes; and environmental factors such as (f) traffic and (g) other concerns that would be identified on an environmental impact report.

It is imperative to locate water treatment plants (a) above the flood plain and (b) where a 15–20 ft (4.5–6 m) elevation difference exists. This latter requirement will eliminate the need to pump the water between processes. Traditional treatment requires a total head of approximately 15 ft (4.5 m), whereas advanced processes such as granular activated charcoal and ozonation increase the total head required to approximately 20 ft (6 m).

The average operational life of equipment and facilities is determined by economics. However, it is unlikely that a lifetime of less than 50 years would be economically viable. Equipment lifetimes of 25–30 years are typical.

**2. PROCESS INTEGRATION**

The processes and sequences used in a water treatment plant depend on the characteristics of the incoming water. However, some sequences are more appropriate than others due to economic and hydraulic considerations. *Conventional filtration*, also referred to as *complete filtration*, is a term used to describe the traditional sequence of adding coagulation chemicals, flash mixing, coagulation-flocculation, sedimentation, and subsequent filtration. Coagulants, chlorine (or an alternative disinfectant), fluoride, and other chemicals are added at various points along the path, as indicated by Fig. 26.1. Conventional filtration is still the best choice when incoming water has high color, turbidity, or other impurities.

*Direct filtration* refers to a modern sequence of adding coagulation chemicals, flash mixing, minimal flocculation, and subsequent filtration. In direct filtration, the physical chemical reactions of flocculation occur to some extent, but special flocculation and sedimentation facilities are eliminated. This reduces the amount of sludge that has to be treated and disposed of. Direct filtration is applicable when the incoming water is of high initial quality.

*In-line filtration* refers to another modern sequence that starts with adding coagulation chemicals at the filter inlet pipe. Mixing occurs during the turbulent flow toward a filter, which is commonly of the pressure-filter variety. As with direct filtration, flocculation and sedimentation facilities are not used.

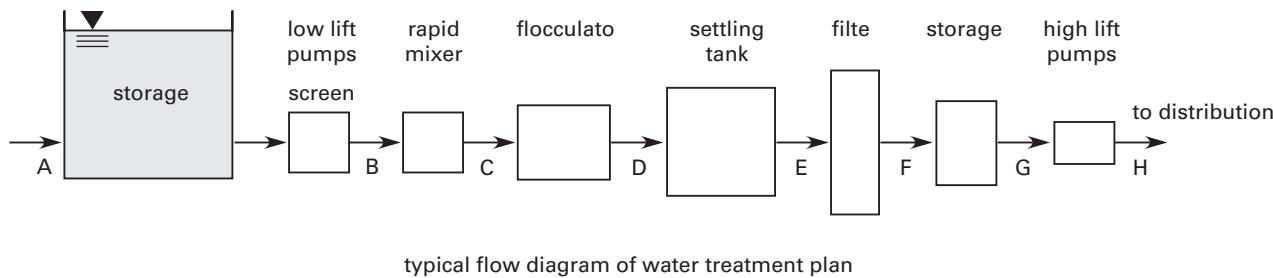

Table 26.1 provides guidelines based on incoming water characteristics for choosing processes required to achieve satisfactory quality.

**3. PRETREATMENT**

*Preliminary treatment* is a general term that usually includes all processes prior to the first flocculation operation (i.e., pretreatment, screening, presedimentation, microstraining, aeration, and chlorination). Flow measurement is usually considered to be part of the pretreatment sequence.

**4. SCREENING**

Screens are used to protect pumps and mixing equipment from large objects. The degree of screening required will depend on the nature of solids expected. Screens can be either manually or automatically cleaned.

**Figure 26.1** Chemical Application Points

category of chemicals	possible points of application							
	A	B	C	D	E	F	G	H
algicide	X				X			
disinfectant		X	X		X	X	X	X
activated carbon		X	X	X	X			
coagulants		X	X					
coagulation aids		X	X		X

for flocculation				X				
for corrosion control						X		
for softening					X			
acidifie				X		X		
fluorid						X		
cupric-chloramine						X		
dechlorinating agent						X	X	

Note: With solids contact reactors, point C is the same as point D.

## 5. MICROSTRAINING

*Microstrainers* are effective at removing 50–95% of the algae in incoming water. Microstrainers are constructed from woven stainless steel fabric mounted on a hollow drum that rotates at 4–7 rpm. Flow is usually radially outward through the drum. The accumulated filter cake is removed by backwashing.

## 6. ALGAE PRETREATMENT

Biological growth in water from impounding reservoirs, lakes, storage reservoirs, and settling basins can be prevented or eliminated with an *algicide* such as copper sulfate. Such growth can produce unwanted taste and odors, clog fine-mesh filters, and contribute to the buildup of slime.

Typical dosages of copper sulfate vary from 0.54 lbm/ac-ft to 5.4 lbm/ac-ft (0.2 mg/L to 2.0 mg/L), with the lower dose usually being adequate for waters that are soft or have alkalinites less than 50 mg/L as CaCO<sub>3</sub>. (For aqueous solutions, units of mg/L and ppm are equivalent.) Since it is toxic, copper sulfate should not be used without considering and monitoring the effects on aquatic life (e.g., fish).

## 7. PRECHLORINATION

A prechlorination process was traditionally employed in most water treatment plants. Many plants have now eliminated all or part of the prechlorination due to the

formation of THMs. In so doing, benefits such as algae control have been eliminated. Alternative disinfection chemicals (e.g., ozone and potassium permanganate) can be used. Otherwise, coagulant doses must be increased.

## 8. PRESEDIMENTATION

The purpose of presedimentation is to remove easily settled sand and grit. This can be accomplished by using pure sedimentation basins, sand and grit chambers, and various passive cyclone degritters. *Trash racks* may be integrated into sedimentation basins to remove leaves and other floating debris.

## 9. FLOW MEASUREMENT

*Flow measurement* is incorporated into the treatment process whenever the water is conditioned enough to be compatible with the measurement equipment. Flow measurement devices should not be exposed to scour from grit or highly corrosive chemicals (e.g., chlorine).

Flow measurement often takes place in a Parshall flume. Chemicals may be added in the flume to take advantage of the turbulent mixing that occurs at that point. All of the traditional fluid measurement devices are also applicable, including venturi meters, orifice plates, propeller and turbine meters, and modern passive devices such as magnetic and ultrasonic flowmeters.

**Table 26.1** Treatment Methods

incoming water quality		pretreatment			treatment					special treatments				
constituents	concentration (mg/L)	screening	prechlorination	plain settling	aeration	lime softening	coagulation and sedimentation	rapid sand filtration	slow sand filtration	postchlorination	superchlorination <sup>a</sup> or chloramination	active carbon	special chemical treatment	salt water conversion <sup>b</sup>

less critical chemicals											O	O		

Note: E = essential, O = optional

<sup>a</sup>Superchlorination shall be followed by dechlorination.

<sup>b</sup>As an alternative, dilute with low chloride water.

<sup>c</sup>Double settling shall be provided for coliform exceeding 20,000 MPN/100 mL.

<sup>d</sup>For extremely muddy water, presedimentation by plain settling may be provided.

<sup>e</sup>MPN = most probable number

## 10. AERATION

Aeration is used to reduce taste- and odor-causing compounds, to lower the concentration of dissolved gases (e.g., hydrogen sulfide), to increase dissolved CO<sub>2</sub> (i.e., recarbonation) or decrease CO<sub>2</sub>, to reduce iron and manganese, and to increase dissolved oxygen.

Various types of aerators are used. The best transfer efficiencies are achieved when the air-water contact area is large, the air is changed rapidly, and the aeration period is long. *Force draft air injection* is common. The release depth varies from 10 ft to 25 ft (3 m to 7.5 m). The ideal compression power required to aerate water with a simple air injector depends on the air flow rate, *Q*, and head (i.e., which must be greater than the release depth), *h*, at the point where the air is injected. Motor-compression-distribution efficiencies are typically around 75%.

$$P_{\text{kW}} = \frac{Q_{\text{L/s}} h_{\text{m}}}{100} \quad [\text{SI}] \quad 26.1(a)$$

$$P_{\text{hp}} = \frac{Q_{\text{cfm}} h_{\text{ft}}}{528} \quad [\text{U.S.}] \quad 26.1(b)$$

*Diffused air systems* with compressed air at 5–10 psig (35–70 kPa) are the most efficient methods of aerating water. The air injection volume is 0.2–0.3 ft<sup>3</sup>/gal. However, the equipment required to produce and deliver compressed air is more complex than with simple injectors. The *transfer efficiency* of a diffused air system varies with depth and bubble size. With injection depths of 5–10 ft (1.5–3.0 m), if coarse bubbles are produced, only 4–8% of the available oxygen will be transferred to the water. With medium-sized bubbles, the efficiency can be 6–15%, and it can approach 10–30% with fine bubble systems.

## 11. SEDIMENTATION PHYSICS

Water containing suspended sediment can be held in a *plain sedimentation tank* (basin) that allows the particles to settle out.<sup>1</sup> Settling velocity and settling time for sediment depends on the water temperature (i.e., viscosity), particle size, and particle specific gravity. (The specific gravity of sand is usually taken as 2.65.) Typical settling velocities are as follows: gravel, 1 m/s; coarse sand, 0.1 m/s; fine sand, 0.01 m/s; and silt, 0.0001 m/s. Bacteria and colloidal particles are generally considered to be nonsettleable during the detention periods available in water treatment facilities.

Settlement time can be calculated from the settling velocity and the depth of the tank. If it is necessary to determine the settling velocity of a particle with diameter  $D$ , the following procedure can be used.<sup>2</sup>

*step 1:* Assume a settling velocity,  $v_s$ .

*step 2:* Calculate the settling Reynolds number,  $Re$ .

$$Re = \frac{v_s D}{\nu} \quad 26.2$$

*step 3:* (a) If  $Re < 1$ , use *Stokes' law*.

$$\begin{aligned} v_{s,m/s} &= \frac{(\rho_{\text{particle}} - \rho_{\text{water}}) D_m^2 g}{18\mu} \\ &= \frac{(\text{SG}_{\text{particle}} - 1) D_m^2 g}{18\nu} \quad [\text{SI}] \quad 26.3(a) \end{aligned}$$

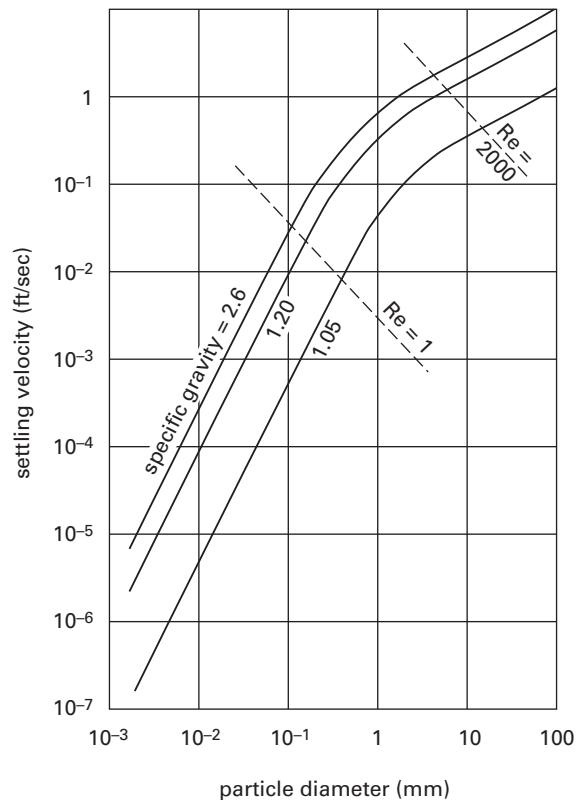

$$\begin{aligned} v_{s,ft/sec} &= \frac{(\rho_{\text{particle}} - \rho_{\text{water}}) D_{ft}^2 g}{18\mu g_c} \\ &= \frac{(\text{SG}_{\text{particle}} - 1) D_{ft}^2 g}{18\nu} \quad [\text{U.S.}] \quad 26.3(b) \end{aligned}$$

(b) If  $1 < Re < 2000$ , use Fig. 26.2, which gives theoretical settling velocities in 68°F (20°C) water for spherical particles with specific gravities of 1.05, 1.2, and 2.65. Actual settling velocities will be much less than shown because particles are not actually spherical.

(c) If  $Re > 2000$ , use *Newton's first law of motion* and balance the weight of the particle against the buoyant and drag forces. A spherical shape is often assumed in determining the drag coefficient,  $C_D$ . In that case, for laminar descent, use  $C_D = 24/Re$ .

$$v_s = \sqrt{\frac{4gD(\text{SG}_{\text{particle}} - 1)}{3C_D}} \quad 26.4$$

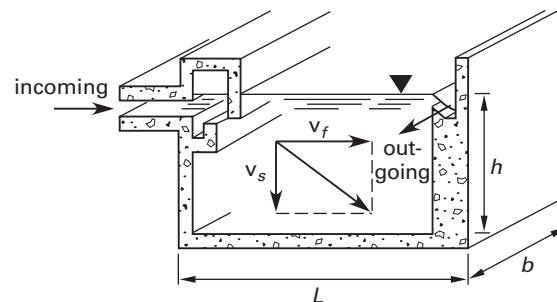

Figure 26.2 Settling Velocities, 68°F (20°C)

## 12. SEDIMENTATION TANKS

Sedimentation tanks are usually concrete, rectangular or circular in plan, and are equipped with scrapers or raking arms to periodically remove accumulated sediment. (See Fig. 26.3.) Steel should be used only for small or temporary installations. Where steel parts are unavoidable, as in the case of some rotor parts, adequate corrosion resistance is necessary.

Figure 26.3 Sedimentation Basin

Water flows through the tank at the average *flow-through velocity*,  $v_f$ . The flow-through velocity can be found by injecting a colored dye into the tank. It should not exceed 1 ft/min (0.5 cm/sec). The time that water spends in the tank depends on the flow-through velocity and the tank length,  $L$ , typically 100–200 ft (30–60 m).

<sup>1</sup>The term "plain" refers to the fact that no chemicals are used as coagulants.

<sup>2</sup>This calculation procedure is appropriate for the *Type I settling* that describes sand, sediment, and grit particle performance. It is not appropriate for *Type II settling*, which describes floc and other particles that grow as they settle.

The minimum settling time depends on the tank depth,  $h$ , typically 6–15 ft (1.8–4.5 m).

$$t_{\text{settling}} = \frac{h}{v_s} \quad 26.5$$

The time that water remains in the basin is known as the *detention time* (*retention time*, *detention period*, etc.). Typical detention times range from 2 hr to 6 hr, although periods from 1 hr to 12 hr are used depending on the size of particles. All particles will be removed whose  $t_{\text{settling}}$  is less than  $t_d$ .

$$t_d = \frac{V_{\text{tank}}}{Q} = \frac{Ah}{Q} \quad 26.6$$

Rectangular basins are preferred. Rectangular basins should be constructed with aspect ratios greater than 3:1, and preferably greater than 4:1. The bottom should be sloped toward the drain at no less than 1%. Multiple inlet ports along the entire inlet wall should be used. If there are fewer than four inlet ports, an inlet baffle should be provided.

Square or circular basins are appropriate only when space is limited. The slope toward the drain should be greater, typically 8%. A baffled center inlet should be provided. For radial-flow basins, the diameter is on the order of 100 ft (30 m).

Basin efficiency can approach 80% for fine sediments. Virtually all of the coarse particles are removed. Theoretically, all particles with settling velocities greater than the *overflow rate*,  $v^*$ , also known as the *surface loading* or *critical velocity*, will be removed. In Eq. 26.7,  $b$  is the tank width, typically 30–40 ft (9–12 m). At least two basins should be constructed (both normally operating) so that one can be out of service for cleaning during low-volume periods without interrupting plant operation. Therefore,  $Q_{\text{filter}}$  in Eq. 26.7 should be calculated by dividing the total plant flow by 2 or more. The overflow rate is typically 600–1000 gpd/ft<sup>2</sup> (24–40 kL/d·m<sup>2</sup>) for rectangular tanks. For square and circular basins, the range is approximately 500–750 gpd/ft<sup>2</sup> (20–30 kL/d·m<sup>2</sup>).

$$v^* = \frac{Q_{\text{filter}}}{A_{\text{surface}}} = \frac{Q_{\text{filter}}}{bL} \quad 26.7$$

In some modern designs, sedimentation has been enhanced by the installation of vertically inclined *laminar tubes* or inclined plates (*lamella plates*) at the tank bottom. These passive tubes, which are typically about 2 in (50 mm) in diameter, allow the particles to fall only a short distance in more turbulent water before entering the tube in which the flow is laminar. Incoming solids settle to the lower surface of the tube, slide downward, exit the tube, and settle to the sedimentation basin floor.

*Weir loading* is the daily flow rate divided by the total effluent weir length. Weir loading is commonly specified as 15,000–20,000 gal/day-ft (190–250 kL/d·m), but certainly less than 50,000 gal/day-ft (630 kL/d·m).

The accumulated sediment is referred to as *sludge*. It is removed either periodically or on a continual basis, when it has reached a concentration of 25 mg/L or is organic. Various methods of removing the sludge are used, including scrapers and pumps. The linear velocity of sludge scrapers should be 15 ft/min (7.5 cm/sec) or higher.

### 13. SEDIMENTATION REMOVAL EFFICIENCY: UNMIXED BASINS

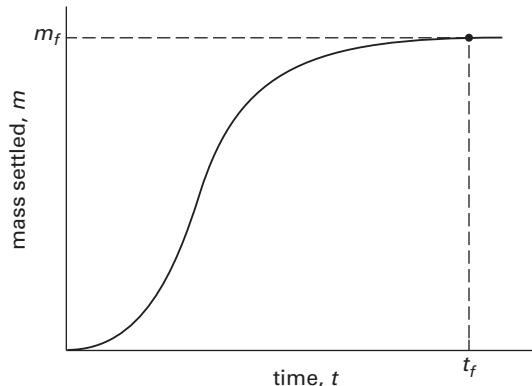

*Sedimentation efficiency*, also known as *removal fraction* and *collection efficiency*, refers to the gravimetric fraction (i.e., fraction by weight) of suspended particles that is removed by sedimentation. Since the suspended particles vary in size, shape, and specific gravity, the distribution of particles is characterized by a distribution of settling velocities,  $v_s$ . The distribution is determined, almost always, by a *laboratory settling column test*. Turbid water is placed in a 3–8 ft (1–2.4 m) long vertical column and allowed to settle, with the settled mass being measured over time.

The settling test produces multiple discrete cumulative mass fraction settled,  $1 - x$ , versus settling time,  $t_s$ , data pairs. These are transformed to mass fraction remaining,  $x$ , versus settling velocity,  $v_s = h_{\text{sc}}/t_s$  data pairs, where  $h_{\text{sc}}$  is the height of the settling column. The distribution data can be presented in several ways, including settling test results and cumulative curves of fraction remaining or fraction removed, as shown in Fig. 26.4. The *fraction remaining curve* (shown in Fig. 26.4(c)) plots the mass fraction,  $x$ , remaining in suspension and is also known as the *mass fraction curve*. The curve shape is the same as the original settling test results. This curve is usually drawn visually through the settling test data points, although more sophisticated curve fitting methods can be used. The curve may also be drawn simply as linear segments between the data points.

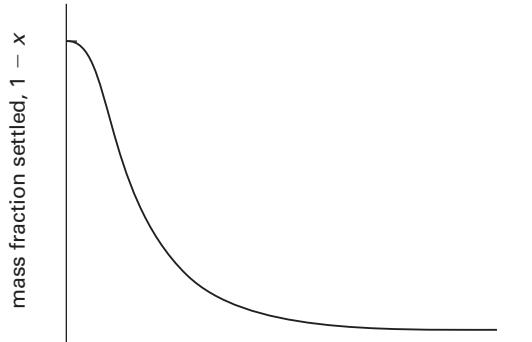

Consider a *quiet sedimentation basin* where water enters on one side and is withdrawn on the other side, without any mixing. Some particles have such a high settling velocity that they will settle no matter where they are introduced into the settling basin. Other particles have such a low settling velocity that they will never settle out during the hydraulic retention time of the basin. In between, some particles will settle to various degrees, depending on their initial depths in the settling basin. This leads to two parameters being used to describe the removal fraction: the removal fraction of particles that are completely removed and the total fraction of all particles removed.<sup>3</sup>

Whether or not a particle settles depends on its settling velocity, the time available to settle, and its initial location. The time available to settle depends on the horizontal component of flow velocity and on the horizontal distance between the settling basin's points of flow entry and removal.

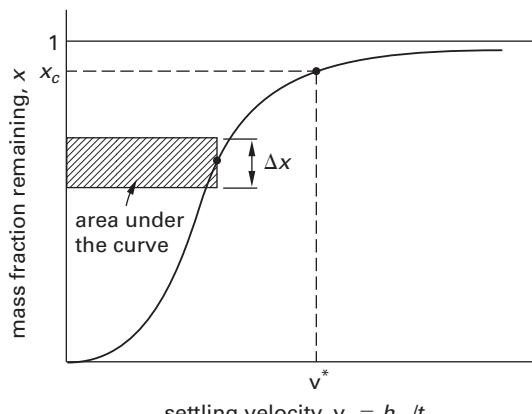

<sup>3</sup>That is, the “fraction completely collected” is different from the “total fraction collected.”

**Figure 26.4** Settling Test Data Representations

(a) settling test results (mass settled vs. time)

(b) fraction settled vs. settling velocity

(c) fraction remaining vs. settling velocity

Due to the continuous outflow, the tank contents experience a horizontal flow-through velocity,  $v_f$ , between the entry and removal points. If a particle settles with speed  $v_s$ , its vertical fall,  $y$ , over the flow path length (generally, the length of the tank),  $L$ , is

$$y = v_s t = \frac{v_s L}{v_f} \quad 26.8$$

The vertical fall distance,  $y$ , may be less than or greater than the basin depth,  $h$ . If  $y \geq h$ , the particle will reach

the bottom before reaching the end of the basin and will be collected. If  $y < h$ , the particle may or may not settle, depending on the depth at which it starts. If it starts settling close to the bottom, it will settle; otherwise, it will not fall enough and will escape with the outflow.

The *critical settling velocity*,  $v_c$ , is numerically the same as the overflow rate,  $v^*$ , and corresponds to the limiting velocity for particles experiencing total removal. Therefore, the fraction of particles experiencing total removal (a collection efficiency of 100%) can be read directly from the mass fraction remaining curve as  $1 - x_c$ , where  $x_c$  is the mass fraction remaining corresponding to  $v_s = v_c = v^*$ . If the mass fraction curve has not been plotted (or, has been plotted only roughly, as is usually the case), the value of  $x_c$  can be determined from the settling test data points by linear interpolation.

The total fraction of all particles removed,  $f$ , includes the fraction of particles with settling velocities greater than the critical velocity plus some fraction of the particles with settling velocities less than the critical velocity. For particles with settling velocities less than the critical velocity, the collection efficiency in both rectangular and circular sedimentation basins is

$$\eta = \frac{v_s}{v^*} \quad [v_s \leq v^*] \quad 26.9$$

The total removal fraction (total collection efficiency) is

$$f = 1 - x_c + \int_{x=0}^{x=x_c} \frac{v_s}{v^*} dx \approx 1 - x_c + \frac{1}{v^*} \sum_{x=0}^{x=x_c} v_s \Delta x \quad 26.10$$

The area beneath the mass fraction curve corresponds to the integral term in Eq. 26.10.<sup>4</sup> Since it will almost never be possible to describe the mass fraction curve mathematically, integrating the area of the curve must be done manually by dividing the area under the curve into rectangles (i.e., replacing the curve with a histogram), as is represented by the second form of Eq. 26.10. The rectangle widths,  $\Delta x$ , may vary and are chosen for convenience. The values of  $v_s$  in the second form of Eq. 26.10 correspond to the midpoints of the rectangle widths.

#### 14. SEDIMENTATION EFFICIENCY: MIXED BASINS

Quiet (unmixed) settling basins have the highest removal fractions, but mixing is incorporated into some designs for various reasons. Two types of ideal basins that can be mathematically evaluated are basins with pure transverse mixing and basins with thorough mixing. With transverse mixing, a particle may be moved

<sup>4</sup>The variable of integration,  $x$ , is the fraction remaining and is plotted vertically on a mass fraction curve.  $x$  is not the horizontal axis. The “area under the curve” is approximated by horizontal (not vertical) histogram bars.

vertically or side to side in either direction, randomly, but it will not move forward or backwards. In other words, the particle is constrained to a transverse plane perpendicular to the overall travel path between entry and discharge points. The collection efficiency as a function of settling velocity for a specific particle is given by Eq. 26.11. While a quiet settling basin has a 100% removal efficiency for a particle with  $v_s = v^*$ , a basin with transverse mixing has a 63.2% efficiency for the same particle.

$$\eta = 1 - e^{-v_s/v^*} \quad [\text{transverse mixing}] \quad 26.11$$

For a basin with thorough mixing, particles may move three dimensionally—vertically, horizontally, and longitudinally. The collection efficiency is given by Eq. 26.12. When  $v_s = v^*$ , the efficiency is 50%.

$$\eta = \frac{v_s}{v_s + v^*} \quad [\text{thorough mixing}] \quad 26.12$$

As a function of  $v_s$  (or as a function of the dimensionless ratio  $v_s/v^*$ ), the removal efficiencies for transverse- and thoroughly-mixed basins both approach 100% asymptotically. Since large values of  $v_s/v^*$  correspond to large basins, any basin removal efficiency can be achieved by making the basin large enough. However, the smallest basin size will be achieved when the basin is unmixed.

## 15. COAGULANTS

Various chemicals can be added to remove fine solids. There are two main categories of coagulating chemicals: hydrolyzing metal ions (based on either aluminum or iron) and ionic polymers. Since the chemicals work by agglomerating particles in the water to form floc, they are known as *coagulants*. *Floc* is the precipitate that forms when the coagulant allows the colloidal particles to agglomerate.

Common *hydrolyzing metal ion* coagulants are aluminum sulfate ( $\text{Al}_2(\text{SO}_4)_3 \cdot n\text{H}_2\text{O}$ , commonly referred to as “alum”), ferrous sulfate ( $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ , sometimes referred to as “copperas”), and chlorinated copperas (a mixture of ferrous sulfate and ferric chloride).  $n$  is the number of waters of hydration, approximately 14.3.

*Alum* is, by far, the most common compound used in water treatment.<sup>5</sup> Alum provides the positive charges needed to attract and neutralize negative colloidal particles. It reacts with alkalinity in the water to form gelatinous aluminum hydroxide ( $\text{Al}(\text{OH})_3$ ) in the proportion of 1 mg/L alum:<sup>1/2</sup> mg/L alkalinity. The aluminum hydroxide forms the nucleus for floc agglomeration.

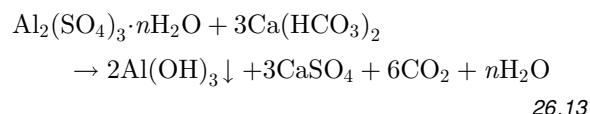

For alum coagulation to be effective, the following requirements must be met: (a) Enough alum must be used to neutralize all of the incoming negative particles. (b) Enough alkalinity must be present to permit as complete as possible a conversion of the aluminum

<sup>5</sup>Lime is the second most-used compound.

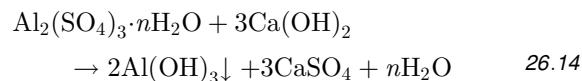

sulfate to aluminum hydroxide. (c) The pH must be maintained within the effective range.

Alum dosage is generally 5–50 mg/L, depending on the turbidity. Alum floc is effective within a wide pH range of 5.5–8.0. However, the hydrolysis of the aluminum ion depends on pH and other factors in complex ways, and stoichiometric relationships rarely tell the entire story. Although a pH of 6–7 is a typical operating range for alum coagulation, depending on the contaminant, the pH can range as high as 9. Alum removal of chromium, for example, is effective within a pH range of 7–9.

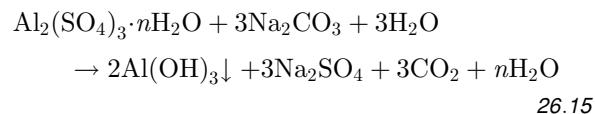

Alum reacts with natural alkalinity in the water according to the following reaction.

Since alum is naturally acidic, if the water is not sufficiently alkaline, lime ( $\text{CaO}$ ) and soda ash (“caustic soda,”  $\text{Na}_2\text{CO}_3$ ) can be added for preliminary pH adjustment.<sup>6</sup> If there is inadequate alkalinity and lime is added, the reaction is

Alum reacts with soda ash according to

Ferrous sulfate ( $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$ ) reacts with slaked lime ( $\text{Ca}(\text{OH})_2$ ) to flocculate ferric hydroxide ( $\text{Fe}(\text{OH})_3$ ). This is an effective method of clarifying turbid water at higher pH.

Ferric sulfate ( $\text{Fe}_2(\text{SO}_4)_3$ ) reacts with natural alkalinity and lime. It can also be used for color removal at low pH. At high pH, it is useful for iron and manganese removal, as well as a coagulant with precipitation softening.

If alkalinity is high, it may be necessary to use hydrochloric or sulfuric acid for pH control rather than adding lime. The iron salts are effective above a pH of 7, so they may be advantageous in alkaline waters.<sup>7</sup>

*Polymers* are chains or groups of repeating identical molecules (*mers*) with many available active adsorption sites. Their molecular weights range from several hundred to several million. Polymers can be positively charged (cationic polymers), negatively charged (anionic polymers), or neutral (nonionic polymers). The charge can vary with pH. *Organic polymers (polyelectrolytes)*,

<sup>6</sup>The cost of soda ash used for pH adjustment is about three times that of lime. Also, soda ash leaves sodium ions in solution, an increasingly undesirable contaminant for people with hypertension.

<sup>7</sup>Optimum pH for ferric floc is approximately 7.5. However, iron salts are active over the pH range of 3.8–10.

such as starches and polysaccharides, and *synthetic polymers*, such as polyacrylamides, are used.

Polymers are useful in specialized situations, such as when particular metallic ions are to be removed. For example, conventional alum will not remove positive iron ions. However, an anionic polymer will combine with the iron. Polymers are effective in narrow ranges of turbidity and alkalinity. In some cases, it may be necessary to artificially seed the water with clay or alum (to produce floc).

## 16. FLOCCULATION ADDITIVES

*Flocculation additives* improve the coagulation efficiency by changing the floc size. Additives include *weighting agents* (e.g., bentonite clays), *adsorbents* (e.g., powdered activated carbon), and *oxidants* (chlorine). Polymers are also used in conjunction with metallic ion coagulants.

## 17. DOSES OF COAGULANTS AND OTHER COMPOUNDS

The amount of a substance added to a water supply is known as the *dose*. *Purity*, *P*, and *availability*, *G*, both affect dose. A substance's purity decreases when it is mixed with another substance. A substance's availability decreases when some of the substance does not dissolve or react chemically.

For example, *lime* is a term that describes various calcium compounds. Lime is typically quarried from naturally occurring limestone ( $\text{CaCO}_3$ ). Limestone contains silica and other non-calcium compounds, which reduces the as-delivered lime purity. *Quicklime* ( $\text{CaO}$ ) is produced by heating (i.e., burning)  $\text{CaCO}_3$  in a lime kiln. Accordingly, quicklime may contain some calcium in the form of calcium carbonate rather than calcium oxide. The *total lime* (i.e., total calcium) content includes both calcium compounds, while the *available lime* only includes the  $\text{CaO}$  form.

Feed rate, *F*, of a compound with purity *P* and fractional availability *G* can be calculated from the *dose equation*, Eq. 26.16. Doses in mg/L and ppm for aqueous solutions are the same. Each 1% by weight of concentration is equivalent to 10,000 mg/L of solution. Doses may be given in terms of grains per gallon. There are 7000 grains per pound.

$$F_{\text{kg/d}} = \frac{D_{\text{mg/L}} Q_{\text{ML/d}}}{PG} \quad [\text{SI}] \quad 26.16(a)$$

$$F_{\text{lbm/day}} = \frac{D_{\text{mg/L}} Q_{\text{MGD}} \left( 8.345 \frac{\text{lbm-L}}{\text{mg-MG}} \right)}{PG} \quad [\text{U.S.}] \quad 26.16(b)$$

### Example 26.1

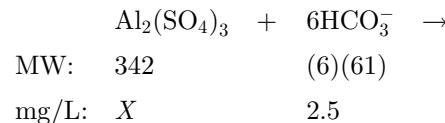

Incoming water contains 2.5 mg/L as a substance of natural alkalinity ( $\text{HCO}_3^-$ ). The flow rate is 2.5 MGD (9.5 ML/day). (a) What feed rate is required if the alum (purity 48%) dose is 7 mg/L? (b) How much lime (purity 85%) in the form of  $\text{Ca(OH)}_2$  is required to react completely with the alum?

*SI Solution*

(a) The dose is specifically in terms of mg/L of alum. Therefore, Eq. 26.16 can be used.

$$F_{\text{kg/d}} = \frac{D_{\text{mg/L}} Q_{\text{ML/d}}}{PG} = \frac{\left( 7 \frac{\text{mg}}{\text{L}} \right) \left( 9.5 \frac{\text{ML}}{\text{d}} \right)}{(0.48)(1.0)} \\ = 138.5 \text{ kg/d}$$

(b) From Eq. 26.13, each alum molecule reacts with six ions of alkalinity.

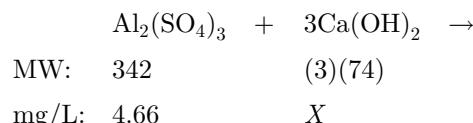

By simple proportion, the amount of alum used to counteract the natural alkalinity is

$$X = \frac{\left( 2.5 \frac{\text{mg}}{\text{L}} \right) (342)}{(6)(61)} = 2.34 \text{ mg/L}$$

The alum remaining is

$$7 \frac{\text{mg}}{\text{L}} - 2.34 \frac{\text{mg}}{\text{L}} = 4.66 \text{ mg/L}$$

From Eq. 26.14, one alum molecule reacts with three slaked lime molecules.

By simple proportion, the amount of lime needed is

$$X = \frac{\left( 4.66 \frac{\text{mg}}{\text{L}} \right) (3)(74)}{342} = 3.02 \text{ mg/L}$$

Using Eq. 26.16,

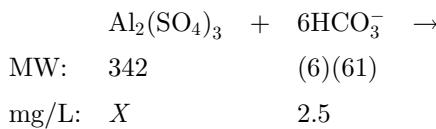

$$F_{\text{kg/d}} = \frac{D_{\text{mg/L}} Q_{\text{ML/d}}}{PG} \\ = \frac{\left( 3.02 \frac{\text{mg}}{\text{L}} \right) \left( 9.5 \frac{\text{ML}}{\text{d}} \right)}{(0.85)(1.0)} \\ = 33.8 \text{ kg/d}$$

*Customary U.S. Solution*

(a) The dose is specifically in terms of mg/L of alum. Therefore, Eq. 26.16 can be used.

$$\begin{aligned} F_{\text{lbm/day}} &= \frac{D_{\text{mg/L}} Q_{\text{MGD}} \left( 8.345 \frac{\text{lbm-L}}{\text{mg-MG}} \right)}{PG} \\ &= \frac{\left( 7 \frac{\text{mg}}{\text{L}} \right) (2.5 \text{ MGD}) \left( 8.345 \frac{\text{lbm-L}}{\text{mg-MG}} \right)}{(0.48)(1.0)} \\ &= 304.2 \text{ lbm/day} \end{aligned}$$

(b) From Eq. 26.13, each alum molecule reacts with six ions of alkalinity.

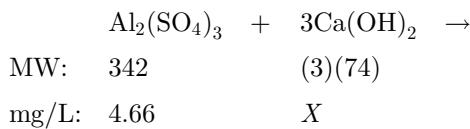

By simple proportion, the amount of alum used to counteract the natural alkalinity is

$$X = \frac{\left( 2.5 \frac{\text{mg}}{\text{L}} \right) (342)}{(6)(61)} = 2.34 \text{ mg/L}$$

The alum remaining is

$$7 \frac{\text{mg}}{\text{L}} - 2.34 \frac{\text{mg}}{\text{L}} = 4.66 \text{ mg/L}$$

From Eq. 26.14, one alum molecule reacts with three lime molecules.

By simple proportion, the amount of lime needed is

$$X = \frac{\left( 4.66 \frac{\text{mg}}{\text{L}} \right) (3)(74)}{342} = 3.02 \text{ mg/L}$$

Using Eq. 26.16,

$$\begin{aligned} F_{\text{lbm/day}} &= \frac{D_{\text{mg/L}} Q_{\text{MGD}} \left( 8.345 \frac{\text{lbm-L}}{\text{mg-MG}} \right)}{PG} \\ &= \frac{\left( 3.02 \frac{\text{mg}}{\text{L}} \right) (2.5 \text{ MGD}) \left( 8.345 \frac{\text{lbm-L}}{\text{mg-MG}} \right)}{(0.85)(1.0)} \\ &= 74.1 \text{ lbm/day} \end{aligned}$$

**18. MIXERS AND MIXING KINETICS**

Coagulants and other water treatment chemicals are added in *mixers*. If the mixer adds a coagulant for the removal of colloidal sediment, a downstream location (i.e., a tank or basin) with a reduced velocity gradient may be known as a *flocculator*.

There are two basic models: plug flow mixing and complete mixing. The *complete mixing model* is appropriate when the chemical is distributed throughout by impellers or paddles. If the basin volume is small, so that time for mixing is low, the tank is known as a *flash mixer*, *rapid mixer*, or *quick mixer*. The volume of flash mixers is seldom greater than 300 ft<sup>3</sup> (8 m<sup>3</sup>), and flash mixer detention time is usually 30–60 sec. Flash mixing kinetics are described by the complete mixing model.

Flash mixers are usually concrete tanks, square in horizontal cross section, and fitted with vertical shaft impellers. The size of a mixing basin can be determined from various combinations of dimensions that satisfy the volume-flow rate relationship.

$$V = tQ \quad 26.17$$

The detention time required for complete mixing in a tank of volume *V* depends on the *mixing rate constant*, *K*, and the incoming and outgoing concentrations.

$$t_{\text{complete}} = \frac{V}{Q} = \frac{1}{K} \left( \frac{C_i}{C_o} - 1 \right) \quad 26.18$$

The *plug flow mixing model* is appropriate when the water flows through a long narrow chamber, the chemical is added at the entrance, and there is no mechanical agitation. All of the molecules remain in the plug flow mixer for the same amount of time as they flow through. For any mixer, the maximum chemical conversion will occur with plug flow, since all of the molecules have the maximum opportunity to react. The detention time in a plug flow mixer of length *L* is

$$\begin{aligned} t_{\text{plug flow}} &= \frac{V}{Q} = \frac{L}{v_f} \\ &= \frac{1}{K} \ln \frac{C_i}{C_o} \end{aligned} \quad 26.19$$

**19. MIXING PHYSICS**

The drag force on a paddle is given by the standard fluid drag force equation. For flat plates, the coefficient of drag, *C<sub>D</sub>*, is approximately 1.8.

$$F_D = \frac{C_D A \rho v_{\text{mixing}}^2}{2} \quad [\text{SI}] \quad 26.20(a)$$

$$F_D = \frac{C_D A \rho v_{\text{mixing}}^2}{2g_c} = \frac{C_D A \gamma v_{\text{mixing}}^2}{2g} \quad [\text{U.S.}] \quad 26.20(b)$$

The power required is calculated from the drag force and the mixing velocity. The average *mixing velocity*,  $v_{\text{mixing}}$ , also known as the *relative paddle velocity*, is the difference in paddle and average water velocities. The mixing velocity is approximately 0.7–0.8 times the tip speed.

$$v_{\text{paddle,ft/sec}} = \frac{2\pi R n_{\text{rpm}}}{60 \frac{\text{sec}}{\text{min}}} \quad 26.21$$

$$v_{\text{mixing}} = v_{\text{paddle}} - v_{\text{water}} \quad 26.22$$

$$\begin{aligned} P_{\text{kW}} &= \frac{F_D v_{\text{mixing}}}{1000 \frac{\text{W}}{\text{kW}}} \\ &= \frac{C_D A \rho v_{\text{mixing}}^3}{2 \left( 1000 \frac{\text{W}}{\text{kW}} \right)} \quad [\text{SI}] \quad 26.23(a) \end{aligned}$$

$$\begin{aligned} P_{\text{hp}} &= \frac{F_D v_{\text{mixing}}}{550 \frac{\text{ft-lbf}}{\text{hp-sec}}} = \frac{C_D A \rho v_{\text{mixing}}^3}{2 g_c \left( 550 \frac{\text{ft-lbf}}{\text{hp-sec}} \right)} \\ &= \frac{C_D A \gamma v_{\text{mixing}}^3}{2 g \left( 550 \frac{\text{ft-lbf}}{\text{hp-sec}} \right)} \quad [\text{U.S.}] \quad 26.23(b) \end{aligned}$$

For slow-moving paddle mixers, the *velocity gradient*,  $G$ , varies from  $20 \text{ sec}^{-1}$  to  $75 \text{ sec}^{-1}$  for a 15 min to 30 min mixing period. Typical units in Eq. 26.24 are ft-lbf/sec for power (multiply hp by 550 to obtain ft-lbf/sec), lbf-sec/ft<sup>2</sup> for  $\mu$ , and ft<sup>3</sup> for volume. In the SI system, power in kW is multiplied by 1000 to obtain W, viscosity is in Pa·s, and volume is in m<sup>3</sup>. (Multiply viscosity in cP by 0.001 to obtain Pa·s.)

$$G = \sqrt{\frac{P}{\mu V_{\text{tank}}}} \quad 26.24$$

Equation 26.24 can also be used for rapid mixers, in which case the mean velocity gradient is much higher: approximately  $500$ – $1000 \text{ sec}^{-1}$  for  $10$ – $30 \text{ sec}$  mixing period, or  $3000$ – $5000 \text{ sec}^{-1}$  for a  $0.5$ – $1.0 \text{ sec}$  mixing period in an in-line blender configuration.

Equation 26.24 can be rearranged to calculate the power requirement. Power is typically 0.5–1.5 hp/MGD for rapid mixers.

$$P = \mu G^2 V_{\text{tank}} \quad 26.25$$

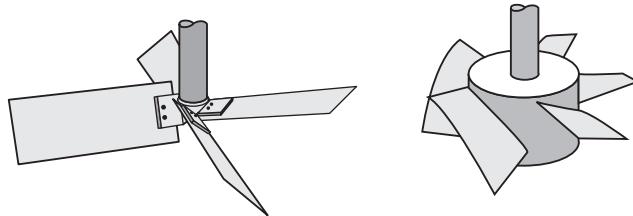

The dimensionless product,  $Gt_d$ , of the velocity gradient and detention time is known as the *mixing opportunity parameter*. Typical values range from  $10^4$  to  $10^5$ .

$$\begin{aligned} Gt_d &= \frac{V_{\text{tank}}}{Q} \sqrt{\frac{P}{\mu V_{\text{tank}}}} \\ &= \frac{1}{Q} \sqrt{\frac{PV_{\text{tank}}}{\mu}} \quad 26.26 \end{aligned}$$

## 20. IMPELLER CHARACTERISTICS

Mixing equipment uses rotating impellers on rotating shafts. The blades of *radial-flow impellers* (paddle-type impellers, turbine impellers, etc.) are parallel to the drive shaft. *Axial-flow impellers* (propellers, pitched-blade impellers, etc.) have blades inclined with respect to the drive shaft. (See Fig. 26.5.) Axial-flow impellers are better at keeping materials (e.g., water softening chemicals) in suspension.

**Figure 26.5** Typical Axial Flow Mixing Impellers

The *mixing Reynolds number* depends on the impeller diameter,  $D$ , suspension specific gravity, SG, liquid viscosity,  $\mu$ , and rotational speed,  $n$ , in rev/sec. Flow is in transition for  $10 < \text{Re} < 10,000$ , is laminar below 10, and is turbulent above 10,000.

$$\text{Re} = \frac{D^2 n \rho}{\mu} \quad [\text{SI}] \quad 26.27(a)$$

$$\text{Re} = \frac{D^2 n \rho}{g_c \mu} \quad [\text{U.S.}] \quad 26.27(b)$$

The dimensionless *power number*,  $N_P$ , of the impeller is defined implicitly by the power required to drive the impeller. For any given level of suspension, Eq. 26.28 through Eq. 26.31 apply to geometrically similar impellers and turbulent flow.

$$P = N_P n^3 D^5 \rho \quad [\text{SI}] \quad 26.28(a)$$

$$P = \frac{N_P n^3 D^5 \rho}{g_c} \quad [\text{U.S.}] \quad 26.28(b)$$

$$P = \rho g Q h_v \quad [\text{SI}] \quad 26.29(a)$$

$$P = \frac{\rho g Q h_v}{g_c} \quad [\text{U.S.}] \quad 26.29(b)$$

The impeller's dimensionless *flow number*,  $N_Q$ , is defined implicitly by the *flow rate equation*.

$$Q = N_Q n D^3 \quad 26.30$$

The velocity head can be calculated from a combination of the power and flow numbers.

$$h_v = \frac{N_P n^2 D^2}{N_Q g} \quad 26.31$$

Vibration near the critical speed can be a major problem with modern, high-efficiency, high-speed impellers. Mixing speed should be well below (i.e., less than 80% of) the first critical speed of the shaft. Other important design factors include tip speed and shaft bending moment.

The critical speed of a shaft corresponds to its natural harmonic frequency of vibration when loaded as a flexing beam. If the harmonic frequency,  $f_c$ , is in hertz, the shaft's critical rotational speed (in rev/min) will be  $60f_c$ . The critical speed depends on many factors, including the masses and locations of paddles and other shaft loads, shaft material, length, and end restraints. It is not important whether the shaft is vertical or horizontal, and the damping effects of the mixing fluid and any stabilizing devices are disregarded in calculations. For a lightweight (i.e., massless) mixing impeller that is on a suspended (cantilever) shaft of length  $L$ , has a uniform cross section, a mass per unit length of  $m_L$ , and is supported by a fixed upper bearing, the first critical speed,  $f_c$ , in hertz, will be the same as that of a cantilever beam and can be approximated from Eq. 26.32. Other configurations, including mixed shaft materials, stepped or varying shaft diameters, two or more support bearings, substantial impeller mass, and multiple impellers require different analysis methods.

$$f_c = 0.56 \sqrt{\frac{EI}{L^4 m_L}} \quad [\text{SI}] \quad 26.32(a)$$

$$f_c = 0.56 \sqrt{\frac{EIg_c}{L^4 m_L}} \quad [\text{U.S.}] \quad 26.32(b)$$

## 21. FLOCCULATION

After flash mixing, the floc is allowed to form during a 20–60 min period of gentle mixing. Flocculation is enhanced by the gentle agitation, but floc disintegrates with violent agitation. During this period, the flow-through velocity should be limited to 0.5–1.5 ft/min (0.25–0.75 cm/s). The peripheral speed of mixing paddles should vary approximately from 0.5 ft/sec (0.15 m/s) for fragile, cold-water floc to 3.0 ft/sec (0.9 m/s) for warm-water floc.

Many modern designs make use of *tapered flocculation*, also known as *tapered energy*, a process in which the amount (severity) of flocculation gradually decreases as

the treated water progresses through the flocculation basin.

Flocculation is followed by sedimentation for two to eight hours (four hours typical) in a low-velocity portion of the basin. (The flocculation time is determined from settling column data.) A good settling process will remove 90% of the settleable solids. Poor design, usually resulting in some form of *short-circuiting* of the flow path, will reduce the effective time in which particles have to settle.

## 22. FLOCCULATOR-CLARIFIERS

A *flocculator-clarifier* combines mixing, flocculation, and sedimentation into a single tank. Such units are called *solid contact units* and *upflow tanks*. They are generally round in construction, with mixing and flocculation taking place near the central hub and sedimentation occurring at the periphery. Flocculator-clarifiers are most suitable when combined with softening, since the precipitated solids help seed the floc.

Typical operational characteristics of flocculator-clarifiers are given in Table 26.2.

**Table 26.2** Characteristics of Flocculator-Clarifiers

typical flocculation and mixing time	20–60 min
minimum detention time	1.5–2.0 hr
maximum weir loading	10 gpm/ft (2 L/s·m)
upflow rate	0.8–1.7 gpm/ft <sup>2</sup> ; 1.0 gpm/ft <sup>2</sup> typical (0.54–1.2 L/s·m <sup>2</sup> ; 0.68 L/s·m <sup>2</sup> typical)
maximum sludge formation rate	5% of water flow

(Multiply gpm/ft by 0.207 to obtain L/s·m.)  
(Multiply gpm/ft<sup>2</sup> by 0.679 to obtain L/s·m<sup>2</sup>.)

## 23. SLUDGE QUANTITIES

*Sludge* is the watery waste that carries off the settled floc and the water softening precipitates. The sludge volume produced is given by Eq. 26.33, in which  $G$  is the gravimetric fraction of solids. The gravimetric solids fraction for coagulation sludge is generally less than 0.02. For water softening sludge, it is on the order of 0.10. In Eq. 26.33,  $m_{\text{sludge}}$  can be either a specific quantity or a rate of production per unit time.

$$V_{\text{sludge}} = \frac{m_{\text{sludge}}}{\rho_{\text{water}} (\text{SG})_{\text{sludge}} G} \quad 26.33$$

The most accurate way to calculate the mass of sludge is to extrapolate from jar or pilot test data. There is no absolute correlation between the mass generated and other water quality measurements. However, a few generalizations are possible. (a) Each unit mass (lbm, mg/L,

etc.) of alum produces 0.46 unit mass of floc.<sup>8</sup> (b) 100% of the reduction in suspended solids (expressed as substance) shows up as floc. (c) 100% of any supplemental flocculation aids is recovered in the sludge.

Suspended solids in water may be reported in turbidity units. There is no easy way to calculate total suspended solids (TSS) in mg/L from turbidity in NTU. The ratio of TSS to NTU normally varies from 1.0–2.0, and can be as high as 10. A value of 1 or 1.5 is generally appropriate.

The rate of dry sludge production from coagulation processes can be estimated from Eq. 26.34.  $M$  is an extra factor that accounts for the use of any miscellaneous inorganic additives such as clay.

$$m_{\text{sludge,kg/d}} = \frac{\left( 86\,400 \frac{\text{s}}{\text{d}} \right) Q_{\text{m}^3/\text{s}} \left( 1000 \frac{\text{L}}{\text{m}^3} \right)}{10^6 \frac{\text{mg}}{\text{kg}}} \times (0.46 D_{\text{alum,mg/L}} + \Delta \text{TSS}_{\text{mg/L}} + M_{\text{mg/L}})$$

[SI] 26.34(a)

$$m_{\text{sludge,lbm/day}} = \left( 8.345 \frac{\text{lbm-L}}{\text{mg-MG}} \right) Q_{\text{MGD}}$$

$$\times (0.46 D_{\text{alum,mg/L}} + \Delta \text{TSS}_{\text{mg/L}} + M_{\text{mg/L}})$$

[U.S.] 26.34(b)

After a sludge dewatering process from sludge solids constant  $G_1$  to  $G_2$ , the resulting volume will be

$$V_{2,\text{sludge}} \approx V_{1,\text{sludge}} \frac{G_1}{G_2}$$

26.35

## 24. FILTRATION

Nonsettling floc, algae, suspended precipitates from softening, and metallic ions (iron and manganese) are removed by filtering. *Sand filters* (and in particular, rapid sand filters) are commonly used for this purpose. Sand filters are beds of gravel, sand, and other granulated materials.<sup>9</sup>

Although filter box heights are on the order of 10 ft (3 m) to provide for expansion and freeboard during backwashing, the almost-universal specification used before 1960 for a single-media filter was 24–30 in (610–760 mm) of sand or ground coal. Filters are usually square or nearly square in plan, and they operate with a hydraulic head of 1–8 ft (0.3–2.4 m).

<sup>8</sup>0.456 is the stoichiometric ratio of floc ( $\text{Al(OH)}_3$ ) to alum ( $\text{Al}_2(\text{SO}_4)_3 \cdot 14.3\text{H}_2\text{O}$ ) in Eq. 26.13 when the water of hydration ( $14.3\text{H}_2\text{O}$ ) is included. 0.26 is the ratio if the water of hydration is not included.

<sup>9</sup>Most early sand filter beds were designed when a turbidity level of 5 NTU was acceptable. With the U.S. federal MCL at 1 NTU, some states at 0.5 NTU, and planning “on the horizon” for 0.2 NTU, these early conventional filters are clearly inadequate.

Although most plants have six or more filters, there should be at least three filters so that two can be operational when one is being cleaned. Cleaning of multiple filters should be staged.

Filter operation is enhanced when the top layer of sand is slightly more coarse than the deeper sand. During backwashing, however, the finest sand rises to the top. Various *dual-layer* and *multi-layer* (also known as *dual-media* and *multi-media*) filter designs using layers of coal (“anthrafilt”) and (more recently) granular activated carbon, alone or in conjunction with sand, overcome this problem. Since coal has a lower specific gravity than sand, media particle size is larger, as is pore space.

Historically, the *loading rate* (i.e., *flow rate*) for *rapid sand filters* was set at 2–3 gpm/ft<sup>2</sup> (1.4–2.0 L/s·m<sup>2</sup>). A range of 4–6 gpm/ft<sup>2</sup> (2.7–4.1 L/s·m<sup>2</sup>) is a reasonable minimum rate for dual-media filters. Multi-media filters operate at 5–10 gpm/ft<sup>2</sup> (3.4–6.8 L/s·m<sup>2</sup>) and above.<sup>10</sup> The filter loading rate is

$$\text{loading rate} = \frac{Q}{A}$$

26.36

Filters discharge into a storage reservoir known as a *clearwell*. The *hydraulic head* (the distance between the water surfaces in the filter and clearwell) is usually 9–12 ft (2.7–3.6 m). This allows for a substantial decrease in available head prior to backwashing. Clearwell storage volume is 30–60% of the daily filter output, with a minimum capacity of 12 hr of the maximum daily demand so that demand can be satisfied from the clearwell while the filter is being cleaned or serviced.

## 25. FILTER BACKWASHING

The most common type of service needed by filters is backwashing, which is needed when the pores between the filter particles clog up. Typically, this occurs after 1 to 3 days of operation, when the head loss reaches 6–8 ft (1.6–2.4 m). There are two parameters that can trigger backwashing: head loss and turbidity. Head loss increases almost linearly with time, while turbidity remains constant for several days before suddenly increasing. The point of sudden increase is known as *breakthrough*.<sup>11</sup> Since head loss is more easily monitored than turbidity, it is desired to have head loss trigger the backwashing cycle.

Backwashing with filtered water pumped back through the filter from the bottom to the top expands the sand layer 30–50%, which dislodges trapped material. Backwashing for 3–5 min at 8–15 gpm/ft<sup>2</sup> (5.4–10 L/s·m<sup>2</sup>) is

<sup>10</sup>Testing has demonstrated that deep-bed, uniformly graded anthracite filters can operate at 10–15 gpm/ft<sup>2</sup> (7–10 L/s·m<sup>2</sup>), although this requires high-efficiency preozonation and microflocculation.

<sup>11</sup>Technically, *breakthrough* is the point at which the turbidity rises above the MCL permitted. With low MCLs, this occurs very soon after the beginning of filter performance degradation.

a typical specification.<sup>12</sup> The head loss is reduced to approximately 1 ft (0.3 m) after washing.

Experience has shown that supplementary agitation of the filter media is necessary to prevent “caking” and “mudballs” in almost all installations. Prior to backwashing, the filter material may be expanded by an *air prewash* volume of 1–8 (2–5 typical) times the sand filter volume per minute for 2–10 min (3–5 min typical). Alternatively, turbulence in the filter material may be encouraged during backwashing with an *air wash* or with rotating hydraulic surface jets.

During backwashing, the water in the filter housing will rise at a rate of 1–3 ft/min (0.5–1.5 cm/s). This rise should not exceed the settling velocity of the smallest particle that is to be retained in the filter. The wash water, which is collected in troughs for disposal, constitutes approximately 1–5% of the total processed water. The total water used is approximately 75–100 gal/ft<sup>2</sup> (3–4 kL/m<sup>2</sup>). The actual amount of backwash water is

$$V = A_{\text{filter}}(\text{rate of rise})t_{\text{backwash}} \quad 26.37$$

The temperature of the water used in backwashing is important since the viscosity changes. (The effect of temperature on water density is negligible.) 40°F (4°C) water is more viscous than 70°F (21°C) water. Media particles, therefore, may be expanded to the same extent using lower upflow rates at the lower backwash temperature.

## 26. OTHER FILTRATION METHODS

*Pressure (sand) filters* for water supply treatment operate similarly to rapid sand filters except that incoming water is typically pressurized 25–75 psig (170–520 kPa gage). Single media filter rates are 2–10 gpm/ft<sup>2</sup>, with 4–5 gpm/ft<sup>2</sup> being typical (1.4–14 L/s·m<sup>2</sup> (2.7–3.4 L/s·m<sup>2</sup> typical)), with dual media filters running at 1.5 to 2.0 times these rates. Pressure filters are not used in large installations.

*Ultrafilters* are membranes that act as sieves to retain turbidity, microorganisms, and large organic molecules that are THM precursors, while allowing water, salts, and small molecules to pass through. Ultrafiltration is effective in removing particles ranging in size of 0.001–10 µm.<sup>13</sup> A pressure of 15–75 psig (100–500 kPa) is required to drive the water through the membrane.

*Biofilm filtration (biofilm process)* uses microorganisms to remove selected contaminants (e.g., aromatics and other hydrocarbons). Operation of biofilters is similar to trickling filters used in wastewater processing. Sand filter facilities are relatively easy to modify—sand is replaced with gravel in the 4–14 mm size range, application rates are decreased, and exposure to chlorine from incoming and backwash water is eliminated.

<sup>12</sup>While the maximum may never be used, a maximum backwash rate of 20 gpm/ft<sup>2</sup> (14 L/s·m<sup>2</sup>) should be provided for.

<sup>13</sup>A µm is the same as a micron.

*Slow sand filters* are primarily of historical interest, though there are some similarities with modern biomethods used to remediate toxic spills. Slow sand filters operate similarly to rapid sand filters except that the exposed surface (loading) area is much larger and the flow rate is much lower (0.05–0.1 gpm/ft<sup>2</sup>, 0.03–0.07 L/s·m<sup>2</sup>). Slow sand filters are limited to low turbidity applications not requiring chemical treatment and where large rural areas are available to spread out the facilities. Slow sand filters can be operated as biofilm processes if a layer of biological slime is allowed to form on the top of the filter medium.<sup>14</sup> Slow filter cleaning usually involves removing a few inches of sand.

## 27. ADSORPTION

Many dissolved organic molecules and inorganic ions can be removed by adsorption processes. *Adsorption* is not a straining process, but occurs when contaminants are trapped on the surface or interior of the adsorption particles.

*Granular activated carbon* (GAC) is considered to be the best available technology for removal of THMs and synthetic organic chemicals from water.<sup>15</sup> GAC is also useful in removing compounds that contribute to taste, color, and odor. Activated carbon can be used in the form of powder (which must be subsequently removed) or granules. GAC can be integrated into the design of sand filters.<sup>16</sup>

Eventually, the GAC becomes saturated and must be removed and reactivated. In such dual-media filters, the reactivation interval for GAC is approximately one to two years.

## 28. FLUORIDATION

Fluoridation can occur any time after filtering and can involve solid compounds or liquid solutions. Small utilities may manufacturer their own liquid solution on-site from sodium silicofluoride ( $\text{Na}_2\text{SiF}_6$ , typically 22–30% purity) or sodium fluoride ( $\text{NaF}$ , typically 90–98% purity) for use with a volumetric metering system. Larger utilities use gravimetric dry feeders with sodium silicofluoride ( $\text{Na}_2\text{SiF}_6$ , typically 98–99% purity) or solution feeders with fluorosilic acid ( $\text{H}_2\text{SiF}_6$ ).

Assuming 100% ionization, the application rate,  $F$  (in pounds per day), of a compound with fluoride gravimetric fraction,  $G$ , and a fractional purity,  $P$ , needed to obtain a final concentration,  $C$ , of fluoride is

$$F_{\text{kg/d}} = \frac{C_{\text{mg/L}} Q_{\text{L/d}}}{PG} \quad [\text{SI}] \quad 26.38(a)$$

<sup>14</sup>The biological slime is called *schmutzdecke*. The slime forms a physical barrier that traps particles.

<sup>15</sup>Enhanced coagulation is also a “best available” technology for THM removal that may be economically more attractive.

<sup>16</sup>For example, an 80 in (2032 mm) GAC layer may be placed on top of a 40 in (1016 mm) sand layer.

$$F_{\text{lbm/day}} = \frac{C_{\text{mg/L}} Q_{\text{MGD}} \left( 8.345 \frac{\text{lbm-L}}{\text{mg-MG}} \right)}{PG}$$

[U.S.] 26.38(b)

## 29. IRON AND MANGANESE REMOVAL

Several methods can be used to remove iron and manganese. Most involve aeration with chemical oxidation since manganese is not easily removed by aeration alone. These processes are described in Table 26.3.

## 30. TASTE AND ODOR CONTROL

A number of different processes affect taste and odor. Some are more effective and appropriate than others. *Microstraining*, using a 35 µm or finer metal cloth, can be used to reduce the number of algae and other organisms in the water, since these are sources of subsequent tastes and odors. Microstraining does not remove dissolved or colloidal organic material, however.

Activated carbon removes more tastes and odors, as well as a wide variety of chemical contaminants.

Aeration can be used when dissolved oxygen is low or when hydrogen sulfide is present. Aeration has little effect on most other tastes and odors.

Chlorination disinfects and reduces odors caused by organic matter and industrial wastes. Normally, the dosage required will be several times greater than those for ordinary disinfection, and the term *superchlorination* is used to describe applying enough chlorine to maintain an excessively large residual. Subsequent dechlorination will be required to remove the excess chlorine. Similar results will be obtained with chlorine dioxide and other disinfection products.

A quantitative odor ranking is the *threshold odor number* (TON), which is determined by adding increasing amounts of odor-free dilution water to a sample until the combined sample is virtually odor free.

$$\text{TON} = \frac{V_{\text{raw sample}} + V_{\text{dilution water}}}{V_{\text{raw sample}}} \quad 26.39$$

A TON of 3 or less is ideal. Untreated river water usually has a TON between 6 and 24. Treated water normally has a TON between 3 and 6. At TON of 5 and above, customers will begin to notice the taste and odor of their water.

## 31. PRECIPITATION SOFTENING

*Precipitation softening* using the *lime-soda ash process* adds lime ( $\text{CaO}$ ), also known as quicklime, and soda ash ( $\text{Na}_2\text{CO}_3$ ) to remove calcium and magnesium from hard

water.<sup>17</sup> Granular quicklime is available with a minimum purity of 90%, and soda ash is available with a 98% purity.

Lime forms *slaked lime* (also known as *hydrated lime*),  $\text{Ca}(\text{OH})_2$ , in an exothermic reaction when added to feed water. The slaked lime is delivered to the water supply as a *milk of lime* suspension.

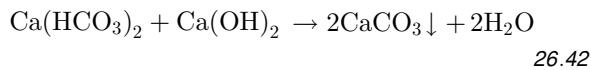

Slaked lime reacts first with any carbon dioxide dissolved in the water, as in Eq. 26.41. No softening occurs, but the carbon dioxide demand must be satisfied before any reactions involving calcium or magnesium can occur.

*carbon dioxide removal:*

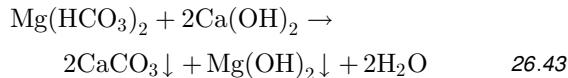

Lime next reacts with any carbonate hardness, precipitating calcium carbonate and magnesium hydroxide, as shown in Eq. 26.42 and Eq. 26.43. The removal of carbonate hardness caused by magnesium (characterized by magnesium bicarbonate in Eq. 26.43) requires two molecules of calcium hydroxide to precipitate calcium carbonate and magnesium hydroxide.

*calcium carbonate hardness removal:*

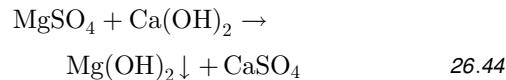

*magnesium carbonate hardness removal:*

To remove noncarbonate hardness (characterized by sulfate ions in Eq. 26.44 and Eq. 26.45), it is necessary to add soda ash and more lime. The sodium sulfate that remains in solution does not contribute to hardness, for sodium is a single-valent ion (i.e.,  $\text{Na}^+$ ).

*magnesium noncarbonate hardness removal:*

*calcium noncarbonate hardness removal:*

The calcium ion can be effectively reduced by the lime addition shown in the previous equations, raising the pH of the water to approximately 10.3. (Thus, the lime added removes itself.) Precipitation of the magnesium ion, however, requires a higher pH and the presence of excess lime in the amount of approximately 35 mg/L of  $\text{CaO}$  or 50 mg/L of  $\text{Ca}(\text{OH})_2$  above the stoichiometric

<sup>17</sup>Soda ash does not always need to be used. When lime alone is used, the process may be referred to as *lime softening*.

**Table 26.3** Processes for Iron and Manganese Removal

processes	iron and/or manganese removed	pH required	remarks
aeration, settling, and filtration	ferrous bicarbonate	7.5	provide aeration unless incoming water contains adequate dissolved oxygen
	ferrous sulfate	8.0	
	manganous bicarbonate	10.3	
	manganous sulfate	10.0	
aeration, free residual chlorination, settling, and filtration	ferrous bicarbonate	5.0	provide aeration unless incoming water contains adequate dissolved oxygen
	manganous bicarbonate	9.0	
aeration, lime softening, settling, and filtration	ferrous bicarbonate	8.5–9.6	require lime, and alum or iron coagulant
	manganous bicarbonate		
aeration, coagulation, lime softening, settling, and filtration	colloidal or organic iron	8.5–9.6	require lime, and alum or iron coagulant
	colloidal or organic manganese	10.0	
ion exchange	ferrous bicarbonate	≈ 6.5	water must be devoid of oxygen iron and manganese in raw water not to exceed 2.0 mg/L consult manufacturers for type of ion exchange resin to be used
	manganous bicarbonate		

requirements. The practical limits of precipitation softening are 30–40 mg/L of CaCO<sub>3</sub> and 10 mg/L of Mg(OH)<sub>2</sub>, both as CaCO<sub>3</sub>.

After softening, the water must be recarbonated to lower its pH and to reduce its scale-forming potential. This is accomplished by bubbling carbon dioxide gas through the water.

The treatment process could be designed such that all of these reactions take place sequentially. That is, first slaked lime would be added (see Eq. 26.42 and Eq. 26.43), then the water would be recarbonated (see Eq. 26.46), then excess lime would be added to raise the pH, followed by soda ash treatment and recarbonation. In fact, essentially such a sequence is used in a *double-stage process*: two chemical application points and two recarbonation points.

A *split process* can be used to reduce the amount of lime that is neutralized in recarbonation. The excess lime needed to raise the pH is added prior to the first flocculator/clarifier stage. The soda ash is added to the first stage effluent, prior to the second flocculator/clarifier stage. Recarbonation, if used, is applied to the effluent of the second stage. A portion of the flow is bypassed (i.e., is not softened) and is later recombined with softened water to obtain the desired hardness.

### Example 26.2

Water contains 130 mg/L of calcium bicarbonate (Ca(HCO<sub>3</sub>)<sub>2</sub>) as CaCO<sub>3</sub>. How much slaked lime (Ca(OH)<sub>2</sub>) is required to remove the hardness?

*Solution*

The hardness is given as a CaCO<sub>3</sub> equivalent. Therefore, the amount of slaked lime required is implicitly the

same: 130 mg/L as CaCO<sub>3</sub>. Convert the quantity to an “as substance” measurement. The conversion factor for Ca(OH)<sub>2</sub> is 1.35.

$$\text{Ca}(\text{OH})_2: \frac{130 \frac{\text{mg}}{\text{L}}}{1.35} = 96.3 \text{ mg/L as substance}$$

### Example 26.3

Water is received with the following characteristics.

total hardness	250 mg/L as CaCO <sub>3</sub>
alkalinity	150 mg/L as CaCO <sub>3</sub>
carbon dioxide	5 mg/L as substance

The water is to be treated with precipitation softening and recarbonation. Lime (90% pure) and soda ash (98% pure) are available.

Using 50 mg/L of Ca(OH)<sub>2</sub> as substance to raise the pH for magnesium precipitation, what stoichiometric amounts (as substance) of (a) slaked lime, (b) soda ash, and (c) carbon dioxide are required to reduce the hardness of the water to zero?

*Solution*

(a) First, convert the carbon dioxide concentration to a CaCO<sub>3</sub> equivalent. The factor is 2.27.

$$\text{CO}_2: \left(5 \frac{\text{mg}}{\text{L}}\right)(2.27) = 11.35 \text{ mg/L as CaCO}_3$$

Since the alkalinity is less than the hardness and no hydroxides or calcium are reported, it is concluded that the carbonate hardness is equal to the alkalinity, and the noncarbonate hardness is equal to the difference in total hardness and alkalinity.

Since the alkalinity is reported as a  $\text{CaCO}_3$  equivalent, the first-state treatment to remove carbon dioxide and carbonate hardness requires lime in the amount of

$$\text{Ca}(\text{OH})_2: 11.35 \frac{\text{mg}}{\text{L}} + 150 \frac{\text{mg}}{\text{L}} = 161.35 \text{ mg/L as CaCO}_3$$

50 mg/L of  $\text{Ca}(\text{OH})_2$  are added to raise the pH so that the magnesium (noncarbonate) hardness can be removed. The factor that converts  $\text{Ca}(\text{OH})_2$  to  $\text{CaCO}_3$  is 1.35.

$$\begin{aligned}\text{Ca}(\text{OH})_2: 161.35 \frac{\text{mg}}{\text{L}} &+ (1.35)(50 \frac{\text{mg}}{\text{L}}) \\ &= 228.85 \text{ mg/L as CaCO}_3\end{aligned}$$

Use the 90% fractional purity to convert to quantity as substance.

$$\text{Ca}(\text{OH})_2: \frac{228.85 \frac{\text{mg}}{\text{L}}}{(1.35)(0.9)} = 188.4 \text{ mg/L as substance}$$

(b) The noncarbonate hardness is

$$250 \frac{\text{mg}}{\text{L}} - 150 \frac{\text{mg}}{\text{L}} = 100 \text{ mg/L as CaCO}_3$$

The soda ash requirement is

$$\text{Na}_2\text{CO}_3: \frac{100 \frac{\text{mg}}{\text{L}}}{(0.94)(0.98)} = 108.6 \text{ mg/L as substance}$$

(c) The recarbonation required to lower the pH depends on the amount of excess lime added.

$$\text{CO}_2: \frac{(1.35)(50 \frac{\text{mg}}{\text{L}})}{2.27} = 29.74 \text{ mg/L as substance}$$

## 32. ADVANTAGES AND DISADVANTAGES OF PRECIPITATION SOFTENING

Precipitation softening is relatively inexpensive for large quantities of water. Both alkalinity and total solids are reduced. The high pH and lime help disinfect the water.

However, the process produces large quantities of sludge that constitute a disposal problem. The intrinsic solubility of some of the compounds means that complete softening cannot be achieved. Flow rates and chemical feed rates must be closely monitored.

## 33. WATER SOFTENING BY ION EXCHANGE

In the *ion exchange process* (also known as the *zeolite process* and the *base exchange method*), water is passed through a filter bed of exchange material. Ions in the insoluble exchange material are displaced by ions in the water. The processed water leaves with zero hardness. However, since there is no need for water with zero hardness, some of the water is typically bypassed around the process.

If dissolved solids or sodium concentration of the water are issues, then ion exchange may not be suitable.

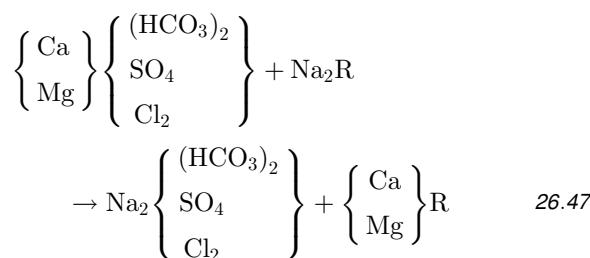

There are several types of ion exchange materials. *Green sand (glauconite)* is a natural substance that is mined and treated with manganese dioxide. Green sand is not used commercially.

*Synthetic zeolites* have historically been the workhorses of water softening and demineralization. Porosity of continuous-phase *gelular resins* is low, and dry contact surface areas of  $500 \text{ ft}^2/\text{lbm}$  ( $0.1 \text{ m}^2/\text{g}$ ) or less is common. This makes gel-based zeolites suitable only for small volumes.

*Synthetic macroporous resins (macroreticular resins)* are suitable for use in large-volume water processing systems, when chemical resistance is required, and when specific ions are to be removed. These are discontinuous, three-dimensional copolymer beads in a rigid-sponge type formation.<sup>18</sup> Each bead is made up of thousands of microspheres of the resin. Porosity is much higher than with gelular resins, and dry contact specific surface areas are approximately  $270,000$ – $320,000 \text{ ft}^2/\text{lbm}$  ( $55$ – $65 \text{ m}^2/\text{g}$ ).

There are four primary resin families: strong acid, strong base, weak acid, and weak base. Each family has different resistances to fouling by organic and inorganic chemicals, stabilities, and lifetimes. For example, strong acid resins can last for 20 years. Strong base resins, on the other hand, may have lifetimes of only three years. Each family can be used in either gelular or macroporous forms.

During operation, calcium and magnesium ions in hard water are removed according to the following reaction in which  $R$  is the zeolite anion. The resulting sodium compounds are soluble.

The typical saturation capacity ranges of synthetic resins are 1.0–1.5 meq/mL for anion exchange resins and 1.7–1.9 meq/mL for cation exchange resins. However, working capacities are more realistic measures than saturation capacities. The specific working capacity for zeolites is approximately 3–11 kilograins/ $\text{ft}^3$  ( $6.9$ – $25 \text{ kg/m}^3$ ) of hardness before regeneration.<sup>19</sup> For synthetic resins, the specific working capacity is

<sup>18</sup>The differences in structure between gel polymers and macroporous polymers occur during the polymerization step. Either can be obtained from the same zeolite.

<sup>19</sup>There are 7000 grains in a pound. 1000 grains of hardness (i.e.,  $1/7$  of a pound) is known as a *kilogram*. It should not be confused with a kilogram. Other conversions are 1 grain = 64.8 mg, and 1 grain/gal = 17.12 mg/L.

approximately 10–15 kilograms/ft<sup>3</sup> (23–35 kg/m<sup>3</sup>) of hardness.

The volume of water that can be softened per cycle (between regenerations) is

$$V_{\text{water}} = \frac{(\text{specific working capacity}) V_{\text{exchange material}}}{\text{hardness}} \quad 26.48$$

Flow rates are typically 1–6 gpm/ft<sup>3</sup> (2–13 L/s·m<sup>3</sup>) of resin volume. The flow rate across the exposed surface will depend on the geometry of the bed, but values of 3–15 gpm/ft<sup>2</sup> (2–10 L/s·m<sup>2</sup>) are typical.

#### Example 26.4

A municipal plant processes water with a total initial hardness of 200 mg/L. The desired discharge hardness is 50 mg/L. If an ion exchange process is used, what is the bypass factor?

*Solution*

The water passing through the ion exchange unit is reduced to zero hardness. If  $x$  is the water fraction bypassed around the zeolite bed,

$$(1 - x)(0) + x(200 \frac{\text{mg}}{\text{L}}) = 50 \frac{\text{mg}}{\text{L}}$$

$$x = 0.25$$

#### 34. REGENERATION OF ION EXCHANGE RESINS

Ion exchange material has a finite capacity for ion removal. When the zeolite approaches saturation, it is regenerated (rejuvenated). Standard ion exchange units are regenerated when the alkalinity of their effluent increases to the *set point*. Most units that collect *crud* are operated to a pressure-drop endpoint.<sup>20</sup> The pressure drop through the ion exchange unit is primarily dependent on the amount of crud collected.

Regeneration of synthetic ion exchange resins is accomplished by passing a *regenerating solution* over/through the resin. Although regeneration can occur in the ion exchange unit itself, external regeneration is becoming common. This involves removing the bed contents hydraulically, backwashing to separate the components (for mixed beds), regenerating the bed components separately, washing, and then recombining and transferring the bed components back into service. For complete regeneration, a contact time of 30–45 min may be required.

Common regeneration compounds are NaCl (for water hardness removal units), H<sub>2</sub>SO<sub>4</sub> (for cation exchange resins), and NaOH (for anion exchange resins). The amount of regeneration solution depends on the resin's

<sup>20</sup>Since water has been filtered before reaching the zeolite bed, *crud* consists primarily of iron-corrosion products ranging from dissolved to particulate matter.

degree of saturation. A rule of thumb is to expect to use 5–25 lbm of regeneration compound per cubic foot of resin (80–400 kg/m<sup>3</sup>). Alternatively, dosage of the regeneration compound may be specified in terms of hardness removed (e.g., 0.4 lbm of salt per 1000 grains of hardness removed).

The salt requirement per regeneration cycle is

$$m_{\text{salt}} = (\text{specific working capacity}) V_{\text{exchange material}} \times (\text{salt requirement}) \quad 26.49$$

#### 35. STABILIZATION AND SCALING POTENTIAL

Water that is stable will not gain or lose ions as it passes through the distribution system. Deposits in pipes from dissolved compounds are known as *scale*. Although various types of scale are possible, deposits of calcium carbonate (CaCO<sub>3</sub>, calcite) are the most prevalent. *Stabilization treatment* is used to eliminate or reduce the potential for scaling in a pipe after the treated water is distributed. Various factors influence the stability of water, including temperature, dissolved oxygen, dissolved solids, pH, and alkalinity. Increased temperature greatly increases the likelihood of scaling.

*Stability* is a general term used to describe a water's tendency to cause scaling. Four indices are commonly used to quantify the stability of water: the Langelier stability index, Ryznar stability index, Puckorius scaling index, and aggressive index. The Langelier and Ryznar indices are widely used in municipal water works, while the Puckorius index is encountered in installations with cooling water (e.g., cooling towers). Each index has its proponents, strengths and weaknesses, and imprecisions. Conclusions drawn from them are not always in agreement.

The common *Langelier stability index* (LSI) (also known as the *Langelier saturation index*) is significantly positive (e.g., greater than 1.5) when a water is supersaturated and will continue to deposit CaCO<sub>3</sub> scale in the pipes downstream of the treatment plant. When LSI is significantly negative (e.g., less than –1.5), the water has little scaling potential and may actually dissolve existing scale encountered.

$$\text{LSI} = \text{pH} - \text{pH}_{\text{sat}} \quad 26.50$$

The *Ryznar stability index* (RSI) arranges the same parameters as LSI differently, but avoids the use of negative numbers. Water is considered to be essentially neutral when  $6.5 < \text{RSI} < 7$ . When  $\text{RSI} > 8$ , the water has little scaling potential and will dissolve scale deposits already present. When  $\text{RSI} < 6.5$ , the water has scaling potential.

$$\text{RSI} = 2\text{pH}_{\text{sat}} - \text{pH} = \text{pH} - 2(\text{LSI}) \quad 26.51$$

The *Puckorius scaling index* (PSI) (also known as the *practical scaling index*) does not use the actual pH in its calculation. To account for the buffering effects of other ions, it uses an equilibrium pH. Like RSI, PSI is always positive, and it has the same index interpretation ranges as RSI.

$$\text{PSI} = 2\text{pH}_{\text{sat}} - \text{pH}_{\text{eq}} \quad 26.52$$

$$\text{pH}_{\text{eq}} = 4.54 + 1.465 \log_{10}[M] \quad 26.53$$

Equation 26.51, Eq. 26.52, and Eq. 26.53 require knowing the pH when the water is saturated with  $\text{CaCO}_3$ . This value depends on the ionic concentrations in a complex manner, and it is calculated or estimated in a variety of ways. The saturation pH can be calculated from Eq. 26.54, where  $K_{\text{sp}}$  is the solubility product constant for  $\text{CaCO}_3$ , and  $K_a$  is the ionization constant for  $\text{H}_2\text{CO}_3$ .<sup>21,22</sup>  $M$  is the alkalinity (often reported as the  $\text{HCO}_3^-$  concentration) in mg/L as  $\text{CaCO}_3$ .  $\text{Ca}^{++}$  is the calcium ion content in mg/L, also as  $\text{CaCO}_3$ .

$$\begin{aligned} \text{pH}_{\text{sat}} &= (\text{p}K_a - \text{p}K_{\text{sp}}) + \text{pCa} + \text{pM} \\ &= -\log_{10}\left(\frac{K_a[\text{Ca}^{++}][M]}{K_{\text{sp}}}\right) \end{aligned} \quad 26.54$$

$$M = [\text{HCO}_3^-] + 2[\text{CO}_3^{--}] + [\text{OH}^-] \quad 26.55$$

Since the solubility product constants are rarely known and depend in a complex manner on the total ion strength (total dissolved solids) and temperature, if the water chemistry is fully known, the correlation of Eq. 26.56 can be used.<sup>23</sup> Hard water is typically two-thirds calcium hardness and one-third magnesium. However, if only total hardness is known (i.e., calcium hardness is not known) the worst case of calcium hardness equaling total hardness can be assumed. Total dissolved solids (TDS) can be estimated from water conductivity using Table 26.4.

$$\text{pH}_{\text{sat}} = 9.3 + A + B - C - D \quad 26.56$$

$$A = \frac{\log_{10}[\text{TDS}] - 1}{10} \quad 26.57$$

$$B = -13.12 \log_{10}(T^{\circ}\text{C} + 273^{\circ}) + 34.55 \quad 26.58$$

$$C = \log_{10}[\text{Ca}^{++}] - 0.4 \quad 26.59$$

$$D = \log_{10}[M] \quad 26.60$$

The *aggressive index* (AI) was originally developed to monitor water in asbestos pipe, but can be encountered in other environments. It is calculated from Eq. 26.61, but disregards the effects of dissolved solids and water

<sup>21</sup> $\text{pK} = -\log K$ ;  $\text{pCa} = -\log[\text{Ca}^{++}]$ ;  $\text{pM} = -\log[M]$

<sup>22</sup>Equation 26.54 is an approximation to the stoichiometric reaction equation because it assumes the activities of the  $\text{H}^+$ ,  $\text{CO}_3^{--}$ , and  $\text{HCO}_3^-$  ions present in the water are all 1. This is essentially, but not exactly, true.

<sup>23</sup>As reported in *Industrial Water Treatment, Operation and Maintenance*, UFC 3-240-13FN, Appendix B. Department of Defense (Unified Facilities), 2005.

**Table 26.4** Total Dissolved Solids vs. Conductivity

conductivity (S/cm)	total dissolved solids (mg/L as $\text{CaCO}_3$ )
1	0.42
10.6	4.2
21.2	8.5
42.4	17.0
63.7	25.5
84.8	34.0
106.0	42.5
127.3	51.0
148.5	59.5
169.6	68.0
190.8	76.5
212.0	85.0
410.0	170.0
610.0	255.0
812.0	340.0
1008.0	425.0

temperature. Therefore, it is less accurate than the other indices.

$$\text{AI} = \text{pH} + \log_{10}[M] + \log_{10}[\text{Ca}^{++}] \quad 26.61$$

LSI, RSI, PSI, and AI predict tendencies only for calcium carbonate scaling. They do not estimate scaling potential for calcium phosphate, calcium sulfate, silica, or magnesium silicate scale. They are generally only accurate with untreated water. Although water treated with phosphonates and acrylates to dissolve or stabilize calcium carbonate can be evaluated, the scaling potential of water treated with crystal modifiers (e.g., polymaleates, sulfonated styrene/maleic anhydride, and terpolymers) should not be evaluated with these indices.

The primary stabilization processes are pH and alkalinity adjustment using lime or soda ash (if the pH is low), and with carbon dioxide, sulfuric acid, or hydrochloric acid if the pH is too high. Scaling can also be prevented within the treatment plan by using protective pipe linings and coatings. Various inhibitors and sequestering agents can also be used.<sup>24</sup> If lime is used for pH adjustment, care must be exercised that excess lime does not form clinker particles that are carried out into the water distribution system.

Some waters (including cooling waters in some industries) are always corrosive because of the presence of dissolved oxygen, carbon dioxide, and various solids, regardless of whether calcium carbonate is present.  $\text{CaCO}_3$  scaling indices were never intended to be used as indices or corrosion potential of mild steel pipes, but that has occurred. LSI, RSI, and PSI are blind to the presence of chloride and sulfate content, as well as to the nature of the pipe and fitting materials and to the galvanic potential differences. For that reason, stability

<sup>24</sup>A sequestering agent (*chelant*, *chelator*, *chelating agent*) is a compound that works by sequestering positive metallic ions in a complex negative ion.

indices should not be used for corrosion prediction. However, the LSI, RSI, and PSI scaling potential continuums continue to be inappropriately divided by some authorities into scaling and corrosion regions.

## 36. DISINFECTION

Chlorination is commonly used for disinfection. Chlorine can be added as a gas or as a liquid. If it is added to the water as a gas, it is stored as a liquid, which vaporizes around  $-31^{\circ}\text{F}$  ( $-35^{\circ}\text{C}$ ). Liquid chlorine is the primary form used since it is less expensive than calcium hypochlorite solid ( $\text{Ca}(\text{OCl})_2$ ) and sodium hypochlorite ( $\text{NaOCl}$ ).

Chlorine is corrosive and toxic. Special safety and handling procedures must be followed with its use.

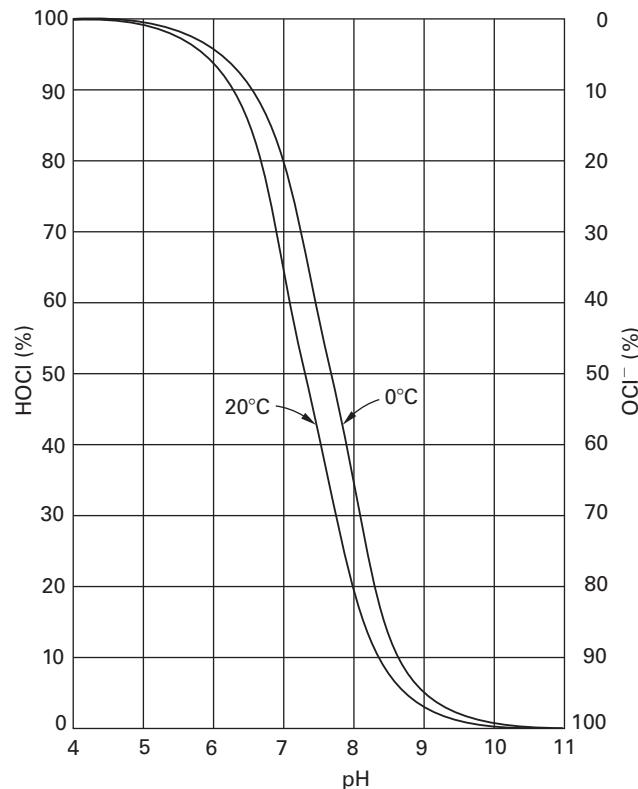

## 37. CHLORINATION CHEMISTRY

When chlorine gas dissolves in water, it forms hydrochloric acid ( $\text{HCl}$ ) and hypochlorous acid ( $\text{HOCl}$ ).

The fraction of  $\text{HOCl}$  ionized into  $\text{H}^+$  and  $\text{OCl}^-$  depends on the pH and can be determined from Fig. 26.6.

**Figure 26.6** Ionized HOCl Fraction vs. pH

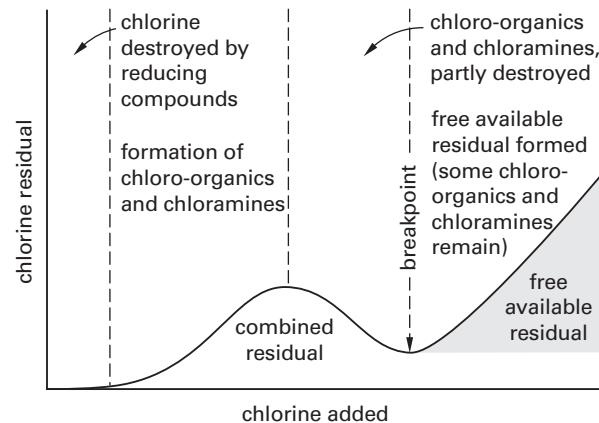

When calcium hypochlorite solid is added to water, the ionization reaction is

## 38. CHLORINE DOSE

Figure 26.7 illustrates a breakpoint chlorination curve. Basically, the concept of *breakpoint chlorination* is to continue adding chlorine until the desired quantity of free residuals appears. This cannot occur until after the demand for combined residuals has been satisfied.

**Figure 26.7** Breakpoint Chlorination Curve

The amount of chlorine necessary for disinfection varies with the organic and inorganic material present in the water, the pH, the temperature, and the contact time. Thirty minutes of chlorine contact time is generally sufficient to deactivate giardia cysts. Satisfactory results can generally be obtained if a free chlorine residual (consisting of hypochlorous acid and hypochlorite ions) of 0.2–0.5 mg/L can be maintained throughout the distribution system. Combined residuals, if use is approved by health authorities, should be 1.0–2.0 mg/L at distant points in the distribution system.

### Example 26.5

The flow rate through a treatment plant is 2 MGD (7.5 ML/day). The hypochlorite ion ( $\text{OCl}^-$ ) dose is 20 mg/L as substance. The purity of calcium hypochlorite,  $\text{Ca}(\text{OCl})_2$ , is 97.5% as delivered. How many pounds of calcium hypochlorite are needed to treat the water?

#### SI Solution

The approximate molecular weights for the components of calcium hypochlorite are

Ca:	40.1
O: (2)(16)	= 32.0
Cl: (2)(35.5)	= 71.0
total	143.1

The fraction of available chlorine in the form of the hypochlorite ion is

$$G = \frac{32.0 + 71.0}{143.1} = 0.720$$

Use the standard dose equation with adjustments for both purity and availability.

$$\begin{aligned} F_{\text{kg/d}} &= \frac{D_{\text{mg/L}} Q_{\text{ML/d}}}{PG} \\ &= \frac{\left(20 \frac{\text{mg}}{\text{L}}\right) \left(7.5 \frac{\text{ML}}{\text{d}}\right)}{(0.975)(0.720)} \\ &= 213.7 \text{ kg/d} \end{aligned}$$

#### *Customary U.S. Solution*

The approximate molecular weights for the components of calcium hypochlorite are

Ca:	40.1
O: (2)(16)	= 32.0
Cl: (2)(35.5)	= 71.0
total	143.1

The fraction of available chlorine in the form of the hypochlorite ion is

$$\frac{32.0 + 71.0}{143.1} = 0.720$$

Use the standard dose equation with adjustments for both purity and availability.

$$\begin{aligned} F_{\text{lbm/day}} &= \frac{D_{\text{mg/L}} Q_{\text{MGD}} \left(8.345 \frac{\text{lbm-L}}{\text{mg-MG}}\right)}{PG} \\ &= \frac{\left(20 \frac{\text{mg}}{\text{L}}\right)(2 \text{ MGD}) \left(8.345 \frac{\text{lbm-L}}{\text{mg-MG}}\right)}{(0.975)(0.720)} \\ &= 475.5 \text{ lbm/day} \end{aligned}$$

#### **39. ADVANCED OXIDATION PROCESSES**

Alternatives to chlorination have become necessary since THMs were traced to the chlorination process. These alternatives are categorized as *advanced oxidation processes* (AOPs).

Both bromine and iodine have properties similar to chlorine and can be used for disinfection. They are seldom used because they are relatively costly and produce their own disinfection by-products.

*Chlorine dioxide* ( $\text{ClO}_2$ ) is manufactured at the water treatment plant from chlorine and sodium chlorite. Its

ionization by-products (chlorite and chlorate) and high cost have limited its use.

*Ozone* is used extensively throughout the world, though not in large quantities in the United States. Ozone is a more powerful disinfectant than chlorine. Ozone can be used alone or (in several developing technologies) in conjunction with hydrogen peroxide. Ozone is generated on-site by running high voltage electricity through dry air or pure oxygen. Gases (oxygen and unused ozone) developing during ozonation must be collected and destroyed in an ozone-destruct unit to ensure that no ozone escapes into the atmosphere.

*Ultraviolet radiation* is effective in disinfecting shallow (e.g., less than 10 cm) bodies of water. Its primary disadvantages are cost and the absence of any residual disinfection for downstream protection.

#### **40. CHLORAMINATION**

Before leaving the plant, treated water may be *chloraminated* (i.e., treated with both ammonia and chlorine to form chloramines). This step ensures lasting disinfection by providing a residual level of chloramines, protecting the water against bacteria regrowth as it travels through the distribution system.

#### **41. DECHLORINATION**

In addition to its routine disinfection use, chlorine can enter water supply systems during operation and maintenance activities such as disinfection of mains, testing of hydrants, and routine flushing of distribution systems. Such flows are often discharged to wastewater sewer systems. Chlorine reacts with some organic compounds to produce THMs and is toxic to aquatic life. For these reasons, most water supply and wastewater facilities dechlorinate their discharges for regulatory compliance.

Excess chlorine can be removed with a reducing agent, referred to as a *dechlor*. Table 26.5 lists common dechlor chemicals. Dechlers reduce all forms of active chlorine (chlorine gas, hypochlorites, and chloramines) to chloride. Aeration also reduces chlorine content, as does contact with granular activated charcoal (GAC). Carbon absorption processes are more costly than chemical treatments and are used only when total dechlorination is required.

Sulfur dioxide is a toxic gas and is most frequently used by large wastewater. Sodium bisulfite, sodium sulfite, and sodium thiosulfate are most frequently used by smaller water utilities. Sodium bisulfite is low in cost and has a high rate of dechlorination. Sodium sulfite tablets are easy to store and handle. Sodium thiosulfate is less hazardous and depletes oxygen less than sodium bisulfite and sodium sulfite. Ascorbic acid and sodium ascorbate are used because they do not impact DO concentrations. Monitoring is required to prevent the

**Table 26.5** Dechlorinating Chemicals Used in Water Supply and Wastewater Facilities

name	formula	stoichiometric dose <sup>*</sup> (mg/mg Cl <sub>2</sub> )
ascorbic acid	C <sub>6</sub> H <sub>8</sub> O <sub>6</sub>	2.48
calcium thiosulfate	CaS <sub>2</sub> O <sub>3</sub>	1.19
hydrogen peroxide	H <sub>2</sub> O <sub>2</sub>	0.488
sodium ascorbate	C <sub>6</sub> H <sub>7</sub> NaO <sub>6</sub>	2.78
sodium bisulfite	NaHSO <sub>3</sub>	1.46
sodium metabisulfite	Na <sub>2</sub> S <sub>2</sub> O <sub>5</sub>	1.34
sodium sulfite	Na <sub>2</sub> SO <sub>3</sub>	1.78

sulfur dioxide	SO <sub>2</sub>	0.903

\*Doses are approximate and depend on pH and assumed reaction chemistry. Theoretical values may be used for initial approximations and equipment sizing. Under the best conditions, 10% excess is required.

over-application of chemicals that may deplete the dissolved oxygen concentration or alter the pH of receiving streams.

## 42. DEMINERALIZATION AND DESALINATION

Demineralization and desalination (*salt water conversion*) are required when only brackish water supplies are available.<sup>25</sup> These processes are carried out in distillation, electrodialysis, ion exchange, and membrane processes.

*Distillation* is a process whereby the raw water is vaporized, leaving the salt and minerals behind. The water vapor is reclaimed by condensation. Distillation cannot be used to economically provide large quantities of water.

*Reverse osmosis* is the least costly and most attractive membrane demineralization process. A thin membrane separates two solutions of different concentrations. Pore size is smaller (0.0001–0.001 µm) than with ultrafilter membranes, as salt ions are not permitted to pass through. (See Sec. 26.26.) Typical large-scale osmosis units operate at 150–500 psi (1.0–5.2 MPa).<sup>26</sup>

*Nanofiltration* is similar to ultrafiltration and reverse osmosis, with pore size (0.001 µm) and operating pressure (75–250 psig; 0.5–1.7 MPa) intermediate between the two. Nanofilters are commonly referred to as *softening membranes*.

In *electrodialysis*, positive and negative ions flow through selective membranes under the influence of an induced electrical current. Unlike pressure-driven filtration processes, however, the ions (not the water molecules) pass

<sup>25</sup>In the United States, Florida, Arizona, and Texas are leaders in desalination installations. Potable water is routinely made from sea water in the Middle East.

<sup>26</sup>Membrane processes operate in a *fixed flux* condition. In order to keep the yield constant over time, the pressure must be constantly increased in order to compensate for the effects of fouling and compaction. Fouling by inorganic substances and biofilms is the biggest problem with membranes.

through the membrane. The ions removed from the water form a concentrate stream that is discarded.

The *ion exchange* process is an excellent solution to demineralization and desalination. (See Sec. 26.33.)

## 43. WATER DEMAND

Normal water demand is specified in gallons per capita day (gpcd) or liters per capita day (Lpcd)—the average number of gallons (liters) used by each person each day. This is referred to as *average annual daily flow* (AADF) if the average is taken over a period of a year. Residential (i.e., domestic), commercial, industrial, and public uses all contribute to normal water demand, as do waste and unavoidable loss.<sup>27</sup>

As Table 26.6 illustrates, an AADF of 165 gpcd (625 Lpcd) is a typical minimum for planning purposes. If large industries are present (e.g., canning, steel making, automobile production, and electronics), then their special demand requirements must be added.

**Table 26.6** Annual Average Water Requirements<sup>a</sup>

use	demand	
	gpcd	Lpcd <sup>b</sup>
residential	75–130	284–490
commercial and industrial	70–100	265–380
public	10–20	38–80
loss and waste	10–20	38–80
totals	165–270	625–1030

(Multiply gpcd by 3.79 to obtain Lpcd.)

<sup>a</sup>exclusive of fire fighting requirements

<sup>b</sup>liters per capita-day

Water demand varies with the time of day and season. Each community will have its own demand distribution curve. Table 26.7 gives typical multipliers, *M*, that might be used to estimate instantaneous demand from the average daily flow.

$$Q_{\text{instantaneous}} = M(\text{AADF}) \quad 26.66$$

**Table 26.7** Typical Demand Multipliers  
(to be used with average annual daily flow)

period of usage	multiplier, <i>M</i>
maximum daily	1.5–1.8
maximum hourly	2.0–3.0
early morning	0.25–0.40
noon	1.5–2.0
winter	0.80
summer	1.30

<sup>27</sup>“Public” use includes washing streets, flushing water and sewer mains, flushing fire hydrants, filling public fountains, and fighting fires.

Per capita demand must be multiplied by the population to obtain the total system demand. Since a population can be expected to change in number, a supply system must be designed to handle the water demand for a reasonable amount of time into the future. Several methods can be used for estimating future demand, including mathematical, comparative, and correlative methods. Various assumptions can be made for mathematical predictions, including uniform growth rate (same as straight-line extrapolation) and constant percentage growth rate. (In the case of decreasing population, the "growth" rate would be negative.)

Economic aspects will dictate the number of years of future capacity that are installed. Excess capacities of 25% for large systems and 50% for small systems are typically built into the system initially.

#### 44. FIRE FIGHTING DEMAND

The amount of water that should be budgeted for municipal fire protection depends on the degree of protection desired, construction types, and the size of the population to be protected. Municipal capacity decisions are almost always made on the basis of economics driven by the insurance industry. The Insurance Services Office (ISO) rates municipalities according to multiple criteria it publishes in its Fire Suppression Rating Schedule.<sup>28</sup>

One of the criteria is the ability of a municipality to provide what the ISO refers to as the *needed fire flow*, NFF, at various locations around the community. The NFF methodology has been determined from measurement of historical events (i.e., past fires) over many years. The ISO awards credit points dependent on how well actual capacities (availability) matches the NFFs at these locations. Adequacy may be limited by the water works, main capacity, and hydrant distribution.

The ISO also calculates a community's *basic fire flow*, BFF, which is the fifth highest needed fire flow (not to exceed 3500 gpm (13 250 L/m) among the locations listed in the ISO batch report. BFF is used to determine the numbers of engine companies, crews, and number, nature, and size of the fire-fighting apparatus that the community needs.

Calculating the NFF is highly codified, requiring specific knowledge of construction types, floor areas, and usage (occupancy). NFF is calculated in gallons per minute and is rounded up or down to the nearest 250 gpm (16 L/s) if less than 2500 gpm (160 L/s), and up or down to the nearest 500 gpm (32 L/s) if greater than 2500 gpm (160 L/s). The minimum NFF value is 250 gpm (16 L/s), corresponding to the discharge from a single standard 1.125 in (29 mm) diameter smooth fire nozzle,

<sup>28</sup>Other methods exist and are in use around the world. The ISO method works well for large diameter hoses preferred in the United States and needed to achieve the high flow rates necessary with fires involving the wood-framed buildings that predominate in the United States.

and the maximum value is 12,000 gpm (760 L/s). Calculated values are increased by 500 gpm (32 L/s) if the building has a wood shingle roof covering that can contribute to the spread of a fire. Reductions in NFF are given for structures having sprinkler systems designed in accordance with National Fire Protection Association (NFPA) standards.

As a convenience, the NFF for 1- and 2-family dwellings not exceeding two stories in height can be read directly from Table 26.8, without the need of calculations.

**Table 26.8** Needed Fire Flow for 1- and 2-Family Dwellings

distance between buildings (ft)	needed fire flow (gpm)
≤ 10	1500
11–30	1000
31–100	750
> 100	500

(Multiply ft by 0.3048 to obtain m.)

(Multiply gpm by 0.06309 to obtain L/s.)

Source: *Guide for Determination of Needed Fire Flow*, Chap. 7, Insurance Services Office

For other than 1- and 2-family dwellings, NFF must be calculated based on construction type, occupancy, area, and other factors. Equation 26.67 is the ISO formula for an individual, nonsprinklered building. Some of the factors are evaluated for each exposure (side) of the building. ISO provides guidance and examples of application for selecting values for the factors, but specialized knowledge and expertise is still needed to use Eq. 26.67 accurately, particularly for buildings with mixed construction classes and occupancies.

$$\text{NFF} = CO(1 + X + P) \quad 26.67$$

C is a factor dependent on the type of construction. In Eq. 26.68, F is a *construction class coefficient*. F = 1.5 for wood frame construction (class 1), 1.0 for joisted masonry (class 2), 0.8 for noncombustible construction (class 3) including masonry (class 4), and 0.6 for fire-resistant construction (classes 5 and 6). A is the effective area in square feet, determined as the area of the largest floor in the building plus 50% of all the other floors for classes 1, 2, 3, and 4. Other modifications apply to classes 5 and 6. Special rules apply to finding areas of multi-story, fire-resistant buildings with sprinkler systems. C is rounded up or down to the nearest 250 gpm (16 L/s) (prior to the rounding of NFF), may not be less than 500 gpm (32 L/s), is limited to a maximum of 8000 gpm (500 L/s) for classes 1 and 2, is limited to 6000 gpm (380 L/s) for classes 3, 4, 5, and 6, and for any 1-story building of any class.

$$C = 18F\sqrt{A} \quad 26.68$$

The *occupancy combustible factor*, O, accounts for the combustibility of a building's contents and is 1.25 for

rapid burning (class C-5), 1.15 for free-burning (class C-4), 1.0 for combustible (class C-3), 0.85 for limited-combustible (class C-2), and 0.75 for noncombustible (class C-1). The exact definitions and examples of these classes are specified by the ISO.

The *exposure factor*,  $X$ , reflects the influence of an adjoining or connected building less than 100 ft (30 m) from a wall of the subject building. Its value is read from an ISO table as a function of separation, lateral exposure length, and construction class. Values vary from essentially 0 to 0.25.

The *communication factor*,  $P$ , reflects any connections (passageways) between adjacent structures. Like the exposure factor, it is read from ISO tables as a function of the length and nature of the passageway and closures. Values vary from 0 to 0.35.

The exposure and communication factors are summed for all exposures (sides) of a building. However, the total of  $X + P$  over all exposures need not exceed 0.6.

## 45. OTHER FORMULAS FOR FIRE FIGHTING NEEDS

Although modern methods calculate fire fighting demand based on the area and nature of construction to be protected, the earliest methods of predicting fire-fighting demand were based on population.<sup>29</sup> The 1911 *American Insurance Association equation* (also referred to as the *National Board of Fire Underwriters equation* after AIA's predecessor) for cities with populations less than 200,000 was used widely up until the 1980s.  $P$  in Eq. 26.69 is in thousands of people.

$$Q_{\text{gpm}} = 1020\sqrt{P}(1 - 0.01\sqrt{P}) \quad 26.69$$

Other authorities who have developed alternative methods include Thomas (1959), Iowa State University (1967), Illinois Institutes of Technology Research Institute (1968), and Ontario Building Code (Office of the Fire Marshal, 1995).

## 46. DURATION OF FIRE FIGHTING FLOW

A municipality must continue to provide water to its domestic, commercial, and industrial customers while meeting its fire fighting needs. In the ISO's *Fire Suppression Rating Schedule*, in order for a municipality to get full credit, it is required that a fire system must be operable with the potable water system operating at the maximum 24 hour average daily rate, plus the fire demand at a minimum of 20 psig (140 kPa) for a minimum time depending on the needed fire flow: 2 hours,  $\text{NFF} < 3000 \text{ gpm}$  (190 L/s); 3 hours,  $3000 \text{ gpm} < \text{NFF} < 3500 \text{ gpm}$  (220 L/s); and 4 hours,  $\text{NFF} > 3500 \text{ gpm}$  (220 L/s).

<sup>29</sup>Freeman's formula (1892) and Kuchling's formula (1897) were among the earliest.

Another approach, published<sup>30</sup> by the American Water Works Association, is to require the fire fighting flow to be maintained for a duration equal to  $Q_{\text{gpm}}/1000$  (rounded up to the next integer) in hours.

## 47. FIRE HYDRANTS

Other factors considered by the ISO are the type, size, capacity, installation, and inspection program of fire hydrants. The actual separation of hydrants can be specified in building codes, local ordinances, and other published standards. However, in order to be considered for ISO credits, only hydrants within 1000 ft (300 m) of a building are considered, and this distance often is used for maximum hydrant spacing (so that no building is more than 500 ft (150 m) distant from a hydrant). Additional credit is given for hydrants within 300 ft (90 m), and this distance is often selected for hydrant spacing in residential areas. Hydrants are ordinarily located near street corners where use from four directions is possible.

## 48. STORAGE AND DISTRIBUTION

Water is stored to provide water pressure, equalize pumping rates, equalize supply and demand over periods of high consumption, provide surge relief, and furnish water during fires and other emergencies when power is disrupted. Storage may also serve as part of the treatment process, either by providing increased detention time or by blending water supplies to obtain a desired concentration.

Several methods are used to distribute water depending on terrain, economics, and other local conditions. *Gravity distribution* is used when a lake or reservoir is located significantly higher in elevation than the population.

Distribution from *pumped storage* is the most common option when gravity distribution cannot be used. Excess water is pumped during periods of low hydraulic and electrical demands (usually at night) into elevated storage. During periods of high consumption, water is drawn from the storage. With pumped storage, pumps are able to operate at a uniform rate and near their rated capacity most of the time.

Using pumps without storage to force water directly into the mains is the least desirable option. Without storage, pumps and motors will not always be able to run in their most efficient ranges since they must operate during low, average, and peak flows. In a power outage, all water supply will be lost unless a backup power source comes online quickly or water can be obtained by gravity flow.

Water is commonly stored in surface and elevated tanks. The elevation of the water surface in the tank directly determines the distribution pressure. This elevation is

<sup>30</sup>*Distribution System Requirements for Fire Protection (M31)*, American Water Works Association, 1992.

controlled by an *altitude valve* that operates on the differential in pressure between the height of the water and an adjustable spring-loaded pilot on the valve. Altitude valves are installed at ground level and, when properly adjusted, can maintain the water levels to within 4 in (102 mm). Tanks must be vented to the atmosphere. Otherwise, a rapid withdrawal of water will create a vacuum that could easily cause the tank to collapse inward.

The preferred location of an elevated tank is on the opposite side of the high-consumption district from the pumping station. During periods of high water use, the district will be fed from both sides, reducing the loss of head in the mains below what would occur without elevated storage.

Equalizing the pumping rate during the day ordinarily requires storage of at least 15–20% of the maximum daily use. Storage for fires and emergencies is more difficult to determine. Fire storage is essentially dictated by building ordinances and insurance (i.e., economic benefits to the public). Private on-site storage volume for large industries may be dictated by local codes and ordinances.

## 49. WATER PIPE

Several types of pipe are used in water distribution depending on the flow rate, installed location (i.e., above or below ground), depth of installation, and surface surcharge. Pipes must have adequate strength to withstand external loads from backfill, traffic, and earth movement. They must have high burst strength to withstand internal pressure, a smooth interior surface to reduce friction, corrosion resistance, and tight joints to minimize loss. Once all other requirements have been satisfied, the choice of pipe material can be made on the basis of economics.

*Asbestos-cement pipe* was used extensively in the past. It has a smooth inner surface and is immune to galvanic corrosion. However, it has low flexural strength. *Concrete pipe* is durable, watertight, has a smooth interior, and requires little maintenance. It is manufactured in

plain and reinforced varieties. *Cast-iron pipe* (ductile and gray varieties) is strong, offers long life, and is impervious. However, it has a high initial cost and is heavy (i.e., difficult to transport and install). It may need to be coated on the exterior and interior to resist corrosion of various types. *Steel pipe* offers a smooth interior, high strength, and high ductility, but it is susceptible to corrosion inside and out. The exterior and interior may both need to be coated for protection. *Plastic pipe* (ABS and PVC) has a smooth interior and is chemically inert, corrosion resistant, and easily transported and installed. However, it has low strength.

## 50. SERVICE PRESSURE

For ordinary domestic use, the minimum water pressure at the tap should be 25–40 psig (170–280 kPa). A minimum of 60 psig (400 kPa) at the fire hydrant is usually adequate, since that allows for up to a 20 psig (140 kPa) pressure drop in fire hoses. 75 psig (500 kPa) and higher is common in commercial and industrial districts. *Pressure regulators* can be installed if delivery pressure is too high.

## 51. WATER MANAGEMENT

*Unaccounted-for water* is the potable water that is produced at the water treatment plant but is not accounted for in billing. It includes known unmetered uses (such as fire fighting and hydrant flushing) and all unknown uses (e.g., from leaks, broken meters, theft, and illegal connections).

Unaccounted-for water can be controlled with proper attention to meter selection, master metering, leak detection, quality control (installation and maintenance of meters), control of system pressures, and accurate data collection.

Since delivery is under pressure, infiltration of groundwater into pipe joints is not normally an issue with distribution.

### 1. CELL STRUCTURE

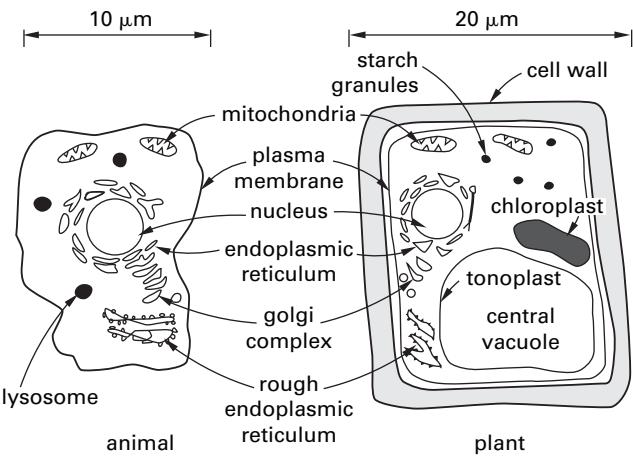

A cell is the fundamental unit of living organisms. Organisms are classified as either prokaryotes or eukaryotes. A *prokaryote* is a cellular organism that does not have a distinct nucleus. Examples of prokaryotes are bacteria and blue-green algae. Figure 27.1 shows the features of a typical prokaryotic cell.

**Figure 27.1** Prokaryotic Cell Features

A *eukaryote* is an organism composed of one or more cells containing visibly evident nuclei and *organelles* (structures with specialized functions). Eukaryotic cells are found in protozoa, fungi, plants, and animals. For a long time, it was thought that eukaryotic cells were composed of an outer membrane, an inner nucleus, and a large mass of cytoplasm within the cell. Better experimental techniques revealed that eukaryotic cells also contain many organelles. Figure 27.2 shows the features of a typical animal and a typical plant cell. Note the size scale for the cells in Fig. 27.1 and Fig. 27.2.

**Figure 27.2** Eukaryotic Cell Features

A cell membrane consists of a double phospholipid layer in which the polar ends of the molecules point to the outer and inner surfaces of the membrane and the nonpolar ends point to the center. A cell membrane also contains proteins, cholesterol, and glycoproteins. Some organisms, such as plant cells, have a cell wall made of carbohydrates that surrounds the cell membrane. Many single-celled organisms have specialized structures called *flagella* that extend outside the cell and help them to move.

Some cell membranes can be stained crystal violet (i.e., red) for ease of research in the gram stain process. Many pathogenic cells, however, do not readily accept such staining and are referred to as *gram-negative cells*.

Cell size is limited by the transport of materials through the cell membrane. The volume of a cell is proportional to the cubic power of its average linear dimension; the surface area of a cell is proportional to the square of the average linear dimension. The material (nutrients, etc.) transported through a cell's membrane is proportional to its surface area, while the material composing the cell is proportional to the volume of the cell.

The *cytoplasm* includes all the contents of the cell other than the nucleus. *Cytosol* is the watery solution of the cytoplasm. It contains dissolved glucose and other nutrients, salts, enzymes, carbon dioxide, and oxygen. In eukaryotic cells, the cytoplasm also surrounds the organelles.

The *endoplasmic reticulum* is one example of an organelle that is found in all eukaryotic cells. A rough endoplasmic reticulum has sub-microscopic organelles called ribosomes attached to it. Amino acids are bound together at the surface of ribosomes to form proteins.

The *Golgi apparatus*, or Golgi complex, is an organelle found in most eukaryotic cells. It looks like a stack of flattened sacks. The Golgi apparatus is responsible for accepting materials (mostly proteins), making modifications, and packaging the materials for transport to specific areas of the cell.

The *mitochondria* are specialized organelles that are the major site of energy production via aerobic respiration in eukaryotic cells. They convert organic materials into energy.

*Lysosomes* are other organelles located within eukaryotic cells that serve the specialized function of digestion within the cell. They break lipids, carbohydrates, and proteins into smaller particles that can be used by the rest of the cell.

*Chloroplasts* are organelles located within plant cells and algae that conduct photosynthesis. Chlorophyll is the green pigment that absorbs energy from sunlight during photosynthesis. During photosynthesis, the energy from light is captured and eventually stored as sugar.

*Vacuoles* are found in some eukaryotic cells. They serve many functions including storage, separation of harmful

materials from the remainder of the cell, and maintaining fluid balance or cell size. Vacuoles are separated from the cytoplasm by a single membrane called the tonoplast. Most mature plant cells contain a large central vacuole that occupies the largest volume of any single structure within the cell.

Two main types of nucleic acids are found in cells—*deoxyribonucleic acid* (DNA) and *ribonucleic acid* (RNA). DNA is found within the nucleus of eukaryotic cells and within the cytoplasm in prokaryotic cells. DNA contains the genetic sequence that is passed on during reproduction. This sequence governs the functions of cells by determining the sequence of amino acids that are combined to form proteins. Each species manufactures its own unique proteins.

RNA is found both within the nucleus and in the cytoplasm of prokaryotic and eukaryotic cells. Most RNA molecules are involved in protein synthesis. Messenger RNA (mRNA) serves the function of carrying the DNA sequence from the nucleus to the rest of the cell. Ribosomal RNA (rRNA) makes up part of the ribosomes, where amino acids are bound together to form proteins. Transfer RNA (tRNA) carries amino acids to the ribosomes for protein synthesis.

## 2. CELL TRANSPORT

The transfer of materials across membrane barriers occurs by means of several mechanisms.

- *Passive diffusion* in cells is similar to the transfer that occurs in non-living systems. Material moves spontaneously from a region of high concentration to a region of low concentration. The rate of transfer obeys Fick's Law, the principle governing passive diffusion in dilute solutions. The rate is proportional to the concentration gradient across the membrane. In the case of living beings, passive diffusion is affected by lipid solubility (high solubility increases the rate of transport), the size of the molecules (the rate of transport increases with decreasing size of molecules), and the degree of ionization (the rate of transport increases with decreasing ionization). A *partition coefficient*,  $K_a$ , or the relative solubility of the solute in lipid to its solubility in water, can be used to describe the effect of lipid solubility on transport.

$$K_a = \frac{\text{concentration in lipid}}{\text{concentration in water}} \quad 27.1$$

It is more common to report  $\log K_a$  than  $K_a$  because the relationship between  $pK_a$  and permeability is fairly linear.

$$pK_a = \log K_a = \log_{10} \left( \frac{\text{concentration in lipid}}{\text{concentration in water}} \right) \quad 27.2$$

The permeability of a molecule across a membrane of thickness  $x$  is

$$\text{permeability}_{\text{cm/s}} = \frac{\text{pK}_a \left( \begin{array}{l} \text{diffusion} \\ \text{coefficient} \\ \text{in water} \end{array} \right)_{\text{cm}^2/\text{s}}}{x_{\text{cm}}} \quad 27.3$$

The pH of a solution will have an effect on the partition coefficient. Although the relationship is complex, for weakly acidic and basic solutions  $\text{pK}_a$  and pH are approximately related by the *Henderson-Hasselbach equation*. In Eq. 27.4 and Eq. 27.5,  $[\text{X}]$  designates the molar concentration of component X. Equation 27.4 is based on the dissociation of a weak acid according to

Or,

Equation 27.5 is based on the dissociation of the salt of a weak base according to

Or,

$$\begin{aligned} \text{pK}_a - \text{pH} &= \log_{10} \left( \frac{\text{nonionized form}}{\text{ionized form}} \right) \\ &= \log_{10} \frac{[\text{HA}]}{[\text{A}^-]} \quad [\text{weakly acidic}] \end{aligned} \quad 27.4$$

$$\begin{aligned} \text{pK}_a - \text{pH} &= \log_{10} \left( \frac{\text{ionized form}}{\text{nonionized form}} \right) \\ &= \log_{10} \frac{[\text{HB}^+]}{[\text{B}]} \quad [\text{weakly basic}] \end{aligned} \quad 27.5$$

- *Facilitated diffusion* is transfer during which a permease or membrane enzyme carries the substance across the membrane.
- Active diffusion, of which there are three categories, is transfer forced by a pressure gradient or “piggy-back” function.

*Membrane pumping*, where cell membrane proteins called *permeases* transport the substance in a direction opposite the direction of passive diffusion.

*Endocytosis*, a process where cells absorb a material by surrounding (i.e., engulfing) it with their membrane.

*Exocytosis*, during which a secretory vesicle expels material that was within the cell to an area *outside the cell*.

- Other specialized mechanisms for specific organs.

In the case of many gram-negative bacteria with dual (i.e., inner and outer) wall membranes, including *Escherichia coli* (*E. coli*), sugars and amino acids are

transported across the inner plasma membrane by water-soluble proteins located in the periplasmic space between the two membranes.

### Example 27.1

$\text{HC}_2\text{H}_3\text{O}_2$  has an acid dissociation constant of  $1.8 \times 10^{-5}$ . Calculate the pH of a buffer solution made from 0.25M  $\text{HC}_2\text{H}_3\text{O}_2$  and 0.050M  $\text{C}_2\text{H}_3\text{O}_2^-$ .

*Solution*

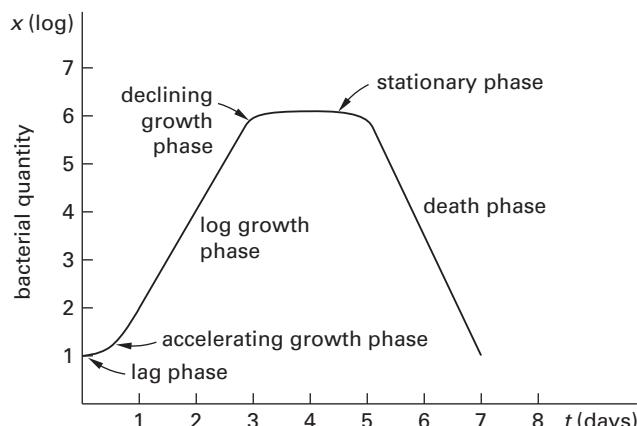

$\text{HC}_2\text{H}_3\text{O}_2$  is acetic acid, a weak acid. Use the Henderson-Hasselbach equation with Eq. 27.2.

$$\begin{aligned} \text{pH} &= \text{pK}_a + \log \frac{[\text{A}^-]}{[\text{HA}]} \\ &= \text{pK}_a + \log \frac{[\text{C}_2\text{H}_3\text{O}_2^-]}{[\text{HC}_2\text{H}_3\text{O}_2]} \\ &= -\log(1.8 \times 10^{-5}) + \log \frac{0.050\text{M}}{0.25\text{M}} \\ &= 4.7 + 0.30 = 5.0 \end{aligned}$$

### 3. ORGANISMAL GROWTH IN A BATCH CULTURE

Bacterial organisms can be grown (cultured) in a nutritive medium. The rate of growth follows the phases depicted in Fig. 27.3.

**Figure 27.3** Organismal Growth in Batch Culture

As Fig. 27.3 shows, the *lag phase* begins immediately after inoculation of the microbes into the nutrient medium. In this period, the microbial cells adapt to their new environment. The microbes might have to produce new enzymes to take advantage of new nutrients they are being exposed to, or they may need to adapt to different concentrations of solutes or to different temperatures than they are accustomed to. The length of the lag phase depends on the differences between the conditions the microbes experience before and after

inoculation. The cells will start to divide when the requirements for growth are satisfied.

The *exponential*, or *logarithmic*, *growth phase* follows the lag phase. During this phase the number of cells increases according to the following equation.

$$\mu = \frac{1}{x} \frac{dx}{dt} \quad 27.6$$

In this equation,  $x$  is the cell or organism number or concentration,  $t$  is time, and  $\mu$  is the specific growth rate during the exponential phase.

The *declining growth phase* follows the log phase. During this phase, one or more essential nutrients are depleted and/or waste products are accumulated at levels that slow cell growth.

The *stationary phase* begins after the decelerating growth phase. During the stationary phase, the net growth rate of the cells is zero. New cells are created at the same rate at which cells are dying.

The *death phase* follows the stationary phase. During this phase, the death rate exceeds the growth rate.

The *logistic equation* is used to represent the population quantity up to (but excluding) the death phase. The curve takes on a *sigmoidal shape*, also known as an *S-curve* or *bounded exponential growth curve*. In the logistic formulation, the specific growth rate is related to the *carrying capacity*,  $x_\infty$ , which is the maximum population the environment can support. Carrying capacity depends on the specific culture, medium, and conditions. The equation for exponential growth rate is

$$\mu = k \left(1 - \frac{x}{x_\infty}\right) \quad 27.7$$

In this equation,  $k$  is the *logistic growth rate constant*, and  $x$  is the number of organisms at time  $t$ . Equation 27.7 can be written for growth including the initial stationary phase as

$$\frac{dx}{dt} = kx \left(1 - \frac{x}{x_\infty}\right) \quad 27.8$$

Integration of Eq. 27.8 gives the equation for the number of cells or organisms as a function of time.

$$x = \frac{x_0}{x_\infty} (1 - e^{-kt}) \quad 27.9$$

#### 4. MICROORGANISMS

*Microorganisms* include viruses, bacteria, fungi, algae, protozoa, worms, rotifers, and crustaceans. Microorganisms are organized into three broad groups based on their structural and functional differences. The groups are called *kingdoms*. The three kingdoms are animals (rotifers and crustaceans), plants (mosses and ferns),

and *Protista* (bacteria, algae, fungi, and protozoa). Bacteria and protozoa of the kingdom Protista make up the major groups of microorganisms in the biological system that is used in secondary treatment of wastewater.

#### Pathogens

Organisms causing infectious diseases are categorized as *pathogens*. Pathogens are found in fecal wastes that are transmitted by exposure to wastewater. Pathogens will proliferate in areas where sanitary disposal of feces is not adequately practiced and where contamination of water supply from infected individuals is not properly controlled. The wastes may also be improperly discharged into surface waters, making the water *nonpotable* (unfit for drinking). Certain shellfish can become toxic when they concentrate pathogenic organisms in their tissues, increasing the toxic levels much higher than the levels in the surrounding waters.

Organisms that are considered to be pathogens include bacteria, protozoa, viruses, and helminths (worms). Table 27.1 lists potential waterborne diseases, the causative organisms, and the typical infection sources.

Not all microorganisms are considered pathogens. Some microorganisms are exploited for their usefulness in wastewater processing. Most wastewater engineering (and an increasing portion of environmental engineering) involves designing processes and facilities that use microorganisms to destroy organic and inorganic substances.

#### Microbe Categorization

Carbon is the basic building block for cell synthesis, and it is prevalent in large quantities in wastewater. Wastewater treatment mixes carbon with microorganisms that are subsequently removed from the water by settling. The growth of organisms that use organic material as energy is encouraged.

If a microorganism uses organic material as its carbon supply, it is *heterotrophic*. *Autotrophs* require only carbon to supply their energy needs. Organisms that rely only on the sun for energy are called *phototrophs*. *Chemotrophs* extract energy from organic or inorganic oxidation/reduction (redox) reactions. *Organotrophs* use organic materials, while *lithotrophs* oxidize inorganic compounds. Figure 27.4 may be used to categorize microbes.

Most microorganisms in wastewater treatment processes are bacteria. Conditions in the treatment plant are readjusted at certain times so that chemoheterotrophs predominate.

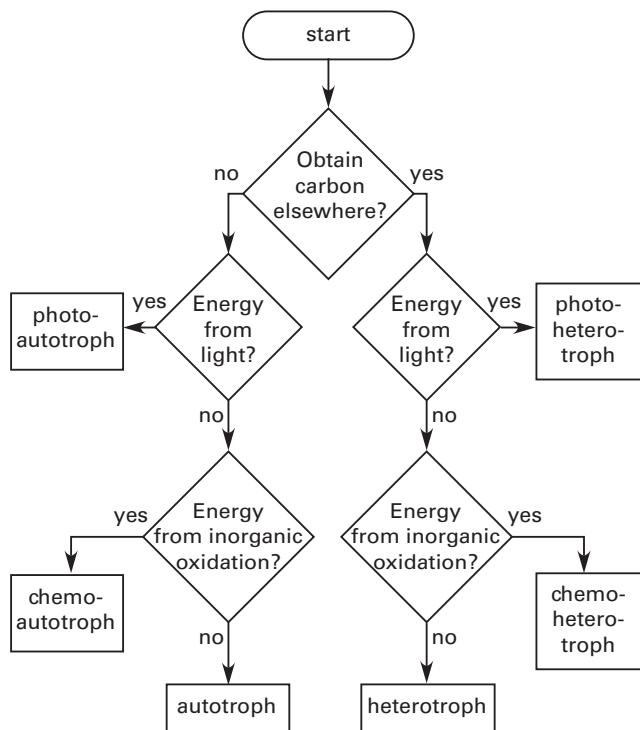

Each species of bacteria reproduces most efficiently within a limited range of temperatures. Table 27.2 shows these types and their most viable temperature ranges.

Because most reactions proceed slowly at some temperatures, cells use *enzymes* to speed up the reactions and control the rate of growth. Enzymes are proteins,

**Table 27.1** Potential Pathogens

name of organism	major disease	source
<b>Bacteria</b>		
<i>Salmonella typhi</i>	typhoid fever	human feces
<i>Salmonella paratyphi</i>	paratyphoid fever	human feces
other <i>Salmonella</i>	salmonellosis	human/animal feces
<i>Shigella</i>	bacillary dysentery	human feces
<i>Vibrio cholerae</i>	cholera	human feces
<i>Enteropathogenic coli</i>	gastroenteritis	human feces
<i>Yersinia enterocolitica</i>	gastroenteritis	human/animal feces
<i>Campylobacter jejuni</i>	gastroenteritis	human/animal feces
<i>Legionella pneumophila</i>	acute respiratory illness	thermally enriched waters
<i>Mycobacterium</i>	tuberculosis	human respiratory exudates
other <i>Mycobacteria</i>	pulmonary illness	soil and water
opportunistic bacteria	variable	natural waters
<b>Enteric Viruses/Enteroviruses</b>		
<i>Poioviruses</i>	poliomyelitis	human feces
<i>Coxsackieviruses A</i>	aseptic meningitis	human feces
<i>Coxsackieviruses B</i>	aseptic meningitis	human feces
<i>Echoviruses</i>	aseptic meningitis	human feces
other <i>Enteroviruses</i>	encephalitis	human feces
<i>Reoviruses</i>	upper respiratory and gastrointestinal illness	human/animal feces
<i>Rotaviruses</i>	gastroenteritis	human feces
<i>Adenoviruses</i>	upper respiratory and gastrointestinal illness	human feces
<i>Hepatitis A</i> virus	infectious hepatitis	human feces
<i>Norwalk</i> and related gastrointestinal viruses	gastroenteritis	human feces
<b>Fungi</b>		
<i>Aspergillus</i>	ear, sinus, lung, and skin infections	airborne spores
<i>Candida</i>	yeast infections	various
<b>Protozoa</b>		
<i>Acanthamoeba castellani</i>	amoebic meningoencephalitis	soil and water
<i>Balantidium coli</i>	balantidiosis (dysentery)	human feces
<i>Cryptosporidium</i> *	cryptosporidiosis	human/animal feces
<i>Entamoeba histolytica</i>	amoebic dysentery	human feces
<i>Giardia lamblia</i>	giardiasis (gastroenteritis)	human/animal feces
<i>Naegleria fowleri</i>	amoebic meningoencephalitis	soil and water
<b>Algae (blue-green)</b>		
<i>Anabaena flos-aquae</i>	gastroenteritis (possible)	natural waters
<i>Microcystis aeruginosa</i>	gastroenteritis (possible)	natural waters
<i>Alphanizomenon flos-aquae</i>	gastroenteritis (possible)	natural waters
<i>Schizothrix calciola</i>	gastroenteritis (possible)	natural waters
<b>Helminths (intestinal parasites/worms)</b>		
<i>Ascaris lumbricoides</i> (roundworm)	digestive disturbances	ingested worm eggs
<i>E. vericularis</i> (pinworm)	any part of the body	ingested worm eggs
hookworm	pneumonia, anemia	ingested worm eggs
threadworm	abdominal pain, nausea, weight loss	ingested worm eggs
<i>T. trichiuro</i> (whipworm)	trichinosis	ingested worm eggs
tapeworm	digestive disturbances	ingested worm eggs

\*Disinfectants have little effect on *Cryptosporidium*. Most large systems now use filtration, the most effective treatment to date against *Cryptosporidium*.

**Figure 27.4** Microbe Categorization Decision Tree**Table 27.2** Best Temperatures for Bacterial Growth

bacteria type	best temperature range for growth
psychrophiles	below 68°F (20°C)
mesophiles	68°F (20°C) to 113°F (45°C)
thermophiles	113°F (45°C) to 140°F (60°C)
stenothermophiles	above 140°F (60°C)

ranging from simple structures to complex conjugates, and are specialized for the reactions they catalyze.

The temperature ranges in Table 27.2 are qualitative and somewhat subjective. The growth range of facultative thermophiles extends from the thermophilic range into the mesophilic range. Bacteria will grow and survive in a very large range of temperatures. *E. coli*, for example, is classified as a mesophile. It grows best at temperatures between 68°F (20°C) and 122°F (50°C) but can continue to reproduce at temperatures down to 32°F (0°C).

*Nonphotosynthetic bacteria* are classified into two groups, heterotrophic and autotrophic, by their sources of nutrients and energy. *Heterotrophs* use organic matter as both an energy source and a carbon source for synthesis. Heterotrophs are further subdivided into groups depending on their behavior toward free oxygen: aerobes, anaerobes, and facultative bacteria. *Obligate aerobes* require free dissolved oxygen while they decompose organic matter to gain energy for growth and reproduction. *Obligate anaerobes* oxidize organics in the complete absence of dissolved oxygen by using the oxygen bound in other compounds, such as nitrate and

sulfate. *Facultative bacteria* comprise a group that uses free dissolved oxygen when available but that can also behave anaerobically in the absence of free dissolved oxygen (also known as *anoxic conditions*). Under anoxic conditions, a group of facultative anaerobes, called *denitrifiers*, uses nitrites and nitrates instead of oxygen. Nitrate nitrogen is converted to nitrogen gas in the absence of oxygen. This process is called *anoxic denitrification*.

*Autotrophic bacteria (autotrophs)* oxidize inorganic compounds for energy, use free oxygen, and use carbon dioxide as a carbon source. Significant members of this group are the *Leptothrix* and *Crenothrix* families of *iron bacteria*. These have the ability to oxidize soluble ferrous iron into insoluble ferric iron. Because soluble iron is often found in well waters and iron pipes, these bacteria deserve some attention. They thrive in water pipes where dissolved iron is available as an energy source and bicarbonates are available as a carbon source. As the colonies die and decompose, they release foul tastes and odors and have the potential to cause staining of porcelain or fabrics.

Table 27.3 lists selected microbial cells and describes some of their characteristics.

## Viruses

*Viruses* are parasitic organisms that can only be seen with an electron microscope and grow and reproduce only inside living cells, although they can survive outside the host. They are not cells, but particles composed of a protein sheath surrounding a nucleic-acid core. Most viruses of interest in supply water range in size from 10 nm to 25 nm. They pass through filters that retain bacteria.

Viruses invade living cells, and the viral genetic material redirects cell activities toward production of new viral particles. A large number of viruses are released when the infected cell dies. Most viruses are host-specific, attacking only one type of organism.

There are more than 100 types of human enteric viruses. Those of interest in drinking water are *Hepatitis A*, *Norwalk-type viruses*, *Rotaviruses*, *Adenoviruses*, *Enteroviruses*, and *Reoviruses*.

## Bacteria

*Bacteria* are microscopic organisms with round, rodlike, spiral, or filamentous single-celled or noncellular bodies. They are often aggregated into colonies. Bacteria use soluble food and reproduce through binary fission. Most bacteria are not pathogenic to humans, but they do play a significant role in the decomposition of organic material and can have an impact on the aesthetic quality of water.

## Fungi

*Fungi* are aerobic, multicellular, nonphotosynthetic, heterotrophic, eukaryotic protists. Most fungi are saprophytes that degrade dead organic matter. Fungi grow in

**Table 27.3** Characteristics of Selected Microbial Cells

organism genus or type	type	metabolism <sup>a</sup>	gram reaction <sup>b</sup>	morphological characteristics <sup>c</sup>
aspergillus	mold	chemoorganotroph-aerobic and facultative	—	filamentous fan-like or cylindrical conidia and various spores
bacillus	bacteria	chemoorganotroph-aerobic	positive	rod—usually motile; spore; can be significant extracellular material
candida	yeast	chemoorganotroph-aerobic and facultative	—	usually oval, but can form elongated cells, mycelia and various spores
chromatium	bacteria	photoautotroph-anaerobic	—	rods—motile; some extracellular material
clostridium	bacteria	chemoorganotroph-anaerobic	positive	rods—usually motile; spore; some extracellular slime
enterobacter	bacteria	chemoorganotroph-facultative	negative	rod—motile; significant extracellular material
escherichia	bacteria	chemoorganotroph-facultative	negative	rod—may or may not be motile, variable extracellular material
lactobacillus	bacteria	chemoorganotroph-facultative	variable	rod—chains—usually nonmotile; little extracellular material
methanobacterium	bacteria	chemoautotroph-anaerobic	unknown	rods or cocci—motility unknown; some extracellular slime
nitrobacter	bacteria	chemoautotroph-aerobic; can use nitrite as electron donor	negative	short rod—usually nonmotile; little extracellular material
pseudomonas	bacteria	chemoorganotroph-aerobic and some chemolithotroph facultative (using NO <sub>3</sub> as electron acceptor)	negative	rods—motile; little extracellular slime
rhizobium	bacteria	chemoorganotroph-aerobic; nitrogen fixing	negative	rods—motile; copius extracellular slime
saccharomyces	yeast	chemoorganotroph-facultative	—	spherical or ellipsoidal; reproduced by budding; can form various spores
spiroyra	algae	photoautotroph-aerobic	—	rod/filaments; little extracellular material
staphylococcus	bacteria	chemoorganotroph-facultative	positive	cocci—nonmotile; moderate extracellular material
thiobacillus	bacteria	chemoautotroph-facultative	negative	rods—motile; little extracellular slime

<sup>a</sup>aerobic—requires or can use oxygen as an electron receptor facultative—can vary the electron receptor from oxygen to organic materials  
 anaerobic—organic or inorganics other than oxygen serve as electron acceptor

chemoorganotrophs—derive energy and carbon from organic materials

chemoautotrophs—derive energy from organic carbons and carbon from carbon dioxide. Some species can also derive energy from inorganic sources.

photoautotrophs—derive energy from light and carbon from carbon dioxide. May be aerobic or anaerobic.

<sup>b</sup>Gram negative indicates a complex cell wall with a lipopolysaccharide outer layer; gram positive indicates a less complicated cell wall with a peptide-based outer layer.

<sup>c</sup>Extracellular material production usually increases with reduced oxygen levels (e.g., facultative). Carbon source also affects production; extracellular material may be polysaccharides and/or proteins; statements are to be understood as general in nature.

low-moisture areas, and they are tolerant of low-pH environments. Fungi release carbon dioxide and nitrogen during the breakdown of organic material.

Fungi are obligate aerobes that reproduce by a variety of methods including fission, budding, and spore formation. They form normal cell material with one-half the nitrogen required by bacteria. In nitrogen-deficient wastewater, they may replace bacteria as the dominant species.

## Algae

Algae are autotrophic, photosynthetic organisms (*photoautotrophs*) and may be either unicellular or multicellular. They take on the color of the pigment that is the catalyst for photosynthesis. In addition to chlorophyll (green), different algae have different pigments, such as carotenes (orange), phycocyanin (blue), phycoerythrin (red), fucoxanthin (brown), and xanthophylls (yellow).

Algae derive carbon from carbon dioxide and bicarbonates in water. The energy required for cell synthesis is obtained through photosynthesis. Algae and bacteria have a symbiotic relationship in aquatic systems, with the algae producing oxygen used by the bacterial population.

In the presence of sunlight, the photosynthetic production of oxygen is greater than the amount used in respiration. At night algae use up oxygen in respiration. If the daylight hours exceed the night hours by a reasonable amount, there is a net production of oxygen.

Excessive algal growth (*algal blooms*) can result in supersaturated oxygen conditions in the daytime and anaerobic conditions at night.

Some algae create tastes and odors in natural water. While they are not generally considered pathogenic to

humans, algae do cause turbidity, and turbidity favors microorganisms that are pathogenic.

### Protozoa

*Protozoa* are single-celled animals that reproduce by *binary fission* (dividing in two). Most are aerobic chemoheterotrophs (*facultative heterotrophs*). Protozoa have complex digestive systems and use solid organic matter, including algae and bacteria, as food. Protozoa are desirable in wastewater effluent because they act as polishers by consuming any remaining bacteria.

Protozoa are categorized into *flagellates*, *amoeboids*, *sporozoans*, and *ciliates* according to their means of locomotion.

*Flagellated protozoa* are the smallest protozoans. Their *flagella* (long hairlike strands) provide mobility through a whiplike action. *Amoeba* move and take in food through the action of a mobile protoplasm. Free-swimming protozoa have *cilia* (small hairlike features) used for propulsion and gathering in organic matter. Sporozoans do not locomote under their own power at all.

### Worms and Rotifers

A number of worms and rotifers are of importance to water quality. *Rotifers* are aerobic, multicellular chemoheterotrophs. The rotifer derives its name from the apparent rotating motion of two sets of cilia on its head. The cilia provide mobility and a mechanism for catching food. Rotifers consume bacteria and small particles of organic matter.

Many worms are aquatic parasites. *Flatworms* of the class *Trematoda* are known as *flukes*, and the *Cestoda* are tapeworms. *Nematodes* of public health concern are *Trichinella*, which causes trichinosis; *Necator*, which causes pneumonia; *Ascaris*, which is the common round-worm; and *Filaria*, which causes filariasis.

### Mollusks

*Mollusks*, such as mussels and clams, are characterized by a shell structure. They are aerobic chemoheterotrophs that feed on bacteria and algae. They are a source of food for fish and are not found in wastewater treatment systems to any extent, except in underloaded lagoons. Their presence is indicative of a high level of dissolved oxygen and a very low level of organic matter.

*Macrofouling* is a term referring to infestation of water inlets and outlets by clams and mussels. For example, *zebra mussels* were accidentally introduced into the United States in 1986 and are particularly troublesome for several reasons. First, young zebra mussels are microscopic and can easily pass through intake screens. Second, they attach to anything, even other mussels, and produce thick mussel colonies. Third, adult zebra mussels quickly sense biocides, most notably those that

are halogen-based, like chlorine. They quickly close and remain closed for days or weeks.

The use of biocides to control the growth of zebra mussels is controversial. Chlorination treatment is recommended with some caution since it results in increased toxicity, affecting other species, and THM (trihalomethane) production. An ongoing biocide program aimed at pre-adult mussels, combined with slippery polymer-based surface coatings, is most likely the best approach to prevention. Once a pipe is colonized, mechanical removal by scraping or water blasting is the only practical option.

### Indicator Organisms

The techniques for comprehensive bacteriological examination for pathogens are complex and time consuming. Isolating and identifying specific pathogenic microorganisms is a difficult and lengthy task. Many of these organisms require sophisticated tests that take several days to produce results. Because of these difficulties, and also because the number of pathogens relative to other microorganisms in water can be very small, *indicator organisms* are used as a measure of the quality of the water. The primary function of an indicator organism is to provide evidence of recent fecal contamination from warm-blooded animals.

Characteristics of a good indicator organism are:

- The indicator is always present when the pathogenic organism of concern is present. It is absent in clean, uncontaminated water.
- The indicator is present in fecal material in large numbers.
- The indicator responds to natural environmental conditions and to treatment processes in a manner similar to the pathogens of interest.
- The indicator is easy to isolate, identify, and enumerate.
- The ratio of indicator to pathogen should be high.
- The indicator and pathogen should come from the same source, such as the gastrointestinal tract.

While there are several microorganisms that meet these criteria, *total coliform* and *fecal coliform* are the indicators generally used. Total coliform refers to the group of aerobic and facultatively anaerobic, gram-negative, non-spore-forming, rod-shaped bacteria that ferment lactose with gas formation within 48 hr at 95°F (35°C). This encompasses a variety of organisms, mostly of intestinal origin, including *E. coli*, which is the most numerous facultative bacterium in the feces of warm-blooded animals. Unfortunately, this group also includes *Enterobacter*, *Klebsiella*, and *Citrobacter*, which are present in wastewater but can be derived from other environmental sources such as soil and plant materials.

*Fecal coliforms* are a subgroup of the total coliforms that come from the intestines of warm-blooded animals.

They are measured by running the standard total coliform fermentation test at an elevated temperature of 112°F (44.5°C), providing a means to distinguish false positives in the total coliform test.

Results of fermentation tests are reported as a *most probable number index* (MPN). This is an index of the number of coliform bacteria that, more than any other number, would give the results shown by the laboratory examination. MPN is not an actual enumeration.

### **Metabolism/Metabolic Processes**

*Metabolism* is a term given to describe all chemical activities performed by a cell. The cell uses *adenosine triphosphate* (ATP) as the principal energy currency in all processes. Those processes that allow the bacterium to synthesize new cells from the energy stored within its body are called *anabolic*. All biochemical processes in which cells convert substrate into useful energy and waste products are called *catabolic*.

### **Decomposition of Waste**

Decomposition of waste involves oxidation/reduction reactions and is classified as aerobic or anaerobic. The type of electron acceptor available for catabolism determines the type of decomposition used by a mixed culture of microorganisms. Each type of decomposition has peculiar characteristics that affect its use in waste treatment.

### **Aerobic Decomposition**

Molecular oxygen, O<sub>2</sub>, must be present in order for decomposition to proceed by aerobic oxidation. The chemical end products of decomposition are primarily carbon dioxide, water, and new cell material as shown in Table 27.4. Odoriferous, gaseous end-products are kept to a minimum. In healthy natural water systems, aerobic decomposition is the principal means of self-purification.

A wide spectrum of organic material can be oxidized by aerobic decomposition. Aerobic oxidation releases large amounts of energy, meaning most aerobic organisms are capable of high growth rates. Consequently, there is a relatively large production of new cells in comparison with the other oxidation systems. This means that more biological sludge is generated in aerobic oxidation than in the other oxidation systems.

A laboratory analysis of organic matter in water often includes a biochemical oxygen demand (BOD) test.

Water quality laboratories have a ready supply of water that is saturated with oxygen, obtained by sparging air overnight through the water. To measure BOD, a sample of wastewater is diluted with oxygen-saturated water, and a small amount of bacteria is added to the sample. Oxygen concentrations are measured at the beginning of the test and also on a daily basis. The difference between the oxygen concentration at the

initial time and at time *t* reported in mg/L gives a measure of the concentration of organic compounds in the water and is called the *BOD exerted* at time *t* (typically five days). In this way, BOD provides a measure of the concentration of organic compounds in water without the complexity of analyzing the different compounds.

Aerobic decomposition is the preferred method for large quantities of dilute (BOD<sub>5</sub> < 500 mg/L) wastewater because decomposition is rapid and efficient and has a low odor potential. For concentrated wastewater (BOD<sub>5</sub> > 1000 mg/L), aerobic decomposition is not suitable because of the difficulty in supplying enough oxygen and because of the large amount of biological sludge that is produced.

### **Anoxic Decomposition**

Some microorganisms can use nitrates in the absence of oxygen to oxidize carbon. In wastewater treatment for the removal of nitrogen compounds, this is known as *denitrification*. The end products from denitrification are nitrogen gas, carbon dioxide, water, and new cell material. The amount of energy made available to the cell during denitrification is about the same as that made during aerobic decomposition. The production of cells, though not as high as in aerobic decomposition, is relatively high.

Denitrification is especially important in wastewater treatment when nitrogen must be removed. In such cases, a separate treatment process is used. An important consideration regarding anoxic decomposition relates to the final clarification of the treated wastewater. If the final clarifier becomes anoxic, the formation of nitrogen gas will cause large masses of sludge to float to the surface and escape from the treatment plant into the receiving do not develop in the final clarifier.

### **Anaerobic Decomposition**

In order to achieve anaerobic decomposition, molecular oxygen and nitrate must not be present. Sulfate, carbon dioxide, and organic compounds that can be reduced serve as terminal electron acceptors. The reduction of sulfate results in the production of hydrogen sulfide, H<sub>2</sub>S, and a group of equally odoriferous organic sulfur compounds called *mercaptans*.

The anaerobic decomposition of organic matter, also known as *fermentation*, is generally considered to be a two-step process. In the first step, complex organic compounds are fermented to low molecular weight *fatty acids* (*volatile acids*). In the second step, the organic acids are converted to methane. Carbon dioxide serves as the electron acceptor.

Anaerobic decomposition produces carbon dioxide, methane, and water as the major end products. Additional end products include ammonia, hydrogen sulfide, and mercaptans. As a consequence of these last three

**Table 27.4** Waste Decomposition End Products

substrates	aerobic decomposition	anoxic decomposition	anaerobic decomposition
proteins and other organic nitrogen compounds	amino acids ammonia → nitrites → nitrates alcohols organic acids } → CO <sub>2</sub> + H <sub>2</sub> O	amino acids nitrates → nitrites → N <sub>2</sub> alcohols organic acids } → CO <sub>2</sub> + H <sub>2</sub> O	amino acids ammonia hydrogen sulfide methane carbon dioxide alcohols organic acids
carbohydrates	alcohols fatty acids } → CO <sub>2</sub> + H <sub>2</sub> O	alcohols fatty acids } → CO <sub>2</sub> + H <sub>2</sub> O	carbon dioxide alcohols fatty acids
fats and related substances	fatty acids + glycerol alcohols lower fatty acids } → CO <sub>2</sub> + H <sub>2</sub> O	fatty acids + glycerol alcohols lower fatty acids } → CO <sub>2</sub> + H <sub>2</sub> O	fatty acids + glycerol carbon dioxide alcohols lower fatty acids

compounds, anaerobic decomposition is characterized by a malodorous stench.

Because only small amounts of energy are released during anaerobic oxidation, the amount of cell production is low, and sludge production is correspondingly low. Wastewater treatment based on anaerobic decomposition is used to stabilize sludge produced during aerobic and anoxic decomposition.

Direct anaerobic decomposition of wastewater generally is not feasible for dilute waste. The optimum growth temperature for the anaerobic bacteria is at the upper end of the mesophilic range. To get reasonable biodegradation, the temperature of the culture must first be elevated. For dilute wastewater, this is not practical. Anaerobic digestion is quite appropriate for concentrated wastes ( $BOD_5 > 1000 \text{ mg/L}$ ).

## 5. FACTORS AFFECTING DISEASE TRANSMISSION

Waterborne disease transmission is influenced by the latency, persistence, and quantity (dose) of the pathogens. *Latency* is the period of time between excretion of a pathogen and its becoming infectious to a new host. *Persistence* is the length of time that a pathogen remains viable in the environment outside a human host. The *infective dose* is the number of organisms that must be ingested to result in disease.

## AIDS

*Acquired immunodeficiency syndrome* (AIDS) is caused by the *human immunodeficiency virus* (HIV). HIV is present in virtually all body excretions of infected persons and is present in wastewater. However, the risk of contracting AIDS through contact with wastewater or working at a wastewater plant is very small, based on the following facts.

- HIV is relatively weak and does not remain viable for long in harsh environments such as wastewater.
- HIV is quickly inactivated by alcohol, chlorine, and exposure to air. The chlorine concentration present in many toilets, for example, is enough to inactivate HIV.
- HIV that survives disinfection has been found to be too dilute to be infectious.
- HIV replicates in white blood cells, not in the human intestinal tract. It has not been found to reproduce in wastewater.
- There is no evidence that HIV can be transmitted through water, air, food, or casual contact. HIV must enter the bloodstream directly, through a wound. It cannot enter through unbroken skin or through respiration.
- There are no reported AIDS cases linked to occupational exposure in wastewater collection and treatment.

## 6. STOICHIOMETRY OF SELECTED BIOLOGICAL SYSTEMS

This section shows four classes of biological reactions involving microorganisms, each with simplified stoichiometric equations.

Stoichiometric problems are known as *weight and proportion problems* because their solutions use simple ratios to determine the masses of reactants required to produce given masses of products, or vice versa. The procedure for solving these problems is essentially the same regardless of the reaction.

*step 1:* Write and balance the chemical equation. (For convenience in using the degree of reduction equation, reduce the reactant's chemical formula to a single carbon atom.)

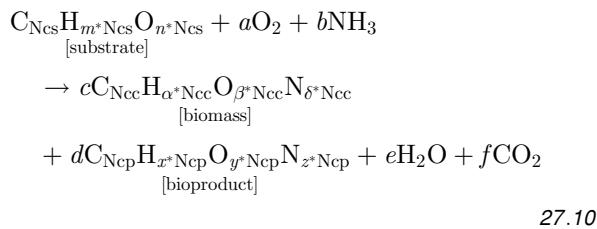

*step 2:* Determine the atomic (molecular) weight of each element (compound) in the equation.

*step 3:* Multiply the atomic (molecular) weights by their respective coefficients and write the products under the formulas.

*step 4:* Write the given mass data under the weights determined in step 3.

*step 5:* Fill in the missing information by calculating simple ratios.

The first biological reaction is the production of biomass with a single extracellular product. Water and carbon dioxide are also produced as shown in the reaction equation.

Equation 27.11 through Eq. 27.13 are used to calculate degrees of reduction (available electrons per unit of carbon) for substrate, *s*, biomass, *b*, and product, *p*.

$$\gamma_s = 4 + m - 2n \quad 27.11$$

$$\gamma_b = 4 + \alpha - 2\beta - 3\delta \quad 27.12$$

$$\gamma_p = 4 + x - 2y - 3z \quad 27.13$$

Table 27.5 shows typical degrees of reduction,  $\gamma$ . A high *degree of reduction* denotes a low degree of oxidation. Solving for the coefficients in Eq. 27.10 requires satisfying the carbon, nitrogen, and electron balances, plus knowing the respiratory coefficient and a yield coefficient. The key biomass production and reduction factors involved in determining carbon, nitrogen, electron, and energy balances are shown in Eq. 27.14 through Eq. 27.17.

**Table 27.5** Composition Data for Biomass and Selected Organic Compounds

compound	molecular formula	degree of reduction, $\gamma$	molecular weight, MW
generic biomass*	$\text{CH}_{1.64}\text{N}_{0.16}\text{O}_{0.52}$	4.17 ( $\text{NH}_3$ )	24.5
	$\text{P}_{0.0054}\text{S}_{0.005}$	4.65 ( $\text{N}_3$ ) 5.45 ( $\text{HNO}_3$ )	
methane	$\text{CH}_4$	8	16.0
<i>n</i> -alkane	$\text{C}_4\text{H}_{32}$	6.13	14.1
methanol	$\text{CH}_4\text{O}$	6.0	32.0
ethanol	$\text{C}_2\text{H}_6\text{O}$	6.0	23.0
glycerol	$\text{C}_2\text{H}_6\text{O}_3$	4.67	30.7
mannitol	$\text{C}_6\text{H}_{14}\text{O}_6$	4.33	30.3
acetic acid	$\text{C}_2\text{H}_4\text{O}_2$	4.0	30.0
lactic acid	$\text{C}_3\text{H}_6\text{O}_3$	4.0	30.0
glucose	$\text{C}_6\text{H}_{12}\text{O}_6$	4.0	30.0
formaldehyde	$\text{CH}_2\text{O}$	4.0	30.0
gluconic acid	$\text{C}_6\text{H}_{12}\text{O}_7$	3.67	32.7
succinic acid	$\text{C}_4\text{H}_6\text{O}_4$	3.50	29.5
citric acid	$\text{C}_6\text{H}_8\text{O}_7$	3.0	32.0
malic acid	$\text{C}_4\text{H}_6\text{O}_5$	3.0	33.5
formic acid	$\text{CH}_2\text{O}_2$	2.0	46.0
oxalic acid	$\text{C}_2\text{H}_2\text{O}_4$	1.0	45.0

\*Sulfur is present in proteins.

Adapted from *Biochemical Engineering and Biotechnology Handbook* by B. Atkinson and F. Mavitona, Macmillan, Inc., 1983.

$$c\text{Ncc} + d\text{Ncp} + f = \text{Ncs} \quad [\text{carbon}] \quad 27.14$$

$$c\delta\text{Ncc} + dz\text{Ncp} = b \quad [\text{nitrogen}] \quad 27.15$$

$$c\gamma_b\text{Ncb} + d\gamma_p\text{Ncp} = \gamma_s\text{Ncs} - 4a \quad [\text{electron}] \quad 27.16$$

$$Q_o c\gamma_b\text{Ncc} + Q_o d\gamma_p\text{Ncp} = Q_o \gamma_s\text{Ncs} - Q_o 4a \quad [\text{energy}] \quad 27.17$$

$Q_o$  is the heat evolved per equivalent (gram mole) of available electrons, approximately 26.95 kcal/mole of electrons.

The *respiratory quotient* (RQ) is the  $\text{CO}_2$  produced per unit of  $\text{O}_2$ .

$$\text{RQ} = \frac{f}{a} \quad 27.18$$

The coefficients *c* and *d* in Eq. 27.10 are referred to as maximum theoretical *yield coefficients* when expressed per gram of substrate. The yield coefficient can be given either as grams of cells or grams of product per gram of substrate.

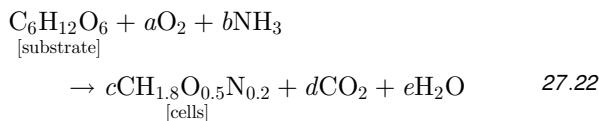

$$Y_{\text{ideal},b} = \frac{m_b}{m_s} \quad 27.19$$

$$Y_{\text{ideal},p} = \frac{m_p}{m_s} \quad 27.20$$

The ideal yield coefficients are related to the actual yield coefficients by the *yield factor*.

$$\text{yield factor} = \frac{Y_{\text{actual}}}{Y_{\text{ideal}}} \quad 27.21$$

The second reaction is the aerobic biodegradation of glucose in the presence of oxygen and ammonia. In this reaction, cells are formed, and carbon dioxide and water are the only products. The stoichiometric equation is

For Eq. 27.22,

$$a = 1.94$$

$$b = 0.77$$

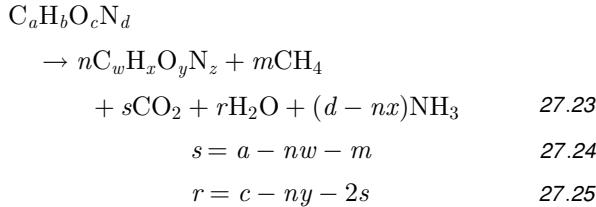

$$c = 3.88$$

$$d = 2.13$$

$$e = 3.68$$

The coefficient  $c$  is the theoretical maximum yield coefficient, which may be reduced by a yield factor.

The third reaction is the anaerobic (no oxygen) biodegradation of organic wastes with incomplete stabilization (i.e., incomplete treatment). Methane, carbon dioxide, ammonia, and water as well as smaller organic waste molecules are the products. The stoichiometric equation is

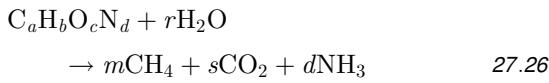

$$s = a - nw - m \quad 27.24$$

$$r = c - ny - 2s \quad 27.25$$

Knowledge of product composition, yield coefficient, and methane CO<sub>2</sub> ratio is needed to solve the stoichiometric equation.

The fourth reaction is the anaerobic biodegradation of organic wastes with complete stabilization. Besides organic waste, water is consumed in this reaction and the products are methane, carbon dioxide, and ammonia. The stoichiometric equation is

$$r = \frac{4a - b - 2c + 3d}{4} \quad 27.27$$

$$s = \frac{4a - b + 2c + 3d}{8} \quad 27.28$$

$$m = \frac{4a + b - 2c - 3d}{8} \quad 27.29$$

Composition data for biomass and selected organic compounds is given in Table 27.5.

### Example 27.2

An organic compound has an empirical formula of CH<sub>1.8</sub>O<sub>0.5</sub>N<sub>0.2</sub>. During combustion in oxygen gas, the compound dissociates and nitrogen is produced. What is the standard heat of combustion for one gram of this compound expressed in kJ/g?

*Solution*

Since this organic compound's chemical formula contains nitrogen, it matches the generic empirical formula for a "biomass" in Eq. 27.10. However, the compound is the reactant, not the product, and it should be considered as a substrate.

Write Eq. 27.10 for this compound with  $c = \alpha = \beta = \delta = x = y = 0$ .

Balance this reaction.

carbon, C:  $f = 1$

nitrogen, N:  $2d = 0.2$ ;  $d = 0.1$

hydrogen, H:  $2e = 1.8$ ;  $e = 0.9$

oxygen, O:  $2f + e = 0.5 + 2a$ ;  $a = 1.2$

The balanced stoichiometric combustion reaction is

Use Eq. 27.11 (with  $m = 1.8$  and  $n = 0.5$ ) to determine the degree of reduction for a substrate with a single carbon atom.

$$\begin{aligned} \gamma_s &= 4 + m - 2n \\ &= 4 + 1.8 - (2)(0.5) \\ &= 4.8 \end{aligned}$$

Now, use Eq. 27.17 to determine the molar heat of combustion.

molar heat of combustion

$$\begin{aligned} &= -\gamma_s Q_o \\ &= (4.8) \left( 26.95 \frac{\text{kcal}}{\text{mol}} \right) \left( 4.1868 \frac{\text{kJ}}{\text{kcal}} \right) \\ &= 541.6 \text{ kJ/mol} \end{aligned}$$

The approximate molecular weight of this compound is

$$\text{MW} = 12 + (1.8)(1) + (0.5)(16) + (0.2)(14) = 24.6$$

The ideal heat of combustion per unit mass is

$$\frac{541.6 \text{ kJ}}{24.6 \frac{\text{mol}}{\text{g}}} = 22.0 \text{ kJ/g}$$

The higher heat of combustion of a solid fuel in MJ/mg or kJ/g is approximately

$$\begin{aligned} \text{HHV} &= 32.78 G_C + 141.8 \left( G_H - \frac{G_O}{8} \right) \\ &= (32.78)(0.488) + (141.8) \left( 0.073 - \frac{0.325}{8} \right) \\ &= 20.59 \text{ kJ/g} \end{aligned}$$

### Example 27.3

Verify the heat of combustion from Ex. 27.2 using traditional combustion reaction methods.

*Solution*

The gravimetric fractions,  $G$ , of the elements in this fuel are

$$\begin{aligned} \text{carbon, C: } &12/24.6 = 0.488 \\ \text{hydrogen, H: } &1.8/24.6 = 0.073 \\ \text{oxygen, O: } &8/24.6 = 0.325 \\ \text{nitrogen, N: } &2.8/24.6 = 0.114 \end{aligned}$$

## 1. DOMESTIC WASTEWATER

*Domestic wastewater* refers to *sanitary wastewater* discharged from residences, commercial buildings, and institutions. Other examples of domestic wastewater sources are mobile homes, hotels, schools, offices, factories, and other commercial enterprises, excluding manufacturing facilities.

The volume of domestic wastewater varies from 50–250 gallons per capita day (gpcd) (190–950 Lpcd) depending on sewer uses. A more common range for domestic wastewater flow is 100–120 gpcd (380–450 Lpcd), which assumes that residential dwellings have major water-using appliances such as dishwashers and washing machines.

## 2. INDUSTRIAL WASTEWATER

Small manufacturing facilities within municipal limits ordinarily discharge *industrial wastewater* into the city sewer system only after pretreatment. In *joint processing* of wastewater, the municipality accepts responsibility for final treatment and disposal. The manufacturing plant may be required to pretreat the wastewater and equalize flow by holding it in a basin for stabilization prior to discharge to the sewer.

Uncontaminated streams (e.g., cooling water), in many cases, can be discharged into sewers directly. However, pretreatment at the industrial site is required for wastewaters having strengths and/or characteristics significantly different from sanitary wastewater.

To minimize the impact on the sewage treatment plant, consideration is given to modifications in industrial processes, segregation of wastes, flow equalization, and waste strength reduction. Modern industrial/manufacturing processes require segregation of separate waste streams for individual pretreatment, controlled mixing, and/or separate disposal. Process changes, equipment modifications, by-product recovery, and in-plant wastewater reuse can result in cost savings for both water supply and wastewater treatment.

Toxic waste streams are not generally accepted into the municipal treatment plant at all. Toxic substances require appropriate pretreatment prior to disposal by other means.

## 3. MUNICIPAL WASTEWATER

*Municipal wastewater* is the general name given to the liquid collected in sanitary sewers and routed to municipal sewage treatment plants. Many older cities have *combined sewer systems* where storm water and sanitary wastewaters are collected in the same lines. The combined flows are conveyed to the treatment plant for processing during dry weather. During wet weather, when the combined flow exceeds the plant's treatment capacity, the excess flow often bypasses the plant and is discharged directly into the watercourse.

## 4. WASTEWATER QUANTITY

Approximately 70–80% of a community's domestic and industrial water supply returns as wastewater. This water is discharged into the sewer systems, which may or may not also function as storm drains. Therefore, the nature of the return system must be known before sizing can occur.

*Infiltration*, due to cracks and poor joints in old or broken lines, can increase the sewer flow significantly. Infiltration per mile (kilometer) per in (mm) of pipe diameter is limited by some municipal codes to 500 gpd/mi-in (46 Lpd/km·mm). Modern piping materials and joints easily reduce the infiltration to 200 gpd/in-mi (18 Lpd/km·mm) and below. Infiltration can also be

roughly estimated as 3–5% of the peak hourly domestic rate or as 10% of the average rate.

*Inflow* is another contributor to the flow in sewers. Inflow is water discharged into a sewer system from such sources as roof down spouts, yard and area drains, parking area catch basins, curb inlets, and holes in manhole covers.

Sanitary sewer sizing is commonly based on an assumed average of 100–125 gpcd (380–474 Lpcd). There will be variations in the flow over time, although the variations are not as pronounced as they are for water supply. Hourly variations are the most significant. The flow rate pattern is essentially the same from day to day. Weekend flow patterns are not significantly different from weekday flow patterns. Seasonal variation depends on the location, local industries, and infiltration.

Table 28.1 lists typical *peaking factors* (i.e., peak multipliers) for treatment plant influent volume. Due to storage in ponds, clarifiers, and sedimentation basins, these multipliers are not applicable throughout all processes in the treatment plant.

**Table 28.1** Typical Variations in Wastewater Flows  
(based on average annual daily flow)

flow description	typical time	peaking factor
daily average	—	1.0
daily peak	10–12 a.m.	2.25
daily minimum	4–5 a.m.	0.4
seasonal average	May, June	1.0
seasonal peak	late summer	1.25
seasonal minimum	late winter	0.9

*Recommended Standards for Sewage Works (Ten States' Standards, abbreviated TSS)* specifies that new sanitary sewer systems should be designed to have an average flow of 100 gpcd (380 Lpcd or 0.38 m<sup>3</sup>/d), which includes an allowance for normal infiltration [TSS Sec. 33.94]. However, the sewer pipe must be sized to carry the peak flow as a gravity flow. In the absence of any studies or other justifiable methods, the ratio of peak hourly flow to average flow should be estimated from the following relationship, in which *P* is the population served in thousands of people at a particular point in the network.

$$\frac{Q_{\text{peak}}}{Q_{\text{ave}}} = \frac{18 + \sqrt{P}}{4 + \sqrt{P}} \quad 28.1$$

The peaking factor can also be estimated by using *Harmon's peaking factor* equation.

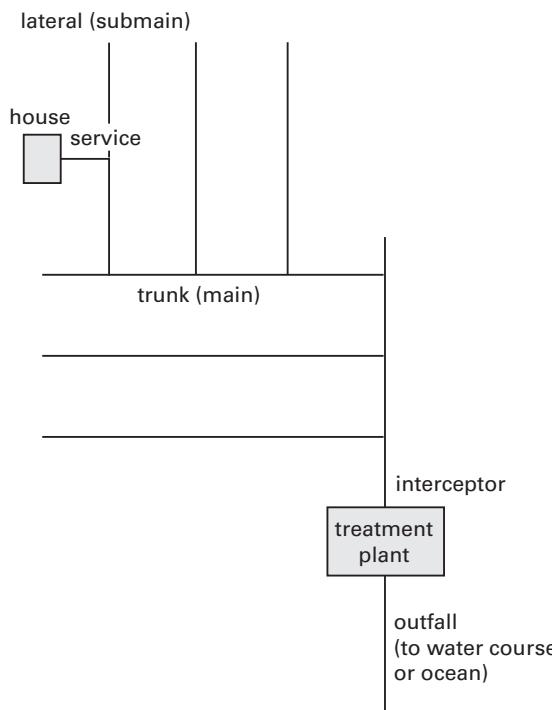

$$\frac{Q_{\text{peak}}}{Q_{\text{ave}}} = \frac{1 + 14}{4 + \sqrt{P}} \geq 2.5 \quad 28.2$$

*Collectors* (i.e., *collector sewers, trunks, or mains*) are pipes that collect wastewater from individual sources

and carry it to interceptors. (See Fig. 28.1.) Collectors must be designed to handle the maximum hourly flow, including domestic and infiltration, as well as additional discharge from industrial plants nearby. Peak flows of 400 gpcd (1500 Lpcd) for laterals and submains flowing full and 250 gpcd (950 Lpcd) for main, trunk, and outfall sewers can be assumed for design purposes, making the peaking factors approximately 4.0 and 2.5 for submains and mains, respectively. Both of these generalizations include generous allowances for infiltration. The lower flow rates take into consideration the averaging effect of larger contributing populations and the damping (storage) effect of larger distances from the source.

*Interceptors* are major sewer lines receiving wastewater from collector sewers and carrying it to a treatment plant or to another interceptor.

**Figure 28.1** Classification of Sewer Lines

## 5. TREATMENT PLANT LOADING

Ideally, the quantity and organic strength of wastewater should be based on actual measurements taken throughout the year in order to account for variations that result from seasonal, climatic changes and other factors.

The *hydraulic loading* for over 75% of the sewage treatment plants in the United States is 1 MGD or less. Plants with flows less than 1 MGD are categorized as *minors*. Treatment plants handling 1 MGD or more, or serving equivalent service populations of 10,000, are categorized as *majors*.

The *organic loading* of treatment units is expressed in terms of pounds (kilograms) of biochemical oxygen

demand (BOD) per day or pounds (kilograms) of solids per day. In communities where a substantial portion of household kitchen wastes is discharged to the sewer system through garbage disposals, the average organic matter contributed by each person each day to domestic wastewater is approximately 0.24 lbm (110 g) of suspended solids and approximately 0.17–0.20 lbm (77–90 g) of BOD.

Since the average BOD of domestic waste is typically taken as 0.2 pounds per capita day (90 g per capita day), the *population equivalent* of any wastewater source, including industrial sources, can be calculated.

$$P_{e,1000s} = \frac{\text{BOD}_{\text{mg/L}} Q_{\text{ML/d}}}{90 \frac{\text{g}}{\text{person}\cdot\text{d}}} \quad [\text{SI}] \quad 28.3(a)$$

$$P_{e,1000s} = \frac{\text{BOD}_{\text{mg/L}} Q_{\text{gal/day}}}{\left( \frac{10^6 \text{ gal}}{\text{MG}} \right) (1000 \text{ persons})} \times \left( 8.345 \frac{\text{lrbm-L}}{\text{MG-mg}} \right) \times \left( 0.20 \frac{\text{lrbm}}{\text{person-day}} \right) \quad [\text{U.S.}] \quad 28.3(b)$$

## 6. SEWER PIPE MATERIALS

In the past, sewer pipes were constructed from clay, concrete, asbestos-cement, steel, and cast iron. Due to cost, modern large-diameter sewer lines are now almost always concrete, and new small-diameter lines are generally plastic.

*Concrete pipe* is used for gravity sewers and pressure mains. Circular pipe is used in most applications, although special shapes (e.g., arch, egg, elliptical) can be used. Concrete pipe in diameters up to 24 in (610 mm) is available in standard 3 ft and 4 ft (0.9 m and 1.2 m) lengths and is usually not reinforced. *Reinforced concrete pipe* (RCP) in diameters ranging from 12 in to 144 in (305–3660 mm) is available in lengths from 4 ft to 12 ft (1.2–3.6 m).

Concrete pipe is used for large diameter (16 in (406 mm) or larger) trunk and interceptor sewers. In some geographical regions, concrete pipe is used for smaller domestic sewers. However, concrete domestic lines should be selected only where stale or septic sewage is not anticipated. They should not be used with corrosive wastes or in corrosive soils.

*Cast-iron pipe* is particularly suited to installations where scour, high velocity waste, and high external loads are anticipated. It can be used for domestic connections, although it is more expensive than plastic. Special linings, coatings, wrappings, or encasements are required for corrosive wastes and soils.

Polyvinyl chloride (PVC) and acrylonitrile-butadiene-styrene (ABS) are two *plastic pipe* compositions that can be used for normal domestic sewage and industrial wastewater lines. They have excellent resistance to corrosive soils. However, special attention and care must be given to trench loading and pipe bedding.

ABS plastic can also be combined with concrete reinforcement for collector lines for use with corrosive domestic sewage and industrial waste. Such pipe is known as *truss pipe* due to its construction. The plastic is extruded with inner and outer web-connected pipe walls. The annular voids and the inner and outer walls are filled with lightweight concrete.

For pressure lines (i.e., *force mains*), welded steel pipe with an epoxy liner and cement-lined and coated-steel pipe are also used.

*Vitrified clay pipe* is resistant to acids, alkalies, hydrogen sulfide (septic sewage), erosion, and scour. Two strengths of clay pipe are available. The standard strength is suitable for pipes less than 12 in (300 mm) in diameter,  $D$ , for any depth of cover if the "4D/3 + 8 in trench width" (4D/3 + 200 mm) rule is observed. Double-strength pipe is recommended for large pipe that is deeply trenched. Clay is seldom used for diameters greater than 36 in (910 mm).

*Asbestos-cement pipe* has been used in the past for both gravity and pressure sewers carrying non-septic and non-corrosive waste through non-corrosive soils. The lightweight and longer laying lengths are inherent advantages of asbestos-cement pipe. However, such pipes have fallen from favor due to the asbestos content.

## 7. GRAVITY AND FORCE COLLECTION SYSTEMS

Wastewater collection systems are made up of a network of discharge and flow lines, drains, inlets, valve works, and connections for transporting domestic and industrial wastewater flows to treatment facilities.

Flow through gradually sloping *gravity sewers* is the most desirable means of moving sewage since it does not require pumping energy. In some instances, though, it may be necessary to use pressurized *force mains* to carry sewage uphill or over long, flat distances.

*Alternative sewers* are used in some remote housing developments for domestic sewage where neither the conventional sanitary sewer nor the septic tank/leach field is acceptable. Alternative sewers use pumps to force raw or communitied sewage through small-diameter plastic lines to a more distant communal treatment or collection system.

There are four categories of alternative sewer systems. In the *G-P system*, a grinder-pump pushes chopped-up but untreated wastewater through a small-diameter plastic pipe. The *STEP system* (septic-tank-effluent pumping) uses a septic tank at each house, but there is

no leach field. The clear overflow goes to a pump that pushes the effluent through a small-diameter plastic sewer line operating under low pressure. The *vacuum sewer system* uses a vacuum valve at each house that periodically charges a slug of wastewater into a vacuum sewer line. The vacuum is created by a central pumping station. The *small-diameter gravity sewer (SDG)* also uses a small-diameter plastic pipe but relies on gravity instead of pumps. The pipe carries the effluent from a septic tank at each house. Costs in all four systems can be reduced greatly by having two or more houses share septic tanks, pumps, and vacuum valves.

## 8. SEWER VELOCITIES

The minimum design velocity actually depends on the particulate matter size. However, 2 ft/sec (0.6 m/s) is commonly quoted as the minimum *self-cleansing velocity*, although 1.5 ft/sec (0.45 m/s) may be acceptable if the line is occasionally flushed out by peak flows [TSS Sec. 33.42]. Table 28.2 gives minimum flow velocities based on fluid type.

**Table 28.2** Minimum Flow Velocities

fluid	minimum velocity to keep particles in suspension (ft/sec)	minimum resuspension velocity (ft/sec)	minimum (m/s)	minimum (m/s)
raw sewage	2.5	(0.75)	3.5	(1.1)
grit tank effluent	2	(0.6)	2.5	(0.75)
primary settling tank effluent	1.5	(0.45)	2	(0.6)
mixed liquor	1.5	(0.45)	2	(0.6)
trickling filter effluent	1.5	(0.45)	2	(0.6)
secondary settling tank effluent	0.5	(0.15)	1	(0.3)

(Multiply ft/sec by 0.3 to obtain m/s.)

Table 28.3 lists the approximate minimum slope needed to achieve a 2 ft/sec (0.6 m/s) flow. Slopes slightly less than those listed may be permitted (with justification) in lines where design average flow provides a depth of flow greater than 30% of the pipe diameter. Velocity greater than 10–15 ft/sec (3–4.5 m/s) requires special provisions to protect the pipe and manholes against erosion and displacement by shock hydraulic loadings.

## 9. SEWER SIZING

The Manning equation is traditionally used to size gravity sewers. Depth of flow at the design flow rate is usually less than 70–80% of the pipe diameter. (See Table 28.2.) A pipe should be sized to be able to carry the peak flow (including normal infiltration) at a depth of approximately 70% of its diameter.

In general, sewers in the collection system (including laterals, interceptors, trunks, and mains) should have diameters of at least 8 in (203 mm). Building service connections can be as small as 4 in (101 mm).

**Table 28.3** Minimum Slopes and Capacities for Sewers<sup>a</sup>

sewer diameter (in)	minimum change in elevation <sup>b</sup> (ft/100 ft or m/100 m)	full flow discharge at minimum slope <sup>c,d</sup> (ft <sup>3</sup> /sec)
8 (200)	0.40	0.771
9 (230)	0.33	0.996
10 (250)	0.28	1.17
12 (300)	0.22	1.61
14 (360)	0.17	2.23
15 (380)	0.15	2.52
16 (410)	0.14	2.90
18 (460)	0.12	3.67
21 (530)	0.10	5.05
24 (610)	0.08	6.45
27 (690)	0.067	8.08
30 (760)	0.058	9.96
36 (910)	0.046	14.4

(Multiply in by 25.4 to obtain mm.)

(Multiply ft/100 ft by 1 to obtain m/100 m.)

(Multiply ft<sup>3</sup>/sec by 448.8 to obtain gal/min.)(Multiply ft<sup>3</sup>/sec by 28.32 to obtain L/s.)

(Multiply gal/min by 0.0631 to obtain L/s.)

<sup>a</sup>to achieve a velocity of 2 ft/sec (0.6 m/s) when flowing full<sup>b</sup>as specified in Sec. 24.31 of *Recommended Standards for Sewage Works* (RSSW), also known as "Ten States' Standards" (TSS), published by the Health Education Service, Inc. [TSS Sec. 33.41]<sup>c</sup>*n* = 0.013 assumed<sup>d</sup>For any diameter in inches and *n* = 0.013, calculate the full flow as

$$Q = 0.0472 d_{\text{in}}^{8/3} \sqrt{S}$$

## 10. STREET INLETS

*Street inlets* are required at all low points where ponding could occur, and they should be placed no more than 600 ft (180 m) apart; a limit of 300 ft (90 m) is preferred. A common practice is to install three inlets in a sag vertical curve—one at the lowest point and one on each side with an elevation of 0.2 ft (60 mm) above the center inlet.

Depth of gutter flow is found using Manning's equation. Inlet capacities of street inlets have traditionally been calculated from semi-empirical formulas.

*Grate-type street inlets* (known as *gutter inlets*) less than 0.4 ft (120 mm) deep have approximate capacities given by Eq. 28.4. Equation 28.4 should also be used for combined curb-grate inlets. All dimensions are in feet. For gutter inlets, the bars should ideally be parallel to the flow and be at least 1.5 ft (450 mm) long. Gutter inlets are more efficient than curb inlets, but clogging is a problem. Depressing the grating level below the street level increases the capacity.

$$Q_{\text{ft}^3/\text{sec}} = 3.0(\text{grate perimeter length}) \times (\text{inlet flow depth})^{3/2} \quad 28.4$$

The capacity of a *curb inlet* (where there is an opening in the vertical plane of the gutter rather than in the

horizontal plane) is given by Eq. 28.5. All dimensions are in feet. Not all curb inlets have inlet depressions. A typical curb inlet depression is 0.4 ft (130 mm).

$$Q_{\text{ft}^3/\text{sec}} = 0.7(\text{curb opening length}) \times (\text{inlet flow depth} + \text{curb inlet depression})^{3/2} \quad 28.5$$

## 11. MANHOLES

Manholes along sewer lines should be provided at sewer line intersections and at changes in elevation, direction, size, diameter, and slope. If a sewer line is too small for a person to enter, manholes should be placed every 400 ft (120 m) to allow for cleaning. Recommended maximum spacings are 400 ft (120 m) for pipes with diameters less than 18 in (460 mm), 500 ft (150 m) for 18–48 in (460–1220 mm) pipes, and 600–700 ft (180–210 m) for larger pipes.

## 12. SULFIDE ATTACK

Wastewater flowing through sewers often turns septic and releases *hydrogen sulfide* gas, H<sub>2</sub>S. The common *Thiobacillus* sulfur bacterium converts the hydrogen sulfide to sulfuric acid. The acid attacks the crowns of concrete pipes that are not flowing full.

In warm climates, hydrogen sulfide can be generated in sanitary sewers placed on flat grades. Hydrogen sulfide also occurs in sewers supporting food processing industries. Sulfide generation is aggravated by the use of home garbage disposals and, to a lesser extent, by recycling. Interest in nutrition and fresh foods has also added to food wastes.

*Sulfide attack* in partially full sewers can be prevented by maintaining the flow rate above 5 ft/sec (1.5 m/s), raising the pH above 10.4, using biocides, precipitating the sulfides, or a combination thereof. Not all methods may be possible or economical, however. In sewers, the least expensive method generally involves intermittent (e.g., biweekly during the critical months) *shock treatments* of sodium hydroxide and ferrous chloride. The sodium hydroxide is a sterilization treatment that works by raising the pH, while the ferrous chloride precipitates the sulfides.

Sulfide attack is generally not an issue in force mains because sewage is continually moving and always makes contact with all of the pipe wall.

### 13. WASTEWATER CHARACTERISTICS

Not all sewage flows are the same. Some sewages are stronger than others. Table 28.4 lists typical values for strong and weak domestic sewages.

**Table 28.4** Strong and Weak Domestic Sewages\*

constituent	strong	weak
solids, total	1200	350
dissolved, total	850	250
fixed	525	145
volatile	325	105
suspended, total	350	100
fixed	75	30
volatile	275	70
settleable solids (mL/L)	20	5
biochemical oxygen demand, five-day, 20°C	300	100
total organic carbon	300	100
chemical oxygen demand	1000	250
nitrogen (total as N)	85	20
organic	35	8
free ammonia	50	12
nitrites	0	0
nitrates	0	0
phosphorus (total as P)	20	6
organic	5	2
inorganic	15	4
chlorides	100	30
alkalinity (as CaCO <sub>3</sub> )	200	50
grease	150	50

\*All concentrations are in mg/L unless otherwise noted.

### 14. SOLIDS

Solids in wastewater are categorized in the same manner as in water supplies. *Total solids* consist of *suspended* and *dissolved solids*. Generally, total solids constitute only a small amount of the incoming flow—less than 1/10% by mass. Therefore, wastewater fluid transport properties are essentially those of water. Figure 28.2 illustrates the solids categorization, along with typical percentages. Each category can be further divided into organic and inorganic groups.

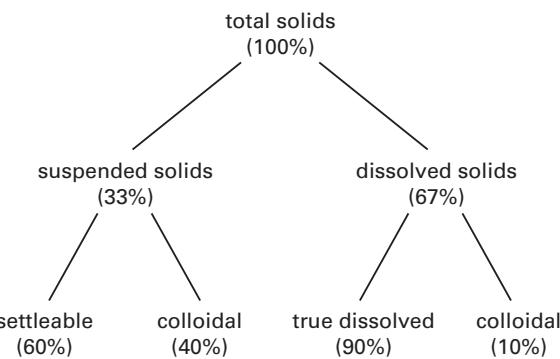

The amount of *volatile solids* can be used as a measure of the organic pollutants capable of affecting the oxygen content. As in water supply testing, volatile solids are measured by igniting filtered solids and measuring the decrease in mass.

*Refractory solids (refractory organics)* are solids that are difficult to remove by common wastewater treatment processes.

### 15. MICROBIAL GROWTH

For the large numbers and mixed cultures of microorganisms found in waste treatment systems, it is more convenient to measure biomass than numbers of organisms. This is accomplished by measuring suspended or

**Figure 28.2** Wastewater Solids\*

\*typical percentages given

volatile suspended solids. An expression that depicts the rate of conversion of food into biomass for wastewater treatment was developed by Monod.

Equation 28.8 calculates the rate of growth,  $r_g$ , of a bacterial culture as a function of the rate of concentration of limiting food in solution. The concentration,  $X$ , of microorganisms, with dimensions of mass per unit volume (e.g., mg/L) is given by Eq. 28.8.  $\mu$  is a specific growth rate factor with dimensions of time<sup>-1</sup>.

$$r_g = \frac{dX}{dt} = \mu X \quad 28.8$$

When one essential nutrient (referred to as a *substrate*) is present in a limited amount, the specific growth rate will increase up to a maximum value, as shown in Fig. 28.3 and as given by *Monod's equation*, Eq. 28.9.  $\mu_m$  is the *maximum specific growth rate coefficient* with dimensions of time<sup>-1</sup>.  $S$  is the concentration of the growth-limiting nutrient with dimensions of mass/unit volume.  $K_s$  is the *half-velocity coefficient*, the nutrient concentration at one half of the maximum growth rate, with dimensions of mass per unit volume.

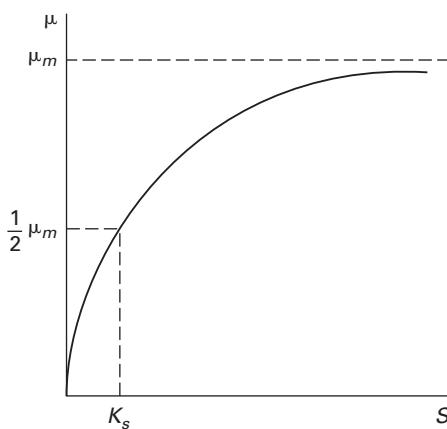

$$\mu = \mu_m \left( \frac{S}{K_s + S} \right) \quad 28.9$$

Combining Eq. 28.8 and Eq. 28.9, the rate of growth is

$$r_g = \frac{\mu_m X S}{K_s + S} \quad 28.10$$

The rate of substrate (nutrient) utilization is easily calculated if the *maximum yield coefficient*,  $Y$ , defined as the ratio of the mass of cells formed to the mass of nutrient consumed (with dimensions of mass/mass) is known.

$$r_{su} = \frac{dS}{dt} = \frac{-\mu_m X S}{Y(K_s + S)} \quad 28.11$$

**Figure 28.3** Bacterial Growth Rate with Limited Nutrient

The maximum rate of substrate utilization per unit mass of microorganisms is

$$k = \frac{\mu_m}{Y} \quad 28.12$$

Combining Eq. 28.11 and Eq. 28.12,

$$\frac{dS}{dt} = \frac{-kXS}{K_s + S} \quad 28.13$$

The Monod equation assumes that all microorganisms are the same age. The actual distribution of ages and other factors (death and predation of cells) decreases the rate of cell growth. The decrease is referred to as *endogenous decay* and is accounted for with an *endogenous decay coefficient*,  $k_d$ , with dimensions of time<sup>-1</sup>. The rate of endogenous decay is

$$r_d = -k_d X \quad 28.14$$

The *net rate of cell growth* and *net specific growth rate* are

$$\begin{aligned} r'_g &= \frac{\mu_m XS}{K_s + S} - k_d X \\ &= -Y r_{su} - k_d X \end{aligned} \quad 28.15$$

$$\mu' = \mu_m \left( \frac{S}{K_s + S} \right) - k_d \quad 28.16$$

## 16. DISSOLVED OXYGEN IN WASTEWATER

A body of water exposed to the atmosphere will normally become saturated with oxygen. If the dissolved oxygen content, DO, of water is less than the saturated

values, there will be good reason to believe that the water is organically polluted.

The difference between the saturated and actual dissolved oxygen concentration is known as the *oxygen deficit*,  $D$ .

$$D = DO_{\text{sat}} - DO \quad 28.17$$

## 17. REOXYGENATION

The oxygen deficit can be reduced (i.e., the dissolved oxygen concentration can be increased) only by aerating the water. This occurs naturally in free-running water (e.g., in rivers). The rate of reaeration is

$$r_r = K_r (DO_{\text{sat}} - DO) \quad 28.18$$

$K_r$  is the *reoxygenation (reaeration) rate constant*, which depends on the type of flow and temperature and with common units of day<sup>-1</sup>. ( $K_r$  may be written as  $K_R$  and  $K_2$  by some authorities.) Typical values of  $K_r$  (base-10) are: small stagnant ponds, 0.05–0.10; sluggish streams, 0.10–0.15; large lakes, 0.10–0.15; large streams, 0.15–0.30; swiftly flowing rivers and streams, 0.3–0.5; whitewater and waterfalls, 0.5 and above.

An exponential model is used to predict the oxygen deficit,  $D$ , as a function of time during a pure reoxygenation process. Reoxygenation constants are given for use with a base-10 and natural logarithmic base.

$$D_t = D_0 10^{-K_r t} \quad [\text{base-10}] \quad 28.19$$

$$D_t = D_0 e^{-K'_r t} \quad [\text{base-e}] \quad 28.20$$

The base-e constant  $K'_r$  may be written as  $K_{r,\text{base-e}}$  by some authorities. The constants  $K_r$  and  $K'_r$  are different but related.

$$K'_r = 2.303 K_r \quad 28.21$$

$K'_r$  can be approximated from the *O'Connor and Dobbs formula* for moderate to deep natural streams with low to moderate velocities. Both  $v$  and  $d$  are average values.

$$K'_{r,20^\circ\text{C}} \approx \frac{3.93 \sqrt{v_{\text{m/s}}}}{d_{\text{m}}^{1.5}} \quad \begin{cases} 0.3 \text{ m} < d < 9.14 \text{ m} \\ 0.15 \text{ m/s} < v < 0.49 \text{ m/s} \end{cases} \quad [\text{SI}] \quad 28.22(a)$$

$$K'_{r,68^\circ\text{F}} \approx \frac{12.9 \sqrt{v_{\text{ft/sec}}}}{d_{\text{ft}}^{1.5}} \quad \begin{cases} 1 \text{ ft} < d < 30 \text{ ft} \\ 0.5 \text{ ft/sec} < v < 1.6 \text{ ft} \end{cases} \quad [\text{U.S.}] \quad 28.22(b)$$

An empirical formula that has been proposed for faster moving water is the *Churchill formula*.

$$K'_{r,20^\circ\text{C}} \approx \frac{5.049v^{0.969}}{d_m^{1.67}} \quad \begin{cases} 0.61 \text{ m} < d < 3.35 \text{ m} \\ 0.55 \text{ m/s} < v < 1.52 \text{ m/s} \end{cases} \quad [\text{SI}] \quad 28.23(a)$$

$$K'_{r,68^\circ\text{F}} \approx \frac{11.61v^{0.969}}{d_{\text{ft}}^{1.67}} \quad \begin{cases} 2 \text{ ft} < d < 11 \text{ ft} \\ 1.8 \text{ ft/sec} < v < 5 \text{ ft/sec} \end{cases} \quad [\text{U.S.}] \quad 28.23(b)$$

The variation in  $K'_r$  with temperature is given approximately by Eq. 28.24. The temperature constant 1.024 has been reported as 1.016 by some authorities.

$$K'_{r,T} = K'_{r,20^\circ\text{C}}(1.024)^{T-20^\circ\text{C}} \quad 28.24$$

Equation 28.24 is actually a special case of Eq. 28.25, which gives the relationship between values of  $K'_r$  between any two temperatures.

$$K'_{r,T_1} = K'_{r,T_2} \theta_r^{T_1-T_2} \quad 28.25$$

## 18. DEOXYGENATION

The rate of deoxygenation at time  $t$  is

$$r_{d,t} = -K_d \text{DO} \quad 28.26$$

The *deoxygenation rate constant*,  $K_d$ , for treatment plant effluent is approximately  $0.05\text{--}0.10 \text{ day}^{-1}$  and is typically taken as  $0.1 \text{ day}^{-1}$  (base-10 values). ( $K_d$  may be represented as  $K$  and  $K_1$  by some authorities.) For highly polluted shallow streams,  $K_d$  can be as high as  $0.25 \text{ day}^{-1}$ . For raw sewage, it is approximately  $0.15\text{--}0.30 \text{ day}^{-1}$ .  $K'_d$  is the base-e version of  $K_d$ .

$$K'_d = 2.303K_d \quad 28.27$$

$K_d$  for other temperatures can be found from Eq. 28.28. The *temperature variation constant*,  $\theta_d$ , is often quoted in literature as 1.047. However, this value should not be used with temperatures below  $68^\circ\text{F}$  ( $20^\circ\text{C}$ ). Additional research suggests that  $\theta_d$  varies from 1.135 for temperatures between  $39^\circ\text{F}$  and  $68^\circ\text{F}$  ( $4^\circ\text{C}$  and  $20^\circ\text{C}$ ) up to 1.056 for temperatures between  $68^\circ\text{F}$  and  $86^\circ\text{F}$  ( $20^\circ\text{C}$  and  $30^\circ\text{C}$ ).

$$K'_{d,T} = K'_{d,20^\circ\text{C}} \theta_d^{T-20^\circ\text{C}} \quad 28.28$$

Equation 28.28 is actually a special case of Eq. 28.29, which gives the relationship between values of  $K'_d$  between any two temperatures.

$$K'_{d,T_1} = K'_{d,T_2} \theta_d^{T_1-T_2} \quad 28.29$$

## 19. TESTS OF WASTEWATER CHARACTERISTICS

The most common wastewater analyses used to determine characteristics of a municipal wastewater determine biochemical oxygen demand (BOD) and suspended solids (SS). BOD and flow data are basic requirements for the operation of biological treatment units. The concentration of suspended solids relative to BOD indicates the degree that organic matter is removable by primary settling. Additionally, temperature, pH, chemical oxygen demand (COD), alkalinity, color, grease, and the quantity of heavy metals are necessary to characterize municipal wastewater characteristics.

## 20. BIOCHEMICAL OXYGEN DEMAND

When oxidizing organic material in water, biological organisms also remove oxygen from the water. This is typically considered to occur through oxidation of organic material to  $\text{CO}_2$  and  $\text{H}_2\text{O}$  by microorganisms at the molecular level and is referred to as *biochemical oxygen demand* (BOD). Therefore, oxygen use is an indication of the organic waste content.

Typical values of BOD for various industrial wastewaters are given in Table 28.5. A BOD of  $100 \text{ mg/L}$  is considered to be a weak wastewater; a BOD of  $200\text{--}250 \text{ mg/L}$  is considered to be a medium strength wastewater; and a BOD above  $300 \text{ mg/L}$  is considered to be a strong wastewater.

In the past, the BOD has been determined in a lab using a traditional standardized BOD testing procedure. Since this procedure requires five days of incubating, inline measurement systems have been developed to provide

**Table 28.5** Typical BOD and COD of Industrial Wastewaters

industry/ type of waste	BOD	COD
canning		
corn	19.5 lbm/ton corn	
tomatoes	8.4 lbm/ton tomatoes	
dairy milk		
processing	1150 lbm/ton raw milk 1000 mg/L	1900 mg/L
beer brewing	1.2 lbm/barrel beer	
commercial		
laundry	1250 lbm/1000 lbm dry 700 mg/L	2400 mg/L
slaughterhouse	7.7 lbm/animal	2100 mg/L
(meat packing)	1400 mg/L	
papermill	121 lbm/ton pulp	
synthetic textile	1500 mg/L	3300 mg/L
chlorophenolic		
manufacturing	4300 mg/L	5400 mg/L
milk bottling	230 mg/L	420 mg/L
cheese production	3200 mg/L	5600 mg/L
candy production	1600 mg/L	3000 mg/L

essentially instantaneous and continuous BOD information at wastewater plants.

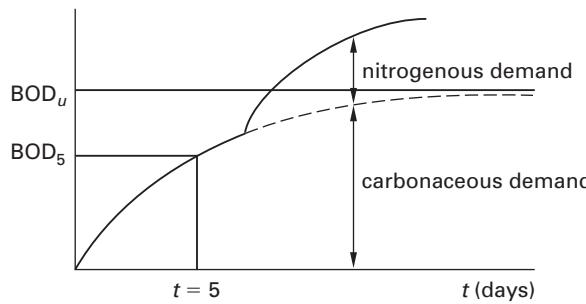

The standardized BOD test consists of adding a measured amount of wastewater (which supplies the organic material) to a measured amount of dilution water (which reduces toxicity and supplies dissolved oxygen) and then incubating the mixture at a specific temperature. The standard procedure calls for a five-day incubation period at 68°F (20°C), though other temperatures are used. The measured BOD is designated as  $BOD_5$  or BOD-5. The BOD of a biologically active sample at the end of the incubation period is given by Eq. 28.30.

$$BOD_5 = \frac{DO_i - DO_f}{V_{sample}} \quad 28.30$$

$$\frac{V_{sample} + V_{dilution}}$$

If more than one identical sample is prepared, the increase in BOD over time can be determined, rather than just the final BOD. Figure 28.4 illustrates a typical plot of BOD versus time. The BOD at any time  $t$  is known as the *BOD exertion*.

**Figure 28.4** BOD Exertion

BOD exertion can be found from Eq. 28.31. The ultimate BOD ( $BOD_u$ ) is the total oxygen used by *carbonaceous bacteria* if the test is run for a long period of time, usually taken as 20 days. (The symbols  $L$ ,  $BOD_L$ , and  $BOD_{ult}$  are also widely used to represent the ultimate BOD.) Use the proper form of Eq. 28.31 depending on the base of the deoxygenation rate constant.

$$BOD_t = BOD_u(1 - 10^{-K_d t})$$

$$= BOD_u(1 - e^{-K'_d t}) \quad 28.31$$

The ultimate BOD ( $BOD_u$ ) usually cannot be found from long-term studies due to the effect of nitrogen-consuming bacteria in the sample. However, if  $K_d$  is  $0.1 \text{ day}^{-1}$ , the ultimate BOD can be approximated from Eq. 28.32 derived from Eq. 28.31.

$$BOD_u \approx 1.463 BOD_5 \quad 28.32$$

The approximate variation in first-stage BOD (either  $BOD_5$  or  $BOD_u$ ) municipal wastewater with temperature is given by Eq. 28.33.<sup>1</sup>

$$BOD_{T^\circ C} = BOD_{20^\circ C}(0.02 T^\circ C + 0.6) \quad 28.33$$

The deviation from the expected exponential growth curve in Fig. 28.4 is due to nitrification and is considered to be *nitrogenous demand*. *Nitrification* is the use of oxygen by autotrophic bacteria. Autotrophic bacteria oxidize ammonia to nitrites and nitrates.

The number of autotrophic bacteria in a wastewater sample is initially small. Generally, 6 to 10 days are required for the autotrophic population to become sufficiently large to affect a BOD test. Therefore, the standard BOD test is terminated at five days, before the autotrophic contribution to BOD becomes significant.

Until recently, BOD has not played a significant role in the daily operations decisions of treatment plants because of the length of time it took to obtain BOD data. Other measurements, such as COD, TOC, turbidity, suspended solids, respiration rates, or flow have been used.

### Example 28.1

Ten 5 mL samples of wastewater are placed in 300 mL BOD bottles and diluted to full volume. Half of the bottles are titrated immediately, and the average initial concentration of dissolved oxygen is 7.9 mg/L. The remaining bottles are incubated for five days, after which the average dissolved oxygen is determined to be 4.5 mg/L. The deoxygenation rate constant is known to be  $0.13 \text{ day}^{-1}$  (base-10). What are the (a) standard BOD and (b) ultimate carbonaceous BOD?

*Solution*

(a) Use Eq. 28.30.

$$BOD_5 = \frac{DO_i - DO_f}{V_{sample}} \quad \frac{V_{sample} + V_{dilution}}$$

$$= \frac{7.9 \frac{\text{mg}}{\text{L}} - 4.5 \frac{\text{mg}}{\text{L}}}{\frac{5 \text{ mL}}{300 \text{ mL}}} \quad \frac{5 \text{ mL}}{300 \text{ mL}}$$

$$= 204 \text{ mg/L}$$

(b) From Eq. 28.31, the ultimate BOD is

$$BOD_u = \frac{BOD_t}{1 - 10^{-K_d t}}$$

$$= \frac{204 \frac{\text{mg}}{\text{L}}}{1 - 10^{(-0.13 \text{ day}^{-1})(5 \text{ days})}}$$

$$= 263 \text{ mg/L}$$

<sup>1</sup>As reported in *Water-Resources Engineering*, 4th ed., Ray K. Linsley, Joseph B. Franzini, David Freyberg, and George Tchobanoglou, McGraw-Hill Book Co., 1992, New York.

## 21. SEEDED BOD

Industrial wastewater may lack sufficient microorganisms to metabolize the organic matter. In this situation, the standard BOD test will not accurately determine the amount of organic matter unless seed organisms are added.

The BOD in seeded samples is found by measuring dissolved oxygen in the seeded sample after 15 min ( $\text{DO}_i$ ) and after five days ( $\text{DO}_f$ ), as well as by measuring the dissolved oxygen of the seed material itself after 15 min ( $\text{DO}_i^*$ ) and after five days ( $\text{DO}_f^*$ ). In Eq. 28.34,  $x$  is the ratio of the volume of seed added to the sample to the volume of seed used to find  $\text{DO}^*$ .

$$\text{BOD} = \frac{\text{DO}_i - \text{DO}_f - x(\text{DO}_i^* - \text{DO}_f^*)}{V_{\text{sample}}} \quad 28.34$$

$$\qquad \qquad \qquad V_{\text{sample}} + V_{\text{dilution}}$$

### Solution

Both flow rates must have the same units. Convert MGD to  $\text{ft}^3/\text{sec}$ .

$$Q_w = \frac{(6 \text{ MGD}) \left( 10^6 \frac{\text{gal}}{\text{MG}} \right)}{\left( 7.48 \frac{\text{gal}}{\text{ft}^3} \right) \left( 24 \frac{\text{hr}}{\text{day}} \right) \left( 60 \frac{\text{min}}{\text{hr}} \right) \left( 60 \frac{\text{sec}}{\text{min}} \right)}$$

$$= 9.28 \text{ ft}^3/\text{sec}$$

From App. 22.C, the saturated oxygen content at  $50^\circ\text{F}$  ( $10^\circ\text{C}$ ) is 11.3 mg/L. From Eq. 28.35,

$$C_f = \frac{C_w Q_w + C_r Q_r}{Q_w + Q_r}$$

$$= \frac{\left( 0.9 \frac{\text{mg}}{\text{L}} \right) \left( 9.28 \frac{\text{ft}^3}{\text{sec}} \right) + \left( 11.3 \frac{\text{mg}}{\text{L}} \right) \left( 40 \frac{\text{ft}^3}{\text{sec}} \right)}{9.28 \frac{\text{ft}^3}{\text{sec}} + 40 \frac{\text{ft}^3}{\text{sec}}}$$

$$= 9.34 \text{ mg/L}$$

## 22. DILUTION PURIFICATION

*Dilution purification* (also known as *self-purification*) refers to the discharge of untreated or partially treated sewage into a large body of water such as a river. After the treatment plant effluent has mixed with the river water, the river experiences both deoxygenation (from the biological activity of the waste) and reaeration (from the agitation of the flow). If the body is large and is adequately oxygenated, the sewage's BOD may be satisfied without putrefaction.

When two streams merge, the characteristics of the streams are blended in the combined flow. If values of the characteristics of interest are known for the upstream flows, the blended concentration can be found as a weighted average. Equation 28.35 can be used to calculate the final temperature, dissolved oxygen, BOD, or suspended solids content immediately after two flows are mixed. (The subscript  $a$  is also used in literature to represent the condition immediately after mixing.)

$$C_f = \frac{C_1 Q_1 + C_2 Q_2}{Q_1 + Q_2} \quad 28.35$$

### Example 28.2

6 MGD of wastewater with a dissolved oxygen concentration of 0.9 mg/L is discharged into a  $50^\circ\text{F}$  river flowing at  $40 \text{ ft}^3/\text{sec}$ . The river is initially saturated with oxygen. What is the oxygen content of the river immediately after mixing?

## 23. RESPONSE TO DILUTION PURIFICATION

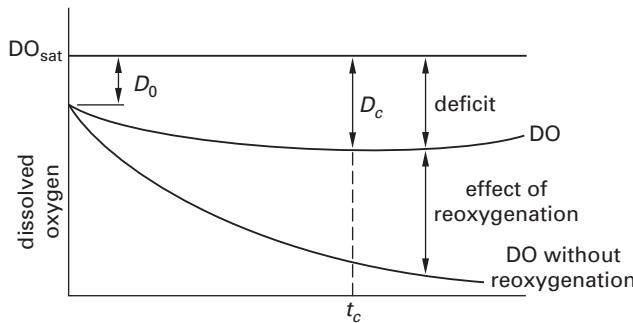

The oxygen deficit is the difference between actual and saturated oxygen concentrations, expressed in mg/L. Since reoxygenation and deoxygenation of a polluted river occur simultaneously, the oxygen deficit will increase if the reoxygenation rate is less than the deoxygenation rate. If the oxygen content goes to zero, anaerobic decomposition and putrefaction will occur.

The minimum dissolved oxygen concentration that will protect aquatic life in the river is the *dissolved oxygen standard* for the river. 4–6 mg/L is the generally accepted range of dissolved oxygen required to support fish populations. 5 mg/L is adequate as is evidenced in high-altitude trout lakes. However, 6 mg/L is preferable, particularly for large fish populations.

The oxygen deficit at time  $t$  is given by the *Streeter-Phelps equation*. In Eq. 28.36,  $\text{BOD}_u$  is the ultimate carbonaceous BOD of the river immediately after mixing.  $D_0$  is the dissolved oxygen deficit immediately after mixing, which is often given the symbol  $D_a$ . (If the constants  $K_r$  and  $K_d$  are base- $e$  constants, the base-10 exponentiation in Eq. 28.36 should be replaced with the base- $e$  exponentiation,  $e^{-Kt}$ .)

$$D_t = \left( \frac{K_d \text{BOD}_u}{K_r - K_d} \right) (10^{-K_d t} - 10^{-K_r t}) + D_0 (10^{-K_r t}) \quad 28.36$$

A graph of dissolved oxygen versus time (or distance downstream) is known as a *dissolved oxygen sag curve* and is shown in Fig. 28.5. The location at which the lowest dissolved oxygen concentration occurs is the

**Figure 28.5** Oxygen Sag Curve

*critical point.* The location of the critical point is found from the river velocity and flow time to that point.

$$x_c = vt_c \quad 28.37$$

The time to the critical point is given by Eq. 28.38. The ratio  $K_r/K_d$  in Eq. 28.38 is known as the *self-purification constant*. (If the constants  $K_r$  and  $K_d$  are base- $e$  constants, the base-10 logarithm in Eq. 28.38 should be replaced with the base- $e$  logarithm, ln.)

$$t_c = \left( \frac{1}{K_r - K_d} \right) \times \log_{10} \left( \left( \frac{K_d \text{BOD}_u - K_r D_0 + K_d D_0}{K_d \text{BOD}_u} \right) \left( \frac{K_r}{K_d} \right) \right) \quad 28.38$$

The critical oxygen deficit can be found by substituting  $t_c$  from Eq. 28.38 into Eq. 28.36. However, it is more expedient to use Eq. 28.39.

$$D_c = \left( \frac{K_d \text{BOD}_u}{K_r} \right) 10^{-K_d t_c} \quad 28.39$$

### Example 28.3

A treatment plant effluent has the following characteristics.

quantity	15 ft <sup>3</sup> /sec
BOD <sub>5,20°C</sub>	45 mg/L
DO	2.9 mg/L
temperature	24°C
$K_{d,20^\circ\text{C}}$	0.1 day <sup>-1</sup> (base-10)
temperature variation constant for $K_d$ , $\theta_d$	1.047
temperature variation constant for $K_r$ , $\theta_r$	1.016

The outfall is located in a river carrying 120 ft<sup>3</sup>/sec of water with the following characteristics.

quantity	120 ft <sup>3</sup> /sec
velocity	0.55 ft/sec
average depth	4 ft
BOD <sub>5,20°C</sub>	4 mg/L
DO	8.3 mg/L
temperature	16°C

When the treatment plant effluent and river are mixed, the mixture temperature persists for a long distance downstream.

- (a) Determine the distance downstream where the oxygen level is at a minimum. (b) Determine if the river can support fish life at that point.

*Solution*

- (a) Find the river conditions immediately after mixing. Use Eq. 28.35 three times.

$$\begin{aligned} C_f &= \frac{C_1 Q_1 + C_2 Q_2}{Q_1 + Q_2} \\ \text{BOD}_{5,20^\circ\text{C}} &= \frac{\left( 15 \frac{\text{ft}^3}{\text{sec}} \right) \left( 45 \frac{\text{mg}}{\text{L}} \right) + \left( 120 \frac{\text{ft}^3}{\text{sec}} \right) \left( 4 \frac{\text{mg}}{\text{L}} \right)}{15 \frac{\text{ft}^3}{\text{sec}} + 120 \frac{\text{ft}^3}{\text{sec}}} \\ &= 8.56 \text{ mg/L} \end{aligned}$$

$$\begin{aligned} \text{DO} &= \frac{\left( 15 \frac{\text{ft}^3}{\text{sec}} \right) \left( 2.9 \frac{\text{mg}}{\text{L}} \right) + \left( 120 \frac{\text{ft}^3}{\text{sec}} \right) \left( 8.3 \frac{\text{mg}}{\text{L}} \right)}{15 \frac{\text{ft}^3}{\text{sec}} + 120 \frac{\text{ft}^3}{\text{sec}}} \\ &= 7.7 \text{ mg/L} \end{aligned}$$

$$\begin{aligned} T &= \frac{\left( 15 \frac{\text{ft}^3}{\text{sec}} \right) (24^\circ\text{C}) + \left( 120 \frac{\text{ft}^3}{\text{sec}} \right) (16^\circ\text{C})}{15 \frac{\text{ft}^3}{\text{sec}} + 120 \frac{\text{ft}^3}{\text{sec}}} \\ &= 16.89^\circ\text{C} \end{aligned}$$

Calculate the approximate rate constants. Although the temperature is low,  $\theta_d$  is specified in the problem statement. From Eq. 28.28,

$$\begin{aligned} K_{d,T} &= K_{d,20^\circ\text{C}} (1.047)^{T-20^\circ\text{C}} \\ K_{d,16.89^\circ\text{C}} &= (0.1 \text{ day}^{-1}) (1.047)^{16.89^\circ\text{C}-20^\circ\text{C}} \\ &= 0.0867 \text{ day}^{-1} \end{aligned}$$

Since  $v = 0.55$  ft/sec, use Eq. 28.21 and Eq. 28.22 to calculate the reoxygenation constant.

$$\begin{aligned} K_{r,20^\circ\text{C}} &= \frac{K'_{r,20^\circ\text{C}}}{2.303} = \frac{12.9\sqrt{v}}{2.303d^{1.5}} \\ &= \frac{12.9\sqrt{0.55}}{(2.303)(4)^{1.5}} \frac{\text{ft}}{\text{sec}} \\ &= 0.519 \text{ day}^{-1} \end{aligned}$$

From Eq. 28.24, and using the given value of  $\theta$ ,

$$K_{r,T} = K_{r,20^\circ\text{C}}(1.016)^{T-20^\circ\text{C}}$$

$$K_{r,16.89^\circ\text{C}} = (0.519 \text{ day}^{-1})(1.016)^{16.89^\circ\text{C}-20^\circ\text{C}}$$

$$= 0.494 \text{ day}^{-1}$$

Estimate  $\text{BOD}_u$  from Eq. 28.31.

$$\text{BOD}_{u,20^\circ\text{C}} = \frac{\text{BOD}_{5,20^\circ\text{C}}}{1 - 10^{-K_d t}}$$

$$= \frac{8.56 \frac{\text{mg}}{\text{L}}}{1 - 10^{(-0.1 \text{ day}^{-1})(5 \text{ days})}}$$

$$= 12.52 \text{ mg/L}$$

From Eq. 28.33,

$$\text{BOD}_{T^\circ\text{C}} = \text{BOD}_{20^\circ\text{C}}(0.02 T^\circ\text{C} + 0.6)$$

$$\text{BOD}_{u,16.89^\circ\text{C}} = \left(12.52 \frac{\text{mg}}{\text{L}}\right) \left((0.02)(16.89^\circ\text{C}) + 0.6\right)$$

$$= 11.74 \text{ mg/L}$$

Calculate the original oxygen deficit. By interpolation from App. 22.B, the dissolved oxygen concentration at  $16.89^\circ\text{C}$  is approximately 9.76 mg/L.

$$D_0 = 9.76 \frac{\text{mg}}{\text{L}} - 7.7 \frac{\text{mg}}{\text{L}}$$

$$= 2.06 \text{ mg/L}$$

Calculate  $t_c$  from Eq. 28.38.

$$t_c = \left( \frac{1}{K_r - K_d} \right) \times \log_{10} \left( \left( \frac{K_d \text{BOD}_u - K_r D_0 + K_d D_0}{K_d \text{BOD}_u} \right) \left( \frac{K_r}{K_d} \right) \right)$$

$$= \left( \frac{1}{0.494 \text{ day}^{-1} - 0.0867 \text{ day}^{-1}} \right) \times \log_{10} \left( \begin{array}{c} \left( 0.0867 \text{ day}^{-1} \right) \left( 11.74 \frac{\text{mg}}{\text{L}} \right) \\ - \left( 0.494 \text{ day}^{-1} \right) \left( 2.06 \frac{\text{mg}}{\text{L}} \right) \\ + \left( 0.0867 \text{ day}^{-1} \right) \left( 2.06 \frac{\text{mg}}{\text{L}} \right) \\ \hline \left( 0.0867 \text{ day}^{-1} \right) \left( 11.74 \frac{\text{mg}}{\text{L}} \right) \end{array} \right) \times \left( \frac{0.494 \text{ day}^{-1}}{0.0867 \text{ day}^{-1}} \right)$$

$$= 0.00107 \text{ day}$$

The distance downstream is

$$x_c = vt_c$$

$$= \frac{\left(0.55 \frac{\text{ft}}{\text{sec}}\right)(0.00107 \text{ day}) \left(86,400 \frac{\text{sec}}{\text{day}}\right)}{5280 \frac{\text{ft}}{\text{mi}}}$$

$$= 0.0096 \text{ mi} \quad [\text{essentially, at the outfall}]$$

(b) The critical oxygen deficit is found from Eq. 28.39.

$$D_c = \left( \frac{K_d \text{BOD}_u}{K_r} \right) 10^{-K_d t_c}$$

$$= \left( \frac{(0.0867 \text{ day}^{-1}) \left( 11.74 \frac{\text{mg}}{\text{L}} \right)}{0.494 \text{ day}^{-1}} \right) \times \left( 10^{(-0.0867 \text{ day}^{-1})(0.00107 \text{ day})} \right)$$

$$= 2.06 \text{ mg/L}$$

The saturated oxygen content at the critical point with a water temperature of  $16.89^\circ\text{C}$  is 9.76 mg/mL. The actual oxygen content is

$$\text{DO} = \text{DO}_{\text{sat}} - D_c = 9.76 \frac{\text{mg}}{\text{L}} - 2.06 \frac{\text{mg}}{\text{L}}$$

$$= 7.70 \text{ mg/L}$$

Since this is greater than 4–6 mg/L, fish life is supported.

## 24. CHEMICAL OXYGEN DEMAND

*Chemical oxygen demand* (COD) is a measure of oxygen removed by both biological organisms feeding on organic material, as well as oxidizable inorganic compounds (unlike biochemical oxygen demand, which is a measure of oxygen removed only by biological organisms). Therefore, COD is a good measure of total effluent strength (organic and inorganic contaminants).

COD testing is required where there is industrial chemical pollution. In such environments, the organisms necessary to metabolize organic compounds may not exist. Furthermore, the toxicity of the wastewater may make the standard BOD test impossible to carry out. Standard COD test results are usually available in a matter of hours.

If toxicity is low, BOD and COD test results can be correlated. The BOD/COD ratio typically varies from 0.4–0.8. This is a wide range but, for any given treatment plant and waste type, the correlation is essentially constant. The correlation can, however, vary along the treatment path.

## 25. RELATIVE STABILITY

The *relative stability* test is easier to perform than the BOD test, although it is less accurate. The relative stability of an effluent is defined as the percentage of initial BOD that has been satisfied. The test consists of taking a sample of effluent and adding a small amount of methylene blue dye. The mixture is then incubated, usually at 20°C. When all oxygen has been removed from the water, anaerobic bacteria start to remove the dye. The amount of time it takes for the color to start degrading is known as the *stabilization time* or *decoloration time*. The relative stability can be found from the stabilization time by using Table 28.6.

**Table 28.6** Relative Stability<sup>a</sup>

stabilization time (day)	relative stability <sup>b</sup> (%)
1/2	11

## 26. CHLORINE DEMAND AND DOSE

Chlorination destroys bacteria, hydrogen sulfide, and other compounds and substances. The *chlorine demand* (*chlorine dose*) must be determined by careful monitoring of coliform counts and free residuals since there are several ways that chlorine can be used up without producing significant disinfection. Only after uncombined (free) chlorine starts showing up is it assumed that all chemical reactions and disinfection are complete.

Chlorine demand is the amount of chlorine (or its chloramine or hypochlorite equivalent) required to leave the desired residual (usually 0.5 mg/L) 15 min after mixing. Fifteen minutes is the recommended mixing and holding time prior to discharge, since during this time nearly all pathogenic bacteria in the water will have been killed.

Typical doses for wastewater effluent depend on the application point and are widely variable, though doses rarely exceed 30 mg/L. For example, chlorine may be applied at 5–25 mg/L prior to primary sedimentation, 2–6 mg/L after sand filtration, and 3–15 mg/L after trickle filtration.

## 27. BREAKPOINT CHLORINATION

Because of their reactivities, chlorine is initially used up in the neutralization of hydrogen sulfide and the rare ferrous and manganous ( $\text{Fe}^{+2}$  and  $\text{Mn}^{+2}$ ) ions. For example, hydrogen sulfide is oxidized according to Eq. 28.40. The resulting  $\text{HCl}$ ,  $\text{FeCl}_2$ , and  $\text{MnCl}_2$  ions do not contribute to disinfection. They are known as *unavailable combined residuals*.

Ammonia nitrogen combines with chlorine to form the family of *chloramines*. Depending on the water pH, monochloramines ( $\text{NH}_2\text{Cl}$ ), dichloramines ( $\text{NHCl}_2$ ), or trichloramines (nitrogen trichloride,  $\text{NCl}_3$ ) may form. Chloramines have long-term disinfection capabilities and are therefore known as *available combined residuals*. Equation 28.41 is a typical chloramine formation reaction.

Continued addition of chlorine after chloramines begin forming changes the pH and allows chloramine destruction to begin. Chloramines are converted to nitrogen gas ( $\text{N}_2$ ) and nitrous oxide ( $\text{N}_2\text{O}$ ). Equation 28.42 is a typical chloramine destruction reaction.

The destruction of chloramines continues, with the repeated application of chlorine, until no ammonia remains in the water. The point at which all ammonia has been removed is known as the *breakpoint*.

In the *breakpoint chlorination* method, additional chlorine is added after the breakpoint in order to obtain free chlorine residuals. The free residuals have a high disinfection capacity. Typical free residuals are free chlorine ( $\text{Cl}_2$ ), hypochlorous acid ( $\text{HOCl}$ ), and hypochlorite ions. Equation 28.43 and Eq. 28.44 illustrate the formation of these free residuals.

There are several undesirable characteristics of breakpoint chlorination. First, it may not be economical to use breakpoint chlorination unless the ammonia nitrogen has been reduced. Second, free chlorine residuals produce trihalomethanes. Third, if free residuals are prohibited to prevent trihalomethanes, the water may need to be dechlorinated using sulfur dioxide gas or

sodium bisulfate. (Where small concentrations of free residuals are permitted, dechlorination may be needed only during the dry months. During winter storm months, the chlorine residuals may be adequately diluted with rainwater.)

## 28. NITROGEN

Nitrogen occurs in water in organic, ammonia, nitrate, nitrite, and dissolved gaseous forms. Nitrogen in municipal wastewater results from human excreta, ground garbage, and industrial wastes (primarily food processing). Bacterial decomposition and the hydrolysis of urea produces ammonia,  $\text{NH}_3$ . Ammonia in water forms the ammonium ion  $\text{NH}_4^+$ , also known as *ammonia nitrogen*. Ammonia nitrogen must be removed from the waste effluent stream due to potential exertion of oxygen demand. The total of organic and ammonia nitrogen is known as *total Kjeldahl nitrogen*, or TKN. *Total nitrogen*, TN, includes TKN plus inorganic nitrates and nitrites.

*Nitrification* (the oxidation of ammonia nitrogen) occurs as follows.

*Denitrification*, the reduction of nitrate nitrogen to nitrogen gas by facultative heterotrophic bacteria, occurs as follows.

Ammonia nitrogen can be removed chemically from water without first converting it to nitrate form by raising the pH level. This converts the ammonium ion back into ammonia, which can then be stripped from the water by passing large quantities of air through the water. Lime is added to provide the hydroxide for the reaction. The *ammonia stripping* reaction (a physical-chemical process) is

Ammonia stripping has no effect on nitrate, which is commonly removed in an activated sludge process with a short cell detention time.

## 29. ORGANIC COMPOUNDS IN WASTEWATER

Biodegradable organic matter in municipal wastewater is classified into three major categories: proteins, carbohydrates, and greases (fats).

*Proteins* are long strings of amino acids containing carbon, hydrogen, oxygen, nitrogen, and phosphorus.

*Carbohydrates* consist of sugar units containing the elements of carbon, hydrogen, and oxygen. They are

identified by the presence of a saccharide ring. The rings range from simple monosaccharides to polysaccharides (long chain sugars categorized as either readily degradable starches found in potatoes, rice, corn, and other edible plants, or as cellulose found in wood and similar plant tissues).

*Greases* are a variety of biochemical substances that have the common property of being soluble to varying degrees in organic solvents (acetone, ether, ethanol, and hexane) while being only sparingly soluble in water. The low solubility of grease in water causes problems in pipes and tanks where it accumulates, reduces contact areas during various filtering processes, and produces a sludge that is difficult to dispose of.

Of the organic matter in wastewater, 60–80% is readily available for biodegradation. Degradation of greases by microorganisms occurs at a very slow rate. A simple fat is a triglyceride composed of a glycerol unit with short-chain or long-chain fatty acids attached.

The majority of carbohydrates, fats, and proteins in wastewater are in the form of large molecules that cannot penetrate the cell membrane of microorganisms. Bacteria, in order to metabolize high molecular-weight substances, must be capable of breaking down the large molecules into diffusible fractions for assimilation into the cell.

Several organic compounds, such as cellulose, long-chain saturated hydrocarbons, and other complex compounds, although available as a bacterial substrate, are considered nonbiodegradable because of the time and environmental limitations of biological wastewater treatment systems.

*Volatile organic chemicals* (VOCs) are released in large quantities in industrial, commercial, agricultural, and household activities. The adverse health effects of VOCs include cancer and chronic effects on the liver, kidney, and nervous system. *Synthetic organic chemicals* (SOCs) and *inorganic chemicals* (IOCs) are used in agricultural and industrial processes as pesticides, insecticides, and herbicides.

Organic petroleum derivatives, detergents, pesticides, and other synthetic, organic compounds are particularly resistant to biodegradation in wastewater treatment plants; some are toxic and inhibit the activity of microorganisms in biological treatment processes.

## 30. HEAVY METALS IN WASTEWATER

Metals are classified by four categories: *Dissolved metals* are those constituents of an unacidified sample that pass through a  $0.45 \mu\text{m}$  membrane filter. *Suspended metals* are those constituents of an unacidified sample retained by a  $0.45 \mu\text{m}$  membrane filter. *Total metals* are the concentration determined on an unfiltered sample after vigorous digestion or the sum of both dissolved and suspended fractions. *Acid-extractable metals* remain in

solution after treatment of an unfiltered sample with hot dilute mineral acid.

The metal concentration in the wastewater is calculated from Eq. 28.48. The sample size is selected so that the product of the sample size (in mL) and the metal concentration ( $C$ , in mg/L) is approximately 1000.

$$C = \frac{C_{\text{digestate}} V_{\text{digested solution}}}{V_{\text{sample}}} \quad 28.48$$

Some metals are biologically essential; others are toxic and adversely affect wastewater treatment systems and receiving waters.

### 31. WASTEWATER COMPOSING

Proper sampling techniques are essential for accurate evaluation of wastewater flows. Samples should be well mixed, representative of the wastewater flow stream in composition, taken at regular time intervals, and stored properly until analysis can be performed. *Compositing* is the sampling procedure that accomplishes these goals.

Samples are collected (i.e., “grabbed,” hence the name *grab sample*) at regular time intervals (e.g., every hour on the hour), stored in a refrigerator or ice chest, and then integrated to formulate the desired combination for a particular test. Flow rates are measured at each sampling to determine the wastewater flow pattern.

The total volume of the composite sample desired depends on the kinds and number of laboratory tests to be performed.

### 32. WASTEWATER STANDARDS

Treatment plants and industrial complexes must meet all applicable wastewater quality standards for surface waters, drinking waters, air, and effluents of various types. For example, standards for discharges from secondary treatment plants are given in terms of *maximum contaminant levels* (MCLs) for five-day BOD, suspended solids, coliform count, and pH. Some chemicals, compounds, and microbial varieties are regulated; others are unregulated but monitored. MCLs for regulated and monitored chemicals, compounds, and microbes are subject to ongoing legislation and change.

## 1. INDUSTRIAL WASTEWATER TREATMENT

The *National Pollution Discharge Elimination System* (NPDES) places strict controls on the discharge of industrial wastewaters into municipal sewers. Any industrial wastes that would harm subsequent municipal treatment facilities or that would upset subsequent biological processes need to be pretreated. Manufacturing plants may also be required to equalize wastewaters by holding them in basins for stabilization prior to their discharge to the sewer. Table 29.1 lists typical limitations on industrial wastewaters.

**Table 29.1** Typical Industrial Wastewater Effluent Limitations

characteristic	concentration <sup>a</sup> (mg/L)
COD	300–2000
BOD	100–300
oil and grease or TPH <sup>b</sup>	15–55
total suspended solids	15–45
pH	6.0–9.0
temperature	less than 40°C
color	2 color units
NH <sub>3</sub> /NO <sub>3</sub>	1.0–10
phosphates	0.2
heavy metals	0.1–5.0
surfactants	0.5–1.0 (total)
sulfides	0.01–0.1
phenol	0.1–1.0
toxic organics	1.0 total
cyanide	0.1

<sup>a</sup>maximum permitted at discharge<sup>b</sup>total petroleum hydrocarbons

## 2. CESSPOOLS

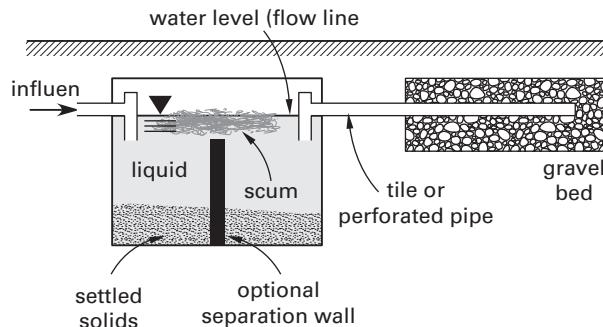

A *cesspool* is a covered pit into which domestic (i.e., household) sewage is discharged. Cesspools for temporary storage can be constructed as watertight enclosures. However, most are *leaching cesspools* that allow seepage of liquid into the soil. Cesspools are rarely used today. They are acceptable for disposal for only very small volumes (e.g., from a few families).

## 3. SEPTIC TANKS

A *septic tank* is a simply constructed tank that holds domestic sewage while sedimentation and digestion occur. (See Fig. 29.1.) Typical detention times are 8–24 hr. Only 30–50% of the suspended solids are digested in a septic tank. The remaining solids settle, eventually clogging the tank, and must be removed. Semi-clarified effluent percolates into the surrounding soil through lateral lines placed at the *flow line* that lead into an underground leach field. In the past, clay drainage tiles were used. The terms “tile field” and “tile bed” are still encountered even though perforated plastic pipe is now widely used.

Most septic tanks are built for use by one to three families. Larger communal tanks can be constructed for small groups. (They should be designed to hold 12–24 hr of flow plus stored sludge.) A general rule is to allow at least 30 gal (0.1 m<sup>3</sup>) of storage per person served by the tank. Typical design parameters of domestic septic tanks are given in Table 29.2.

Proper design of the percolation field is the key to successful operation. Soils studies are essential to ensure adequate absorption into the soil.

**Figure 29.1** Septic Tank**Table 29.2** Typical Characteristics of Domestic Septic Tanks

minimum capacity below flow line	300–500 gal (1.1–1.9 m <sup>3</sup> ), plus 30 gal (0.1 m <sup>3</sup> ) for each person served over 5
plan aspect ratio	1:2
minimum depth below flow line	3–4 ft (0.9–1.2 m)
minimum freeboard above flow line	1 ft (0.3 m)
tank burial depth	1–2 ft (0.3–0.6 m)
drainage field tile length	30 ft (9 m) per person
maximum drainage field tile length	60 ft (18 m)
minimum tile depth	1.5–2.5 ft (0.45–0.75 m)
lateral line spacing	6 ft (1.8 m)
gravel bed	0.33 ft (0.1 m) above lateral, 1–3 ft (0.3–1 m) below
soil layer below tile bed	10 ft (3 m)

(Multiply gal by 0.003785 to obtain m<sup>3</sup>.)

(Multiply ft by 0.3048 to obtain m.)

## 4. DISPOSAL OF SEPTAGE

*Septage* is the water and solid material pumped periodically from septic tanks, cesspools, or privies. In the United States, disposal of septage is controlled by federal sludge disposal regulations, and most local and state governments have their own regulations as well. While surface and land spreading were acceptable disposal methods in the past, septage haulers are now turning to municipal treatment plants for disposal. (Table 29.3 compares septage characteristics to those of municipal sewage. See also Table 28.4.) Since septage is many times more concentrated than sewage, it can cause *shock loads* in preliminary treatment processes. Typical problems are plugged screens and aerator inlets, reduced efficiency in grit chambers and aeration basins, and increased odors. The impact on subsequent processes is less pronounced due to the effect of dilution.

**Table 29.3** Comparison of Typical Septage and Municipal Sewage<sup>a</sup>

characteristic	septage	sewage <sup>b</sup>
BOD	7000	220
COD	15,000	500
total solids	40,000	720
total volatile solids	25,000	365
total suspended solids	15,000	220
volatile suspended solids	10,000	165
TKN	700	40
NH <sub>3</sub> as N	150	25
alkalinity	1000	100
grease	8000	100
pH	6.0	n.a.

<sup>a</sup>all values except pH in mg/L<sup>b</sup>medium strength

## 5. WASTEWATER TREATMENT PLANTS

For traditional *wastewater treatment plants* (WWTP), *preliminary treatment* of the wastewater stream is essentially a mechanical process intended to remove large objects, rags, and wood. Heavy solids and excessive oils and grease are also eliminated. Damage to pumps and other equipment would occur without preliminary treatment.

*Odor control* through chlorination or ozonation, freshening of septic waste by aeration, and flow equalization in holding basins can also be loosely categorized as preliminary processes.

After preliminary treatment, there are three “levels” of wastewater treatment: primary, secondary, and tertiary. *Primary treatment* is a mechanical (settling) process used to remove oil and most (i.e., approximately 50%) of the settleable solids. With domestic wastewater, a 25–35% reduction in BOD is also achieved, but BOD reduction is not the goal of primary treatment.

In the United States, secondary treatment is mandatory for all publicly owned wastewater treatment plants. *Secondary treatment* involves biological treatment in trickling filters, rotating contactors, biological beds, and activated sludge processes. Processing typically reduces the suspended solids and BOD content by more than 85%, volatile solids by 50%, total nitrogen by about 25%, and phosphorus by 20%.

*Tertiary treatment* (also known as *advanced wastewater treatment*, AWT) is targeted at specific pollutants or wastewater characteristics that have passed through previous processes in concentrations that are not allowed in the discharge. *Suspended solids* are removed by micro-strainers or polishing filter beds. *Phosphorus* is removed by chemical precipitation. Aluminum and iron coagulants, as well as lime, are effective in removing phosphates. *Ammonia* can be removed by air stripping, biological denitrification, breakpoint chlorination, anion exchange, and algae ponds. Ions from *inorganic salts* can be removed by electrodialysis and reverse osmosis. The so-called *trace*

organics or *refractory substances*, which are *dissolved organic solids* that are resistant to biological processes, can be removed by filtering through carbon or ozonation.

## 6. WASTEWATER PLANT SITING CONSIDERATIONS

Wastewater plants should be located as far as possible from inhabited areas. A minimum distance of 1000 ft (300 m) for uncovered plants and lagoons is desired. Uncovered plants should be located downwind when a definite wind direction prevails. Soil conditions need to be evaluated, as does the proximity of the water table. Elevation in relationship to the need for sewage pumping (and for dikes around the site) is relevant.

The plant must be protected against flooding. One-hundred-year storms are often chosen as the design flood when designing dikes and similar facilities. Distance to the outfall and possible effluent pumping need to be considered.

Table 29.4 lists the approximate acreage for sizing wastewater treatment plants. Estimates of population expansion should provide for future capacity.

**Table 29.4** Treatment Plant Acreage Requirements

type of treatment	surface area required (ac/MGD)
physical-chemical plants	1.5
activated sludge plants	2
trickling filter plants	3
aerated lagoons	16
stabilization basins	20

## 7. PUMPS USED IN WASTEWATER PLANTS

Wastewater treatment plants should be gravity-fed wherever possible. The influent of most plants is pumped to the starting elevation, and wastewater flows through subsequent processes by gravity thereafter. However, there are still many instances when pumping is required. Table 29.5 lists pump types by application.

At least two identical pumps should be present at every location, each capable of handling the entire peak flow. Three or more pumps are suggested for flows greater than 1 MGD, and peak flow should be handled when one of the pumps is being serviced.

## 8. FLOW EQUALIZATION

Equalization tanks or ponds are used to smooth out variations in flow that would otherwise overload wastewater processes. Graphical or tabular techniques similar to those used in reservoir sizing can be used to size equalization ponds. (See Fig. 29.2.) In practice, up to 25% excess capacity is added as a safety factor.

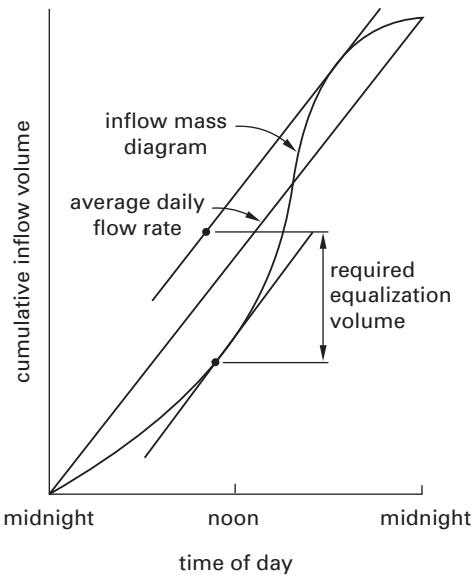

In a pure flow equalization process, there is no settling. Mechanical aerators provide the turbulence necessary to keep the solids in suspension while providing oxygen to

**Table 29.5** Pumps Used in Wastewater Plants

flow	flow rate (gal/min (L/min))	pump type
raw sewage	< 50 (190)	pneumatic ejector
	50–200 (190–760)	submersible or end-suction, nonclog centrifugal
	> 200 (760)	end-suction, nonclog centrifugal
settled sewage	< 500 (1900)	end-suction, nonclog centrifugal
	> 500 (1900)	vertical axial or mixed-flow centrifugal
sludge, primary, thickened, or digested	—	plunger
sludge, secondary	—	end-suction, nonclog centrifugal
scum	—	plunger or recessed impeller
grit	—	recessed impeller, centrifugal, pneumatic ejector, or conveyor rake

(Multiply gal/min by 3.785 to obtain L/min.)

prevent putrefaction. For typical municipal wastewater, air is provided at the rate of 1.25–2.0 ft<sup>3</sup>/min-1000 gal (0.01–0.015 m<sup>3</sup>/min·m<sup>3</sup>). Power requirements are approximately 0.02–0.04 hp/1000 gal (4–8 W/m<sup>3</sup>).

**Figure 29.2** Equalization Volume: Mass Diagram Method

## 9. STABILIZATION PONDS

The term *stabilization pond* (*oxidation pond* or *stabilization lagoon*) refers to a pond used to treat organic waste by biological and physical processes. (See Table 29.6 for typical characteristics.) Aquatic plants, weeds, algae, and microorganisms stabilize the organic matter. The algae give off oxygen that is used by microorganisms to digest the organic matter. The microorganisms give off carbon dioxide, ammonia, and phosphates that the algae use. Even in modern times, such ponds may be necessary in remote areas (e.g., national parks and campgrounds). To keep toxic substances from leaching into the ground, ponds should not be used without strictly enforced industrial pretreatment requirements.

There are several types of stabilization ponds. *Aerobic ponds* are shallow ponds, less than 4 ft (1.2 m) in depth, where dissolved oxygen is maintained throughout the entire depth, mainly by action of photosynthesis. *Facultative ponds* have an anaerobic lower zone, a facultative middle zone, and an aerobic upper zone. The upper zone is maintained in an aerobic condition by photosynthesis and, in some cases, mechanical aeration at the surface. *Anaerobic ponds* are so deep and receive such a high organic loading that anaerobic conditions prevail throughout the entire pond depth. *Maturation ponds* (*tertiary ponds* or *polishing ponds*) are used for polishing effluent from secondary biological processes. Dissolved oxygen is furnished through photosynthesis and mechanical aeration. *Aerated lagoons* are oxygenated through the action of surface or diffused air aeration. They are often used with activated sludge processes. (See also Sec. 29.11.)

## 10. FACULTATIVE PONDS

Facultative ponds are the most common pond type selected for small communities. Approximately 25% of the municipal wastewater treatment plants in this country use ponds, and about 90% of these are located in communities of 5000 people or fewer. Long retention times and large volumes easily handle large fluctuations in wastewater flow and strength with no significant effect on effluent quality. Also, capital, operating, and maintenance costs are less than for other biological systems that provide equivalent treatment.

In a facultative pond, raw wastewater enters at the center of the pond. Suspended solids contained in the wastewater settle to the pond bottom where an anaerobic layer develops. A facultative zone develops just above the anaerobic zone. Molecular oxygen is not available in the region at all times. Generally, the zone is aerobic during the daylight hours and anaerobic during the hours of darkness.

An aerobic zone with molecular oxygen present at all times exists above the facultative zone. Some oxygen is

**Table 29.6** Typical Characteristics of Non-Aerated Stabilization Ponds

	aerobic				
characteristic	algae-growth maximizing (high rate)	oxygen-transfer maximizing (low rate)	facultative	facultative with surface agitation	anaerobic
size (cell)	0.5–2.5 ac (0.25–1 ha)	< 10 ac (< 4 ha)	2.5–10 ac (1–4 ha)	2.5–10 ac (1–4 ha)	0.5–2.5 ac (0.25–1 ha)
depth	1.0–1.5 ft (0.3–0.45 m)	3.0–5.0 ft (1–1.5 m)	3.0–7.0 ft (1–2 m)	3.0–8.5 ft (1–2.5 m)	8.0–15 ft (2.5–5 m)
BOD <sub>5</sub> loading	75–150 lbm/ac-day (80–160 kg/ha·d)	25–100 lbm/ac-day (40–120 kg/ha·d)	12–70 lbm/ac-day (15–80 kg/ha·d)	45–175 lbm/ac-day (50–200 kg/ha·d)	175–450 lbm/ac-day (200–500 kg/ha·d)
BOD <sub>5</sub> conversion	80–90%	80–90%	80–90%	80–90%	50–85%
detention time	4–6 days	10–40 days	7–30 days	7–20 days	20–50 days
temperature	40–85°F (5–30°C)	32–85°F (0–30°C)	32–120°F (0–50°C)	32–120°F (0–50°C)	40–120°F (5–50°C)
algal concentration	100–250 mg/L	40–100 mg/L	20–80 mg/L	5–20 mg/L	0–5 mg/L
suspended solids in effluent	150–300 mg/L	80–140 mg/L	40–100 mg/L	40–60 mg/L	80–160 mg/L
cell arrangement	series	parallel or series	parallel or series	parallel or series	series
minimum dike width			8 ft (2.5 m)		
maximum dike wall slope			1:3 (vertical:horizontal)		
minimum dike wall slope			1:4 (vertical:horizontal)		
minimum freeboard			3 ft (1 m)		

(Multiply lbm/ac-day by 1.12 to obtain kg/ha·d.)

(Multiply ft by 0.3048 to obtain m.)

(Multiply ac by 0.4 to obtain ha.)

(Multiply mg/L by 1.0 to obtain g/m<sup>3</sup>.)

supplied from diffusion across the pond surface, but the majority is supplied through algal photosynthesis.

General guidelines are used to design facultative ponds. Ponds may be round, square, or rectangular. Usually, there are three cells, piped to permit operation in series or in parallel. Two of the three cells should be identical, each capable of handling half of the peak design flow. The third cell should have a minimum volume of one-third of the peak design flow.

## 11. AERATED LAGOONS

An *aerated lagoon* is a stabilization pond that is mechanically aerated. Such lagoons are typically deeper and have shorter detention times than nonaerated ponds. In warm climates and with floating aerators, one acre can support several hundred pounds (a hundred kilograms) of BOD per day.

The basis for the design of aerated lagoons is typically the organic loading and/or detention time. The detention time will depend on the desired BOD removal

fraction,  $\eta$ , and the reaction constant,  $k$ . Other factors that must be considered in the design process are solids removal requirements, oxygen requirements, temperature effects, and energy for mixing.

The BOD reduction can be calculated from the overall, first-order BOD removal rate constant,  $k_1$ . Typical values of  $k_{1,\text{base-10}}$  (as specified by TSS Sec. 93.33) are 0.12 day<sup>-1</sup> at 68°F (20°C) and 0.06 day<sup>-1</sup> at 34°F (1°C).

$$t_d = \frac{V}{Q} = \frac{\eta}{k_{1,\text{base-e}}(1 - \eta)} \quad 29.1$$

$$k_{1,\text{base-e}} = 2.3k_{1,\text{base-10}} \quad 29.2$$

Aeration should maintain a minimum oxygen content of 2 mg/L at all times. Design depth is larger than for nonaerated lagoons—10–15 ft (3–4.5 m). Common design characteristics of mechanically aerated lagoons are shown in Table 29.7. Other characteristics are similar to those listed in Table 29.6.

**Table 29.7** Typical Characteristics of Aerated Lagoons

aspect ratio	less than 3:1
depth	10–15 ft (3.0–4.5 m)
detention time	4–10 days
BOD loading	20–400 lbm/day-ac; 200 lbm/day-ac typical (22–440 kg/ha-d; 220 kg/ha-d typical)
operating temperature	0–38°C (21°C optimum)
typical effluent BOD	20–70 mg/L
oxygen required	0.7–1.4 times BOD removed (mass basis)

(Multiply ft by 0.3048 to obtain m.)

(Multiply lbm/day-ac by 1.12 to obtain kg/ha-d.)

## 12. RACKS AND SCREENS

*Trash racks or coarse screens* with openings 2 in (51 mm) or larger should precede pumps to prevent clogging. *Medium screens* ( $\frac{1}{2}$ – $1\frac{1}{2}$  in (13–38 mm) openings) and *fine screens* ( $\frac{1}{16}$ – $\frac{1}{8}$  in (1.6–3 mm)) are also used to relieve the load on grit chambers and sedimentation basins. Fine screens are rare except when used with selected industrial waste processing plants. Screens in all but the smallest municipal plants are cleaned by automatic scraping arms. A minimum of two screen units is advisable.

Screen capacities and head losses are specified by the manufacturer. Although the flow velocity must be sufficient to maintain sediment in suspension, the approach velocity should be limited to 3 ft/sec (0.9 m/s) to prevent debris from being forced through the screen.

## 13. GRIT CHAMBERS

Abrasive *grit* can erode pumps, clog pipes, and accumulate in excessive volumes. In a *grit chamber* (also known as a *grit clarifier* or *detritus tank*), the wastewater is slowed, allowing the grit to settle out but allowing the organic matter to continue through. (See Table 29.8 for typical characteristics.) Grit can be manually or mechanically removed with buckets or screw conveyors. A minimum of two units is needed.

*Horizontal flow grit chambers* are designed to keep the flow velocity as close to 1 ft/sec (0.3 m/s) as possible. If an analytical design based on settling velocity is required, the *scouring velocity* should not be exceeded. Scouring is the dislodging of particles that have already settled. Scouring velocity is not the same as settling velocity.

Scouring will be prevented if the horizontal velocity is kept below that predicted by Eq. 29.3, the *Camp formula*.  $SG_p$  is the specific gravity of the particle, typically taken as 2.65 for sand.  $d_p$  is the particle diameter.  $k$  is a dimensionless constant with typical values of 0.04 for sand and 0.06 or more for sticky, interlocking matter.

**Table 29.8** Typical Characteristics of Grit Chambers

grit size	0.008 in (0.2 mm) and larger
grit specific gravity	2.65
grit arrival/removal rate	0.5–5 ft <sup>3</sup> /MG (4–40 $\times 10^{-6}$ m <sup>3</sup> /m <sup>3</sup> )
depth of chamber	4–10 ft (1.2–3 m)
length	40–100 ft (12–30 m)
width	varies (not critical)
detention time	90–180 sec
horizontal velocity	0.75–1.25 ft/sec (0.23–0.38 m/s)

(Multiply in by 25.4 to obtain mm.)

(Multiply ft<sup>3</sup>/MG by 7.48  $\times 10^{-6}$  to obtain m<sup>3</sup>/m<sup>3</sup>.)

(Multiply ft by 0.3048 to obtain m.)

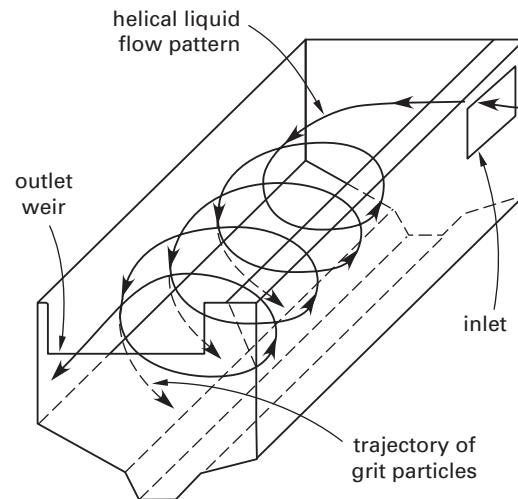

(Multiply ft/sec by 0.3048 to obtain m/s.)

The dimensionless Darcy friction factor,  $f$ , is approximately 0.02–0.03. Any consistent set of units can be used with Eq. 29.3.

$$v = \sqrt{8k \left( \frac{gd_p}{f} \right) (SG_p - 1)} \quad 29.3$$

## 14. AERATED GRIT CHAMBERS

An *aerated grit chamber* is a bottom-hoppered tank, as shown in Fig. 29.3, with a short detention time. Diffused aeration from one side of the tank rolls the water and keeps the organics in suspension while the grit drops into the hopper. The water spirals or rolls through the tank. Influent enters through the side, and degritted wastewater leaves over the outlet weir. A minimum of two units is needed.

**Figure 29.3** Aerated Grit Chamber

Solids are removed by pump, screw conveyor, bucket elevator, or gravity flow. However, the grit will have a significant organic content. A grit washer or cyclone

separator can be used to clean the grit. Common design characteristics of aerated grit chambers are shown in Table 29.9.

**Table 29.9** Typical Characteristics of Aerated Grit Chambers

detention time	2–5 min at peak flow; 3 min typical
air supply shallow tanks	1.5–5 cfm/ft length; 3 typical (0.13–0.45 m <sup>3</sup> /min·m; 0.27 typical)
deep tanks	3–8 cfm/ft length; 5 typical (0.27–0.7 m <sup>3</sup> /min·m; 0.45 typical)
grit and scum quantity	0.5–25 ft <sup>3</sup> /MG; 2 typical (4–190 × 10 <sup>-6</sup> m <sup>3</sup> /m <sup>3</sup> ; 15 typical)
length:width ratio	2.5:1–5:1 (3:1–4:1 typical)
depth	6–15 ft (1.8–4.5 m)
length	20–60 ft (6–18 m)
width	7–20 ft (2.1–6 m)

(Multiply cfm/ft by 0.0929 to obtain m<sup>3</sup>/min·m.)

(Multiply ft<sup>3</sup>/MG by 7.48 × 10<sup>-6</sup> to obtain m<sup>3</sup>/m<sup>3</sup>.)

(Multiply ft by 0.3048 to obtain m.)

## 15. SKIMMING TANKS

If the sewage has more than 50 mg/L of floating grease or oil, a basin 8–10 ft (2.4–3 m) providing 5–15 min of detention time will allow the grease to rise as *floatables* (*scum*) to the surface. An aerating device will help coagulate and float grease to the surface. 40–80 psig (280–550 kPa) air should be provided at the approximate rate of 0.01–0.1 ft<sup>3</sup>/gal (0.07–0.7 m<sup>3</sup>/m<sup>3</sup>) of influent. A small fraction (e.g., 30%) of the influent may be recycled in some cases. Grease rise rates are typically 0.2–1 ft/min (0.06–0.5 m/min), depending on degree of dispersal, amount of colloidal fines, and aeration.

Scum is mechanically removed by skimming troughs. Scum may not generally be disposed of by landfilling. It is processed with other solid wastes in anaerobic digesters. *Scum grinding* may be needed to reduce the scum to a small enough size for thorough digestion. In some cases, scum may be incinerated, although this practice may be affected by air-quality regulations.

## 16. SHREDDERS

*Shredders* (also called *comminutors*) cut waste solids to approximately 1/4 in (6 mm) in size, reducing the amount of screenings that must be disposed of. Shreddings stay with the flow for later settling.

## 17. PLAIN SEDIMENTATION BASINS/CLARIFIERS

*Plain sedimentation basins/clarifiers* (i.e., basins in which no chemicals are added to encourage clarification)

are similar in concept and design to those used to treat water supplies. Typical design characteristics for wastewater treatment sedimentation basins are listed in Table 29.10. Since the bottom slopes slightly, the depth varies with location. Therefore, the *side water depth* is usually quoted. The *surface loading* (*surface loading rate*, *overflow rate*, or *settling rate*), v\*, along with sludge storage volume, is the primary design parameter.

$$v^* = \frac{Q}{A} \quad 29.4$$

The *detention time* (*mean residence time* or *retention period*) is

$$t_d = \frac{V}{Q} \quad 29.5$$

The *weir loading* (*weir loading rate*) is

$$\text{weir loading} = \frac{Q}{L} \quad 29.6$$

**Table 29.10** Typical Characteristics of Clarifiers\*

BOD reduction	20–40% (25–35% typical)
total suspended solids reduction	35–65%
bacteria reduction	50–60%
organic content of settled solids	50–75%
specific gravity of settled solids	1.2 or less
minimum settling velocity	4 ft/hr (1.2 m/hr) typical
plan shape	rectangular (or circular)
basin depth	6–15 ft; 10–12 ft typical (side water depth) (1.8–4.5 m; 3–3.6 m typical)
basin width	10–50 ft (3–15 m)
plan aspect ratio	3:1 to 5:1
basin diameter (circular only)	50–150 ft; 100 ft typical (15–45 m; 30 m typical)
minimum freeboard	1.5 ft (0.45 m)
minimum hopper wall angle	60°
detention time	1.5–2.5 hr
flow-through velocity	18 ft/hr (1.5 mm/s)
minimum flow-through time	30% of detention time
weir loading	10,000–20,000 gal/day-ft <sup>2</sup> (125–250 m <sup>3</sup> /d·m <sup>2</sup> )
surface loading	400–2000 gal/day-ft <sup>2</sup> ; 800–1200 gal/day-ft <sup>2</sup> typical (16–80 m <sup>3</sup> /d·m <sup>2</sup> ; 32–50 m <sup>3</sup> /d·m <sup>2</sup> typical)
bottom slope to hopper inlet	8%
scum removal	baffled to prevent turbulence mechanical or manual

(Multiply ft/hr by 0.3048 to obtain m/h.)

(Multiply ft by 0.3048 to obtain m.)

(Multiply ft/hr by 0.0847 to obtain mm/s.)

(Multiply gal/day-ft by 0.0124 to obtain m<sup>3</sup>/d·m.)

(Multiply gal/day-ft<sup>2</sup> by 0.0407 to obtain m<sup>3</sup>/d·m<sup>2</sup>.)

\*See Sec. 29.26 and Sec. 29.27 for intermediate and final clarifiers, respectively.

## 18. CHEMICAL SEDIMENTATION BASINS/ CLARIFIERS

*Chemical flocculation* (*clarification* or *coagulation*) operations in chemical sedimentation basins are similar to those encountered in the treatment of water supplies except that the coagulant doses are greater. Chemical precipitation may be used when plain sedimentation is insufficient, or occasionally when the stream into which the outfall discharges is running low, or when there is a large increase in sewage flow. As with water treatment, the five coagulants used most often are (a) aluminum sulfate,  $\text{Al}_2(\text{SO}_4)_3$ ; (b) ferric chloride,  $\text{FeCl}_3$ ; (c) ferric sulfate,  $\text{Fe}_2(\text{SO}_4)_3$ ; (d) ferrous sulfate,  $\text{FeSO}_4$ ; and (e) chlorinated copperas. Lime and sulfuric acid may be used to adjust the pH for proper coagulation.

### Example 29.1

A primary clarifier receives 1.4 MGD of domestic waste. The clarifier has a peripheral weir, is 50 ft in diameter, and is filled to a depth of 7 ft. Determine if the clarifier is operating within typical performance ranges.

*Solution*

The perimeter length is

$$\begin{aligned} L &= \pi D = \pi(50 \text{ ft}) \\ &= 157 \text{ ft} \end{aligned}$$

The surface area is

$$\begin{aligned} A &= \frac{\pi}{4} D^2 = \left(\frac{\pi}{4}\right)(50 \text{ ft})^2 \\ &= 1963 \text{ ft}^2 \end{aligned}$$

The volume is

$$\begin{aligned} V &= AZ = (1963 \text{ ft}^2)(7 \text{ ft}) \\ &= 13,741 \text{ ft}^3 \end{aligned}$$

The surface loading should be 400–2000 gal/day-ft<sup>2</sup>.

$$\begin{aligned} v^* &= \frac{Q}{A} = \frac{1.4 \times 10^6 \frac{\text{gal}}{\text{day}}}{1963 \text{ ft}^2} \\ &= 713 \text{ gal/day-ft}^2 \quad [\text{OK}] \end{aligned}$$

The detention time should be 1.5–2.5 hr.

$$\begin{aligned} t &= \frac{V}{Q} = \frac{(13,741 \text{ ft}^3)\left(24 \frac{\text{hr}}{\text{day}}\right)}{\left(1.4 \times 10^6 \frac{\text{gal}}{\text{day}}\right)\left(0.1337 \frac{\text{ft}^3}{\text{gal}}\right)} \\ &= 1.76 \text{ hr} \quad [\text{OK}] \end{aligned}$$

The weir loading should be 10,000–20,000 gal/day-ft.

$$\begin{aligned} \frac{Q}{L} &= \frac{1.4 \times 10^6 \frac{\text{gal}}{\text{day}}}{157 \text{ ft}} \\ &= 8917 \text{ gal/day-ft} \quad [\text{low, but probably OK}] \end{aligned}$$

## 19. TRICKLING FILTERS

*Trickling filters* (also known as *biological beds* and *fixed media filters*) consist of beds of rounded river rocks with approximate diameters of 2–5 in (50–125 mm), wooden slats, or modern synthetic media. Wastewater from primary sedimentation processing is sprayed intermittently over the bed. The biological and microbial slime growth attached to the bed purifies the wastewater as it trickles down. The water is introduced into the filter by rotating arms that move by virtue of spray reaction (reaction-type) or motors (motor-type). The clarified water is collected by an underdrain system.

The distribution rate is sometimes given by an *SK rating*, where SK is the water depth in mm deposited per pass of the distributor. Though there is strong evidence that rotational speeds of 1–2 rev/hr (high SK) produce significant operational improvement, traditional distribution arms revolve at 1–5 rev/min (low SK).

On the average, one acre of *low-rate filter* (also referred to as *standard-rate filter*) is needed for each 20,000 people served. Trickling filters can remove 70–90% of the suspended solids, 65–85% of the BOD, and 70–95% of the bacteria. Although low-rate filters have rocks to a depth of 6 ft (1.8 m), most of the reduction occurs in the first few feet of bed, and organisms in the lower part of the bed may be in a near-starvation condition.

Due to the low concentration of carbonaceous material in the water near the bottom of the filter, nitrogenous bacteria produce a highly nitrified effluent from low-rate filters. With low-rate filters, the bed will periodically slough off (unload) parts of its slime coating. Therefore, sedimentation after filtering is necessary. *Filter flies* are a major problem with low-rate filters, since fly larvae are provided with an undisturbed environment in which to breed.

Since there are limits to the heights of trickling filters, longer contact times can be achieved by returning some of the collected filter water back to the filter. This is known as *recirculation* or *recycling*. Recirculation is also used to keep the filter medium from drying out and to smooth out fluctuations in the hydraulic loading.

*High-rate filters* are used in most facilities. The higher hydraulic loading flushes the bed and inhibits excess biological growth. High-rate stone filters may be only 3–6 ft (0.9–1.8 m) deep. The high rate is possible because much of the filter discharge is recirculated. With the high flow rates, fly larvae are washed out, minimizing the filter fly problem. Since the biofilm is less thick and provided with carbon-based nutrients at a

high rate, the effluent is nitrified only when the filter experiences low loading.

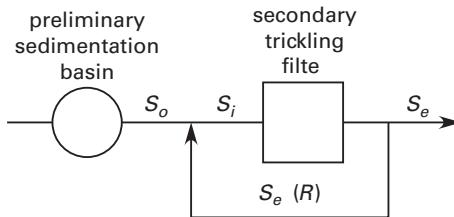

*Super high-rate filters (oxidation towers)* using synthetic media may be up to 40 ft (12 m) tall. High-rate and super high-rate trickling filters may be used as *roughing filters*, receiving wastewater at high hydraulic or organic loading and providing intermediate treatment or the first step of a multistage biological treatment process.

A BOD balance at the mixing point of a filter with recirculation results in Eq. 29.7, in which  $S_i$  is the BOD applied to the filter by the diluted influent,  $S_o$  is the BOD of the effluent from the primary settling tank (or the plant influent BOD if there is no primary sedimentation), and  $S_e$  is the BOD of the trickling filter effluent. (See Fig. 29.4.)

$$S_o + RS_e = (1 + R)S_i \quad 29.7$$

$$S_i = \frac{S_o + RS_e}{1 + R} \quad 29.8$$

Figure 29.4 Trickling Filter Process

BOD is reduced significantly in a trickling filter. Standard-rate filters produce an 80–85% reduction, and high-rate filters remove 65–80% of BOD, less because of reduced contact area and time. The *removal fraction (removal efficiency)* of a single-stage trickling filter is

$$\eta = \frac{S_{\text{removed}}}{S_o} = \frac{S_o - S_e}{S_o} \quad 29.9$$

By definition, the *recirculation ratio*,  $R$ , is zero for standard-rate filters but can be as high as 4:1 for high-rate filters.

$$R = \frac{Q_r}{Q_w} \quad 29.10$$

Filters may be classified as high-rate based on their hydraulic loading, organic loading, or both. The *hydraulic loading* of a trickling filter is the total water flow divided by the plan area. Typical values of hydraulic loading are 25–100 gal/day-ft<sup>2</sup> (1–4 m<sup>3</sup>/d·m<sup>2</sup>) for standard filters and 250–1000 gal/day-ft<sup>2</sup> (10–40 m<sup>3</sup>/d·m<sup>2</sup>) or higher for high-rate filters.

$$L_H = \frac{Q_w + Q_r}{A} = \frac{Q_w(1 + R)}{A} \quad 29.11$$

The *BOD loading (organic loading or surface loading)* is calculated without considering recirculated flow. BOD loading for the filter/clarifier combination is essentially the BOD of the incoming wastewater divided by the filter volume. BOD loading is usually given in lbm per 1000 ft<sup>3</sup> per day (hence the 1000 term in Eq. 29.12.) Typical values are 5–25 lbm/1000 ft<sup>3</sup>·day (0.08–0.4 kg/m<sup>3</sup>·day) for low-rate filters and 25–110 lbm/1000 ft<sup>3</sup>·day (0.4–1.8 kg/m<sup>3</sup>·d) for high-rate filters.

$$L_{\text{BOD,kg/m}^3 \cdot \text{d}} = \frac{Q_{w,\text{m}^3/\text{d}} S_{\text{mg/L}}}{\left( 1000 \frac{\text{mg} \cdot \text{m}^3}{\text{kg} \cdot \text{L}} \right) V_{\text{m}^3}} \quad [\text{SI}] \quad 29.12(a)$$

$$L_{\text{BOD,lbm/1000 ft}^3 \cdot \text{day}} = \frac{Q_{w,\text{MGD}} S_{\text{mg/L}} \left( 8.345 \frac{\text{lbm-L}}{\text{MG-mg}} \right)}{\left( 1000 \frac{\text{ft}^3}{1000 \text{ ft}^3} \right) V_{\text{ft}^3}} \quad [\text{U.S.}] \quad 29.12(b)$$

The *specific surface area* of the filter is the total surface area of the exposed filter medium divided by the total volume of the filter.

### Example 29.2

A single-stage trickling filter plant processes 1.4 MGD of raw domestic waste with a BOD of 170 mg/L. The trickling filter is 90 ft in diameter and has river rock media to a depth of 7 ft. The recirculation rate is 50%, and the filter is classified as high-rate. Water passes through clarification operations both before and after the trickling filter operation. The effluent leaves with a BOD of 45 mg/L. Determine if the trickling filter has been sized properly.

*Solution*

The filter area is

$$A = \frac{\pi}{4} D^2 = \left( \frac{\pi}{4} \right) (90 \text{ ft})^2 = 6362 \text{ ft}^2$$

The rock volume is

$$V = AZ = (6362 \text{ ft}^2)(7 \text{ ft}) = 44,534 \text{ ft}^3$$

The hydraulic load for a high-rate filter should be 250–1000 gal/day-ft<sup>2</sup>.

$$\begin{aligned} L_H &= \frac{Q_w(1 + R)}{A} \\ &= \frac{\left( 1.4 \times 10^6 \frac{\text{gal}}{\text{day}} \right) (1 + 0.5)}{6362 \text{ ft}^2} \\ &= 330 \text{ gal/day-ft}^2 \quad [\text{OK}] \end{aligned}$$

From Table 29.10, the primary clarification process will remove approximately 30% of the BOD. The remaining BOD is

$$S_o = (1 - 0.3) \left( 170 \frac{\text{mg}}{\text{L}} \right)$$

$$= 119 \text{ mg/L}$$

The BOD loading should be approximately 25–110 lbm/1000 ft<sup>3</sup>-day.

$$L_{\text{BOD}} = \frac{Q_{w,\text{MGD}} S_{\text{mg/L}} \left( 8.345 \frac{\text{lbm-L}}{\text{MG-mg}} \right) (1000)}{V_{\text{ft}^3}}$$

$$= \frac{\left( 1.4 \frac{\text{MG}}{\text{day}} \right) \left( 119 \frac{\text{mg}}{\text{L}} \right) \times \left( 8.345 \frac{\text{lbm-L}}{\text{MG-mg}} \right) (1000)}{44,534 \text{ ft}^3}$$

$$= 31.2 \text{ lbm/day-1000 ft}^3 \quad [\text{OK}]$$

## 20. TWO-STAGE TRICKLING FILTERS

If a higher BOD or solids removal fraction is needed, then two filters can be connected in series with an optional intermediate settling tank to form a *two-stage trickling filter* system. The efficiency of the second-stage filter is considerably less than that of the first-stage filter because much of the biological food has been removed from the flow.

## 21. NATIONAL RESEARCH COUNCIL EQUATION

In 1946, the National Research Council (NRC) studied sewage treatment facilities at military installations. The wastewater at these facilities was stronger than typical municipal wastewater. Not surprisingly, the NRC concluded that the organic loading had a greater effect on removal efficiency than did the hydraulic loading.

If it is assumed that the biological layer and hydraulic loading are uniform, the water is at 20°C, and the filter is single-stage rock followed by a settling tank, then the *NRC equation*, Eq. 29.13, can be used to calculate the BOD removal fraction of the single-stage filter/clarifier combination. Inasmuch as installations with high BOD and low hydraulic loads were used as the basis of the studies, BOD removal efficiencies in typical municipal facilities are higher than predicted by Eq. 29.13. The value of  $L_{\text{BOD}}$  excludes recirculation returned directly from the filter outlet, which is accounted for in the value of  $F$ .

$$\eta = \frac{1}{1 + 0.0561 \sqrt{\frac{L_{\text{BOD,lbm/day}}}{V_{1000\text{s ft}^3} F}}} \quad 29.13$$

It is important to recognize the BOD loading,  $L_{\text{BOD}}$ , in Eq. 29.13, has units of lbm/day, not lbm/day-1000 ft<sup>3</sup>. The constant 0.0085 is often encountered in place of 0.0561 in the literature, as in Eq. 29.14. However, this value is for use with filter media volumes,  $V$ , expressed in ac-ft, not in thousands of ft<sup>3</sup>.

$$\eta = \frac{1}{1 + 0.0085 \sqrt{\frac{L_{\text{BOD,lbm/day}}}{V_{\text{ac-ft}} F}}} \quad 29.14$$

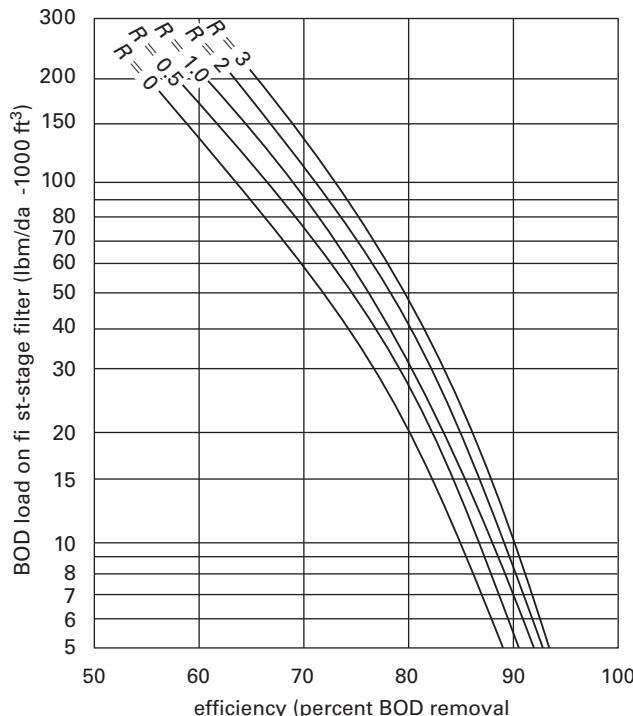

There are a number of ways to recirculate water from the output of the trickling filters back to the filter. Water can be brought back to a wet well, to the primary settling tank, to the filter itself, or to a combination of the three. Variations in performance are not significant as long as sludge is not recirculated. Equation 29.13 and Eq. 29.14 can be used with any of the recirculation schemes.

$F$  is the *effective number of passes* of the organic material through a filter.  $R$  is the ratio of filter discharge returned to the inlet to the raw influent. In Eq. 29.15,  $w$  is a weighting factor typically assigned a value of 0.1.

$$F = \frac{1 + R}{(1 + wR)^2} \quad 29.15$$

It is time-consuming to extract the organic loading,  $L_{\text{BOD}}$ , from Eq. 29.13 given  $\eta$  and  $R$ . Figure 29.5 can be used for this purpose.

Figure 29.5 Trickling Filter Performance\*

\*NRC model, single-stage

Based on the NRC model, the removal fraction for a two-stage filter with an intermediate clarifier is

$$\eta_2 = \frac{1}{1 + \left( \frac{0.0561}{1 - \eta_1} \right) \sqrt{\frac{L_{BOD}}{F}}} \quad 29.16$$

In recent years, the NRC equations have fallen from favor for several reasons. These reasons include applicability only to rock media, inability to correct adequately for temperature variations, inapplicability to industrial waste, and empirical basis.

## 22. VELZ EQUATION

Equation 29.17, known as the *Velz equation*, was the first semi-theoretical analysis of trickling filter performance versus depth of media. It is useful in predicting the BOD removal fraction for any generic trickling filter, including those with synthetic media. The original Velz used the term "total removable fraction of BOD," though this is understood to mean the maximum fraction of removable BOD removed, generally  $S_e$ .

Values of the *Velz decay rate*,  $K$ , an empirical rate constant, are highly dependent on the installation and operating characteristics, particularly the hydraulic loading, which is not included in the formula. Subsequent to Velz' work, the industry has developed a large database of applicable values for numerous application scenarios.

$$\frac{S_e}{S_i} = e^{-KZ} \quad \left[ \text{alternatively } \frac{S_e}{S_i} = 10^{-KZ} \right] \quad 29.17$$

The variation in temperature was assumed to be

$$K_T = K_{20^\circ\text{C}} (1.047)^{T-20^\circ\text{C}} \quad 29.18$$

## 23. MODERN FORMULATIONS

Various researchers have built upon the *Velz equation* and developed correlations of the form of Eq. 29.19 for various situations and types of filters. (In Eq. 29.19,  $S_a$  is the *specific surface area* (colonization surface area per unit volume), not the BOD.) Each researcher used different nomenclature and assumptions. For example, the inclusion of the effects of dilution by recirculation is far from universal. The specific form of the equation, values of constants and exponents, temperature coefficients, limitations, and assumptions are needed before such a correlation can be reliably used.

$$\frac{S_e}{S_i} = \exp \left\{ -KZ S_a^m \left( \frac{A}{Q} \right)^n \right\} \quad 29.19$$

As an example of the difficulty in finding one model that predicts all trickling filter performance, consider the BOD removal efficiency as predicted by the *Schulze*

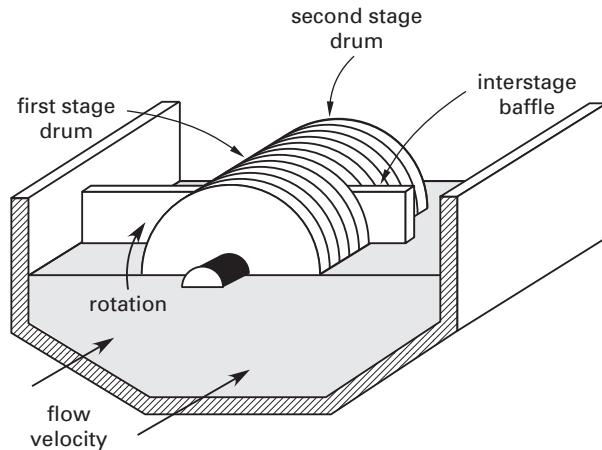

*correlation* (1960) for rock media and the *Germain correlation* (1965) for synthetic media. Though both correlations have the same form, both measured filter depths in feet, and both expressed hydraulic loadings in gal/min-ft<sup>2</sup>, the Schulze correlation included recirculation while the Germain correlation did not. (See Eq. 29.20.) The treatability constant,  $k$ , was 0.51–0.76 day<sup>-1</sup> for the Schulze correlation and 0.088 day<sup>-1</sup> for the Germain correlation. The *media factor* exponent,  $n$ , was 0.67 for the Schulze correlation (rock media) and 0.5 for the Germain correlation (plastic media).

$$\frac{S_e}{S_i} = \exp \left\{ \frac{-kZ}{L_H^n} \right\} \quad 29.20$$

## 24. ROTATING BIOLOGICAL CONTACTORS

*Rotating biological contactors*, RBCs (also known as *rotating biological reactors*), consist of large-diameter plastic disks, partially immersed in wastewater, on which biofilm is allowed to grow. (See Fig. 29.6.) The disks are mounted on shafts that turn slowly. The rotation progressively wets the disks, alternately exposing the biofilm to organic material in the wastewater and to oxygen in the air. The biofilm population, since it is well oxygenated, efficiently removes organic solids from the wastewater. RBCs are primarily used for carbonaceous BOD removal, although they can also be used for nitrification or a combination of both.

Figure 29.6 Rotating Biological Contactor

The primary design criterion is hydraulic loading, not organic (BOD) loading. For a specific hydraulic loading, the BOD removal efficiency will be essentially constant, regardless of variations in BOD. Other design criteria are listed in Table 29.11.

RBC operation is more efficient when several stages are used. Recirculation is not common with RBC processes. The process can be placed in series or in parallel with existing trickling filter or activated sludge processes.

**Table 29.11** Typical Characteristics of Rotating Biological Contactors

number of stages	2–4
disk diameter	10–12 ft (3–3.6 m)
immersion, percentage of area	40%
hydraulic loading	2–4 gal/day-ft <sup>2</sup> (0.08–0.16 m <sup>3</sup> /d·m <sup>2</sup> )
secondary treatment	0.75–2 gal/day-ft <sup>2</sup> (0.03–0.08 m <sup>3</sup> /d·m <sup>2</sup> )
tertiary treatment (nitrification)	1 ft/sec (0.3 m/s)
optimum peripheral rotational speed	0.12 gal/ft <sup>2</sup> (0.0049 m <sup>3</sup> /m <sup>2</sup> ) of biomass area
tank volume	13–32°C
operating temperature	70–80%
BOD removal fraction	

## 25. SAND FILTERS

For small populations, a *slow sand filter* (*intermittent sand filter*) can be used. Because of the lower flow rate, the filter area per person is higher than in the case of a trickling filter. Roughly one acre is needed for each 1000 people. The filter is constructed as a sand bed 2–3 ft (0.6–0.9 m) deep over a 6–12 in (150–300 mm) gravel bed. The filter is alternately exposed to water from a settling tank and to air (hence the term intermittent). Straining and aerobic decomposition clean the water. Application rates are usually 2–2.5 gal/day-ft<sup>2</sup> (0.08–0.1 m<sup>3</sup>/d·m<sup>2</sup>). Up to 95% of the BOD can be satisfied in an intermittent sand filter. The filter is cleaned by removing the top layer of clogged sand.

If the water is applied continuously as a final process following secondary treatment, the filter is known as a *polishing filter* or *rapid sand filter*. The water rate of a polishing filter is typically 2–8 gal/min-ft<sup>2</sup> (0.08–0.32 m<sup>3</sup>/min·m<sup>2</sup>) but may be as high as 10 gal/min-ft<sup>2</sup> (0.4 m<sup>3</sup>/min·m<sup>2</sup>). Although the designs are similar to those used in water supply treatment, coarser media are used since the turbidity requirements are less stringent. Backwashing is required more frequently and is more aggressive than with water supply treatment.

## 26. INTERMEDIATE CLARIFIERS

Sedimentation tanks located between trickling filter stages or between a filter and subsequent aeration are known as *intermediate clarifiers* or *secondary clarifiers*. Typical characteristics of intermediate clarifiers used with trickling filter processes are: maximum overflow rate, 1500 gal/day-ft<sup>2</sup> (61 m<sup>3</sup>/d·m<sup>2</sup>); water depth, 10–13 ft (3–4 m); and maximum weir loading, 10,000 gal/day-ft (125 m<sup>3</sup>/d·m) for plants processing 1 MGD or less and 15,000 gal/day-ft (185 m<sup>3</sup>/d·m) for plants processing over 1 MGD.

## 27. FINAL CLARIFIERS

Sedimentation following secondary treatment occurs in *final clarifiers*. The purpose of final clarification is to collect sloughed-off material from trickling filter processes or to collect sludge and return it for activated sludge processes, not to reduce BOD. The depth is approximately 10–12 ft (3.0–3.7 m), the average overflow rate is 500–600 gal/day-ft<sup>2</sup> (20–24 m<sup>3</sup>/d·m<sup>2</sup>), and the maximum overflow rate is approximately 1100 gal/day-ft<sup>2</sup> (45 m<sup>3</sup>/d·m<sup>2</sup>). The maximum weir loading is the same as for intermediate clarifiers, but the lower rates are preferred. For settling following extended aeration, the overflow rate and loading should be reduced approximately 50%.

## 28. PHOSPHORUS REMOVAL: PRECIPITATION

Phosphorus concentrations of 5–15 mg/L (as P) are experienced in untreated wastewater, most of which originates from synthetic detergents and human waste. Approximately 10% of the total phosphorus is insoluble and can be removed in primary settling. The amount that is removed by absorption in conventional biological processes is small. The remaining phosphorus is soluble and must be removed by converting it into an insoluble precipitate.

Soluble phosphorus is removed by precipitation and settling. Aluminum sulfate, ferric chloride (FeCl<sub>3</sub>), and lime may be used depending on the nature of the phosphorus radical. Aluminum sulfate is more desirable since lime reacts with hardness and forms large quantities of additional precipitates. (Hardness removal is not as important as it is in water supply treatment.) However, the process requires about 10 lbm (10 kg) of aluminum sulfate for each pound (kilogram) of phosphorus removed. The process also produces a chemical sludge that is difficult to dewater, handle, and dispose of.

Due to the many other possible reactions the compounds can participate in, the dosage should be determined from testing. The stoichiometric chemical reactions describe how the phosphorus is removed, but they do not accurately predict the quantities of coagulants needed.

## 29. AMMONIA REMOVAL: AIR STRIPPING

Ammonia may be removed by either biological processing or air stripping. In the biological *nitrification and denitrification process*, ammonia is first aerobically converted to nitrite and then to nitrate (nitrification) by bacteria. Then, the nitrates are converted to nitrogen gas, which escapes (denitrification).

In the *air-stripping (ammonia-stripping)* method, lime is added to water to increase its pH to about 10. This causes the ammonium ions,  $\text{NH}_4^+$ , to change to dissolved ammonia gas,  $\text{NH}_3$ . The water is passed through a packed tower into which air is blown at high rates. The air strips the ammonia gas out of the water. Recarbonation follows to remove the excess lime.

### 30. CARBON ADSORPTION

*Adsorption* uses high surface-area activated carbon to remove organic contaminants. Adsorption can use *granular activated carbon* (GAC) in column or fluidized-bed reactors or *powdered activated carbon* (PAC) in complete-mix reactors. Activated carbon is relatively nonspecific, and it will remove a wide variety of refractory organics as well as some inorganic contaminants. It should generally be considered for organic contaminants that are nonpolar, have low solubility, or have high molecular weights.

The most common problems associated with columns are breakthrough, excessive headloss due to plugging, and premature exhaustion. *Breakthrough* occurs when the carbon becomes saturated with the target compound and can hold no more. *Plugging* occurs when biological growth blocks the spaces between carbon particles. *Premature exhaustion* occurs when large and high molecular-weight molecules block the internal pores in the carbon particles. These latter two problems can be prevented by locating the carbon columns downstream of filtration.

### 31. CHLORINATION

Chlorination to disinfect and deodorize is one of the final steps prior to discharge. Vacuum-type feeders are used predominantly with chlorine gas. Chlorine under vacuum is combined with wastewater to produce a chlorine solution. A *flow-pacing chlorinator* will reduce the chlorine solution feed rate when the wastewater flow decreases (e.g., at night).

The size of the *contact tank* varies, depending on economics and other factors. An average design detention time is 30 min at average flow, some of which can occur in the plant outfall after the contact basin. Contact tanks are baffled to prevent short-circuiting that would otherwise reduce chlorination time and effectiveness.

Alternatives to disinfection by chlorine include sodium hypochlorite, ozone, ultraviolet light, bromine (as bromine chloride), chlorine dioxide, and hydrogen peroxide. All alternatives have one or more disadvantages when compared to chlorine gas.

### 32. DECHLORINATION

Toxicity, by-products, and strict limits on *total residual oxidants* (TROs) now make dechlorination mandatory at many installations. Sulfur dioxide ( $\text{SO}_2$ ) and sodium thiosulfite ( $\text{Na}_2\text{S}_2\text{SO}_3$ ) are the primary compounds used as dechlorinators today. Other compounds seeing limited use are sodium metabisulfite ( $\text{Na}_2\text{S}_2\text{O}_5$ ), sodium bisulfite ( $\text{NaHSO}_3$ ), sodium sulfite ( $\text{Na}_2\text{SO}_3$ ), hydrogen peroxide ( $\text{H}_2\text{O}_2$ ), and granular activated carbon.

Though reaeration was at one time thought to replace oxygen in water depleted by sulfur dioxide, this is now considered to be unnecessary unless required to meet effluent discharge requirements.

### 33. EFFLUENT DISPOSAL

Organic material and bacteria present in wastewater are generally not removed in their entireties, though the removal efficiency is high (e.g., better than 95% for some processes). Therefore, effluent must be discharged to large bodies of water where the remaining contaminants can be substantially diluted. Discharge to flowing surface water and oceans is the most desirable. Discharge to lakes and reservoirs should be avoided.

In some areas, *combined sewer overflow* (CSO) outfalls still channel wastewater into waterways during heavy storms when treatment plants are overworked. Such pollution can be prevented by the installation of large retention basins (*diversion chambers*), miles of tunnels, reservoirs to capture overflows for later controlled release to treatment plants, screening devices to separate solids from wastewater, swirl concentrators to capture solids for treatment while permitting the clearer portion to be chlorinated and released to waterways, and more innovative vortex solids separators.

### 34. WASTEWATER RECLAMATION

Treated wastewater can be used for irrigation, fire-fighting, road maintenance, or flushing. Public access to areas where reclaimed water is disposed of through spray-irrigation (e.g., in sod farms, fodder crops, and pasture lands) should be restricted. When the reclaimed water is to be used for irrigation of public areas, the water quality standards regarding suspended solids, fecal coliforms, and viruses should be strictly controlled.

Although it has been demonstrated that wastewater can be made potable at great expense, such practice has not gained widespread favor.

**1. SLUDGE**

*Sludge* is the mixture of water, organic and inorganic solids, and treatment chemicals that accumulates in settling tanks. The term is also used to refer to the dried residue (screenings, grit, filter cake, and drying bed scraping) from separation and drying processes, although the term *biosolids* is becoming more common in this regard. (The term *residuals* is also used, though this term more commonly refers to sludge from water treatment plants.)

**2. ACTIVATED SLUDGE PROCESS**

The *activated sludge process* is a secondary biological wastewater treatment technique in which a mixture of wastewater and sludge solids is aerated. (See Fig. 30.1.) The sludge mixture produced during this oxidation process contains an extremely high concentration of aerobic bacteria, most of which are near starvation. This condition makes the sludge an ideal medium for the destruction of any organic material in the mixture. Since the bacteria are voraciously active, the sludge is called *activated sludge*.

**Figure 30.1** Typical Activated Sludge Plant

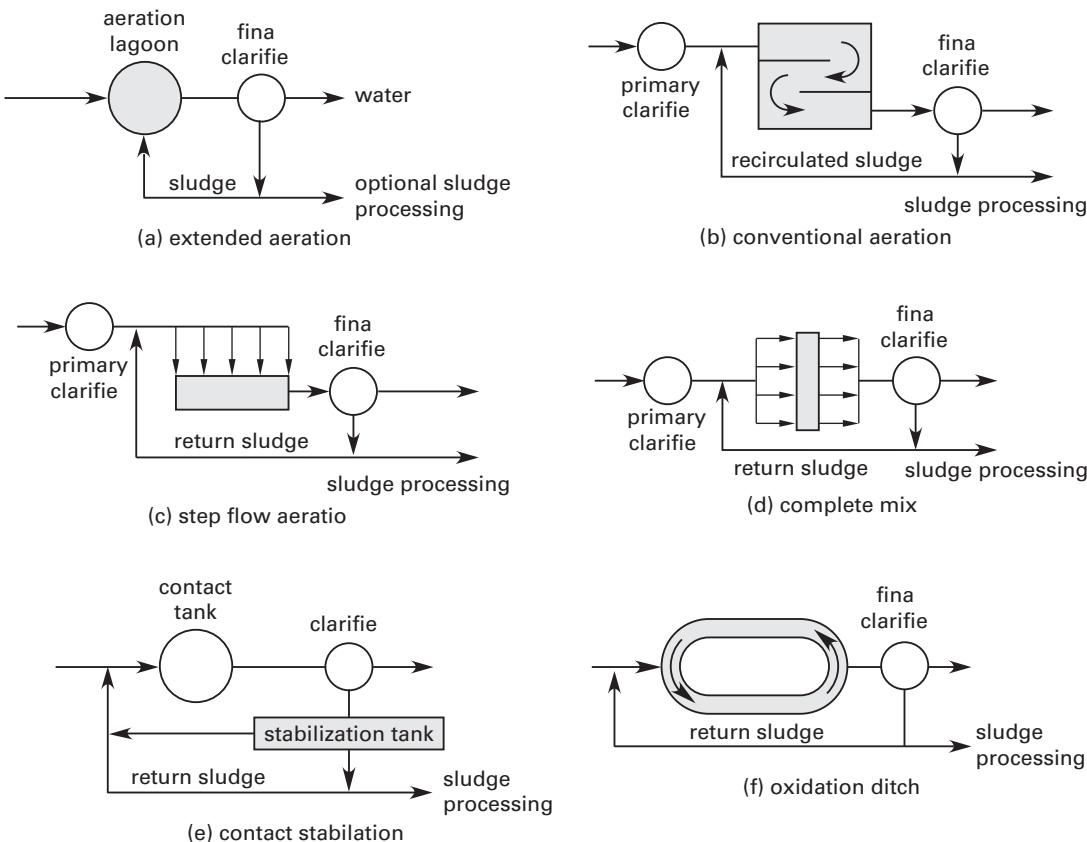

The well-aerated mixture of wastewater and sludge, known as *mixed liquor*, flows from the aeration tank to a secondary clarifier where the sludge solids settle out. Most of the settled sludge solids are returned to the aeration tank in order to maintain the high population of bacteria needed for rapid breakdown of the organic material. However, because more sludge is produced than is needed, some of the return sludge is diverted ("wasted") for subsequent treatment and disposal. This wasted sludge is referred to as *waste activated sludge*, WAS. The volume of sludge returned to the aeration basin is typically 20–30% of the wastewater flow. The liquid fraction removed from the secondary clarifier weir is chlorinated and discharged.

Though diffused aeration and mechanical aeration are the most common methods of oxygenating the mixed liquor, various methods of staging the aeration are used, each having its own characteristic ranges of operating parameters. (See Table 30.1 for typical characteristics of activated sludge plants, Table 30.2 for additional information, and Table 30.3 for *Ten States' Standards*.)

In a traditional activated sludge plant using conventional aeration, the wastewater is typically aerated for 6–8 hours in long, rectangular aeration basins. Sufficient air, about eight volumes for each volume of wastewater treated, is provided to keep the sludge in suspension. The air is injected near the bottom of the aeration tank through a system of diffusers.

**3. AERATION STAGING METHODS**

Small wastewater quantities can be treated with *extended aeration*. (See Fig. 30.2 for available aeration methods.) This method uses mechanical floating or fixed subsurface aerators to oxygenate the mixed liquor for 24–36 hours in a large lagoon. There is no primary clarification, and there is generally no sludge wasting process. Sludge is allowed to accumulate at the bottom

**Figure 30.2** Methods of Aeration

of the lagoon for several months. Then, the system is shut down and the lagoon is pumped out. Sedimentation basins are sized very small, with low overflow rates of 200–600 gal/day-ft<sup>2</sup> (8.1–24 m<sup>3</sup>/d·m<sup>2</sup>) and long retention times.

An *oxidation ditch* is a type of extended aeration system, configured in a continuous long and narrow oval. The basin contents circulate continuously to maintain mixing and aeration. Mixing occurs by brush aerators or by a combination of low-head pumping and diffused aeration.

In *conventional aeration*, the influent is taken from a primary clarifier and then aerated. The amount of aeration is usually decreased as the wastewater travels along the aeration path since the BOD also decreases along the route. This is known as *tapered aeration*.

With *step-flow aeration*, aeration is constant along the length of the aeration path, but influent is introduced at various points along the path.

With *complete-mix aeration*, wastewater is added uniformly and the mixed liquor is removed uniformly over the length of the tank. The mixture is essentially uniform in composition throughout.

Units for the *contact stabilization (biosorption)* process are typically factory-built and brought to the site for installation, although permanent facilities can be built for the same process. Prebuilt units are compact but not

**Table 30.1** Typical Characteristics of Conventional Activated Sludge Plants

BOD reduction	90–95%
effluent BOD	5–30 mg/L
effluent COD	15–90 mg/L
effluent suspended solids	5–30 mg/L

 (Multiply gal/day-ft by 0.0124 to obtain m<sup>3</sup>/d·m.)

as economical or efficient as larger plants running on the same process. The aeration tank is called a *contact tank*. The *stabilization tank* takes the sludge from the clarifier and aerates it. With this process, colloidal solids are absorbed in the activated sludge during the 30–90 min of aeration in the contact tank. Then, the sludge is removed by clarification and the return sludge is aerated for 3–6 more hours in the stabilization tank. Less time and space is required for this process because the sludge stabilization is done while the sludge is still concentrated. This method is very efficient in handling colloidal wastes.

The *high-rate aeration* method uses mechanical mixing along with aeration to decrease the aeration period and increase the BOD load per unit volume.

The *high purity oxygen aeration* method requires the use of bottled or manufactured oxygen that is introduced into closed/covered aerating tanks. Mechanical mixers are needed to take full advantage of the oxygen supply because little excess oxygen is provided. Retention times in aeration basins are longer than for other aerobic systems, producing higher concentrations of MLSS and better stabilization of sludge that is ultimately wasted. This method is applicable to high-strength sewage and industrial wastewater.

*Sequencing batch reactors* (SBRs) operate in a fill-and-drain sequence. The reactor is filled with influent,

contents are aerated, and sludge is allowed to settle. Effluent is drawn from the basin along with some of the settled sludge, and new effluent is added to repeat the process. The “return sludge” is the sludge that remains in the basin.

#### 4. FINAL CLARIFIERS

Table 30.4 lists typical operating characteristics for clarifiers in activated sludge processes. Sludge should be removed rapidly from the entire bottom of the clarifier.

#### 5. SLUDGE PARAMETERS

The bacteria and other suspended material in the mixed liquor is known as *mixed liquor suspended solids* (MLSS) and is measured in mg/L. Suspended solids are further divided into fixed solids and volatile solids. *Fixed solids* (also referred to as *nonvolatile solids*) are those inert solids that are left behind after being fired in a furnace. *Volatile solids* are essentially those carbonaceous solids that are consumed in the furnace. The volatile solids are considered to be the measure of solids capable of being digested. Approximately 60–75% of sludge solids are volatile. The volatile material in the mixed liquor is known as the *mixed liquor volatile suspended solids* (MLVSS).

<sup>a</sup>MLSS values are dependent upon the surface area provided for sedimentation and the rate of sludge return as well as the aeration process.<sup>b</sup>Total aeration capacity; includes both contact and reaeration capacities. Normally the contact zone equals 30–35% of the total aeration capacity.Reprinted from *Recommended Standards for Sewage Works*, 2004, Sec. 92.31, Great Lakes-Upper Mississippi River Board of State Sanitary Engineers, published by Health Education Service, Albany, NY.

The organic material in the incoming wastewater constitutes “food” for the activated organisms. The food arrival rate is given by Eq. 30.1.  $S_o$  is usually taken as the incoming BOD<sub>5</sub>, although COD is used in rare situations.

$$F = S_o Q_o \quad 30.1$$

The mass of microorganisms,  $M$ , is determined from the *volatile suspended solids concentration*,  $X$ , in the aeration tank.

$$M = V_a X \quad 30.2$$

The *food-to-microorganism ratio*, (F:M) is displayed in Eq. 30.3. For conventional aeration, typical values are 0.20–0.50 lbm/lbm-day (0.20–0.50 kg/kg·d), though values between 0.05 and 1.0 have been reported.  $\theta$  in Eq. 30.3 is the *hydraulic detention time*.

$$\text{F:M} = \frac{S_{o,\text{mg/L}} Q_{o,\text{MGD}}}{V_{a,\text{MG}} X_{\text{mg/L}}} = \frac{S_{o,\text{mg/L}}}{\theta_{\text{days}} X_{\text{mg/L}}} \quad 30.3$$

**Table 30.4** Characteristics of Final Clarifiers for Activated Sludge Processes

type of aeration	design flow (MGD)	minimum	maximum
		detention time (hr)	overflow rate (gpd/ft <sup>2</sup> )
conventional, high rate and step	< 0.5	3.0	600
	0.5–1.5	2.5	700
	> 1.5	2.0	800
contact stabilization	< 0.5	3.6	500
	0.5–1.5	3.0	600
	> 1.5	2.5	700
extended aeration	< 0.05	4.0	300
	0.05–0.15	3.6	300
	> 0.15	3.0	600

(Multiply MGD by 0.0438 to obtain m<sup>3</sup>/s.)(Multiply gal/day-ft<sup>2</sup> by 0.0407 m<sup>3</sup>/d·m<sup>2</sup>.)

Some authorities include the entire suspended solids content (MLSS), not just the volatile portion ( $X$ ), when calculating the food-to-microorganism ratio, although this interpretation is less common.

$$\text{F:M} = \frac{S_{o,\text{mg/L}} Q_{o,\text{MGD}}}{V_{a,\text{MG}} \text{MLSS}_{\text{mg/L}}} \quad 30.4$$

The liquid fraction of the wastewater passes through an activated sludge process in a matter of hours. However, the sludge solids are recycled continuously and have an average stay much longer in duration. There are two measures of *sludge age*: the *mean cell residence time* (also known as the *age of the suspended solids* and *solids residence time*), essentially the age of the microorganisms, and *age of the BOD*, essentially the age of the food. For conventional aeration, typical values of the mean cell residence time,  $\theta_c$ , are 6 to 15 days for high-quality effluent and sludge.

$$\theta_c = \frac{V_a X}{Q_e X_e + Q_w X_w} \quad 30.5$$

The *BOD sludge age (age of the BOD)*,  $\theta_{\text{BOD}}$ , is the reciprocal of the food-to-microorganism ratio.

$$\theta_{\text{BOD}} = \frac{1}{\text{F:M}} = \frac{V_{a,\text{m}^3} X_{\text{mg/L}}}{S_{o,\text{mg/L}} Q_{o,\text{m}^3/\text{d}}} \quad [\text{SI}] \quad 30.6(a)$$

$$\theta_{\text{BOD}} = \frac{1}{\text{F:M}} = \frac{V_{a,\text{MG}} X_{\text{mg/L}}}{S_{o,\text{mg/L}} Q_{o,\text{MGD}}} \quad [\text{U.S.}] \quad 30.6(b)$$

The *sludge volume index*, SVI, is a measure of the sludge's settleability. SVI can be used to determine the tendency toward *sludge bulking*. (See Sec. 30.14.) SVI is determined by taking 1 L of mixed liquor and measuring the volume of settled solids after 30 minutes. SVI is the

volume in mL occupied by 1 g of settled volatile and nonvolatile suspended solids.

$$\text{SVI}_{\text{mg/L}} = \frac{\left(1000 \frac{\text{mg}}{\text{g}}\right) V_{\text{settled,mL/L}}}{\text{MLSS}_{\text{mg/L}}} \quad 30.7$$

A similar control parameter is the *settled sludge volume*, SSV, which is the volume of sludge per liter sample after settling for 30 or 60 minutes.

$$\text{SSV} = \frac{V_{\text{settled sludge,mL}} \left(1000 \frac{\text{mL}}{\text{L}}\right)}{V_{\text{sample,mL}}} \quad 30.8$$

The concentration of total suspended solids, TSS, in the recirculated sludge can be found from Eq. 30.9. This equation is useful in calculating the solids concentration for any sludge that is wasted from the return sludge line. (Suspended sludge solids wasted include both fixed and volatile portions.)

$$\text{TSS}_{\text{mg/L}} = \frac{\left(1000 \frac{\text{mg}}{\text{g}}\right) \left(1000 \frac{\text{mL}}{\text{L}}\right)}{\text{SVI}_{\text{mL/g}}} \quad 30.9$$

## 6. SOLUBLE BOD ESCAPING TREATMENT

$S$  is a variable used to indicate the growth-limiting substrate in solution. Specifically,  $S$  (without a subscript) is defined as the soluble  $\text{BOD}_5$  escaping treatment (i.e., the effluent  $\text{BOD}_5$  leaving the activated sludge process). This may need to be calculated from the effluent suspended solids and the fraction,  $G$ , of the suspended solids that is ultimately biodegradable.

$$\begin{aligned} \text{BOD}_e &= \text{BOD}_{\text{escaping treatment}} \\ &\quad + \text{BOD}_{\text{effluent suspended solids}} \\ &= S + S_e \\ &= S + 1.42fGX_e \end{aligned} \quad 30.10$$

Care must be taken to distinguish between the standard five-day BOD and the ultimate BOD. The ratio of these two parameters, typically approximately 70%, is

$$f = \frac{\text{BOD}_5}{\text{BOD}_u} \quad 30.11$$

In some cases, the terms in the product  $1.42fG$  in Eq. 30.10 are combined, and  $S_e$  is known directly as a percentage of  $X_e$ . However, this format is less common.

## 7. PROCESS EFFICIENCY

The *treatment efficiency* (*BOD removal efficiency*, *removal fraction*, etc.), typically 90–95% for conventional aeration, is given by Eq. 30.12.  $S_o$  is the BOD as received from the primary settling tank. If the overall plant efficiency is wanted, the effluent  $S$  is taken as the total  $\text{BOD}_5$  of the effluent. Depending on convention, efficiency can also be based on only the soluble BOD escaping treatment (i.e.,  $S$  from Eq. 30.10).

$$\eta_{\text{BOD}} = \frac{S_o - S}{S_o} \quad 30.12$$

## 8. PLUG FLOW AND STIRRED TANK MODELS

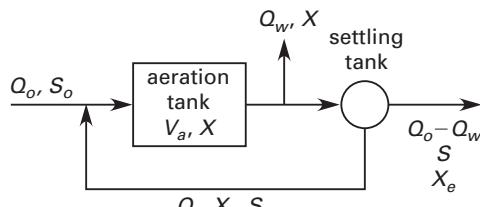

Conventional aeration and complete-mix aeration represent two extremes for continuous-flow reactions. Ideal conventional aeration is described by a *plug-flow reaction* (PFR, also known as *tubular flow*) kinetic model. (The term *reactor* is commonly used to describe the aeration tank.) In a plug-flow reactor, material progresses along the reaction path, changing in composition as it goes. Mixing is considered to be ideal in the lateral plane but totally absent in the longitudinal direction. That is, the properties (in this case, BOD and suspended solids) change along the path, as though only a “plug” of material was progressing forward.

A complete-mix aerator, however, is a type of *continuous-flow stirred tank reactor* (CSTR or CFSTR). In a CSTR model, the material is assumed to be homogeneous in properties throughout as a result of continuous perfect mixing. It is assumed that incoming material is immediately diluted to the tank concentration, and the outflow properties are the same as the tank properties.

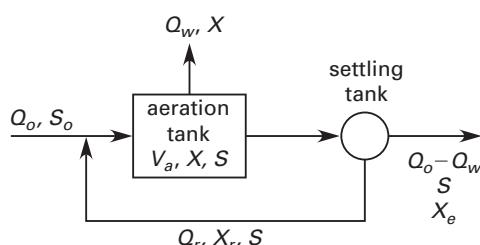

Modifications of the basic kinetic models are made to account for return/recycle and wastage. Many, but not all, of the same equations can be used to describe the performance of both the PFR and CSTR models. (See Fig. 30.3.)

Until the late 1950s, nearly all activated sludge aeration tanks were long and narrow with length-to-width ratios greater than 5, and performance was assumed to be predicted by PFR equations. However, extensive testing has shown that substantial longitudinal mixing actually occurs, and many conventional systems are actually CSTRs. In fact, the long basin configuration gives an oxidation ditch the attributes of a PFR while maintaining CSTR characteristics.

The kinetic model for the PFR is complex, but it can be simplified under certain conditions. If the ratio of  $\theta_c/\theta$  is greater than 5, the concentration of microorganisms in the influent to the reactor (aeration tank)

**Figure 30.3** Kinetic Model Process Variables

(a) plug flow reactor with recycle

(b) continuously stirred tank reactor with recycle

will be approximately the same as in the effluent from the reactor.

$$\frac{1}{\theta_c} = \frac{\mu_m(S_o - S)}{S_o - S + (1 + R)K_s \ln \frac{S_i}{S}} - k_d \quad [\text{PFR only}] \quad 30.13$$

The *maximum specific growth rate*,  $\mu_m$ , is calculated from the first-order reaction constant,  $k$ .

$$\mu_m = kY \quad 30.14$$

The influent concentration after dilution with recycle flow is

$$S_i = \frac{S_o + RS}{1 + R} \quad [\text{PFR only}] \quad 30.15$$

The *rate of substrate utilization* as the waste passes through the aerating reactor is

$$r_{su} = \frac{-\mu_m S X}{Y(K_s + S)} \quad [\text{PFR only}] \quad 30.16$$

For the CSTR, the *specific substrate utilization (specific utilization)*,  $U$ , is the food-to-microorganism ratio multiplied by the fractional process efficiency.

$$U = \eta(\text{F:M}) = \frac{-r_{su}}{X}$$

$$= \frac{S_o - S}{\theta X} \quad 30.17$$

For the CSTR, the equivalent relationship between mean cell residence time, food-to-microorganism ratio, and specific utilization rate,  $U$ , is given by Eq. 30.18.

$$\begin{aligned} \frac{1}{\theta_c} &= Y(\text{F:M})\eta - k_d \\ &= -Y\left(\frac{r_{su}}{X}\right) - k_d \\ &= YU - k_d \quad [\text{CSTR only}] \end{aligned} \quad 30.18$$

$Y$  and  $k_d$  are the kinetic coefficients describing the bacterial growth process.  $Y$  is the *yield coefficient*, the ratio of the mass of cells formed to the mass of substrate (food) consumed, in mg/mg.  $k_d$  is the *endogenous decay coefficient* (rate) of the microorganisms in day<sup>-1</sup>. For a specified waste, biological community, and set of environmental conditions,  $Y$  and  $k_d$  are fixed. Equation 30.18 is a linear equation of the general form  $y = mx + b$ . Figure 30.4 illustrates how these coefficients can be determined graphically from bench-scale testing.

For a continuously stirred tank reactor, the kinetic model predicts the effluent substrate concentration.

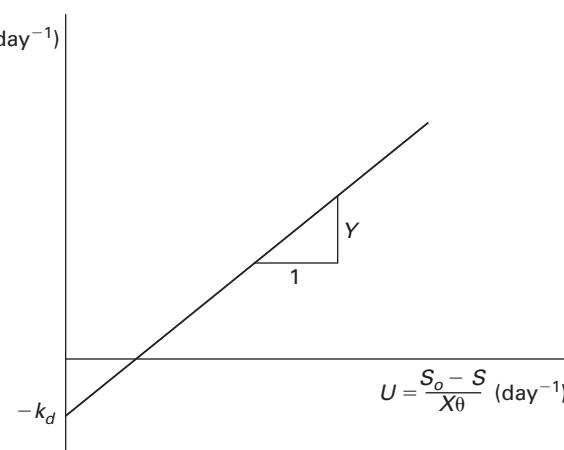

$$S = \frac{K_s(1 + k_d\theta_c)}{\theta_c(\mu_m - k_d) - 1} \quad [\text{CSTR only}] \quad 30.19$$

The *hydraulic retention time*,  $\theta$ , for the reactor is

$$\theta = \frac{V_a}{Q_o} \quad [\text{PFR and CSTR}] \quad 30.20$$

The *hydraulic retention time*,  $\theta_s$ , for the system is

$$\theta_s = \frac{V_a + V_s}{Q_o} \quad [\text{PFR and CSTR}] \quad 30.21$$

**Figure 30.4** Kinetic Growth Constants\*

\*As determined from bench-scale activated sludge studies using a continuous flow stirred tank reactor without recycle

The reactor volume,  $V_a$ , is

$$\begin{aligned} V_a &= \theta Q_o \\ &= \frac{\theta_c Q_o Y(S_o - S)}{X(1 + k_d \theta_c)} \quad [\text{PFR and CSTR}] \end{aligned} \quad 30.22$$

The average concentration of microorganisms,  $X$ , in the reactor is

$$X = \frac{\left(\frac{\theta_c}{\theta}\right) Y(S_o - S)}{1 + k_d \theta_c} \quad [\text{PFR and CSTR}] \quad 30.23$$

The observed yield is

$$Y_{\text{obs}} = \frac{Y}{1 + k_d \theta_c} \quad [\text{PFR and CSTR}] \quad 30.24$$

The volatile portion of the mass of activated sludge that must be wasted each day is given by Eq. 30.25. The total (fixed and volatile) mass of sludge wasted each day must be calculated from the ratio of MLVSS and MLSS.

$$\begin{aligned} P_{x,\text{kg/d}} &= \frac{Q_{w,\text{m}^3/\text{d}} X_{r,\text{mg/L}}}{1000 \frac{\text{g}}{\text{kg}}} \\ &= \frac{Y_{\text{obs},\text{mg/mg}} Q_{o,\text{m}^3/\text{d}} (S_o - S)_{\text{mg/L}}}{1000 \frac{\text{g}}{\text{kg}}} \\ &\quad [\text{SI; PFR and CSTR}] \end{aligned} \quad 30.25(a)$$

$$\begin{aligned} P_{x,\text{lbm/day}} &= Q_{w,\text{MGD}} X_{r,\text{mg/L}} \left( 8.345 \frac{\text{lbm-L}}{\text{MG-mg}} \right) \\ &= Y_{\text{obs},\text{lbm/lbm}} Q_{o,\text{MGD}} (S_o - S)_{\text{mg/L}} \\ &\quad \times \left( 8.345 \frac{\text{lbm-L}}{\text{MG-mg}} \right) \\ &\quad [\text{U.S.; PFR and CSTR}] \end{aligned} \quad 30.25(b)$$

The sludge that must be wasted is reduced by the sludge that escapes in the clarifier effluent, which is ideally zero. The actual sludge solids escaping can be calculated as

$$m_{e,\text{solids}} = Q_e X_e \quad [\text{PFR and CSTR}] \quad 30.26$$

The mean cell residence time given in Eq. 30.5 can be calculated from Eq. 30.27. The sludge wasting rate,  $Q_w$ , can also be found from this equation. In most activated sludge processes, waste sludge is drawn from the sludge recycle line. Therefore,  $Q_w$  is the cell wastage rate from the recycle line, and  $X_r$  is the microorganism concentration in the return sludge line.

$$\begin{aligned} \theta_c &= \frac{V_a X}{Q_w X_r + Q_e X_e} \\ &= \frac{V_a X}{Q_w X_r + (Q_o - Q_w) X_e} \quad [\text{PFR and CSTR}] \end{aligned} \quad 30.27$$

Since the average mass of cells in the effluent,  $X_e$ , is very small, Eq. 30.28 gives the mean cell residence time for sludge wastage from the return line. Centrifuge testing can be used to determine the ratio of  $X/X_r$ . (There is another reason for omitting  $X_e$  from the calculation: It may be too small to measure conveniently.)

$$\theta_c \approx \frac{V_a X}{Q_w X_r} \quad [\text{PFR and CSTR}] \quad 30.28$$

For wastage directly from the aeration basin,  $X_r = X$ . In this case, Eq. 30.29 shows that the process can be controlled by wasting a flow equal to the volume of the aeration tank divided by the mean cell residence time.

$$\theta_c \approx \frac{V_a}{Q_w} \quad [\text{CSTR}] \quad 30.29$$

## 9. ATMOSPHERIC AIR

Atmospheric air is a mixture of oxygen, nitrogen, and small amounts of carbon dioxide, water vapor, argon, and other inert gases. If all constituents except oxygen are grouped with the nitrogen, the air composition is as given in Table 30.5. It is necessary to supply by weight  $1/0.2315 = 4.32$  masses of air to obtain one mass of oxygen. The average molecular weight of air is 28.9.

**Table 30.5** Composition of Air<sup>a</sup>

component	fraction by mass	fraction by volume
oxygen	0.2315	0.209
nitrogen	0.7685	0.791
-----	-----	-----
ratio of nitrogen to oxygen	3.320	3.773 <sup>b</sup>
ratio of air to oxygen	4.320	4.773

<sup>a</sup>Inert gases and CO<sub>2</sub> are included in N<sub>2</sub>.

<sup>b</sup>This value is also reported by various sources as 3.76, 3.78, and 3.784.

## 10. AERATION TANKS

The aeration period is the same as the hydraulic detention time and is calculated without considering recirculation.

$$\theta = \frac{V_a}{Q_o} \quad 30.30$$

The organic (BOD) volumetric loading rate (with units of kg BOD<sub>5</sub>/d·m<sup>3</sup>) for the aeration tank is given by Eq. 30.31. In the United States, volumetric loading is often specified in lbm/day-1000 ft<sup>3</sup>.

$$L_{\text{BOD}} = \frac{S_o Q_o}{V_a \left( 1000 \frac{\text{mg} \cdot \text{m}^3}{\text{kg} \cdot \text{L}} \right)} \quad [\text{SI}] \quad 30.31(a)$$

$$L_{BOD} = \frac{S_{o,mg/L} Q_{o,MGD} \left( 8.345 \frac{\text{lbm-L}}{\text{MG-mg}} \right) (1000)}{V_{a,ft^3}} \quad [\text{U.S.}] \quad 30.31(b)$$

The *rate of oxygen transfer* from the air to the mixed liquor during aeration is given by Eq. 30.32.  $K_t$  is a macroscopic transfer coefficient that depends on the equipment and characteristics of the mixed liquor and that has typical dimensions of 1/time. The dissolved oxygen deficit,  $D$  in mg/L, is given by Eq. 30.33.  $\beta$  is the mixed liquor's *oxygen saturation coefficient*, approximately 0.8 to 0.9.  $\beta$  corrects for the fact that the mixed liquor does not absorb as much oxygen as pure water does. The minimum dissolved oxygen content is approximately 0.5 mg/L, below which the processing would be limited by oxygen. However, a lower limit of 2 mg/L is typically specified.

$$\dot{m}_{\text{oxygen}} = K_t D \quad 30.32$$

$$D = \beta \text{DO}_{\text{saturated water}} - \text{DO}_{\text{mixed liquor}} \quad 30.33$$

The *oxygen demand* is given by Eq. 30.34. The factor 1.42 is the theoretical gravimetric ratio of oxygen required for carbonaceous organic material based on an ideal stoichiometric reaction. Equation 30.34 neglects nitrogenous demand, which can also be significant.

$$\dot{m}_{\text{oxygen,kg/d}} = \frac{Q_{o,m^3/d} (S_o - S)_{\text{mg/L}}}{f \left( 1000 \frac{\text{mg}\cdot\text{m}^3}{\text{kg}\cdot\text{L}} \right)} - 1.42 P_{x,\text{kg/d}} \quad [\text{SI}] \quad 30.34(a)$$

$$\dot{m}_{\text{oxygen,lbm/day}} = \frac{Q_{o,MGD} (S_o - S)_{\text{mg/L}} \left( 8.345 \frac{\text{lbm-L}}{\text{MG-mg}} \right)}{f} - 1.42 P_{x,\text{lbm/day}} \quad [\text{U.S.}] \quad 30.34(b)$$

Air is approximately 23.2% oxygen by mass. Considering a *transfer efficiency* of  $\eta_{\text{transfer}}$  (typically less than 10%), the air requirement is calculated from the oxygen demand.

$$\dot{m}_{\text{air}} = \frac{\dot{m}_{\text{oxygen}}}{0.232 \eta_{\text{transfer}}} \quad 30.35$$

The volume of air required is given by Eq. 30.36. The density of air is approximately 0.075 lbm/ft<sup>3</sup> (1.2 kg/m<sup>3</sup>). Typical volumes for conventional aeration are 500–900 ft<sup>3</sup>/lbm BOD<sub>5</sub> (30–55 m<sup>3</sup>/kg BOD<sub>5</sub>) for F:M ratios greater than 0.3, and 1200–1800 ft<sup>3</sup>/lbm BOD<sub>5</sub> (75–115 m<sup>3</sup>/kg BOD<sub>5</sub>) for F:M ratios less than 0.3 day<sup>-1</sup>. Air flows in SCFM (*standard cubic feet per*

*minute*) are based on a temperature of 70°F (21°C) and pressure of 14.7 psia (101 kPa).

$$\dot{V}_{\text{air}} = \frac{\dot{m}_{\text{air}}}{\rho_{\text{air}}} \quad [\text{PFR and CSTR}] \quad 30.36$$

Aeration equipment should be designed with an excess-capacity safety factor of 1.5–2.0. *Ten States' Standards* requires 200% of calculated capacity for air diffusion systems, which is assumed to be 1500 ft<sup>3</sup>/lbm BOD<sub>5</sub> (94 m<sup>3</sup>/kg BOD<sub>5</sub>) [TSS Sec. 92.332].

The air requirement per unit volume (m<sup>3</sup>/m<sup>3</sup> or ft<sup>3</sup>/MG, calculated using consistent units) is  $V_{\text{air}}/Q_o$ . The air requirement in cubic meters per kilogram of soluble BOD<sub>5</sub> removed is

$$V_{\text{air,m}^3/\text{kg BOD}} = \frac{\dot{V}_{\text{air,m}^3/\text{d}} \left( 1000 \frac{\text{mg}\cdot\text{m}^3}{\text{kg}\cdot\text{L}} \right)}{Q_{o,MGD} (S_o - S)_{\text{mg/L}}} \quad [\text{SI}] \quad 30.37(a)$$

$$V_{\text{air,ft}^3/\text{lbm BOD}} = \frac{\dot{V}_{\text{air,ft}^3/\text{day}}}{Q_{o,MGD} (S_o - S)_{\text{mg/L}} \left( 8.345 \frac{\text{lbm-L}}{\text{MG-mg}} \right)} \quad [\text{U.S.}] \quad 30.37(b)$$

### Example 30.1

Mixed liquor ( $\beta = 0.9$ , DO = 3 mg/L) is aerated at 20°C. The transfer coefficient,  $K_t$ , is 2.7 h<sup>-1</sup>. What is the rate of oxygen transfer?

*Solution*

At 20°C, the saturated oxygen content of pure water is 9.2 mg/L. The oxygen deficit is found from Eq. 30.33.

$$\begin{aligned} D &= \beta \text{DO}_{\text{saturated water}} - \text{DO}_{\text{mixed liquor}} \\ &= (0.9) \left( 9.17 \frac{\text{mg}}{\text{L}} \right) - 3 \frac{\text{mg}}{\text{L}} \\ &= 5.25 \text{ mg/L} \end{aligned}$$

The rate of oxygen transfer is found from Eq. 30.32.

$$\begin{aligned} \dot{m} &= K_t D = (2.7 \text{ h}^{-1}) \left( 5.25 \frac{\text{mg}}{\text{L}} \right) \\ &= 14.18 \text{ mg/L}\cdot\text{h} \end{aligned}$$

## 11. AERATION POWER AND COST

The work required to compress a unit mass of air from atmospheric pressure to the discharge pressure depends on the nature of the compression. Various assumptions can be made, but generally an *isentropic compression* is assumed. Inefficiencies (thermodynamic and mechanical) are combined into a single *compressor efficiency*,  $\eta_c$ , which is essentially an *isentropic efficiency* for the compression process.

The ideal power,  $P$ , to compress a volumetric flow rate,  $\dot{V}$ , or mass flow rate,  $\dot{m}$ , of air from pressure  $p_1$  to pressure  $p_2$  in an isentropic steady-flow compression process is given by Eq. 30.38.  $k$  is the ratio of specific heats, which has an approximate value of 1.4.  $c_p$  is the specific heat at constant pressure, which has a value of 0.24 Btu/lbm·°R (1005 J/kg·K).  $R_{\text{air}}$  is the specific gas constant, 53.3 ft-lbf/lbm·°R (287 J/kg·K). In Eq. 30.38, temperatures must be absolute. Volumetric and mass flow rates are per second.

$$\begin{aligned} P_{\text{ideal,kW}} &= - \left( \frac{k p_1 \dot{V}_1}{(k-1) \left( 1000 \frac{W}{kW} \right)} \right) \left( 1 - \left( \frac{p_2}{p_1} \right)^{(k-1)/k} \right) \\ &= - \left( \frac{k \dot{m} R_{\text{air}} T_1}{(k-1) \left( 1000 \frac{W}{kW} \right)} \right) \left( 1 - \left( \frac{p_2}{p_1} \right)^{(k-1)/k} \right) \\ &= - \left( \frac{c_p \dot{m} T_1}{1000 \frac{W}{kW}} \right) \left( 1 - \left( \frac{p_2}{p_1} \right)^{(k-1)/k} \right) \end{aligned} \quad [\text{SI}] \quad 30.38(a)$$

$$\begin{aligned} P_{\text{ideal,hp}} &= - \left( \frac{k p_1 \dot{V}_1}{(k-1) \left( 550 \frac{\text{ft-lbf}}{\text{hp-sec}} \right)} \right) \left( 1 - \left( \frac{p_2}{p_1} \right)^{(k-1)/k} \right) \\ &= - \left( \frac{k \dot{m} R_{\text{air}} T_1}{(k-1) \left( 550 \frac{\text{ft-lbf}}{\text{hp-sec}} \right)} \right) \left( 1 - \left( \frac{p_2}{p_1} \right)^{(k-1)/k} \right) \\ &= - \left( \frac{c_p J \dot{m} T_1}{550 \frac{\text{ft-lbf}}{\text{hp-sec}}} \right) \left( 1 - \left( \frac{p_2}{p_1} \right)^{(k-1)/k} \right) \end{aligned} \quad [\text{U.S.}] \quad 30.38(b)$$

The actual compression power is

$$P_{\text{actual}} = \frac{P_{\text{ideal}}}{\eta_c} \quad 30.39$$

The cost of running the compressor for a duration,  $t$ , is

$$\text{total cost} = C_{\text{kW-hr}} P_{\text{actual}} t \quad 30.40$$

## 12. RECYCLE RATIO AND RECIRCULATION RATE

For any given wastewater and treatment facility, the influent flow rate, BOD, and tank volume cannot be changed. Of all the variables appearing in Eq. 30.3, only

the suspended solids can be controlled. Therefore, the primary process control variable is the amount of organic material in the wastewater. This is controlled by the sludge return rate. Equation 30.41 gives the sludge *recycle ratio*,  $R$ , which is typically 0.20–0.30. (Some authorities use the symbol  $\alpha$  to represent the recycle ratio.)

$$R = \frac{Q_r}{Q_o} \quad 30.41$$

The actual *recirculation rate* can be found by writing a suspended solids mass balance around the inlet to the reactor and solving for the recirculation rate,  $Q_r$ , noting  $X_o = 0$ .

$$X_o Q_o + X_r Q_r = X(Q_o + Q_r) \quad 30.42$$

$$\frac{Q_r}{Q_o + Q_r} = \frac{X}{X_r} \quad 30.43$$

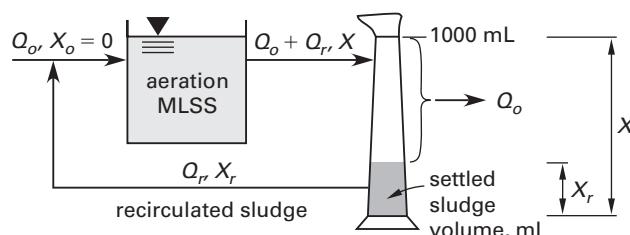

The theoretical required return rate for the current MLSS content can be calculated from the *sludge volume index* (SVI; see Sec. 30.5). Figure 30.5 shows the theoretical relationship between the SVI test and the return rate. Equation 30.44 assumes that the settling tank responds identically to the graduated 1000 mL cylinder used in the SVI test. Equation 30.43 and Eq. 30.44 are analogous.

$$\frac{Q_r}{Q_o + Q_r} = \frac{V_{\text{settled,mL/L}}}{1000 \frac{\text{mL}}{\text{L}}} \quad 30.44$$

$$\begin{aligned} R &= \frac{V_{\text{settled,mL/L}}}{1000 \frac{\text{mL}}{\text{L}} - V_{\text{settled,mL/L}}} \\ &= \frac{1}{\frac{10^6}{(\text{SVI}_{\text{mL/g}})(\text{MLSS}_{\text{mg/L}})} - 1} \end{aligned} \quad 30.45$$

Equation 30.45 is based on settling and represents a theoretical value, but it does not necessarily correspond to the actual recirculation rate. Greater-than-necessary recirculation returns clarified liquid unnecessarily, and less recirculation leaves settled solids in the clarifier.

**Figure 30.5** Theoretical Relationship Between SVI Test and Return Rate

**Example 30.2**

Two 1 L samples of mixed liquor are taken from an aerating lagoon. After settling for 30 min in a graduated cylinder, 250 mL of solids have settled out in the first sample. The total suspended solids concentration in the second sample is found to be 2300 mg/L. (a) What is the sludge volume index? (b) What is the theoretical required sludge recycle rate?

*Solution*

(a) Use Eq. 30.7.

$$\begin{aligned} \text{SVI} &= \frac{\left(1000 \frac{\text{mg}}{\text{g}}\right) V_{\text{settled,mL/L}}}{\text{MLSS}_{\text{mg/L}}} \\ &= \frac{\left(1000 \frac{\text{mg}}{\text{g}}\right) (250 \frac{\text{mL}}{\text{L}})}{2300 \frac{\text{mg}}{\text{L}}} \\ &= 109 \text{ mL/g} \end{aligned}$$

(b) The theoretical required recycle rate is given by Eq. 30.45.

$$\begin{aligned} R &= \frac{V_{\text{settled,mL/L}}}{1000 \frac{\text{mL}}{\text{L}} - V_{\text{settled,mL/L}}} \\ &= \frac{250 \frac{\text{mL}}{\text{L}}}{1000 \frac{\text{mL}}{\text{L}} - 250 \frac{\text{mL}}{\text{L}}} \\ &= 0.33 \end{aligned}$$

**Example 30.3**

An activated sludge plant receives 4.0 MGD of wastewater with a BOD of 200 mg/L. The primary clarifier removes 30% of the BOD. The aeration-settle-waste cycle takes 6 hr. The oxygen transfer efficiency is 6%, and one pound of oxygen is required for each pound of BOD oxidized. The food-to-microorganism ratio based on MLSS is 0.33. The SVI is 100. 30% of the MLSS is wasted each day from the aeration tank. The MLVSS/MLSS ratio is 0.7. The surface settling rate of the secondary clarifier is 800 gal/day-ft<sup>2</sup>. The overflow rate in the secondary clarifier is 800 gal/day-ft<sup>2</sup>. The final effluent has a BOD of 10 mg/L.

Calculate the (a) secondary BOD removal fraction, (b) aeration tank volume, (c) MLSS, (d) total suspended solids content in the recirculated sludge, (e) theoretical recirculation rate, (f) mass of MLSS wasted each day, (g) clarifier surface area, and (h) volumetric air requirements.

*Solution*

(a) Wastewater leaves primary settling with a BOD of  $(1 - 0.3)(200 \text{ mg/L}) = 140 \text{ mg/L}$ . The efficiency of the activated sludge processing is

$$\begin{aligned} \eta_{\text{BOD}} &= \frac{140 \frac{\text{mg}}{\text{L}} - 10 \frac{\text{mg}}{\text{L}}}{140 \frac{\text{mg}}{\text{L}}} \\ &= 0.929 \quad (92.9\%) \end{aligned}$$

(b) The aeration tank volume is

$$\begin{aligned} V_a &= Q_o t = \frac{(4 \text{ MGD}) \left(10^6 \frac{\text{gal}}{\text{MG}}\right) (6 \text{ hr})}{\left(24 \frac{\text{hr}}{\text{day}}\right) \left(7.48 \frac{\text{gal}}{\text{ft}^3}\right)} \\ &= 1.34 \times 10^5 \text{ ft}^3 \end{aligned}$$

(c) The total MLSS can be determined from the food-to-microorganism ratio given. Use Eq. 30.4.

$$\begin{aligned} \text{MLSS} &= \frac{S_o Q_o}{(\text{F:M}) V_a} \\ &= \frac{\left(140 \frac{\text{mg}}{\text{L}}\right) (4 \text{ MGD}) \left(10^6 \frac{\text{gal}}{\text{MG}}\right)}{\left(0.33 \frac{\text{lbm}}{\text{lbm-day}}\right) (1.34 \times 10^5 \text{ ft}^3) \left(7.48 \frac{\text{gal}}{\text{ft}^3}\right)} \\ &= 1693 \text{ mg/L} \end{aligned}$$

(d) The suspended solids content in the recirculated sludge is given by Eq. 30.9.

$$\begin{aligned} \text{TSS}_{\text{mg/L}} &= \frac{\left(1000 \frac{\text{mg}}{\text{g}}\right) \left(1000 \frac{\text{mL}}{\text{L}}\right)}{\text{SVI}_{\text{mL/g}}} \\ &= \frac{\left(1000 \frac{\text{mg}}{\text{g}}\right) \left(1000 \frac{\text{mL}}{\text{L}}\right)}{100 \frac{\text{mL}}{\text{g}}} \\ &= 10,000 \text{ mg/L} \end{aligned}$$

(e) The recirculation ratio can be calculated from the SVI test. However, the settled volume must first be calculated.

Use Eq. 30.7.

$$\begin{aligned} V_{\text{settled,mL/L}} &= \frac{\text{MLSS}_{\text{mg/L}} \text{SVI}_{\text{mL/g}}}{1000 \frac{\text{mg}}{\text{g}}} \\ &= \frac{(1693 \frac{\text{mg}}{\text{L}})(100 \frac{\text{mL}}{\text{g}})}{1000 \frac{\text{mg}}{\text{g}}} \\ &= 169.3 \text{ mL/L} \end{aligned}$$

Use Eq. 30.44.

$$\begin{aligned} R &= \frac{V_{\text{settled,mL/L}}}{1000 \frac{\text{mL}}{\text{L}} - V_{\text{settled,mL/L}}} \\ &= \frac{169.3 \frac{\text{mL}}{\text{L}}}{1000 \frac{\text{mL}}{\text{L}} - 169.3 \frac{\text{mL}}{\text{L}}} \\ &= 0.204 \end{aligned}$$

The recirculation rate is given by Eq. 30.41.

$$Q_r = RQ_o = (0.204)(4 \text{ MGD}) = 0.816 \text{ MGD}$$

(f) The sludge wasted is

$$\begin{aligned} (0.30)(4 \text{ MGD})(1693 \frac{\text{mg}}{\text{L}})(8.345 \frac{\text{lbm-L}}{\text{mg-MG}}) \\ = 16,954 \text{ lbm/day} \end{aligned}$$

(g) The recirculated flow is removed by the bottom drain, so it does not influence the surface area. The clarifier surface area is

$$\begin{aligned} A &= \frac{Q_o}{v^*} \\ &= \frac{(4 \text{ MGD})(10^6 \frac{\text{gal}}{\text{MG}})}{800 \frac{\text{gal}}{\text{day-ft}^2}} \\ &= 5000 \text{ ft}^2 \end{aligned}$$

(h) From part (a), the fraction of BOD reduction in the activated sludge process aeration (exclusive of the wasted sludge) is 0.929.

Since one pound of oxygen is required for each pound of BOD removed, the required oxygen mass is

$$\begin{aligned} m_{\text{oxygen}} &= (0.929)(4 \text{ MGD})(140 \frac{\text{mg}}{\text{L}})(8.345 \frac{\text{lbm-L}}{\text{mg-MG}}) \\ &= 4341 \text{ lbm/day} \end{aligned}$$

The density of air is approximately 0.075 lbm/ft<sup>3</sup>, and air is 20.9% oxygen by volume. Considering the efficiency of the oxygenation process, the air required is

$$\begin{aligned} \dot{V}_{\text{air}} &= \frac{4341 \frac{\text{lbm}}{\text{day}}}{(0.209)(0.06)\left(0.075 \frac{\text{lbm}}{\text{ft}^3}\right)} \\ &= 4.62 \times 10^6 \text{ ft}^3/\text{day} \end{aligned}$$

### 13. SLUDGE WASTING

The activated sludge process is a biological process. Influent brings in BOD ("biomass" or organic food), and the return activated sludge (RAS) brings in micro-organisms (bacteria) to digest the BOD. The food-to-microorganism ratio (F:M) is balanced by adjusting the aeration and how much sludge is recirculated and how much is wasted. As the microorganisms grow and are mixed with air, they clump together (flocculate) and are readily settled as sludge in the secondary clarifier. More sludge is produced in the secondary clarifier than is needed, and without wasting, the sludge would continue to build up.

*Sludge wasting* is the main control of the effluent quality and microorganism population size. The wasting rate affects the mixed liquor suspended solids (MLSS) concentration and the mean cell residence time. Excess sludge may be wasted either from the sludge return line or directly from the aeration tank as mixed liquor. Wasting from the aeration tank is preferred as the sludge concentration is fairly steady in that case. The wasted volume is normally 40% to 60% of the wastewater flow. When wasting is properly adjusted, the MLSS level will remain steady. With an excessive F:M ratio, sludge production will increase, and eventually, sludge will appear in the clarifier effluent.

### 14. OPERATIONAL DIFFICULTIES

*Sludge bulking* refers to a condition in which the sludge does not settle out. Since the solids do not settle, they leave the sedimentation tank and cause problems in subsequent processes. The sludge volume index can often (but not always) be used as a measure of settling characteristics. If the SVI is less than 100, the settling process is probably operating satisfactorily. If SVI is greater than 150, the sludge is bulking. Remedies include addition of lime, chlorination, additional aeration, and a reduction in MLSS.

Some sludge may float back to the surface after settling, a condition known as *rising sludge*. Rising sludge occurs when nitrogen gas is produced from denitrification of the nitrates and nitrites. Remedies include increasing the return sludge rate and decreasing the mean cell residence time. Increasing the speed of the sludge scraper mechanism to dislodge nitrogen bubbles may also help.

It is generally held that after 30 min of settling, the sludge should settle to between 20% and 70% of its original volume. If it occupies more than 70%, there are too many solids in the aeration basin, and more sludge should be wasted. If the sludge occupies less than 20%, less sludge should be wasted.

*Sludge washout (solids washout)* can occur during a period of peak flow or even with excess recirculation. Washout is the loss of solids from the sludge blanket in the settling tank. This often happens with insufficient wasting, such that solids build up (to more than 70% in a settling test), hinder settling in the clarifier, and cannot be contained.

## 15. QUANTITIES OF SLUDGE

The procedure for determining the volume and mass of sludge from activated sludge processing is essentially the same as for sludge from sedimentation and any other processes. Table 30.6 gives characteristics of sludge. The primary variables, other than mass and volume, are density and/or specific gravity.

$$m_{\text{wet}} = V \rho_{\text{sludge}} = V (\text{SG}_{\text{sludge}}) \rho_{\text{water}} \quad 30.46$$

Raw sludge is approximately 95–99% water, and the specific gravity of sludge is only slightly greater than 1.0. The actual specific gravity of sludge can be calculated from the fractional solids content,  $s$ , and specific gravity of the sludge solids, which is approximately 2.5. (If the sludge specific gravity is already known, Eq. 30.47 can be solved for the specific gravity of the solids.) In Eq. 30.47,  $1 - s$  is the fraction of the sludge that is water.

$$\begin{aligned} \frac{1}{\text{SG}_{\text{sludge}}} &= \frac{1 - s}{1} + \frac{s}{\text{SG}_{\text{solids}}} \\ &= \frac{1 - s_{\text{fixed}} - s_{\text{volatile}}}{1} + \frac{s_{\text{fixed}}}{\text{SG}_{\text{fixed solids}}} \\ &\quad + \frac{s_{\text{volatile}}}{\text{SG}_{\text{volatile solids}}} \end{aligned} \quad 30.47$$

The volume of sludge can be estimated from its dried mass. Since the sludge specific gravity is approximately 1.0, the sludge volume is

$$V_{\text{sludge,wet}} = \frac{m_{\text{dried}}}{s \rho_{\text{sludge}}} \approx \frac{m_{\text{dried}}}{s \rho_{\text{water}}} \quad 30.48$$

The dried mass of sludge solids from primary settling basins is easily determined from the decrease in solids. The decrease in suspended solids,  $\Delta\text{SS}$ , due to primary settling is approximately 50% of the total incoming suspended solids.

$$m_{\text{dried,kg/d}} = \frac{(\Delta\text{SS})_{\text{mg/L}} Q_{o,\text{m}^3/\text{d}}}{1000 \frac{\text{mg}\cdot\text{m}^3}{\text{kg}\cdot\text{L}}} \quad [\text{SI}] \quad 30.49(a)$$

$$m_{\text{dried,lbm/day}} = (\Delta\text{SS})_{\text{mg/L}} Q_{o,\text{MGD}} \left( 8.345 \frac{\text{lrbm-L}}{\text{MG-mg}} \right) \quad [\text{U.S.}] \quad 30.49(b)$$

The dried mass of solids for biological filters and secondary aeration (e.g., activated sludge) can be estimated on a macroscopic basis as a fraction of the change in BOD. In Eq. 30.50,  $K$  is the *cell yield*, also known as the *removal efficiency*, the fraction of the total influent BOD that ultimately appears as excess (i.e., settled) biological solids. The cell yield can be estimated from the food-to-microorganism ratio from Fig. 30.6. (The cell yield,  $K$ , and the *yield coefficient*, also known as the *sludge yield* or *biomass yield*,  $Y_{\text{obs}}$ , are not the same, because  $K$  is based on total incoming BOD and  $Y_{\text{obs,lbm/day}}$  is based on consumed BOD. The term “cell yield” is often used for both  $Y_{\text{obs}}$  and  $K$ .)

$$\begin{aligned} m_{\text{dried,kg/d}} &= \frac{K S_{o,\text{mg/L}} Q_{o,\text{m}^3/\text{d}}}{1000 \frac{\text{mg}\cdot\text{m}^3}{\text{kg}\cdot\text{L}}} \\ &= \frac{Y_{\text{obs}} (S_o - S)_{\text{mg/L}} Q_{o,\text{m}^3/\text{d}}}{1000 \frac{\text{mg}\cdot\text{m}^3}{\text{kg}\cdot\text{L}}} \end{aligned} \quad [\text{SI}] \quad 30.50(a)$$

$$\begin{aligned} m_{\text{dried,lbm/day}} &= K S_{o,\text{mg/L}} Q_{o,\text{MGD}} \left( 8.345 \frac{\text{lrbm-L}}{\text{MG-mg}} \right) \\ &= Y_{\text{obs}} (S_o - S)_{\text{mg/L}} Q_{o,\text{MGD}} \\ &\quad \times \left( 8.345 \frac{\text{lrbm-L}}{\text{MG-mg}} \right) \end{aligned} \quad [\text{U.S.}] \quad 30.50(b)$$

**Table 30.6** Characteristics of Sludge

origin of sludge	fraction solids, $s$	dry mass (lbm/day-person)
primary settling tank	0.06–0.08	0.12
trickling filter	0.04–0.06	0.04
mixed primary settling and trickling filter	0.05	0.16
conventional activated sludge	0.005–0.01	0.07
mixed primary and conventional activated sludge	0.02–0.03	0.19
high-rate activated sludge	0.025–0.05	0.06
mixed primary settling and high-rate activated sludge	0.05	0.18
extended aeration activated sludge	0.02	0.02
filter backwashing water	0.01–0.1	n.a.
softening sludge	0.03–0.15	n.a.

(Multiply lbm/day-person by 0.45 to obtain kg/d-person.)

**Example 30.4**

A trickling filter plant processes 4 MGD of domestic wastewater with 190 mg/L BOD and 230 mg/L suspended solids. The primary sedimentation tank removes 50% of the suspended solids and 30% of the BOD. The sludge yield for the trickling filter is 0.25. What is the total sludge volume from the primary sedimentation tank and trickling filter if the combined solids content of the sludge is 5%?

*Solution*

The mass of solids removed in primary settling is given by Eq. 30.49.

$$\begin{aligned} m_{\text{dried}} &= (\Delta S)_{\text{mg/L}} Q_{o,\text{MGD}} \left( 8.345 \frac{\text{lbm-L}}{\text{MG-mg}} \right) \\ &= (0.5) \left( 230 \frac{\text{mg}}{\text{L}} \right) (4 \text{ MGD}) \left( 8.345 \frac{\text{lbm-L}}{\text{MG-mg}} \right) \\ &= 3839 \text{ lbm/day} \end{aligned}$$

The mass of solids removed from the trickling filter's clarifier is calculated from Eq. 30.50.

$$\begin{aligned} m_{\text{dried}} &= K \Delta S_{\text{mg/L}} Q_{o,\text{MGD}} \left( 8.345 \frac{\text{lbm-L}}{\text{MG-mg}} \right) \\ &= (0.25)(1 - 0.3) \left( 190 \frac{\text{mg}}{\text{L}} \right) (4 \text{ MGD}) \\ &\quad \times \left( 8.345 \frac{\text{lbm-L}}{\text{MG-mg}} \right) \\ &= 1110 \text{ lbm/day} \end{aligned}$$

The volume is calculated from Eq. 30.48.

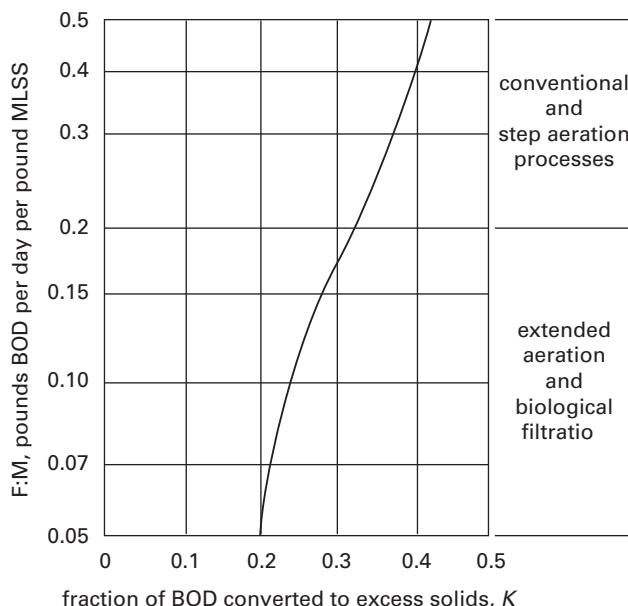

$$\begin{aligned} V &= \frac{m_{\text{dried}}}{s \rho_{\text{water}}} \\ &= \frac{3839 \frac{\text{lbm}}{\text{day}} + 1110 \frac{\text{lbm}}{\text{day}}}{(0.05) \left( 62.4 \frac{\text{lbm}}{\text{ft}^3} \right)} \\ &= 1586 \text{ ft}^3/\text{day} \end{aligned}$$

**16. SLUDGE THICKENING**

Waste-activated sludge (WAS) has a typical solids content of 0.5–1.0%. *Thickening* of sludge is used to reduce the volume of sludge prior to digestion or dewatering. Thickening is accomplished by decreasing the liquid fraction ( $1 - s$ ), thus increasing the solids fraction,  $s$ . Equation 30.48 shows that the volume of wet sludge is inversely proportional to its solids content.

For dewatering, thickening to at least 4% solids (i.e., 96% moisture) is required; for digestion, thickening to at least 5% solids is required. Depending on the nature of the sludge, polymers may be used with all of the thickening methods. Other chemicals (e.g., lime for

**Figure 30.6** Approximate Food:Microorganism Ratio Versus Cell Yield,\*  $K$

\*calculated assuming an effluent BOD of approximately 30 mg/L

Hammer, Mark J., *Water and Wastewater Technology*, 3rd, © 1996. Printed and electronically reproduced by permission of Pearson Education, Inc., New York, New York.

stabilization through pH control and potassium permanganate to react with sulfides) can also be used. However, because of cost and increased disposal problems, the trend is toward the use of fewer inorganic chemicals with new thickening or dewatering applications unless special conditions apply.

*Gravity thickening* occurs in circular sedimentation tanks similar to primary and secondary clarifiers. The settling process is categorized into four zones: the *clarification zone*, containing relatively clear *supernatant*; the *hindered settling zone*, where the solids move downward at essentially a constant rate; the *transition zone*, characterized by a decrease in solids settling rate; and the *compression zone*, where motion is essentially zero.

In *batch gravity thickening*, the tank is filled with thin sludge and allowed to stand. Supernatant is decanted, and the tank is topped off with more thin sludge. The operation is repeated continually or a number of times before the underflow sludge is removed. A heavy-duty (deep-truss) scraper mechanism pushes the settled solids into a hopper in the tank bottom, and the clarified effluent is removed in a peripheral weir. A doubling of solids content is usually possible with gravity thickening. Table 30.7 contains typical characteristics of gravity thickening tanks.

With *dissolved air flotation (DAF) thickening* (DAFT), fine air bubbles are released into the sludge as it enters the DAF tank. The solids particles adhere to the air bubbles and float to the surface where they are skimmed away as scum. The scum has a solids content of

**Table 30.7** Typical Characteristics of Gravity Thickening Tanks

(Multiply gal/day-ft<sup>2</sup> by 0.0407 to obtain m<sup>3</sup>/d·m<sup>2</sup>.)(Multiply lbm/day-ft<sup>2</sup> by 4.882 to obtain kg/d·m<sup>2</sup>.)\*(Multiply ft by 0.3048 to obtain m.)  
unless alternative methods of thickening are available

approximately 4%. Up to 85% of the total solids may be recovered in this manner, and chemical flocculants (e.g., polymers) can increase the recovery to 97%–99%.

With *gravity belt thickening* (GBT), sludge is spread over a drainage belt. Multiple stationary plows in the path of the moving belt may be used to split, turn, and recombine the sludge so that water does not pool on top of the sludge. After thickening, the sludge cake is removed from the belt by a doctor blade.

Gravity thickening is usually best for sludges from primary and secondary settling tanks, while dissolved air flotation and centrifugal thickening are better suited for activated sludge. The current trend is toward using gravity thickening for primary sludge and flotation thickening for activated sludge, then blending the thickened sludge for further processing.

Not all of the solids in sludge are captured in thickening processes. Some sludge solids escape with the liquid portion. Table 30.8 lists typical solids capture fractions.

## 17. SLUDGE STABILIZATION

Raw sludge is too bulky, odorous, and putrescible to be dewatered easily or disposed of by land spreading. Such sludge can be “stabilized” through chemical addition or by digestion prior to dewatering and landfilling. (Sludge that is incinerated does not need to be stabilized.) Stabilization converts the sludge to a stable, inert form that is essentially free from odors and pathogens.

Sludge can be stabilized chemically by adding lime dust to raise the pH. A rule of thumb is that adding enough lime to raise the pH to 12 for at least 2 hr will inhibit or kill bacteria and pathogens in the sludge. Kiln and cement dust is also used in this manner.

Alternatively, ammonia compounds can be added to the sludge prior to land spreading. This has the additional advantage of producing a sludge with high plant nutrient value.

## 18. AEROBIC DIGESTION

Aerobic digestion occurs in an open holding tank digester and is preferable for stabilized primary and combined primary-secondary sludges. Up to 70% (typically 40–50%) of the volatile solids can be removed in an aerobic digester. Mechanical aerators are used in a manner similar to aerated lagoons. Construction details of aerobic digesters are similar to those of aerated lagoons.

## 19. ANAEROBIC DIGESTION

*Anaerobic digestion* occurs in the absence of oxygen. Anaerobic digestion is more complex and more easily upset than aerobic digestion. However, it has a lower operating cost. Table 30.9 gives typical characteristics of aerobic digesters.

Three types of anaerobic bacteria are involved. The first type converts organic compounds into simple fatty or amino acids. The second group of *acid-formed bacteria* converts these compounds into simple organic acids, such as acetic acid. The third group of *acid-splitting bacteria* converts the organic acids to methane, carbon dioxide, and some hydrogen sulfide. The third phase takes the longest time and sets the rate and loadings. The pH should be 6.7–7.8, and temperature should be in the mesophilic range of 85–100°F (29–38°C) for the methane-producing bacteria to be effective. Sufficient alkalinity must be added to buffer acid production.

**Table 30.8** Typical Thickening Solids Fraction and Capture Efficiencies

(Multiply ft by 0.3048 to obtain m.)

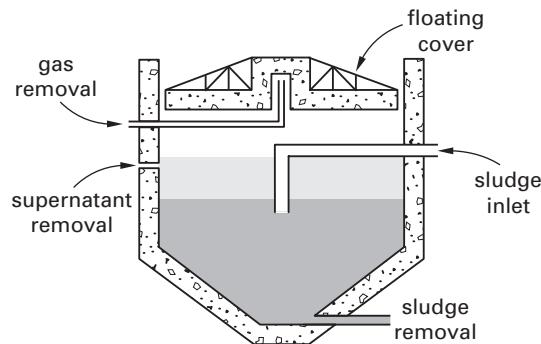

A simple single-stage sludge digestion tank consists of an inlet pipe, outlet pipes for removing both the digested sludge and the clear supernatant liquid, a dome, an outlet pipe for collecting and removing the digester gas, and a series of heating coils for circulating hot water. (See Fig. 30.7.)

In a single-stage, floating-cover digester, sludge is brought into the tank at the top. The contents of the digester stratify into four layers: scum on top, clear supernatant, a layer of actively digesting sludge, and a bottom layer of concentrated sludge. Some of the contents may be withdrawn, heated, and returned in order to maintain a proper digestion temperature.

Supernatant is removed along the periphery of the digester and returned to the input of the processing plant. Digested sludge is removed from the bottom and dewatered prior to disposal. Digester gas is removed from the gas dome. Heat from burning the methane can be used to warm the sludge that is withdrawn or to warm raw sludge prior to entry.

A reasonable loading and well-mixed digester can produce a well-stabilized sludge in 15 days. With poorer mixing, 30–60 days may be required.

A single-stage digester performs the functions of digestion, gravity thickening, and storage in one tank. In a

**Figure 30.7** Simple Anaerobic Digester

two-stage process, two digesters in series are used. Heating and mechanical mixing occur in the first digester. Since the sludge is continually mixed, it will not settle. Settling and further digestion occur in the unheated second tank.

Germany began experimenting with large spherical and egg-shaped digesters in the 1950s. These and similar designs are experiencing popularity in the United States. Volumes are on the order of 100,000–400,000 ft<sup>3</sup> (3000–12,000 m<sup>3</sup>), and digesters can be constructed from either prestressed concrete or steel. Compared with conventional cylindrical digesters, the egg-shaped units minimize problems associated with the accumulation of solids in the lower corners and collection of foam and scum on the upper surfaces. The shape also promotes better mixing that enhances digestion. However, variations in the shape greatly affect grit collection and required mixing power. Mixing can be accomplished with uncombined gas mixing, mechanical mixing using an impeller and draft-tube, and pumped recirculation. Typical volatile suspended solids loading rates are 0.062–0.17 lbm VSS/ft<sup>3</sup>·day (1–2.8 kg VSS/m<sup>3</sup>·d) with a 15–25 day retention time. Operational problems include grit accumulation, gas leakage, and foaming.

## 20. METHANE PRODUCTION

Wastes that contain biologically degradable organics and are free of substances that are toxic to microorganisms (e.g., acids) will be biodegraded. Methane gas is a product of anaerobic degradation. Under anaerobic conditions, degradation of organic wastes yields methane. Inorganic wastes are not candidates for biological treatment and do not produce methane.

The theoretical volume of methane produced from sludge digestion is 5.61 ft<sup>3</sup> (0.35 m<sup>3</sup>) per pound (per kilogram) of BOD converted. Wasted sludge does not contribute to methane production, and the theoretical amount is reduced by various inefficiencies. Therefore, the actual volume of methane produced is predicted by Eq. 30.51. The total volume of digester gas is larger than the methane volume alone since methane constitutes about  $\frac{2}{3}$  of the total volume.  $E$  is the efficiency of waste

utilization, typically 0.6–0.9.  $S_o$  is the ultimate BOD of the influent.  $ES_o$  can be replaced with  $S_o - S$ , as the two terms are equivalent.

$$V_{\text{methane,m}^3/\text{d}} = \left( 0.35 \frac{\text{m}^3}{\text{kg}} \right) \left( \frac{ES_{o,\text{mg/L}} Q_{\text{m}^3/\text{d}}}{1000 \frac{\text{g}}{\text{kg}}} - 1.42 P_{x,\text{kg/d}} \right) \quad [\text{SI}] \quad 30.51(a)$$

$$V_{\text{methane,ft}^3/\text{day}} = \left( 5.61 \frac{\text{ft}^3}{\text{lbm}} \right) \left( \frac{ES_{o,\text{mg/L}} Q_{\text{MGD}}}{\times \left( 8.345 \frac{\text{lbm-L}}{\text{MG-mg}} \right)} - 1.42 P_{x,\text{lbm/day}} \right) \quad [\text{U.S.}] \quad 30.51(b)$$

The heating value of digester gas listed in Table 30.10 is approximately 600 Btu/ft<sup>3</sup> (22 MJ/m<sup>3</sup>). This value is appropriate for digester gas with the composition given: 65% methane and 35% carbon dioxide by volume. Carbon dioxide is not combustible and does not contribute to the heating effect. The actual heating value will depend on the volumetric fraction of methane. The temperature and pressure also affect the gas volume. At 60°F (15.6°C) and 1 atm, the pure methane has a lower heating value, LHV, of 913 Btu/ft<sup>3</sup> (34.0 MJ/m<sup>3</sup>). The higher heating value of 1013 Btu/ft<sup>3</sup> (37.7 MJ/m<sup>3</sup>) should not normally be used, as the water vapor produced during combustion is not allowed to condense out.

The total heating energy is

$$q = (\text{LHV})V_{\text{fuel}} \quad 30.52$$

## 21. HEAT TRANSFER AND LOSS

In an adiabatic reactor, energy is required only to heat the influent sludge to the reactor temperature. In a nonadiabatic reactor, energy will also be required to replace energy lost to the environment through heat transfer from the exposed surfaces.

The energy required to increase the temperature of sludge from  $T_1$  to  $T_2$  is given by Eq. 30.53. The specific heat,  $c_p$ , of sludge is assumed to be the same as for water, 1.0 Btu/lbm·°F (4190 J/kg·°C).

$$\begin{aligned} q &= m_{\text{sludge}} c_p (T_2 - T_1) \\ &= V_{\text{sludge}} \rho_{\text{sludge}} c_p (T_2 - T_1) \end{aligned} \quad 30.53$$

The energy lost from a heated digester can be calculated in several ways. If the surface temperature is known, the convective heat lost from a heated surface to the surrounding air depends on the convective outside film coefficient,  $h$ . The film coefficient depends on the surface temperature, air temperature, orientation, and prevailing wind. Heat losses from digester sides,

top, and other surfaces must be calculated separately and combined.

$$q = hA_{\text{surface}} (T_{\text{surface}} - T_{\text{air}}) \quad 30.54$$

If the temperature of the digester contents is known, it can be used with the *overall coefficient of heat transfer*,  $U$  (a combination of inside and outside film coefficients), as well as the conductive resistance of the digester walls to calculate the heat loss.

$$q = UA_{\text{surface}} (T_{\text{contents}} - T_{\text{air}}) \quad 30.55$$

If the temperatures of the inner and outer surfaces of the digester walls are known, the energy loss can be calculated as a conductive loss.  $k$  is the average thermal conductivity of the digester wall, and  $L$  is the wall thickness.

$$q = \frac{kA(T_{\text{inner}} - T_{\text{outer}})}{L} \quad 30.56$$

**Table 30.10** Typical Characteristics of Single-Stage Heated Anaerobic Digesters

(Multiply ft by 0.3048 to obtain m.)	

## 22. SLUDGE DEWATERING

Once sludge has been thickened, it can be digested or dewatered prior to disposal. At water contents of 75%, sludge can be handled with shovel and spade, and is known as *sludge cake*. A 50% moisture content represents the general lower limit for conventional drying methods. Several methods of dewatering are available, including vacuum filtration, pressure filtration, centrifugation, sand and gravel drying beds, and lagooning.

Generally, vacuum filtration and centrifugation are used with undigested sludge. A common form of vacuum filtration occurs in a *vacuum drum filter*. A hollow drum covered with filter cloth is partially immersed in a vat of sludge. The drum turns at about 1 rpm. Suction is applied from within the drum to attract sludge to the filter surface and to extract moisture. The sludge cake is dewatered to about 75–80% moisture content (solids content of 20–25%) and is then scraped off the belt by a blade or delaminated by a sharp bend in the belt material. This degree of dewatering is sufficient for sanitary landfill. A higher solids content of 30–33% is needed, however, for direct incineration unless external fuel is provided. Chemical flocculants (e.g., polymers or ferric chloride, with or without lime) may be used to collect finer particles on the filter drum. Performance is measured in terms of the amount of dry solids removed per unit area. A typical performance is 3.5 lbm/hr-ft<sup>2</sup> (17 kg/h·m<sup>2</sup>).

*Belt filter presses* accept a continuous feed of conditioned sludge and use a combination of gravity drainage and mechanically applied pressure. Sludge is applied to a continuous-loop woven belt (cotton, wool, nylon, polyester, woven stainless steel, etc.) where the sludge begins to drain by gravity. As the belt continues on, the sludge is compressed under the action of one or more rollers. Belt presses typically have belt widths of 80–140 in (2.0–3.5 m) and are loaded at the rate of 60–450 lbm/ft-hr (90–680 kg/m·h). Moisture content of the cake is typically 70–80%.

*Pressure filtration* is usually chosen only for sludges with poor dewaterability (such as waste-activated sludge) and where it is desired to dewater to a solids content higher than 30%. *Recessed plate filter presses* operate by forcing sludge at pressures of up to 120 psi (830 kPa) into cavities of porous filter cloth. The filtrate passes through the cloth, leaving the filter cake behind. When the filter becomes filled with cake, it is taken offline and opened. The filter cake is either manually or automatically removed.

Filter press sizing is based on a continuity of mass. In Eq. 30.57,  $s$  is the solids content as a decimal fraction in the filter cake.

$$\begin{aligned} V_{\text{press}} \rho_{\text{filter cake}} s_{\text{filter cake}} \\ = V_{\text{sludge,per cycle}} s_{\text{sludge}} \rho_{\text{sludge}} \\ = V_{\text{sludge,per cycle}} s_{\text{sludge}} \rho_{\text{water}} \text{SG}_{\text{sludge}} \end{aligned} \quad 30.57$$

*Centrifuges* can operate continuously and reduce water content to about 70%, but the effluent has a high percentage of suspended solids. The types of centrifuges used include solid bowl (both cocurrent and counter-current varieties) and imperforate basket decanter centrifuges.

With *solid bowl centrifuges*, sludge is continuously fed into a rotating bowl where it is separated into a dilute stream (the *centrate*) and a dense cake consisting of approximately 70–80% water. Since the centrate contains fine, low-density solids, it is returned to the wastewater treatment system. Equation 30.58 gives the number of gravities,  $G$ , acting on a rotating particle. Rotational speed,  $n$ , is typically 1500–2000 rpm. A polymer may be added to increase the capture efficiency (same as reducing the solids content of the centrate) and, accordingly, increase the feed rate.

$$G = \frac{\omega^2 r}{g} = \left( \frac{2\pi n}{60} \right)^2 \left( \frac{r}{g} \right) \quad 30.58$$

*Sand drying beds* are preferable when digested sludge is to be disposed of in a landfill since sand beds produce sludge cake with a low moisture content. Drying beds are enclosed by low concrete walls. A broken stone/gravel base that is 8–20 in (20–50 cm) thick is covered by 4–8 in (10–20 cm) of sand. Drying occurs primarily through drainage, not evaporation. Water that seeps through the sand is removed by a system of drainage pipes. Typically, sludge is added to a depth of about 8–12 in (20–30 cm) and allowed to dry for 10–30 days.

There is little theory-based design, and drying beds are sized by rules of thumb. The drying area required is approximately 1–1.5 ft<sup>2</sup> (0.09–1.4 m<sup>2</sup>) per person for primary digested sludge; 1.25–1.75 ft<sup>2</sup> (0.11–0.16 m<sup>2</sup>) per person for primary and trickling filter digested sludge; 1.75–2.5 ft<sup>2</sup> (0.16–0.23 m<sup>2</sup>) per person for primary and waste-activated digested sludge; and 2–2.5 ft<sup>2</sup> (0.18–0.23 m<sup>2</sup>) per person for primary and chemically precipitated digested sludge. This area can be reduced by approximately 50% if transparent covers are placed over the beds, creating a “greenhouse effect” and preventing the spread of odors.

Other types of drying beds include paved beds (both drainage and decanting types), vacuum-assisted beds, and artificial media (e.g., stainless steel wire and high-density polyurethane panels) beds.

Sludge dewatering by freezing and thawing in exposed beds is effective during some months in parts of the country.

### Example 30.5

A belt filter press handles an average flow of 19,000 gal/day of thickened sludge containing 2.5% solids by weight. Operation is 8 hr/day and 5 days/wk. The belt filter press loading is specified as 500 lbm/m-hr (lbm/hr per meter of belt width). The dewatered sludge

is to have 25% solids by weight, and the suspended solids concentration in the filtrate is 900 mg/L. The belt is continuously washed on its return path at a rate of 24 gal/m-min. The specific gravities of the sludge feed, dewatered cake, and filtrate are 1.02, 1.07, and 1.01, respectively. (a) What size belt is required? (b) What is the volume of filtrate rejected? (c) What is the solids capture fraction?

### Solution

(a) The daily masses of wet and dry influent sludge are

$$\begin{aligned} m_{\text{wet}} &= V\rho_{\text{sludge}} = V\rho_{\text{water}}\text{SG}_{\text{sludge}} \\ &= \left(19,000 \frac{\text{gal}}{\text{day}}\right) \left(\frac{\left(62.4 \frac{\text{lbm}}{\text{ft}^3}\right)(1.02)}{7.48 \frac{\text{gal}}{\text{ft}^3}}\right) \\ &= 1.617 \times 10^5 \text{ lbm/day} \end{aligned}$$

$$\begin{aligned} m_{\text{dry}} &= (\text{fraction solids})m_{\text{wet}} \\ &= (0.025)\left(1.617 \times 10^5 \frac{\text{lbm}}{\text{day}}\right) \\ &= 4042 \text{ lbm/day} \end{aligned}$$

Since the influent is received continuously but the belt filter press operates only 5 days a week for 8 hours per day, the average hourly processing rate is

$$\frac{\left(4042 \frac{\text{lbm}}{\text{day}}\right)\left(\frac{7 \text{ days}}{5 \text{ days}}\right)}{8 \frac{\text{hr}}{\text{day}}} = 707 \text{ lbm/hr}$$

The belt size (width) required is

$$\begin{aligned} w &= \frac{707 \frac{\text{lbm}}{\text{hr}}}{500 \frac{\text{lbm}}{\text{m-hr}}} \\ &= 1.41 \text{ m} \end{aligned}$$

Use one 1.5 m belt filter press. A second standby unit may also be specified.

(b) The mass of solids received each day is

$$\left(707 \frac{\text{lbm}}{\text{hr}}\right)\left(8 \frac{\text{hr}}{\text{day}}\right) = 5656 \text{ lbm/day}$$

The fractional solids in the filtrate is

$$s_{\text{filtrate}} = \frac{900 \frac{\text{mg}}{\text{L}}}{\left(1000 \frac{\text{mg}}{\text{g}}\right)\left(1000 \frac{\text{g}}{\text{L}}\right)} = 0.0009$$

The solids balance is

$$\text{influent solids} = \text{sludge cake solids} + \text{filtrate solids}$$

$$\begin{aligned} 5656 \frac{\text{lbm}}{\text{day}} &= \left(\frac{Q_{\text{cake,gal/day}}}{7.48 \frac{\text{gal}}{\text{ft}^3}}\right)\left(62.4 \frac{\text{lbm}}{\text{ft}^3}\right)(1.07)(0.25) \\ &\quad + \left(\frac{Q_{\text{filtrate,gal/day}}}{7.48 \frac{\text{gal}}{\text{ft}^3}}\right)\left(62.4 \frac{\text{lbm}}{\text{ft}^3}\right) \\ &\quad \times (1.01)(0.0009) \end{aligned}$$

The total liquid flow rate is the sum of the sludge flow rate and the washwater flow rate.

$$\begin{aligned} Q_{\text{total}} &= Q_{\text{cake}} + Q_{\text{filtrate}} \\ &= \left(19,000 \frac{\text{gal}}{\text{day}}\right)\left(\frac{7 \text{ days}}{5 \text{ days}}\right) \\ &\quad + \left(24 \frac{\text{gal}}{\text{m-min}}\right)(1.5 \text{ m})\left(60 \frac{\text{min}}{\text{hr}}\right)\left(8 \frac{\text{hr}}{\text{day}}\right) \\ &= 43,880 \text{ gal/day} \end{aligned}$$

Solving the solids and liquid flow rate equations simultaneously,

$$Q_{\text{cake}} = 2396 \text{ gal/day}$$

$$Q_{\text{filtrate}} = 41,484 \text{ gal/day}$$

(c) The solids in the filtrate are

$$\begin{aligned} m_{\text{filtrate}} &= \left(\frac{41,484 \frac{\text{gal}}{\text{day}}}{7.48 \frac{\text{gal}}{\text{ft}^3}}\right)\left(62.4 \frac{\text{lbm}}{\text{ft}^3}\right)(1.01)(0.0009) \\ &= 315 \text{ lbm/day} \end{aligned}$$

The solids capture fraction is

$$\begin{aligned} \frac{\text{influent solids} - \text{filtrate solids}}{\text{influent solids}} &= \frac{5656 \frac{\text{lbm}}{\text{day}} - 315 \frac{\text{lbm}}{\text{day}}}{5656 \frac{\text{lbm}}{\text{day}}} \\ &= 0.944 \end{aligned}$$

### 23. SLUDGE DISPOSAL

Liquid sludge and sludge cake disposal options are limited to landfills, incineration, nonagricultural land application (e.g., strip-mine reclamation, agricultural land application, commercial applications (known as *distribution and marketing* and *beneficial reuse*) such as composting, special monofills, and surface impoundments), and various state-of-the-art methods. Different environmental contaminants are monitored with each disposal method, making the options difficult to evaluate.

If a satisfactory site is available, sludge, sludge cake, screenings, and scum can be discarded in municipal *landfills*. Approximately 40% of the sludge produced in the United States is disposed of in this manner. This has traditionally been the cheapest disposal method, even when transportation costs are included.

The sludge composition and its potential effects on landfill leachate quality must be considered. Sludge with minute concentrations of monitored substances (e.g., heavy metals such as cadmium, chromium, copper, lead, nickel, and zinc) may be classified as hazardous waste, requiring disposal in hazardous waste landfills.

Sludge-only *monofills* and other surface impoundments may be selected in place of municipal landfills. Monofills are typically open pits protected by liners, slurry cutoff walls, and levees (as protection against floods). Monofills may include a pug mill to combine sludge with soil from the site.

Approximately 25% of the sludge produced in the United States is disposed of in a *beneficial reuse program* such as surface spreading (i.e., “land application”) and/or composting. Isolated cropland, pasture, and forest land (i.e., “silviculture”) are perfect for surface spreading. However, sludge applied to the surface may need to be harrowed into the soil soon after spreading to prevent water pollution from sludge runoff and possible exposure to or spread of bacteria. Alternatively, the sludge can be injected 12–18 in (300–460 mm) below grade directly from distribution equipment. The actual application rate depends on sludge strength (primarily nitrogen content), the condition of the receiving soil, the crop or plants using the applied nutrients, and the spreading technology.

By itself, filter cake is not highly useful as a fertilizer since its nutrient content is low. However, it is a good filler and soil conditioner for more nutrient-rich fertilizers. Other than as filler, filter cake has few practical applications.

Where sludges have low metals contents, *composting* (in static piles or vessels) can be used. *Compost* is a dry, odor-free soil conditioner with applications in turf grass, landscaping, land reclamation, and other horticultural industries. These markets can help to defray the costs of the program. Control of odors, cold weather operations, and concern about airborne pathogens are problems with *static pile composting*. Expensive air-quality scrubbers add to the cost of processing. With *in-vessel composting*, dewatered raw sludge is mixed with a bulking material, placed in an enclosed tank, and mixed with air in the tank.

*Incineration* is the most expensive treatment, though it results in almost total destruction of volatile solids, is odor free, and is independent of the weather. Approximately 20% of sludge is disposed of in this manner. A solids content of 30–33% is needed for direct incineration without the need to provide external fuel (i.e., so that the sludge burns itself). Air quality controls, equipment, and the regulatory permitting needed to meet strict standards may make incineration prohibitively expensive in some areas. The incineration ash produced represents a disposal problem of its own.

State-of-the-art options include using sludge solids in bricks, tiles, and other building materials; below-grade injection; subsurface injection wells; multiple-effect (Carver-Greenfield) evaporation; combined incineration with solid waste in “mass burn” units; and fluidized-bed gasification. The first significant installation attempting to use sludge solids as powdered fuel for power generation was the 25 MW Hyperion Energy Recovery System at the Hyperion treatment plant in Los Angeles. This combined-cycle cogeneration plant unsuccessfully attempted to operate using the Carver-Greenfield process and a fluidized-bed gasifier to convert sludge solids to fuel.

*Ocean dumping*, once a popular option for coastal areas, has been regulated out of existence and is no longer an option for new or existing facilities.

## 1. MUNICIPAL SOLID WASTE

*Municipal solid waste* (MSW, known for many years as “garbage”) consists of the solid material discarded by a community, including excess food, containers and packaging, residential garden wastes, other household discards, and light industrial debris. Hazardous wastes, including paints, insecticides, lead car batteries, used crankcase oil, dead animals, raw animal wastes, and radioactive substances present special disposal problems and are not included in MSW.

MSW is generated at the average rate of approximately 5–8 lbm/capita-day (2.3–3.6 kg/capita·d). A value of 5 lbm/capita-day (2.3 kg/capita·d) is commonly used in design studies.

Although each community’s MSW has its own characteristics, Table 31.1 gives average composition in the United States. The moisture content of MSW is approximately 20%.

**Table 31.1** Typical Characteristics of MSW<sup>a,b</sup>

component	percentage by weight
paper, cardboard	35.6
yard waste	20.1
food waste	8.9
metal	8.9
glass	8.4
plastics	7.3
wood	4.1
rubber, leather	2.8
cloth	2.0
other (ceramic, stone, dirt)	1.9

## 2. LANDFILLS

Municipal solid waste has traditionally been disposed of in *municipal solid waste landfills* (MSWLs, for many years referred to as “*dumps*”). Other wastes, including incineration ash and water treatment sludge, may be included with MSW in some landfills.

The fees charged to deposit waste are known as *tipping fees*. Tipping fees are generally higher in the eastern United States (where landfill sites are becoming scarcer). Tipping fees for resource recovery plants are approximately double those of traditional landfills.

Many early landfills were not designed with liners, not even simple compacted-soil bottom layers. Design was often by rules of thumb, such as the bottom of the

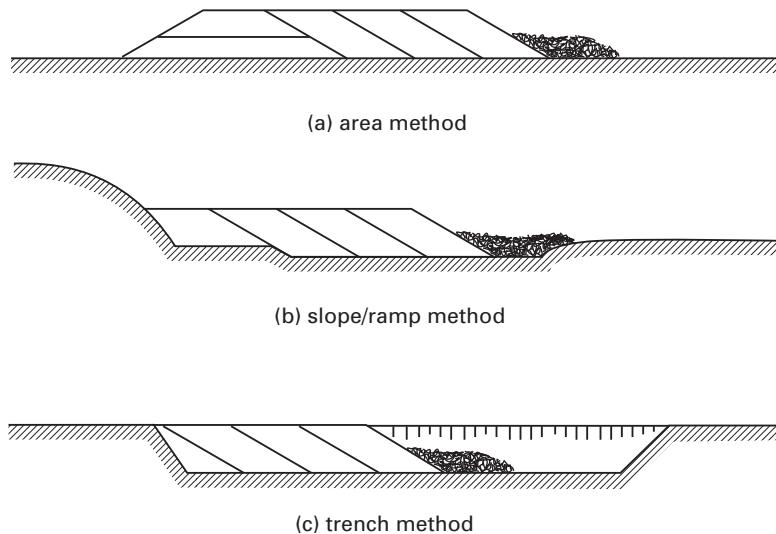

landfill had to be at least 5 ft (1.5 m) above maximum elevation of groundwater and 5 ft (1.5 m) above bedrock. Percolation through the soil was believed sufficient to make the leachate bacteriologically safe. However, inorganic pollutants can be conveyed great distances, and the underlying soil itself can no longer be used as a barrier to pollution and to perform filtering and cleansing functions.

Landfills without bottom liners are known as *natural attenuation (NA) landfills*, since the native soil is used to reduce the concentration of leachate components. Landfills lined with clay (pure or bentonite-amended soil) or synthetic liners are known as *containment landfills*.

Landfills can be incrementally filled in a number of ways, as shown in Fig. 31.1. With the *area method*, solid waste is spread and compacted on flat ground before being covered. With the *trench method*, solid waste is placed in a trench and covered with the trench soil. In the *progressive method* (also known as the *slope/ramp method*), cover soil is taken from the front (toe) of the working face.

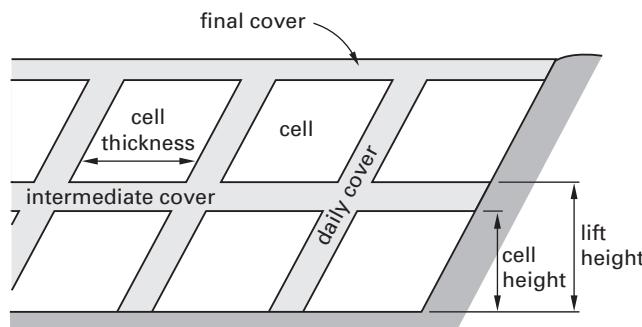

*Land vaults* are essentially above-ground piles of MSW placed on flat terrain. This design, with appropriate covers, liners, and instrumentation, has been successfully used with a variety of industrial wastes, including incineration ash and wastewater sludge. However, except when piggybacking a new landfill on top of a closed landfill, it is not widely used with MSW.

Waste is placed in layers, typically 2–3 ft thick (0.6–0.9 m), and is compacted before soil is added as a cover. Two to five passes by a tracked bulldozer are

**Figure 31.1** Landfill Creation Methods

sufficient to compact the MSW to 800–1500 lbm/yd<sup>3</sup> (470–890 kg/m<sup>3</sup>). (A density of 1000 lbm/yd<sup>3</sup> or 590 kg/m<sup>3</sup> is used in design studies.) The *lift* is the height of the covered layer, as shown in Fig. 31.2. When the landfill layer has reached full height, the ratio of solid waste volume to soil cover volume will be approximately between 4:1 and 3:1.

**Figure 31.2** Landfill Cells

The *cell height* is typically taken as 8 ft (2.4 m) for design studies, although it can actually be much higher. The height should be chosen to minimize the cover material requirement consistent with the regulatory requirements. Cell slopes will be less than 40°, and typically 20–30°.

Each *cell* is covered by a soil layer 0.5–1.0 ft (0.15–0.3 m) in thickness. The final top and side covers should be at least 2 ft (0.6 m) thick. Daily, intermediate, and final soil covers are essential to proper landfill operation. The daily and intermediate covers prevent fly emergence, discourage rodents, reduce odors, and reduce windblown litter. In the event of ignition, the soil layers form fire stops within the landfill.

The final soil cover (cap) is intended to reduce or eliminate entering moisture. The soil cover also contains and channels landfill gas and provides a pleasing appearance and location for growing vegetation.

### 3. LANDFILL CAPACITY

The *compaction factor*, CF, is a multiplicative factor used to calculate the compacted volume for a particular type of waste and compaction method. The compacted volume of MSW or components within the waste is

$$V_c = (CF)V_o \quad 31.1$$

The daily increase in landfill volume is predicted by using Eq. 31.2. *N* is the population size, *G* is the per-capita MSW generation rate per day, and  $\gamma$  is the landfill overall specific weight calculated as a weighted average of soil and compacted MSW specific weights. Soils have specific weights between 70 lbf/ft<sup>3</sup>

and 130 lbf/ft<sup>3</sup> (densities between 1100 kg/m<sup>3</sup> and 2100 kg/m<sup>3</sup>). A value of 100 lbf/ft<sup>3</sup> (1600 kg/m<sup>3</sup>) is commonly used in design studies.

$$\Delta V = \frac{NG(LF)}{\gamma} = \frac{NG(LF)}{\rho g} \quad [\text{SI}] \quad 31.2(a)$$

$$\Delta V = \frac{NG(LF)}{\gamma} = \frac{NG(LF)g_c}{\rho g} \quad [\text{U.S.}] \quad 31.2(b)$$

The *loading factor*, LF, is 1.25 for a 4:1 volumetric ratio and is calculated from Eq. 31.3 for other ratios.

$$LF = \frac{V_{\text{MSW}} + V_{\text{cover soil}}}{V_{\text{MSW}}} \quad 31.3$$

Most large-scale sanitary landfills do not apply daily cover to deposited waste. Time, cost, and reduced capacity are typically cited as the reasons that the landfill is not covered with soil. In the absence of such cover, the loading factor has a value of 1.0.

### 4. SUBTITLE D LANDFILLS

Since 1992, new and expanded municipal landfills in the United States have had to satisfy strict design regulations and are designated “*Subtitle D landfills*,” referring to Subtitle D of the Resource Conservation and Recovery Act (RCRA). The regulations apply to any landfill designed to hold municipal solid waste, biosolids, and ash from MSW incineration.

Construction of landfills is prohibited near sensitive areas such as airports, floodplains, wetlands, earthquake zones, and geologically unstable terrain. Air quality control methods are required to control emission of dust, odors (from hydrogen sulfide and volatile organic vapors), and landfill gas. Runoff from storms must be controlled.

Subtitle D landfills must have *double-liner systems*, as shown in Fig. 31.3, and which are defined as “two or more liners and a leachate collection system above and between such liners.” While states can specify greater protection, the minimum (basic) bottom layer requirements are a 30-mil flexible PVC membrane liner (FML) and at least 2 ft (0.6 m) and up to 5 ft (1.5 m) of compacted soil with a maximum hydraulic conductivity of  $1.2 \times 10^{-5}$  ft/hr ( $1 \times 10^{-7}$  cm/s). If the membrane is high-density polyethylene (HDPE), the minimum thickness is 60 mils. 30-mil PVC costs less than 60-mil HDPE, but the 60-mil product offers superior protection.

The preferred double liner consists of two FMLs separated by a drainage layer (approximately 2 ft (0.6 m) thick) of sand, gravel, or *drainage netting* and placed on low-permeability soil. This is the standard design for *Subtitle C* hazardous waste landfills. The advantage of selecting the preferred design for municipal landfills is realized in the permitting process.

The minimum thickness is 20 mils for the top FML, and the maximum hydraulic conductivity of the cover soil is  $1.8 \times 10^{-5}$  ft/hr ( $1.5 \times 10^{-7}$  cm/s).

A series of wells and other instrumentation are required to detect high hydraulic heads and the accumulation of heavy metals and volatile organic compounds (VOCs) in the leachate.

## 5. CLAY LINERS

Liners constructed of well-compacted bentonite clays fail by fissuring (as during freeze-thaw cycles), dessication (i.e., drying out), chemical interaction, and general disruption. Permeability increases dramatically with organic fluids (hydrocarbons) and acidic or caustic leachates. Clays need to be saturated and swollen to retain their high impermeabilities. Permeabilities measured in the lab as  $1.2 \times 10^{-5}$  ft/hr ( $10^{-7}$  cm/s) can actually be  $1.2 \times 10^{-3}$  ft/hr ( $10^{-5}$  cm/s) in the field.

Although a 0.5–1.0 ft (0.15–0.30 m) thickness could theoretically contain the leachate, the probability of success is not high when typical exposure issues are considered. Clay liners with thicknesses of 4–5 ft (1.2–1.5 m) will still provide adequate protection, even when the top half has degraded.

## 6. FLEXIBLE MEMBRANE LINERS

Synthetic *flexible membrane liners* (FMLs, the term used by the United States EPA), also known as *synthetic membranes*, *synthetic membrane liners* (SMLs), *geosynthetics*, and *geomembranes*, are highly attractive because of their negligible permeabilities, and good chemical resistance. The term *geocomposite liner* is used

when referring to a combination of FML and one or more compacted clay layers.

FML materials include polyvinyl chloride (PVC); chlorinated polyethylene (CPE); low-density polyethylene (LDPE); linear, low-density polyethylene (LLDPE); very low density polyethylene (VLDPE); high-density polyethylene (HDPE); chlorosulfonated polyethylene, also known as Hypalon® (CSM or CSPE); ethylene propylene dienemonomer (EP or EPDM); polychloroprene, also known as neoprene (CR); isobutylene isoprene, also known as butyl (IIR); and oil-resistant polyvinyl chloride (ORPVC). LDPE covers polyethylene with densities in the range of about 56.2–58.3 lbm/ft<sup>3</sup> (0.900–0.935 g/cm<sup>3</sup>), while HDPE covers the range of about 58.3–60.5 lbm/ft<sup>3</sup> (0.935–0.970 g/cm<sup>3</sup>).

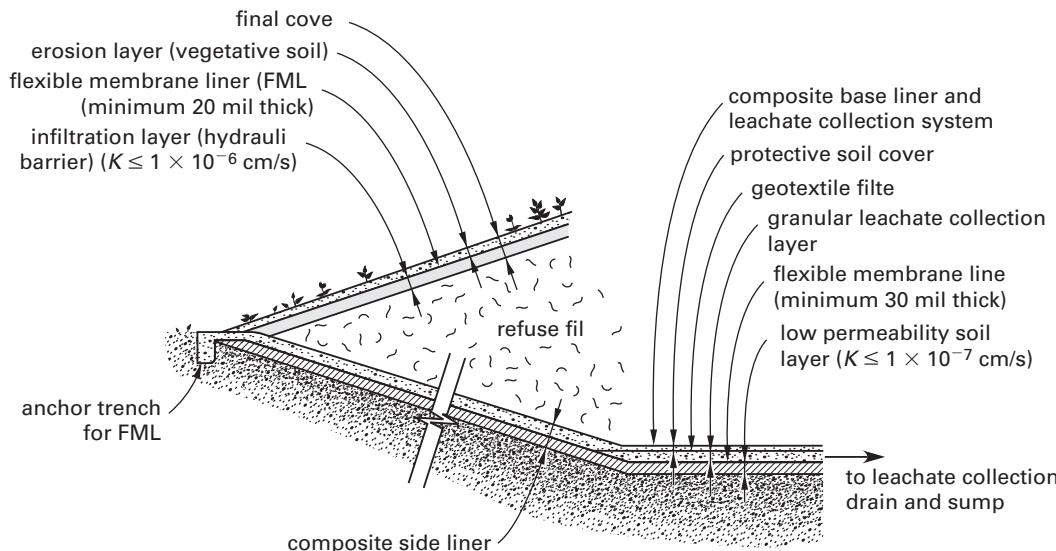

HDPE is preferred for municipal landfills and hazardous waste sites because of its high tensile strength, high toughness (resistance to tear and puncture), and ease of seaming. HDPE has captured the majority of the FML market.

Some FMLs can be manufactured with an internal nylon or dacron mesh, known as a *scrim*, or a spread coating on one side. The resulting membrane is referred to as a *reinforced* or *supported membrane*. An “R” is added to the name to indicate the reinforcement (e.g., “HDPE-R”). Membranes without internal scrims are *unreinforced* or *unsupported membranes*.

FMLs can be embossed or textured to increase the friction between the FML and any soil layer adjacent to it.

FMLs are sealed to the original grade and restrained against movement by deep *anchor trenches* around the periphery of the landfill. (See Fig. 31.3.)

**Figure 31.3** Subtitle D Liner and Cover Detail

FMLs fail primarily by puncturing, tearing, and long-term exposure to ultraviolet (UV) rays. Freezing temperatures may also weaken them. FMLs are protected from UV radiation by a soil backfill with a minimum thickness of approximately 6 in (15 cm). The cover soil should be placed promptly.

## 7. LANDFILL CAPS

The landfill *cap* (*top cap*) is the *final cover* placed over the landfill. Under Subtitle D regulations, caps cannot be any more permeable than the bottom liners. Therefore, only preexisting landfills can be capped with clay.

Caps fail by desiccation, penetration by roots, rodent and other animal activity, freezing and thawing cycles, erosion, settling, and breakdown of synthetic liners from sunlight exposure. Failure can also occur when the cover collapses into the disposal site due to voids opening below or excess loading (rainwater ponding) above.

Synthetic FML caps offer several advantages over clay caps—primarily lower permeability, better gas containment, faster installation, and easier testing and inspection.

In the past, some landfills had slopes as steep as 0.7:1 (horizontal:vertical). Preferred modern landfill design incorporates maximum slopes of 3:1 and occasionally as steep as 2:1 (horizontal:vertical), with horizontal tiers (benches) every so often. This is steep enough to cause concern about cap slope instability. Although clay caps can be constructed this steep, synthetic membranes have lower *interfacial friction angles* and are too smooth for use on steep slopes. (See Table 31.2.) Slippage between different layers in the cap (e.g., between the FML and the soil cover) is known as *veeeneer failure*. Some relief is possible with *textured synthetics*.

A common cap system is a textured synthetic with a nonwoven geotextile. Vertical cap collapse can be prevented by incorporating a high-strength plastic *geogrid*.

**Table 31.2** Typical Interfacial Friction Angles

interface	typical friction angle
nonwoven geotextile/smooth FML	10–13°
compacted sand/smooth FML	15–25°
compacted clay/smooth FML	5–20°
nonwoven geotextile/textured FML	25–35°
compacted sand/textured FML	20–35°
compacted clay/textured FML	15–32°

## 8. LANDFILL SITING

Sanitary landfills should be designed for a five-year minimum life. Sanitary landfill sites are selected on the basis of many relevant factors, including (a) economics and the availability of inexpensive land;

(b) location, including ease of access, transport distance, acceptance by the population, and aesthetics; (c) availability of cover soil, if required; (d) wind direction and speed, including odor, dust, and erosion considerations; (e) flat topography; (f) dry climate and low infiltration rates; (g) location (elevation) of the water table; (h) low risk of aquifer contamination; (i) types and permeabilities of underlying strata; (j) avoidance of winter freezing; (k) future growth and capacity requirements; and (l) ultimate use.

Suitable landfill sites are becoming difficult to find, and once identified, they are subjected to a rigorous permitting process. They are also objected to by residents near the site and MSW transport corridor. This is referred to as the *NIMBY* (not in my backyard) *syndrome*. People agree that landfills are necessary, but they do not want to live near them.

## 9. VECTORS

In landfill parlance, a *vector* is an insect or arthropod, rodent, or other animal of public health significance capable of causing human discomfort or injury, or capable of harboring or transmitting the causative agent of human disease. Vectors include flies, domestic rats, field rodents, mosquitoes, wasps, and cockroaches. Standards for vector control should state the *vector thresholds* (e.g., “six or more flies per square yard”).

## 10. ULTIMATE LANDFILL DISPOSITION

When filled to final capacity and closed, the covered landfill can be used for grassed green areas, shallow-rooted agricultural areas, and recreational areas (soccer fields, golf courses, etc.). Light construction uses are also possible, although there may be problems with gas accumulation, corrosion of pipes and foundation piles, and settlement.

Settlement will generally be uneven. Settlement in areas with high rainfall can be up to 20% of the overall landfill height. In dry areas, the settlement may be much less, 2–3%. Little information on bearing capacity of landfills is available. Some studies have suggested capacities of 500–800 lbf/ft<sup>2</sup> (24–38 kPa).

## 11. LANDFILL GAS

Once covered, the organic material within a landfill cell provides an ideal site for decomposition. Aerobic conditions prevail for approximately the first month. Gaseous products of the initial aerobic decomposition include CO<sub>2</sub> and H<sub>2</sub>O. The following are typical reactions involving carbohydrates and stearic acid.

After the first month or so, the decomposing waste will have exhausted the oxygen in the cell. Digestion continues anaerobically, producing a low-heating value *landfill gas* (LFG) consisting of approximately 50% methane ( $\text{CH}_4$ ), 50% carbon dioxide, and trace amounts of other gases (e.g., CO, N<sub>2</sub>, and H<sub>2</sub>S). Decomposition occurs at temperatures of 100–120°F (40–50°C), but may increase to up to 160°F (70°C).

LFG is essentially saturated with water vapor when formed. However, if the gas collection pipes are vertical or sloped, some of the water vapor will condense on the pipes and drain back into the landfill. Most of the remaining moisture is removed in condensate traps located along the gas collection system line.

From Dalton's law, the total gas pressure within a landfill is the sum of the partial pressures of the component gases. Partial pressure is volumetrically weighted and can be found from the volumetric fraction,  $B$ , of the gas.

$$p_t = p_{\text{CH}_4} + p_{\text{CO}_2} + p_{\text{H}_2\text{O}} + p_{\text{N}_2} + p_{\text{other}} \quad 31.8$$

$$p_i = B_i p_t \quad 31.9$$

If uncontrolled, LFG will migrate to the surface. If the LFG accumulates, an explosion hazard results, since methane is highly explosive in concentrations of 5–15% by volume. Methane will pass through the explosive concentration as it is being diluted. Other environmental problems, including objectionable odors, can also occur. Therefore, various methods are used to prevent gas from escaping or spreading laterally.

Landfill gases can be collected by either passive or active methods. *Passive collection* uses the pressure of the gas itself as the driving force. Passive collection is applicable for sites that generate low volumes of gas and where offsite migration of gas is not expected. This generally applies to small municipal landfills—those with volumes less than approximately 50,000 yd<sup>3</sup> (40 000 m<sup>3</sup>). Common passive control methods include (a) isolated gas (pressure relief) vents in the landfill cover, with or without a common flare; (b) perimeter interceptor gravel trenches; (c) perimeter barrier trenches (e.g., slurry walls); (d) impermeable barriers within the landfill; and (e) sorptive barriers in the landfill.

*Active gas collection* draws the landfill gas out with a vacuum from *extraction wells*. Various types of horizontal and vertical wells can be used through the landfill to extract gas in vertical movement, while perimeter facilities are used to extract gases in lateral movement. Vertical wells are usually perforated PVC pipes packed in sleeves of gravel and bentonite clay. PVC pipe is resistant to the chlorine and sulfur compounds present in the landfill.

Determining the location of isolated vents is essentially heuristic—one vent per 10,000 yd<sup>3</sup> (7500 m<sup>3</sup>) of landfill

is probably sufficient. Regardless, extraction wells should be spaced with overlapping zones of influence. If the *radius of influence*,  $R$ , of each well and the desired fractional overlap,  $O$ , are known, the spacing between wells is given by Eq. 31.10. For example, if the extraction wells are placed on a square grid with spacing of  $L = 1.4R$ , the overlap will be 60%. For a 100% overlap, the spacing would equal the radius of influence.

$$\frac{L}{R} = 2 - O \quad 31.10$$

In many locations, the LFG is incinerated in flares. However, emissions from flaring are problematic. Alternatives to flaring include using the LFG to produce hot water or steam for heating or electricity generation. During the 1980s, reciprocating engines and combustion turbines powered by LFG were tried. However, such engines generated relatively high emissions of their own due to impurities and composition variations in the fuel. True Rankine-cycle power plants (generally without reheat) avoid this problem, since boilers are less sensitive to impurities.

One problem with using LFG commercially is that LFG is withdrawn from landfills at less than atmospheric pressure. Conventional furnace burners need approximately 5 psig at the boiler front. Low-pressure burners that require 2 psig are available, but they are expensive. Therefore, some of the plant power must be used to pressurize the LFG in blowers.

Although production is limited, LFG is produced for a long period after a landfill site is closed. Production slowly drops 3–5% annually to approximately 30% of its original value after about 20–25 years, which is considered to be the economic life of a gas-reclamation system. The theoretical ultimate production of LFG has been estimated by other researchers as 15,000 ft<sup>3</sup> per ton (0.45 m<sup>3</sup>/kg) of solid waste, with an estimated volumetric gas composition of 54% methane and 46% carbon dioxide. (See Table 31.3.) However, unfavorable and non-ideal conditions in the landfill often reduce this yield to approximately 1000–3000 ft<sup>3</sup>/ton (0.03–0.09 m<sup>3</sup>/kg) or even lower.

**Table 31.3** Properties of Methane and Carbon Dioxide

	CH <sub>4</sub>	CO <sub>2</sub>
color	none	none
odor	none	none
density, at STP (g/L)	0.717	1.977
(lbm/ft <sup>3</sup> )	0.0447	0.123
specific gravity, at STP, ref. air	0.554	1.529
solubility (760 mm Hg, 20°C), volumes in one volume of water	0.33	0.88
solubility, qualitative	slight	moderate

(Multiply lbm/ft<sup>3</sup> by 16.02 to obtain g/L.)

## 12. LANDFILL LEACHATE

*Leachates* are liquid wastes containing dissolved and finely suspended solid matter and microbial waste produced in landfills. Leachate becomes more concentrated as the landfill ages. Leachate forms from liquids brought into the landfill, water run-on, and precipitation. Leachate in a natural attenuation landfill will contaminate the surrounding soil and groundwater. In a lined containment landfill, leachate will percolate downward through the refuse and collect at the first landfill liner. Leachate must be removed to reduce hydraulic head on the liner and to reduce unacceptable concentrations of hazardous substances.

When a layer of liquid sludge is disposed of in a landfill, the consolidation of the sludge by higher layers will cause the water to be released. This released water is known as *pore-squeeze liquid*.

Some water will be absorbed by the MSW and will not percolate down. The quantity of water that can be held against the pull of gravity is referred to as the *field capacity*, FC. The potential quantity of leachate is the amount of moisture within the landfill in excess of the FC.

In general, the amount of leachate produced is directly related to the amount of external water entering the landfill. Theoretically, the leachate generation rate can be determined by writing a water mass balance on the landfill. This can be done on a preclosure and a postclosure basis. Typical units for all the terms are units of length (e.g., "1.2 in of rain") or mass per unit volume (e.g., "a field capacity of 4 lbm/yd<sup>3</sup>").

The preclosure leachate generation rate is

$$\begin{aligned} \text{preclosure leachate generation} \\ = & \text{moisture released by incoming waste,} \\ & \quad \text{including pore-squeezed liquid} \\ & + \text{precipitation} \\ & - \text{moisture lost due to evaporation} \\ & - \text{field capacity} \end{aligned} \quad 31.11$$

The postclosure water balance is

$$\begin{aligned} \text{postclosure leachate generation} \\ = & \text{precipitation} \\ & - \text{surface runoff} \\ & - \text{evapotranspiration} \\ & - \text{moisture lost in formation} \\ & \quad \text{of landfill gas and other} \\ & \quad \text{chemical compounds} \\ & - \text{water vapor removed along} \\ & \quad \text{with landfill gas} \\ & - \text{change in soil moisture storage} \end{aligned} \quad 31.12$$

## 13. LEACHATE MIGRATION FROM LANDFILLS

From Darcy's law, migration of leachate contaminants that have passed through liners into aquifers or the groundwater table is proportional to the hydraulic conductivity,  $K$ , and the hydraulic gradient,  $i$ . Hydraulic conductivities of clay liners are  $1.2 \times 10^{-7}$  ft/hr to  $1.2 \times 10^{-5}$  ft/hr ( $10^{-9}$  cm/s to  $10^{-7}$  cm/s). However, the properties of clay liners can change considerably over time due to interactions with materials in the landfill. If the clay dries out (desiccates), it will be much more permeable. For synthetic FMLs, hydraulic conductivities are  $1.2 \times 10^{-10}$  ft/hr to  $1.2 \times 10^{-7}$  ft/hr ( $10^{-12}$  cm/s to  $10^{-9}$  cm/s). The average permeability of high-density polyethylene is approximately  $1.2 \times 10^{-11}$  ft/hr ( $1 \times 10^{-13}$  cm/s).

$$Q = KiA \quad 31.13$$

$$i = \frac{dH}{dL} \quad 31.14$$

## 14. GROUNDWATER DEWATERING

It may be possible to prevent or reduce contaminant migration by reducing the elevation of the groundwater table (GWT). This is accomplished by dewatering the soil with relief-type *extraction drains* (*relief drains*). The *ellipse equation*, also known as the *Donnan formula* and the *Colding equation*, used for calculating pipe spacing,  $L$ , in draining agricultural fields, can be used to determine the spacing of groundwater dewatering systems. In Eq. 31.15,  $K$  is the hydraulic conductivity with units of length/time,  $a$  is the distance between the pipe and the impervious layer barrier ( $a$  is zero if the pipe is installed on the barrier),  $b$  is the maximum allowable table height above the barrier, and  $Q$  is the *recharge rate*, also known as the *drainage coefficient*, with dimensions of length/time. The units of  $K$  and  $Q$  must be on the same time basis.

$$L = 2\sqrt{\left(\frac{K}{Q}\right)(b^2 - a^2)} = 2\sqrt{\frac{b^2 - a^2}{i}} \quad 31.15$$

Equation 31.15 is often used because of its simplicity, but the accuracy is only approximately  $\pm 20\%$ . Therefore, the calculated spacing should be decreased by 10–20%.

For pipes above the impervious stratum, as illustrated in Fig. 31.4, the total discharge per unit length of each pipe (in ft<sup>3</sup>/ft·sec or m<sup>3</sup>/m·s) is given by Eq. 31.16.  $H$  is the maximum height of the water table above the pipe invert elevation.  $D$  is the average depth of flow.

$$Q_{\text{unit length}} = \frac{2\pi KHD}{L} \quad 31.16$$

$$D = a + \frac{H}{2} \quad 31.17$$

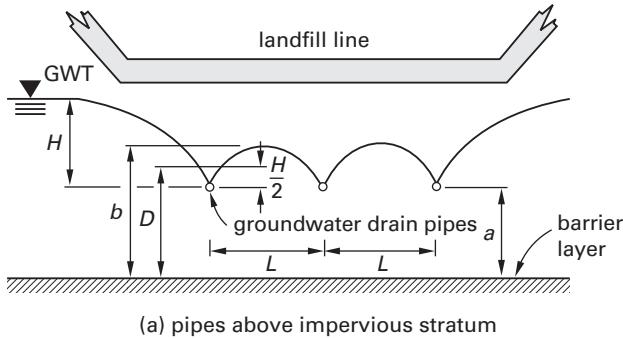

For pipes on the impervious stratum, the total discharge per unit length from the ends of each pipe (in  $\text{ft}^3/\text{ft}\cdot\text{sec}$  or  $\text{m}^3/\text{s}\cdot\text{m}$ ) is

$$Q_{\text{unit length}} = \frac{4KH^2}{L} \quad 31.18$$

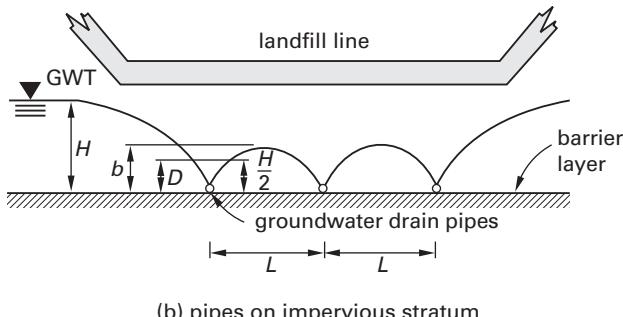

Equation 31.19 gives the total discharge per pipe. If the pipe drains from both ends, the discharge per end would be half of that amount.

$$Q_{\text{pipe}} = LQ_{\text{unit length}} \quad 31.19$$

**Figure 31.4** Geometry for Groundwater Dewatering Systems

(a) pipes above impervious stratum

(b) pipes on impervious stratum

### Example 31.1

Subsurface leachate migration from a landfill is to be mitigated by maintaining the water table that surrounds the landfill site lower than the natural level. The surrounding area consists of 15 ft of saturated, homogeneous soil over an impervious rock layer. The water table, originally at the surface, has been lowered to a depth of 9 ft. Fully pervious parallel collector drains at a depth of 12 ft are present. The hydraulic conductivity of the soil is 0.23 ft/hr. The natural water table will recharge the site in 30 days if drainage stops. What collector drain separation is required?

### Solution

Referring to Fig. 31.4(a),

$$a = 15 \text{ ft} - 12 \text{ ft} = 3 \text{ ft}$$

$$b = 15 \text{ ft} - 9 \text{ ft} = 6 \text{ ft}$$

$$K = \left(0.23 \frac{\text{ft}}{\text{hr}}\right) \left(24 \frac{\text{hr}}{\text{day}}\right) = 5.52 \text{ ft/day}$$

To maintain the lowered water table level, the drainage rate must equal the recharge rate.

$$Q = \frac{9 \text{ ft}}{30 \text{ days}} = 0.3 \text{ ft/day}$$

Use Eq. 31.15 to find the drain spacing.

$$\begin{aligned} L &= 2 \sqrt{\left(\frac{K}{Q}\right)(b^2 - a^2)} \\ &= 2 \sqrt{\left(\frac{5.52 \frac{\text{ft}}{\text{day}}}{0.3 \frac{\text{ft}}{\text{day}}}\right) ((6 \text{ ft})^2 - (3 \text{ ft})^2)} \\ &= 44.57 \text{ ft} \quad (45 \text{ ft}) \end{aligned}$$

## 15. LEACHATE RECOVERY SYSTEMS

At least two distinct leachate recovery systems are required in landfills: one within the landfill to limit the hydraulic head of leachate that has reached the top liner, and another to catch the leachate that has passed through the top liner and drainage layer and has reached the bottom liner.

By removing leachate at the first liner, the hydrostatic pressure on the liner is reduced, minimizing the pressure gradient and hydraulic movement through the liner. A pump is used to raise the collected leachate to the surface once a predetermined level has been reached. Tracer compounds (e.g., lithium compounds or radioactive hydrogen) can be buried with the wastes to signal migration and leakage.

Leachate collection and recovery systems fail because of clogged drainage layers and pipe, crushed collection pipes due to waste load, pump failures, and faulty design.

## 16. LEACHATE TREATMENT

Leachate is essentially a very strong municipal wastewater, and it tends to become more concentrated as the landfill ages. Leachate from landfills contains extremely high concentrations of compounds and cannot be discharged directly into rivers or other water sources.

Leachate is treated with biological (i.e., trickling filter and activated sludge) and physical/chemical processes very similar to those used in wastewater treatment plants. For large landfills, these treatment facilities are located on the landfill site. A typical large landfill treatment facility would include an equalization tank, a primary clarifier, a first-stage activated sludge aerator and clarifier, a second-stage activated sludge aerator and clarifier, and a rapid sand filter. Additional equipment for sludge dewatering and digestion would also be required. Liquid effluent would be discharged to the municipal wastewater treatment plant.

## 17. LANDFILL MONITORING

Monitoring is conducted at sanitary landfills to ensure that no contaminants are released from the landfill. Monitoring is conducted in the vadose zone for gases and liquid, in the groundwater for leachate movements, and in the air for air quality monitoring.

Landfills use *monitoring wells* located outside of the covered cells and extending past the bottom of the disposal site into the aquifer. In general, individual monitoring wells should extend into each stratum upstream and downstream (based on the hydraulic gradient) of the landfill.

## 18. CARBON DIOXIDE IN LEACHATE

Carbon dioxide is formed during both aerobic and anaerobic decomposition. Carbon dioxide combines with water to produce *carbonic acid*,  $\text{H}_2\text{CO}_3$ . In the absence of other mitigating compounds, this will produce a slightly acidic leachate.

The concentration of carbon dioxide (in mg/L) in the leachate (assumed to be water) can be calculated by using the *absorption coefficient (solubility)*,  $K_s$ , as given in Table 31.4. The absorption coefficient for carbon dioxide at 32°F (0°C) and 1 atm is approximately  $K_s = 0.88 \text{ L/L}$ .

$$\rho_{\text{g/L}} = \frac{p(\text{MW})}{R^* T} \\ = \frac{B_{\text{CO}_2} p_{t,\text{atm}} \left( 44 \frac{\text{g}}{\text{mol}} \right)}{\left( 0.08206 \frac{\text{atm}\cdot\text{L}}{\text{mol}\cdot\text{K}} \right) T_K} \quad 31.20$$

$$T_K = T_{\circ\text{C}} + 273^\circ \quad 31.21$$

At a typical internal landfill temperature of 100°F (38°C), Eq. 31.20 reduces to

$$\rho_{\text{g/L}} = 1.72 B_{\text{CO}_2} \quad 31.22$$

The concentration of carbon dioxide in the leachate is

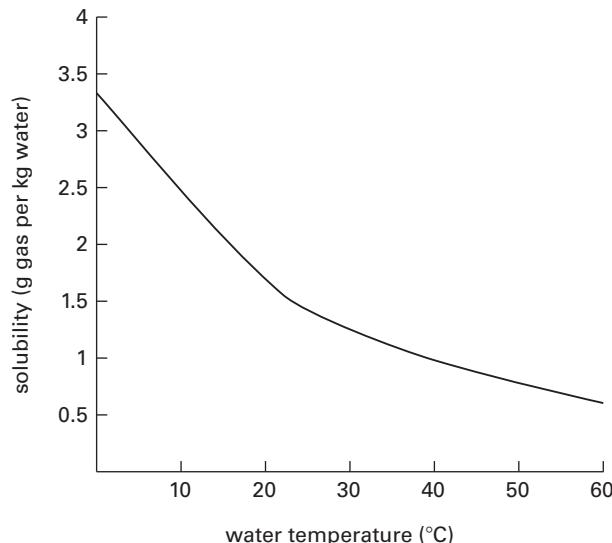

$$C_{\text{CO}_2, \text{mg/L}} = \rho_{\text{g/L}} K_{s, \text{L/L}} \left( 1000 \frac{\text{mg}}{\text{g}} \right) \quad 31.23$$

**Table 31.4** Typical Absorption Coefficients (L/L at 0°C and 1 atm)

element	$K_s$ (L/L)
hydrogen	0.017
nitrogen	0.015
oxygen	0.028
carbon monoxide	0.025
methane	0.33
carbon dioxide	0.88

Values of solubility for carbon dioxide (or any gas) in leachate depend on the leachate composition as well as temperature and are difficult to find. Values of solubilities of gases in water, with typical units of mass of gas per mass of pure water, are commonly available, however. Solubility values with units of L/L (i.e., liters of gas per liter of water) will usually have to be calculated from published values with units of g/kg (i.e., grams of gas per kilograms of water). The total pressure within the landfill is essentially one atmosphere, and pressure of each gas is volumetrically weighted. Reasonable assumptions about the volumetric fraction (or, partial pressure ratio),  $B$ , of carbon dioxide must be made. Carbon dioxide constitutes approximately 0.033–0.039% by volume of atmospheric air, although values within a landfill will be significantly higher. (At maturity, landfill gas is 40–60% carbon dioxide, 45–60% methane, 2–5% nitrogen, and less than 1% oxygen by volume.) Solubility values are also dependent on temperature within the landfill, and solubility decreases with an increase in temperature, as Fig. 31.5 shows. Considering the heat of decomposition, an assumed landfill temperature of 100°F (38°C) is reasonable.

**Figure 31.5** Solubility of Carbon Dioxide in Water

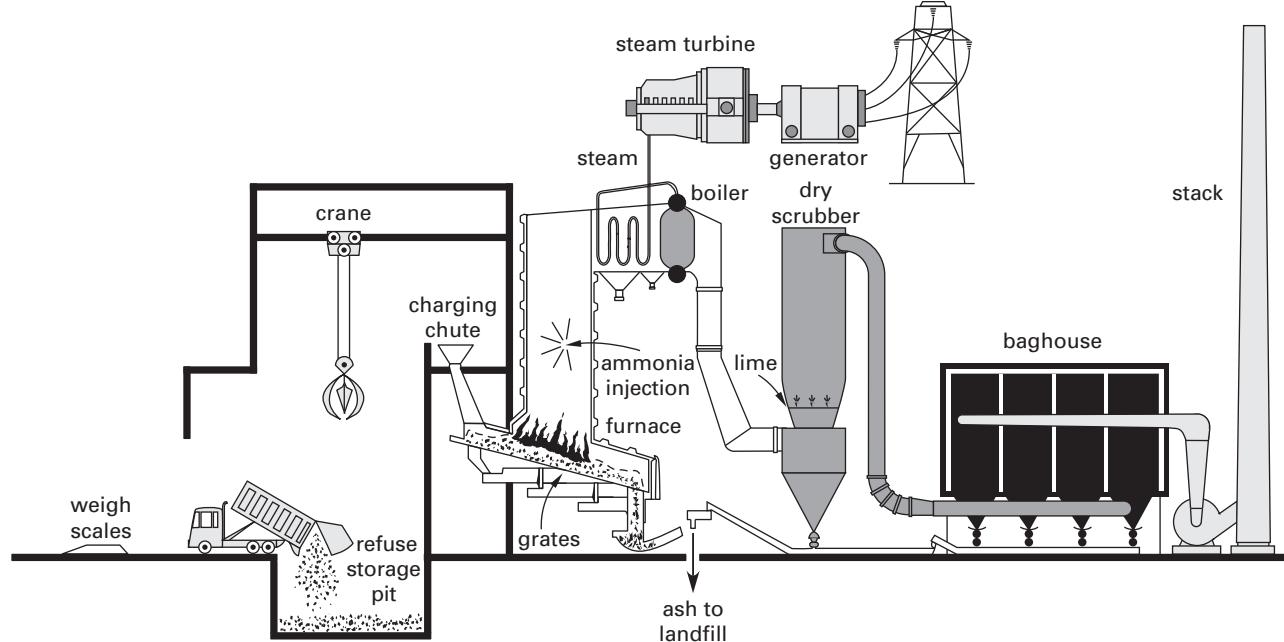

## 19. INCINERATION OF MUNICIPAL SOLID WASTE

Incineration of MSW results in a 90% reduction in waste disposal volume and a mass reduction of 75%.

In *no-boiler incinerators*, MSW is efficiently burned without steam generation. However, incineration at large installations is often accompanied by recycling and steam and/or electrical power generation. Incinerator/generator facilities with separation capability are known as *resource-recovery plants*. Facilities with boilers are referred to as *waste-to-steam plants*. Facilities with boilers and electrical generators are referred to as *waste-to-energy (WTE) facilities*. (See Fig. 31.6.) In WTE plants, the combustion heat is used to generate steam and electrical power.

*Mass burning* is the incineration of unprocessed MSW, typically on stoker grates or in rotary and waterwall combustors to generate steam. With mass burning, MSW is unloaded into a pit and then moved by crane to the furnace conveying mechanism. Approximately 27% of the MSW remains as ash, which consists of glass, sand, stones, aluminum, and other noncombustible materials. It and the fly ash are usually collected and disposed of in municipal landfills. (The U.S. Environmental Protection Agency (EPA) has ruled that ash from the incineration of MSW is not a hazardous waste. However, this is hotly contested and is subject to ongoing evaluation.) Capacities of typical mass burn units vary from less than 400 tons/day (360 Mg/d) to a high of 3000 tons/day (2700 Mg/d), with the majority of units processing 1000–2000 tons/day (910–1800 Mg/d).

Figure 31.6 Typical Mass-Burn Waste-to-Energy Plant

MSW, as collected, has a heating value of approximately 4500 Btu/lbm (10 MJ/kg), though higher values have been reported. For 1000 tons/day (1000 Mg/d) of MSW incinerated, the yields are approximately 150,000–200,000 lbm/hr (75–100 Mg/h) of 650–750 psig (4.5–5.2 MPa) steam at 700–750°F (370–400°C) and 25–30 MW (27.6–33.1 MW) of gross electrical power. Approximately 10% of the electrical power is used internally, and units generating much less than approximately 10 MW (gross) may use all of their generated electrical power internally.

The *burning rate* is approximately 40–60 lbm/hr-ft<sup>2</sup> (200–300 kg/h-m<sup>2</sup>) and is the fueling rate divided by the total effective grate area. Maximum heat release rates are approximately 300,000 Btu/hr-ft<sup>2</sup> (940 kW/m<sup>2</sup>). The *heat release rate*, HRR, is defined as

$$HRR = \frac{(\text{fueling rate})(HV)}{\text{total effective grate area}} \quad 31.24$$

## 20. REFUSE-DERIVED FUEL

*Refuse-derived fuel* (RDF) is derived from MSW. (See Table 31.5.) First-generation RDF plants use “crunch and burn” technology. In these plants, the MSW is shredded after ferrous metals are removed magnetically. First-generation RDF plants suffer from the same problems that have plagued early mass burn units, including ash with excessive quantities of noncombustible materials such as glass, grit and sand, and aluminum.

**Table 31.5** Typical Ultimate Analyses of MSW and RDF

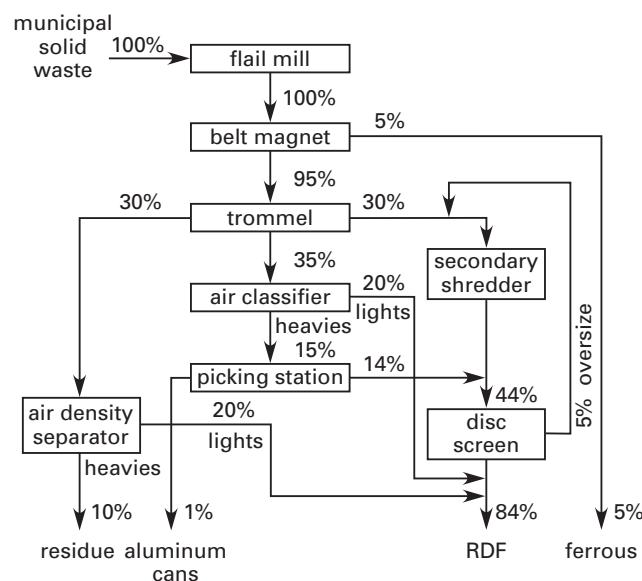

element	percentage by weight	
	MSW	RDF
carbon	26.65	31.00
water	25.30	27.14
ash	23.65	13.63
oxygen	19.61	22.72
hydrogen	3.61	4.17
chlorine	0.55	0.66
nitrogen	0.46	0.49
sulfur	0.17	0.19
total	100.00	100.00

Second-generation plants incorporate screens and air classifiers to reduce noncombustible materials and to increase the recovery of some materials. *Material recovery facilities* (MRFs) specialize in sorting out recyclables from MSW. The ash content is reduced, and the energy content of the RDF is increased. The MSW is converted into RDF pellets between 2½ in and 6 in (6.4 cm and 15 cm) in size and is introduced through feed ports above a traveling grate. Some of fuel is burned in suspension, with the rest burned on the grate. Grate speed is varied so that the fuel is completely incinerated by the time it reaches the ash rejection ports at the front of the burner.

In large (2000–3000 tons/day (1800–2700 Mg/d)), third-generation RDF plants, illustrated in Fig. 31.7, more than 95% of the original MSW combustibles are retained while reducing *mass yield* (i.e., the ratio of RDF mass to MSW mass) to below 85%.

RDF has a heating value of approximately 5500–5900 Btu/lbm (12–14 MJ/kg). The moisture and ash contents of RDF are approximately 24% and 12%, respectively.

The performance of a typical third-generation facility burning RDF is similar to a mass-burn unit. For each 1000 tons/day (1000 Mg/d) of MSW collected, approximately 150,000–250,000 lbm/hr (75–125 Mg/h) of 750–850 psig (5.2–5.9 MPa) steam at 750–825°F (400–440°C) can be generated, resulting in approximately 30–40 MW (33.1–44.1 MW) of electrical power.

**Figure 31.7** Typical RDF Processing

Natural gas is introduced at startup to bring the furnace up to the required 1800°F (1000°C) operating temperature. Natural gas can also be used upon demand, as when a load of particularly wet RDF lowers the furnace temperature.

Coal, oil, or natural gas can be used as a back-up fuel if RDF is unavailable or as an intended part of a *co-firing* design. Co-firing installations are relatively rare, and many have discontinued burning RDF due to poor economic performance. Typical problems with co-firing are (a) upper furnace wall slagging, (b) decreased efficiencies in electrostatic precipitators, (c) increased boiler tube corrosion, (d) excessive amounts of bottoms ash, and (e) difficulties in receiving and handling RDF.

RDF is a low-sulfur fuel, but like MSW, RDF is high in ash and chlorine. Relative to coal, RDF produces less SO<sub>2</sub> but more hydrogen chloride. Bottom ash can also contain trace organics and lead, cadmium, and other heavy metals.

## PART 1: GENERAL CONCEPTS

*Pollution prevention* (sometimes referred to as “P2”) can be achieved in a number of ways. Table 32.1 lists some examples in order of desirability. The most desirable method is reduction at the source. Reduction is accomplished through process modifications, raw material quantity reduction, substitution of materials, improvements in material quality, and increased efficiencies. However, traditional *end-of-pipe* treatment and disposal processes after the pollution is generated remain the main focus. *Pollution control* is the limiting of pollutants in a planned and systematic manner.

**Table 32.1** Pollution Prevention Hierarchy\*

- source reduction
- recycling
- waste separation and concentration
- waste exchange
- energy/material recovery
- waste treatment
- disposal

\*from most to least desirable

Pollution control, hazardous waste, and other environmental regulations vary from nation to nation and are constantly changing. Therefore, regulation-specific issues, including timetables, permit application processes, enforcement, and penalties for violations, are either omitted from this chapter or discussed in general terms. For a similar reason, few limits on pollutant emission rates and concentrations are given in this chapter.<sup>1</sup> Those that are given should be considered merely representative and typical of the general range of values.

<sup>1</sup>Another factor complicating the publication of specific regulations is that the maximum-permitted concentrations and emissions depend on the size and nature of the source.

## PART 2: TYPES AND SOURCES OF POLLUTION

### 1. THE ENVIRONMENT

Specific regulations often deal with parts of the *environment*, such as the atmosphere (i.e., the “air”), oceans and other surface water, subsurface water, and the soil. *Nonattainment areas* are geographical areas identified by regulation that do not meet *national ambient air quality standards* (NAAQS). Nonattainment is usually the result of geography, concentrations of industrial facilities, and excessive vehicular travel, and can apply to any of the regulated substances (e.g., ozone, oxides of sulfur and nitrogen, and heavy metals).

### 2. POLLUTANTS

A *pollutant* is a material or substance that is accidentally or intentionally introduced to the environment in a quantity that exceeds what occurs naturally. Not all pollutants are toxic or hazardous, but the issue is moot when regulations limiting permissible concentrations are specific. As defined by regulations in the United States, *hazardous air pollutants* (HAPs), also known as *air toxics*, consist of trace metals (e.g., lead, beryllium, mercury, cadmium, nickel, and arsenic) and other substances for a total of approximately 200 “listed” substances.<sup>2</sup>

Another categorization defined by regulation in the United States separates pollutants into *criteria pollutants* (e.g., sulfur dioxide, nitrogen oxides, carbon monoxide, volatile organic compounds, particulate matter, and lead) and *noncriteria pollutants* (e.g., fluorides, sulfuric acid mist, reduced sulfur compounds, vinyl chloride, asbestos, beryllium, mercury, and other heavy metals).

### 3. WASTES

*Process wastes* are generated during manufacturing. *Intrinsic wastes* are part of the design of the product and manufacturing process. Examples of intrinsic wastes are impurities in the reactants and raw materials, by-products, residues, and spent materials. Reduction of intrinsic wastes usually means redesigning the product or manufacturing process. *Extrinsic wastes*, on the other hand, are usually reduced by administrative controls, maintenance, training, or recycling. Examples of extrinsic wastes are fugitive leaks and discharges during material handling, testing, or process shutdown.

<sup>2</sup>The most dangerous air toxics include asbestos, benzene, cadmium, carbon tetrachloride, chlorinated dioxins and dibenzofurans, chromium, ethylene dibromide, ethylene dichloride, ethylene oxide and methylene chloride, radionuclides, vinyl chloride, and emissions from coke ovens. Most of these substances are carcinogenic.

*Solid wastes* are garbage, refuse, biosolids, and containerized solid, liquid, and gaseous wastes.<sup>3</sup> *Hazardous waste* is defined as solid waste, alone or in combination with other solids, that because of its quantity, concentration, or physical, chemical, or infectious characteristics may either (a) cause an increase in mortality or serious (irreversible or incapacitating) illness, or (b) pose a present or future hazard to health or the environment when improperly treated, stored, transported, disposed of, or managed.

A substance is *reactive* if it reacts violently with water; if its pH is less than 2 or greater than 12.5, it is *corrosive*; if its flash point is less than 140°F (60°C), it is *ignitable*. The *toxicity characteristic leaching procedure* (TCLP)<sup>4</sup> test is used to determine if the substance is *toxic*. The TCLP tests for the presence of eight metals (e.g., chromium, lead, and mercury) and 25 organic compounds (e.g., benzene and chlorinated hydrocarbons).

Hazardous wastes can be categorized by the nature of their sources. *F-wastes* (e.g., spent solvents and distillation residues) originate from nonspecific sources; *K-wastes* (e.g., separator sludge from petroleum refining) are generated from industry-specific sources; *P-wastes* (e.g., hydrogen cyanide) are acutely hazardous discarded commercial products, off-specification products, and spill residues; *U-wastes* (e.g., benzene and hydrogen sulfide) are other discarded commercial products, off-specification products, and spill residues.

Two notable “rules” pertain to hazardous wastes. The *mixture rule* states that any solid waste mixed with hazardous waste becomes hazardous. The *derived from rule* states that any waste derived from the treatment of a hazardous waste (e.g., ash from the incineration of hazardous waste) remains a hazardous waste.<sup>5</sup>

### 4. POLLUTION SOURCES

A *pollution source* is any facility that produces pollution. A *generator* is any facility that generates hazardous waste. The term “major” (i.e., a *major source*) is defined differently for each class of nonattainment areas.<sup>6</sup>

The combustion of fossil fuels (e.g., coal, fuel oil, and natural gas) to produce steam in electrical generating plants is the most significant source of airborne pollution. For this reason, this industry is among the most highly regulated.

<sup>3</sup>The term *biosolids* is replacing the term *sludge* when it refers to organic waste produced from biological wastewater treatment processes. Sludge from industrial processes and flue gas cleanup (FGC) devices retains its name.

<sup>4</sup>Probably no subject in this book has more acronyms than environmental engineering. All the acronyms used in this chapter are in actual use; none was invented for the benefit of the chapter.

<sup>5</sup>Hazardous waste should not be incinerated with nonhazardous waste, as all of the ash would be considered hazardous by these rules.

<sup>6</sup>A nonattainment area is classified as marginal, moderate, serious, severe, or extreme based on the average pollution (e.g., ozone) level measured in the area.

Specific regulations pertain to generators of hazardous waste. Generators of more than certain amounts (e.g., 100 kg/month) must be registered (i.e., with the Environmental Protection Agency (EPA)). Restrictions are placed on generators in the areas of storage, personnel training, shipping, treatment, and disposal.

## 5. ENVIRONMENTAL IMPACT REPORTS

New installations and large-scale construction projects must be assessed for potential environmental damage before being approved by state and local building officials. The assessment is documented in an *environmental impact report* (EIR). The EIR evaluates all of the potential ways that a project could affect the ecological balance and environment. A report that alleges the absence of any environmental impacts is known as a *negative declaration* ("negative dec").

The following issues are typically addressed in an EIR.

1. the nature of the proposed project
2. the nature of the project area, including distinguishing natural and human-made characteristics
3. current and proposed percentage uses by zoning: residential, commercial, industrial, public, and planned development
4. current and proposed percentage uses by application: built up, landscaped, agricultural, paved streets and highways, paved parking, surface and aerial utilities, railroad, and vacant and unimproved
5. the nature and degree that the earth will be altered:  
(a) changes in topology from excavation and earth movement to and from the site, (b) changes in slope, (c) changes in chemical composition of the soil, and (d) changes in structural capacity of the soil as a result of compaction, tilling, shoring, or changes in moisture content
6. the nature of known geologic hazards such as earthquake faults and soil instability (subsidence, landslides, and severe erosion)
7. increases in dust, smoke, or air pollutants generated by hauling during construction
8. changes in path, direction, and capacity of natural draining or tendency to flood
9. changes in erosion rates on and off the site
10. the extent to which the project will affect the potential use, extraction, or conservation of the earth's resources, such as crops, minerals, and groundwater
11. after construction is complete, the nature and extent to which the completed project's sewage, drainage, airborne particulate matter, and solid waste will affect the quality and characteristics of the soil, water, and air in the immediate project area and in the surrounding community
12. the quantity and source of fresh water consumed as a result of the project
13. effects on the plant and animal life currently on site
14. effects on any unique (i.e., not found anywhere else in the city, county, state, or nation) natural or human-made features
15. effects on any historically significant or archeological site
16. changes to the view of the site from points around the project
17. changes affecting wilderness use, open space, landscaping, recreational use, and other aesthetic considerations
18. effects on the health and safety of the people in the project area
19. changes to existing noise levels
20. changes in the number of people who will (a) live or (b) work in the project area
21. changes in the burden placed on roads, highways, intersections, railroads, mass transit, or other elements of the transportation system
22. changes in the burden placed on other municipal services, including sewage treatment; health, fire, and police services; utility companies; and so on.
23. the extent to which hazardous materials will be involved, generated, or disposed of during or after construction

## PART 3: ENVIRONMENTAL ISSUES

### 6. INTRODUCTION

Engineers face many environmental issues. This part of the chapter discusses (in alphabetical order) some of them. In some cases, "listed substances" (e.g., those that are specifically regulated) are discussed. In other cases, environmental issues are discussed in general terms.

*Environmental engineering* covers an immense subject area, and this chapter is merely an introduction to some of the topics. Some subjects "belong" to other engineering disciplines. For example, coal-fired plants are typically designed by mechanical engineers. Other subjects, such as the storage and destruction of nuclear wastes, are specialized topics subject to changing politics, complex legislation, and sometimes-untested technologies. Finally, some wastes are considered nonhazardous industrial wastes and are virtually unregulated. They are not discussed in this chapter, either. Processing of

medical wastes, personal safety, and the physiological effects of exposure, as important as they are, are beyond the scope of this chapter.

Other philosophical and political issues, such as nuclear fuel versus fossil fuel, plastic bags versus paper bags, and disposable diapers versus cloth diapers, are similarly not covered.

## 7. ACID GAS

*Acid gas* generally refers to *sulfur trioxide*,  $\text{SO}_3$ , in flue gas.<sup>7,8</sup> *Sulfuric acid*,  $\text{H}_2\text{SO}_4$ , formed when sulfur trioxide combines with water, has a low vapor pressure and, consequently, a high boiling point. Hydrochloric (HCl), hydrofluoric (HF), and nitric ( $\text{HNO}_3$ ) acids also form in smaller quantities. However, unlike sulfuric acid, they do not lower the vapor pressure of water significantly. Therefore, any sulfuric acid present will control the dew point.

Sulfur trioxide has a large affinity for water, forming a strong acid even at very low concentrations. At the elevated temperatures in a stack, sulfuric acid attacks steel, almost all plastics, cement, and mortar. Sulfuric acid can be prevented from forming by keeping the temperature of the flue gas above the dew-point temperature. This may require preheating equipment prior to start-up and postheating during shutdown.

*Hydrochloric acid* does not normally occur unless the fuel has a high chlorine content, as chlorinated solvents, municipal solid wastes (MSW), and refuse-derived fuels (RDF) do. Hydrochloric acid formed during the combustion of MSW and RDF can be removed by semidry scrubbing. HCl removal efficiencies of 90–99% are common. (See also Sec. 32.8 and Sec. 32.39.)

## 8. ACID RAIN

*Acid rain* consists of weak solutions of sulfuric, hydrochloric, and to a lesser extent, nitric acids. These acids are formed when emissions of sulfur oxides ( $\text{SO}_x$ ), hydrogen chloride (HCl), and nitrogen oxides ( $\text{NO}_x$ ) return to the ground in rain, fog, or snow, or as dry particles and gases. Acid rain affects lakes and streams, damages buildings and monuments, contributes to reduced visibility, and affects certain tree species. Acid rain may also represent a health hazard. (See also Sec. 32.7 and Sec. 32.39.)

## 9. ALLERGENS AND MICROORGANISMS

Allergens such as molds, viruses, bacteria, animal droppings, mites, cockroaches, and pollen can cause allergic reactions in humans. One form of bacteria, *legionella*, causes the potentially fatal *Legionnaires' disease*. Inside buildings, allergens and microorganisms become particularly concentrated in standing water, carpets, HVAC

<sup>7</sup>The term *stack gas* is used interchangeably with *flue gas*.

<sup>8</sup>Sulfur dioxide normally is not a source of acidity in the flue gas.

filters and humidifier pads, and in locations where birds and rodents have taken up residence. *Legionella* bacteria can also be spread by aerosol mists generated by cooling towers and evaporative condensers if the bacteria are present in the recirculating water.

Some buildings cause large numbers of people to simultaneously become sick, particularly after a major renovation or change has been made. This is known as *sick building syndrome* or *building-related illness*. This phenomenon can be averted by using building materials that do not release vapor over time (e.g., as does plywood impregnated with formaldehyde) or harbor other irritants. Carpets can accumulate dusts. Repainting, wallpapering, and installing new flooring can release new airborne chemicals. Areas must be flushed with fresh air until all noticeable effects have been eliminated.

Care must also be taken to ensure that filters in the HVAC system do not harbor microorganisms and are not contaminated by bird or rodent droppings. Air intakes must not be located near areas of chemical storage or parking garages.

## 10. ASBESTOS

Asbestos is a fibrous silicate mineral material that is inert, strong, and incombustible. Once released into the air, its fibers are light enough to stay airborne for a long time.

Asbestos has typically been used in woven and compressed forms in furnace insulation, gaskets, pipe coverings, boards, roofing felt, and shingles, and has been used as a filler and reinforcement in paint, asphalt, cement, and plastic. Asbestos is no longer banned outright in industrial products. However, regulations, well-publicized health risks associated with cancer and *asbestosis*, and potential liabilities have driven producers to investigate alternatives.

No single product has emerged as a suitable replacement for all asbestos applications. (Almost all replacements are more costly.) *Fiberglass* is an insulator with superior tensile strength but low heat resistance. Fiberglass has a melting temperature of approximately 1000°F (538°C). However, fiberglass treated with hydrochloric acid to leach out most of the silica ( $\text{SiO}_2$ ) can withstand 2000–3500°F (1090–1930°C).

In typical static sealing applications, *aramid fibers* (known by the trade names Kevlar™ and Twaron™) are particularly useful up to approximately 800°F (427°C). However, aramid fibers cannot withstand the caustic, high-temperature environment encountered in curing concrete.

## 11. BOTTOM ASH

*Ash* is the residue left after combustion of a fossil fuel. *Bottom ash* (*bottoms ash* or *bottoms*) is the ash that is removed from the combustor after a fuel is burned. (The

rest of the ash is fly ash.) The ash falls through the combustion grates into quenching troughs below. It may be continuously removed by *submerged scraper conveyors* (SSCs), screw-type devices, or ram dischargers. The ash can be dewatered to approximately 15% moisture content by compression or by being drawn up a dewatering slope. Bottom ash is combined with conditioned fly ash on the way to the ash storage bunker.<sup>9</sup> Most combined ash is eventually landfilled.

## 12. DISPOSAL OF ASH

*Combined ash* (bottom ash and fly ash) is usually landfilled. Other occasional uses for high-quality combustion ash (not ash from the incineration of municipal solid waste) include roadbed subgrades, road surfaces ("ash-phalt"), and building blocks.

## 13. CARBON DIOXIDE

Carbon dioxide, though an environmental issue, is not a hazardous material and is not regulated as a pollutant.<sup>10</sup> Carbon dioxide is not an environmental or human toxin, is not flammable, and is not explosive. Skin contact with solid or liquid carbon dioxide presents a freezing hazard. Other than the remote potential for causing frostbite, carbon dioxide has no long-term health effects. Its major hazard is that of asphyxiation, by excluding oxygen from the lungs.

## 14. CARBON MONOXIDE

Carbon monoxide, CO, is formed during incomplete combustion of carbon in fuels. This is usually the result of an oxygen deficiency at lower temperatures. Carbon monoxide displaces oxygen in the bloodstream, so it represents an asphyxiation hazard. Carbon monoxide does not contribute to smog.

The generation of carbon monoxide can be minimized by furnace monitoring and control. For industrial sources, the American Boiler Manufacturers Association (ABMA) recommends limiting carbon monoxide to 400 ppm (corrected to 3% O<sub>2</sub>) in oil- and gas-fired industrial boilers. This value can usually be met with reasonable ease. Local ordinances may be more limiting, however.

Most carbon monoxide released in highly populated areas comes from vehicles. Vehicular traffic may cause the CO concentration to exceed regulatory limits. For this reason, *oxygenated fuels* are required to be sold in those areas during certain parts of the year. Oxygenated gasoline has a minimum oxygen content of approximately 2.0%. Oxygen is increased in gasoline with

<sup>9</sup>Approximately half of the electrical generating plants in the United States use wet fly ash handling.

<sup>10</sup>Industrial exposure is regulated by the U.S. Occupational Safety and Health Administration (OSHA).

additives such as ethanol (ethyl alcohol). Methyl tertiary butyl ether (MTBE) continues to be used as an oxygenate outside of the United States.

Minimization of carbon monoxide is compromised by efforts to minimize nitrogen oxides. Control of these pollutants is inversely related.

## 15. CHLOROFUOROCARBONS

Most atmospheric oxygen is in the form of two-atom molecules, O<sub>2</sub>. However, there is a thin layer in the stratosphere about 12 miles up where *ozone* molecules, O<sub>3</sub>, are found in large quantities. Ozone filters out ultraviolet radiation that damages crops and causes skin cancer.

Chlorofluorocarbons (i.e., chlorinated fluorocarbons, such as Freon™) contribute to the deterioration of the earth's ozone layer. Ozone in the atmosphere is depleted in a complex process involving pollutants, wind patterns, and atmospheric ice. As chlorofluorocarbon molecules rise through the atmosphere, solar energy breaks the chlorine free. The chlorine molecules attach themselves to ozone molecules, and the new structure eventually decomposes into chlorine oxide and normal oxygen, O<sub>2</sub>. The depletion process is particularly pronounced in the Antarctic because that continent's dry, cold air is filled with ice crystals on whose surfaces the chlorine and ozone can combine. Also, the prevailing winter wind isolates and concentrates the chlorofluorocarbons.

The depletion is not limited to the Antarctic; it also occurs throughout the northern hemisphere, including virtually all of the United States.

The 1987 Montreal Protocol (conference) resulted in an international agreement to phase out worldwide production of chemical compounds that have ozone-depletion characteristics. Since 2000 (the peak of Antarctic ozone depletion), concentrations of atmospheric chlorine have decreased, and ozone layer recovery is increasing.

Over the years, the provisions of the 1987 Montreal Protocol have been modified numerous times. Substance lists have been amended, and action deadlines have been extended. In many cases, though production may have ceased in a particular country, significant recycling and stockpiling keeps chemicals in use. Voluntary compliance by some nations, particularly developing countries, is spotty or nonexistent. In the United States, provisions have been incorporated into the Clean Air Act (Title VI) and other legislation, but such provisions are subject to constant amendment.

Special allowances are made for aviation safety, national security, and fire suppression and explosion prevention if safe or effective substitutes are not available for those purposes. Excise taxes are used as interim disincentives for those who produce the compounds. Large reserves and recycling, however, probably ensure that chlorofluorocarbons and halons will be in use for many years after the deadlines have passed.

Replacements for chlorofluorocarbons (CFCs) include hydrochlorofluorocarbons (HCFCs) and hydrofluorocarbons (HFCs), both of which are environmentally more benign than CFCs, and blends of HCFCs and HFCs. (See Table 32.2.) The additional hydrogen atoms in the molecules make them less stable, allowing nearly all chlorine to dissipate in the lower atmosphere before reaching the ozone layer. The lifetime of HCFC molecules is 2 years to 25 years, compared with 100 years or longer for CFCs. The net result is that HCFCs have only 2–10% of the ozone-depletion ability of CFCs. HFCs have no chlorine and thus cannot deplete the ozone layer.

**Table 32.2** Typical Replacement Compounds for Chlorofluorocarbons

designation	applications
HCFC 22	low- and medium-temperature refrigerant; blowing agent; propellant
HCFC 123	replacement for CFC-11; industrial chillers and applications where potential for exposure is low; somewhat toxic; blowing agent; replacement for perchloroethylene (dry cleaning fluid)
HCFC 124	industrial chillers; blowing agent
HFC 134a	replacement for CFC-12; medium-temperature refrigeration systems; centrifugal and reciprocating chillers; propellant
HCFC 141b	replacement for CFC-11 as a blowing agent; solvent
HCFC 142b	replacement for CFC-12 as a blowing agent; propellant
IPC (isopropyl chloride)	replacement for CFC-11 as a blowing agent

Most chemicals intended to replace CFCs still have chlorine, but at reduced levels. Additional studies are determining if HCFCs and HFCs accumulate in the atmosphere, how they decompose, and whether any by-products could damage the environment.

*Halon* is a generic term used to refer to various liquefied, compressed gas *halomethanes* containing bromine, fluorine, and chlorine. Halons continue to be in widespread legal use for various specialty purposes known as *critical uses* (as defined by the EPA) because they are nonconducting, leave no residue upon evaporation, and are relatively safe for human exposure. For example, halons are commonly found in aircraft, ship engine compartments, military vehicles, cleanrooms, and commercial kitchen fire suppression systems. Halon 1011 (bromochloromethane,  $\text{CH}_2\text{BrCl}$ ) is used in portable fire extinguishers. Halon 1211 (bromochlorodifluoromethane,  $\text{CBrClF}_2$ ) is

used when the fire extinguishing application method is liquid streaming. Halon 1301 (bromotrifluoromethane,  $\text{CBrF}_3$ ) is a gaseous flooding agent, as is required in aircraft suppression systems. Halons are rated for flammable liquids (class B fires) and electrical fires (class C fires), although they are also effective on common combustibles (class A fires). Halons are greenhouse gases, so at least in the United States, production of new halons has ceased. Existing inventory stockpiles, recycling, and importing are used to satisfy current demands.

## 16. COOLING TOWER BLOWDOWN

State-of-the art reuse programs in *cooling towers* (CTs) may recirculate water 15 to 20 times before it is removed through blowdown. Pollutants such as metals, herbicides, and pesticides originally in the makeup water are concentrated to five or six times their incoming concentrations. Most CTs are constructed with copper alloy condenser tubes, so the recirculated water becomes contaminated with copper ions as well. CT water also usually contains chlorine compounds or other biocides added to inhibit biofouling. Ideally, no water should leave the plant (i.e., a *zero-discharge facility*). If discharged, CT blowdown must be treated prior to disposal.

## 17. CONDENSER COOLING WATER

Approximately half of the electrical generation plants in the United States use *once-through* (OT) *cooling water*. The discharged cooling water may be a chemical or thermal pollutant. Since fouling in the main steam condenser significantly reduces performance, water can be treated by the intermittent addition of chlorine, chlorine dioxide, bromine, or ozone, and these chemicals may be present in residual form. *Total residual chlorine* (TRC) is regulated. Methods of chlorine control include *targeted chlorination* (the frequent application of small amounts of chlorine where needed) and *dechlorination*.

## 18. DIOXINS

Dioxins are a family of chlorinated dibenzo-*p*-dioxins (CDDs). The term *dioxin*, however, is commonly used to refer to the specific congener 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD). Primary dioxin sources include herbicides containing 2,4-D, 2,4,5-trichlorophenol, and hexachlorophene. Other potential sources include incinerated municipal and industrial waste, leaded gasoline exhaust, chlorinated chemical wastes, incinerated polychlorinated biphenyls (PCBs), and any combustion in the presence of chlorine.

The exact mechanism of dioxin formation during incineration is complex but probably requires free chlorine (in the form of HCl vapor), heavy metal concentrations (often found in the ash), and a critical temperature window of 570–840°F (300–450°C). Dioxins in incinerators

probably form near waste heat boilers, which operate in this temperature range.

Dioxin destruction is difficult because it is a large organic molecule with a high boiling point. Most destruction methods rely on high temperature since temperatures of 1550°F (850°C) denature the dioxins. Other methods include physical immobilization (i.e., vitrification), dehalogenation, oxidation, and catalytic cracking using catalysts such as platinum.

Dioxins liberated during the combustion of municipal solid waste (MSW) and refuse-derived fuel (RDF) can be controlled by the proper design and operation of the furnace combustion system. Once formed, they can be removed by end-of-pipe processes, including activated charcoal (AC) injection. Success has also been reported using the vanadium oxide catalyst used for NO<sub>x</sub> removal, as well as manganese oxide and tungsten oxide.

## 19. DUST, GENERAL

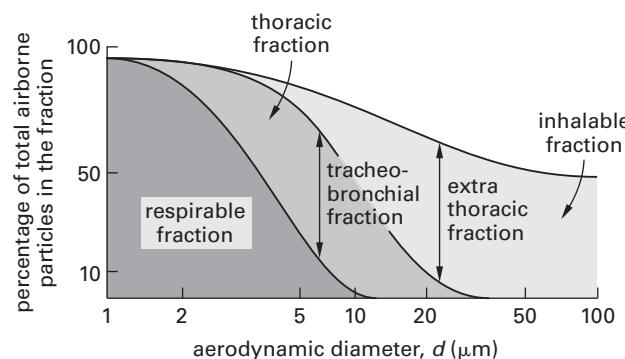

Dust or *fugitive dust* is any solid particulate matter (PM) that becomes airborne, with the exception of PM emitted from the exhaust stack of a combustion process. Nonhazardous fugitive dusts are commonly generated when a material (e.g., coal) is unloaded from trucks and railcars. Dusts are also generated by manufacturing, construction, earth-moving, sand blasting, demolition, and vehicle movement.

Dusts pose three types of hazards. (a) Inhalation of airborne dust or vapors, particularly those that carry hazardous compounds, is the major concern. Even without toxic compounds, odors can be objectionable. Dusts are easily observed and can cover cars and other objects left outside. (b) Dusts can transport hazardous materials, contaminating the environment far from the original source. (c) In closed environments, even nontoxic dusts can represent an explosion hazard.

Dusts are categorized by size according to how deep they can penetrate into the respiratory system. Particle size is based on *aerodynamic equivalent diameter* (AED), the diameter of a sphere with the density of water (62.4 lbm/ft<sup>3</sup> (1000 kg/m<sup>3</sup>)) that would have the same settling velocity as the particle. The distribution of dust sizes is divided into three fractions, also known as *conventions*. The *inhalable fraction* (*inhalable convention*) (< 100 µm AED;  $d_{50} = 100 \mu\text{m}$ ) can be breathed into the nose and mouth; the *thoracic fraction* (< 25 µm AED;  $d_{50} = 10 \mu\text{m}$ ) can enter the larger lung airways; and the *respirable fraction* (< 10 µm AED;  $d_{50} = 4 \mu\text{m}$ ) can penetrate beyond terminal bronchioles into the gas exchange regions. (See Fig. 32.1.)

Dust emission reduction from *spot sources* (e.g., manufacturing processes such as grinders) is accomplished by *inertial separators* such as cyclone separators. Potential dust sources (e.g., truck loads and loose piles) can be covered, and dust generation can be reduced by spraying water mixed with other compounds.

**Figure 32.1** Airborne Particle Fractions

There are three mechanisms of dust control by spraying. (a) In *particle capture* (as occurs in a spray curtain at a railcar unloading station), suspended particles are knocked down, wetted, and captured by liquid droplets. (b) In *bulk agglomeration* (as when a material being carried on a screw conveyor is sprayed), the moisture keeps the dust with the material being transported. (c) Spraying roads and coal piles to inhibit wind-blown dust is an example of *surface stabilization*.

Wetting agents are *surfactant* formulations added to water to improve water's ability to wet and agglomerate fine particles.<sup>11</sup> The resulting solution can be applied as liquid spray or as a foam.<sup>12</sup> *Humectant binders* (e.g., magnesium chloride and calcium chloride) and adhesive binders (e.g., waste oil) may also be added to the mixture to make the dust adhere to the contact surface if other water-based methods are ineffective.<sup>13</sup>

Surface stabilization of materials stored outside and exposed to wind, rain, freeze-thaw cycles, and ultraviolet radiation is enhanced by the addition of *crusting agents*.

## 20. DUST, COAL

Clean coals, western low-sulfur coal, eastern low-sulfur coal, eastern high-sulfur coal, low-rank lignite coal, and varieties in between have their own peculiar handling characteristics.<sup>14</sup> *Dry ultra-fine coal* (DUC) and coal slurries have their own special needs.

Western coals have a lower sulfur content, but because they are easily fractured, they generate more dust. Western coals also pose higher fire and explosion hazards than eastern coals. Water misting or foam must be applied to coal cars, storage piles, and conveyor transfer points.

<sup>11</sup>A *surface-acting agent* (*surfactant*) is a soluble compound that reduces a liquid's surface tension or reduces the interfacial tension between a liquid and a solid.

<sup>12</sup>Collapsible aqueous foam is an increasingly popular means of reducing the potential for explosions in secondary coal crushers.

<sup>13</sup>A *humectant* is a substance that absorbs or retains moisture.

<sup>14</sup>A valuable resource for this subject is NFPA 850, *Recommended Practice for Fire Protection for Electrical Generating Plants and High-Voltage Direct Current Converter Stations*, National Fire Protection Association, Quincy, MA.

Adequate ventilation in storage silos and bunkers is also required, with the added benefit of reducing methane accumulation.

DUC is as fine as talcum ( $10 \mu\text{m}$  with less than 10% moisture).<sup>15</sup> It must be containerized for transport, because traditional railcars are not sufficiently airtight. Also, since the minimum oxygen content for combustion of 14–15% is satisfied by atmospheric air, DUC should be maintained in a pressurized, oxygen-depleted environment until used. Pneumatic flow systems are used to transport DUC through the combustion plant.

## 21. FUGITIVE EMISSIONS

Equipment leaks from plant equipment are called *fugitive emissions* (FEs). Leaks from pump and valve seals are common sources, though compressors, pressure-relief devices, connectors, sampling systems, closed vents, and storage vessels are also potential sources. FEs are reduced administratively by *leak detection and repair programs* (LDARs).

Some common causes of fugitive emissions include (a) equipment in poor condition, (b) off-design pump operation, (c) inadequate seal characteristics, and (d) inadequate boiling-point margin in the seal chamber. Other pump/shaft/seal problems that can increase emissions include improper seal-face material, excessive seal-face loading and seal-face deflections, and improper pressure balance ratio.

Inadequate *boiling-point margin* (BPM) results in poor seal performance and face damage. BPM is the difference between the seal chamber temperature and the initial boiling point temperature of the pumped product at the seal chamber pressure. When seals operate close to the boiling point, seal-generated heat can cause the pumped product between the seal faces to flash and the seal to run dry. A minimum BPM of  $15^\circ\text{F}$  ( $9^\circ\text{C}$ ) or a 25 psig (172 kPa) pressure margin is recommended to avoid flashing. Even greater margins will result in longer seal life and reduced emissions.

## 22. GASOLINE-RELATED POLLUTION

Gasoline-related pollution is primarily in the form of unburned hydrocarbons, nitrogen oxides, lead, and carbon monoxide. (The requirement for lead-free automobile gasoline has severely curtailed gasoline-related lead pollution. Low-lead aviation fuel remains in use.) Though a small reduction in gasoline-related pollution can be achieved by blending detergents into gasoline, reformulation is required for significant improvements. Table 32.3 lists typical characteristics for traditional and reformulated gasolines.

The potential for smog formation can be reduced by reformulating gasoline and/or reducing the summer

<sup>15</sup>A  $\mu\text{m}$  is a *micrometer*,  $10^{-6}\text{ m}$ , and is commonly referred to as a *micron*.

**Table 32.3** Typical Gasoline Characteristics

fuel parameter	traditional	reformulated
sulfur	150 ppmw*	40 ppmw
benzene	2% by vol	1% by vol
olefins	9.9% by vol	4% by vol
aromatic hydrocarbons	32% by vol	25% by vol
oxygen	0	1.8 to 2.2% by wt
T90	$330^\circ\text{F}$ ( $166^\circ\text{C}$ )	$300^\circ\text{F}$ ( $149^\circ\text{C}$ )
T50	$220^\circ\text{F}$ ( $104^\circ\text{C}$ )	$210^\circ\text{F}$ ( $99^\circ\text{C}$ )
RVP	8.5 psig (59 kPa)	7 psig (48 kPa)

(Multiply psi by 6.89 to obtain kPa.)

\*ppmw stands for parts per million by weight (same as ppmm, parts per million by mass).

*Reid vapor pressure* (RVP) of the blend. Regulatory requirements to reduce the RVP can be met by using less butane in the gasoline. However, reformulating to remove pentanes is required when the RVP is required to achieve 7 psig (48 kPa) or below. Sulfur content can be reduced by pretreating the refinery feed in hydrodesulfurization (HDS) units. Heavier gasoline components must be removed to lower the 50% and 90% *distillation temperatures* (T50 and T90).

## 23. GLOBAL WARMING

The *global warming* theory is that increased levels of atmospheric carbon dioxide,  $\text{CO}_2$ , from the combustion of carbon-rich fossil fuels and other *greenhouse gases* (e.g., water vapor, methane, nitrous oxide, and chlorofluorocarbons) trap an increasing amount of solar radiation in a *greenhouse effect*, gradually increasing the earth's temperature.

Recent studies have shown that atmospheric carbon dioxide has increased at the rate of about 0.4% per year since 1958. (For example, in one year carbon dioxide might increase from 390 ppmv to 392 ppmv. By comparison, oxygen is approximately 209,500 ppmv.) There has also been a 100% increase in atmospheric methane since the beginning of the industrial revolution. However, increases in carbon dioxide have not correlated conclusively with surface temperature change. According to most researchers, there has been a global temperature increase of approximately  $1.6^\circ\text{F}$  ( $0.91^\circ\text{C}$ ) during the past 50 years.<sup>16</sup> However, the 2014 NOAA/NASA *GISS Surface Temperature Analysis* data noted that the five-year mean surface temperature has not changed in more than ten years. Other studies have shown that temperatures since 2005 are not well-predicted by climate models, which produced higher results.

In addition to a temperature increase, other evidence of the global warming theory are record-breaking hot

<sup>16</sup>Other researchers detect no discernible upward trend.

summers, widespread aberrations in the traditional seasonal weather patterns (e.g., hurricane-like storms in England), an increase in the length of the arctic melt season, melting of glaciers and the ice caps, and an average 7 in (18 cm) rise in sea level over the last century.<sup>17</sup> It has been predicted that there will be a temperature increase of 2–11.5°F (1.1–6.4°C) by the year 2100.

Although global warming is generally accepted, its anthropogenic (human-made) causes are not. The global warming theory is disputed by some scientists and has not been proven to be an absolute truth. Arguments against the theory center around the fact that manufactured carbon dioxide is a small fraction of what is naturally released (e.g., by wetlands, in rain forest fires, and during volcanic eruptions). It is argued that, in the face of such massive contributors, and since the earth's temperature has remained essentially constant for millenia, the earth already possesses some built-in mechanism, currently not perfectly understood, that reduces the earth's temperature swings.

Most major power generation industries have adopted goals of reducing carbon dioxide emissions. However, efforts to reduce carbon dioxide emissions by converting fossil fuel from one form to another are questioned by many engineers. Natural gas produces the least amount of carbon dioxide of any fossil fuel. Therefore, conversion of coal to a gas or liquid fuel in order to lower the carbon-to-hydrogen ratio would appear to lessen carbon dioxide emissions at the point of final use. However, the conversion processes consume energy derived from carbon-containing fuel. This additional consumption, taken over all sites, results in a net increase in carbon dioxide emission of 10–200%, depending on the process.

The use of ethanol as an alternative for gasoline is also problematic. Manufacturing processes that produce ethanol give off (at least) twice as much carbon dioxide as the gasoline being replaced produces during combustion.

Most synthetic fuels are intrinsically less efficient (based on their actual heating values compared with those theoretically obtainable from the fuels' components in elemental form). This results in an increase in the amount of fuel consumed. Thus, fossil fuels should be used primarily in their raw forms until cleaner sources of energy are available.

## 24. LEAD

Lead, even in low concentrations, is toxic. Inhaled lead accumulates in the blood, bones, and vital organs. It can produce stomach cramps, fatigue, aches, and nausea. It causes irreparable damage to the brain, particularly in young and unborn children, and high blood pressure in

<sup>17</sup>The rise in the level of the oceans is generally accepted though the causes are disputed. Satellite altimetry indicates a current rise rate of 12 in (30 cm) per century.

adults. At high concentrations, lead damages the nervous system and can be fatal.

Lead was outlawed in paint in the late 1970s.<sup>18</sup> Lead has also been removed from most gasoline blends. Lead continues to be used in large quantities in automobile batteries and plating and metal-finishing operations. However, these manufacturing operations are tightly regulated. Lead enters the atmosphere during the combustion of fossil fuels and the smelting of sulfide ore. Lead enters lakes and streams primarily from acid mine drainage.

For lead in industrial and municipal wastewater, current remediation methods include pH adjustment with lime or alkali hydroxides, coagulation-sedimentation, reverse osmosis, and zeolite ion exchange.

## 25. NITROGEN OXIDES

Nitrogen oxides (NOx) are one of the primary causes of smog formation. NOx from the combustion of coal is primarily *nitric oxide* (NO) with small quantities of *nitrogen dioxide* (NO<sub>2</sub>).<sup>19</sup> NO<sub>2</sub> can be a primary or a secondary pollutant. Although some NO<sub>2</sub> is emitted directly from combustion sources, it is also produced from the oxidation of nitric oxide, NO, in the atmosphere.

NOx is produced in two ways: (a) *thermal NOx* produced at high temperatures from free nitrogen and oxygen, and (b) *fuel NOx* (or *fuel-bound NOx*) formed from the decomposition/combustion of fuel-bound nitrogen.<sup>20</sup> When natural gas and light distillate oil are burned, almost all of the NOx produced is thermal. Residual fuel oil, however, can have a nitrogen content as high as 0.3%, and 50–60% of this can be converted to NOx. Coal has an even higher nitrogen content.<sup>21</sup>

Thermal NOx is usually produced in small (but significant) quantities when excess oxygen is present at the highest temperature point in a furnace, such that nitrogen (N<sub>2</sub>) can dissociate.<sup>22</sup> Dissociation of N<sub>2</sub> and O<sub>2</sub> is

<sup>18</sup>Workers can be exposed to lead if they strip away lead-based paint, demolish old buildings, or weld or cut metals that have been coated with lead-based paint.

<sup>19</sup>Other oxides are produced in insignificant amounts. These include *nitrous oxide* (N<sub>2</sub>O), N<sub>2</sub>O<sub>4</sub>, N<sub>2</sub>O<sub>5</sub>, and NO<sub>3</sub>, all of which are eventually oxidized to (and reported as) NO<sub>2</sub>.

<sup>20</sup>Some engineers further divide the production of fuel-bound NOx into low- and high-temperature processes and declare a third fuel-related NOx-production method known as *prompt-NOx*. Prompt-NOx is the generation of the first 15–20 ppm of NOx from partial combustion of the fuel at lower temperatures.

<sup>21</sup>In order of increasing fuel-bound NOx production potential, common boiler fuels are: methanol, ethanol, natural gas, propane, butane, ultra-low-nitrogen fuel oil, fuel oil no. 2, fuel oil no. 6, and coal.

<sup>22</sup>The *mean residence time* at the high temperature points of the combustion gases is also an important parameter. At temperatures below 2500°F (1370°C), several minutes of exposure may be required to generate any significant quantities of NOx. At temperatures above 3000°F (1650°C), dissociation can occur in less than a second. At the highest temperatures—3600°F (1980°C) and above—dissociation takes less than a tenth of a second.

negligible, and little or no thermal NOx is produced below approximately 3000°F (1650°C).

Formation of thermal NOx is approximately exponential with temperature. For this reason, many NOx-reduction techniques attempt to reduce the *peak flame temperature* (PFT). NOx formation can also be reduced by injecting urea or ammonia reagents directly into the furnace.<sup>23</sup> The relationship between NOx production and excess oxygen is complex, but NOx production appears to vary directly with the square root of the oxygen concentration.

In existing plants, retrofit NOx-reduction techniques include using fuel-rich combustion (i.e., staged air burners), recirculating flue gas, changing to a low-nitrogen fuel, reducing air preheat, installing low-NOx burners, and using overfire air.<sup>24</sup> Low-NOx burners using controlled flow/split flame or internal fuel staging technology are essentially direct replacement (i.e., “plug in”) units, differing from the original burners primarily in nozzle configuration. However, some fuel supply and air modifications may also be needed. Use of overfire air requires windbox modifications and separate ducts.

Lime spray-dryer scrubbers of the type found in electrical generating plants do not remove all of the NOx. Further reduction requires that the remaining NOx be destroyed. Reburn, selective catalytic reduction (SCR), and selective noncatalytic methods are required.

Scrubbing, incineration, and other end-of-pipe methods typically have been used to reduce NOx emissions from stationary sources such as gas turbine-generators, although these methods are unwieldy for the smallest units. Water/steam injection, catalytic combustion, and *selective catalytic reduction* (SCR) are particularly suited for gas-turbine and combined-cycle installations. SCR is also effective in NOx reduction in all heater and boiler applications.

The volumetric fraction (in ppm) of NOx in the flue gas is calculated from the molecular weight and mass flow rates. The molecular weight of NOx is assumed to be 46.<sup>25</sup> The ratio of  $\dot{m}_{\text{NOx}} / \dot{m}_{\text{flue gas}}$ , percentage of water vapor, and flue gas molecular weight are derived from flue gas analysis.

$$B_{\text{NOx}} = \left( \frac{\dot{m}_{\text{NOx}}}{\dot{m}_{\text{flue gas}}} \right) (10^6) \left( \frac{\text{MW}_{\text{flue gas}}}{\text{MW}_{\text{NOx}}} \right) \times \left( \frac{100\%}{100\% - \%_{\text{H}_2\text{O}}} \right) \quad 32.1$$

<sup>23</sup> Urea ( $\text{NH}_2\text{CONH}_2$ ), also known as *carbamide urea*, is a water-soluble organic compound prepared from ammonia. Urea has significant biological and industrial usefulness.

<sup>24</sup> Air is injected into the furnace at high velocity over the combustion bed to create turbulence and to provide oxygen.

<sup>25</sup> 46 is the molecular weight of  $\text{NO}_2$ . The predominant oxide in the flue gas is NO, and  $\text{NO}_2$  may be only 10% to 15% of the total NOx. Furthermore, NO is measured, not  $\text{NO}_2$ . However, NO has a short half-life and is quickly oxidized to  $\text{NO}_2$  in the atmosphere.

Since the apparent concentration of NOx could be arbitrarily decreased without reducing the NOx production rate by simply diluting the combustion gas with excess air, it is common to correct NOx readings to 3% O<sub>2</sub> by volume on a dry basis. (This is indicated by the units *ppmvd*.) Standardizing is accomplished by multiplying the measured NOx reading (in ppmvd) by the O<sub>2</sub> correction factor from Eq. 32.2. (Corrections to 7%, 12%, and 15% oxygen content are also used. For a correction to any other percentage of O<sub>2</sub>, replace the 3% in Eq. 32.2 with the new value.)

$$\begin{aligned} \text{O}_2 \text{ correction factor} &= \frac{21\% - 3\%}{21\% - \%_{\text{O}_2}} \\ &= \frac{18\%}{21\% - \%_{\text{O}_2}} \end{aligned} \quad 32.2$$

If the flue gas analysis is on a wet basis, Eq. 32.3 can be used to calculate the multiplicative factor.

$$\begin{aligned} \text{O}_2 \text{ correction factor} &= \frac{21\% - 3\%}{21\% - \left( \frac{100\%}{100\% - \%_{\text{H}_2\text{O}}} \right) (\%_{\text{O}_2})} \\ &= \frac{18\%}{21\% - \left( \frac{100\%}{100\% - \%_{\text{H}_2\text{O}}} \right) (\%_{\text{O}_2})} \end{aligned} \quad 32.3$$

Some regulations specify NOx limitations in terms of pounds per hour or in terms of pounds of NOx per million Btus (MMBtu) of gross heat released. The mass emission ratio, *E*, in lbm/MMBtu, is calculated from the concentration in pounds per dry, standard cubic foot (dscf).

$$\begin{aligned} E_{\text{lbm/MMBtu}} &= \frac{C_{\text{lbm/dscf}} V_{\text{NOx,dscf/hr}}}{q_{\text{MMBtu/hr}}} \\ &= \frac{C_{\text{lbm/dscf}} (100) V_{\text{th,CO}_2}}{C_{\text{m,CO}_2,\%} (\text{HHV MMBtu/lbm})} \end{aligned} \quad 32.4$$

The relationship between the NOx concentrations, *C*, expressed in pounds per dry standard volume and ppm can be calculated from Eq. 32.5.<sup>26</sup> Conversions between ppm and pounds are made assuming NOx has a molecular weight of 46.

$$C_{\text{g/m}^3} = (4.15 \times 10^{-5}) C_{\text{ppm}}(\text{MW}) \quad [\text{SI}] \quad 32.5(a)$$

$$C_{\text{lbm/ft}^3} = (2.59 \times 10^{-9}) C_{\text{ppm}}(\text{MW}) \quad [\text{U.S.}] \quad 32.5(b)$$

The theoretical volume of carbon dioxide,  $V_{\text{th,CO}_2}$ , produced can be determined stoichiometrically. However,

<sup>26</sup> The constants in Eq. 32.5 are the same and can be used for any gas.

Table 32.4 can be used for quick estimates with an accuracy of approximately  $\pm 5.9\%$ .

**Table 32.4** Approximate  $\text{CO}_2$  Production for Various Fuels  
(with 0% excess air)

fuel	standard* $\text{ft}^3/10^6 \text{ Btu}$	standard* $\text{m}^3/10^6 \text{ cal}$
coal, anthracite	1980	0.222
coal, bituminous	1810	0.203
coal, lignite	1810	0.203
gas, butane	1260	0.412
gas, natural	1040	0.117
gas, propane	1200	0.135
oil	1430	0.161

\*Standard conditions are  $70^\circ\text{F}$  ( $21^\circ\text{C}$ ) and 1 atm pressure.

Equation 32.4 is based on the theoretical volume of carbon dioxide gas produced per pound of fuel. Other approximations and correlations are based on the total dry volume of the flue gas in standard cubic feet per million Btu at 3% oxygen,  $V_{t,\text{dry}}$ . For quick estimates on furnaces burning natural gas, propane, and butane,  $V_t$  is approximately  $10,130 \text{ ft}^3/\text{MMBtu}$ ; for fuel oil,  $V_t$  is approximately  $10,680 \text{ ft}^3/\text{MMBtu}$ .

$$E_{\text{lbm/MMBtu}} = (C_{\text{ppmv at } 3\% \text{ O}_2})(V_{t,\text{dry}}) \\ \times \left( \frac{46 \frac{\text{lbm}}{\text{lbmol}}}{\left( 379.3 \frac{\text{ft}^3}{\text{lbmol}} \right) (10^6)} \right) \quad 32.6$$

As with all pollutants, the maximum allowable concentration or discharge of NOx is subject to continuous review and revision. Actual limits may depend on the type of geographical location, type of fuel, size of the facility, and so on. For steam/electrical (gas turbine) plants, the general target is 25 ppm to 40 ppm. The lower values apply to combustion of natural gas, and the higher values apply to combustion of distillate oil. Even lower values (down to 9 ppm to 10 ppm) are imposed in some areas.

### Example 32.1

A combustion turbine produces 25 lbm/hr of NOx while generating 550,000 lbm/hr of exhaust gases. The exhaust gas contains 10% water vapor and 11% oxygen by volume. Assume the molecular weight of NOx is 46 lbm/lbmol. What is the NOx concentration in ppm, dry volume basis, corrected to 3% oxygen?

*Solution*

Some of the gas analysis is missing, so the flue gas is assumed to be mostly nitrogen (the largest component of air) with a molecular weight of 28 lbm/lbmol.

The uncorrected, dry NOx volumetric fraction is

$$B_{\text{NOx}} = \left( \frac{\dot{m}_{\text{NOx}}}{\dot{m}_{\text{flue gas}}} \right) \\ \times \left( \frac{\text{MW}_{\text{flue gas}}}{\text{MW}_{\text{NOx}}} \right) (10^6) \left( \frac{100\%}{100\% - \% \text{H}_2\text{O}} \right) \\ = \left( \frac{25 \frac{\text{lbm}}{\text{hr}}}{550,000 \frac{\text{lbm}}{\text{hr}}} \right) \left( \frac{28 \frac{\text{lbm}}{\text{lbmol}}}{46 \frac{\text{lbm}}{\text{lbmol}}} \right) \\ \times (10^6) \left( \frac{100\%}{100\% - 10\%} \right) \\ = 30.7 \text{ ppmvd} \quad [\text{uncorrected}]$$

Equation 32.2 corrects the value to 3% oxygen.

$$\text{O}_2 \text{ correction factor} = \frac{21\% - 3\%}{21\% - \% \text{O}_2} \\ = \frac{18\%}{21\% - 11\%} \\ = 1.8$$

The corrected value is

$$C = (1.8)(30.7 \text{ ppmvd}) = 55.3 \text{ ppmvd}$$

## 26. ODORS

Odors of unregulated substances can be eliminated at their source, contained by sealing and covering, diluted to unnoticeable levels with clean air, or removed by simple water washing, chemical scrubbing (using acid, alkali, or sodium hypochlorite), bioremediation, and activated carbon adsorption.

## 27. OIL SPILLS IN NAVIGABLE WATERS

Intentional and accidental releases of oil in navigable waters are prohibited. Deleterious effects of such spills include large-scale biological (i.e., sea life and wildlife) damage and destruction of scenic and recreational sites. Long-term toxicity can be harmful for microorganisms that normally live in the sediment.

## 28. OZONE

Ground-level ozone is a secondary pollutant. Ozone is not usually emitted directly, but is formed from hydrocarbons and nitrogen oxides (NO and  $\text{NO}_2$ ) in the presence of sunlight. *Oxidants* are by-products of reactions between combustion products. Nitrogen oxides react with other organic substances (e.g., hydrocarbons) to form the oxidants ozone and peroxyacetyl nitrates (PAN) in complex photochemical reactions. Ozone and

PAN are usually considered to be the major components of smog.<sup>27</sup> (See also Sec. 32.36.)

## 29. PARTICULATE MATTER

*Particulate matter* (PM), also known as *aerosols*, is defined as all particles that are emitted by a combustion source. Particulate matter with aerodynamic diameters of less than or equal to a nominal 10  $\mu\text{m}$  is known as PM-10. Particulate matter is generally inorganic in nature. It can be categorized into metals (or heavy metals), acids, bases, salts, and nonmetallic inorganics.

Metallic inorganic PM from incinerators is controlled with baghouses or electrostatic precipitators (ESPs), while nonmetallic inorganics are removed by scrubbing (wet absorption). Flue gas PM, such as fly ash and lime particles from desulfurization processes, can be removed by fabric baghouses and electrostatic precipitators. These processes must be used with other processes that remove NO<sub>x</sub> and SO<sub>2</sub>.

High temperatures cause the average flue gas particle to decrease in size toward or below 10  $\mu\text{m}$ . With incineration, emission of trace metals into the atmosphere increases significantly. Because of this, incinerators should not operate above 1650°F (900°C).<sup>28</sup>

## 30. PCBs

*Polychlorinated biphenyls* (PCBs) are organic compounds (i.e., *chlorinated organics*) manufactured in oily liquid and solid forms through the late 1970s, and subsequently prohibited. PCBs are carcinogenic and can cause skin lesions and reproductive problems. PCBs build up, rather than dissipate, in the food chain, accumulating in fatty tissues. Most PCBs were used as dielectric and insulating liquids in large electrical transformers and capacitors, and in ballasts for fluorescent lights (which contain capacitors). PCBs were also used as heat transfer and hydraulic fluids, as dye carriers in carbonless copy paper, and as plasticizers in paints, adhesives, and caulking compounds.

Incineration of PCB liquids and PCB-contaminated materials (usually soil) has long been used as an effective remediation technique. Removal and landfilling of contaminated soil is expensive and regulated, but may be appropriate for quick cleanups. In addition to incineration and other thermal destruction processes, methods used to routinely remediate PCB-laden soils include biodegradation, ex situ thermal desorption and soil washing, in situ vaporization by heating or steam injection and subject vacuum extraction, and stabilization to

prevent leaching. The application of quicklime (CaO) or high-calcium fly ash is now known to be ineffective.

Specialized PCB processes targeted at cleaning PCB from spent oil are also available. Final PCB concentrations are below detectable levels, and the cleaned oil can be recycled or used as fuel.

## 31. PESTICIDES

The term *traditional organochlorine pesticide* refers to a narrow group of persistent pesticides, including DDT, the “drins” (aldrin, endrin, and dieldrin), chlordane, endosulfan, hexachlorobenzene, lindane, mirex, and toxaphene. Traditional organochlorine insecticides used extensively between the 1950s and early 1970s have been widely banned because of their environmental persistence. There are, however, notable exceptions, and environmental levels of traditional organochlorine pesticides (especially DDT) are not necessarily declining throughout the world, especially in developing countries and countries with malaria. DDT, with its half-life of up to 60 years, does not always remain in the country where it is used. The semi-volatile nature of the chemicals means that at high temperatures they will tend to evaporate from the land, only to condense in cooler air. This *global distillation* is thought to be responsible for levels of organochlorines increasing in the Arctic.

The term *chlorinated pesticides* refers to a much wider group of insecticides, fungicides, and herbicides that contain organically bound chlorine. A major difference between traditional organochlorine and other chlorinated pesticides is that the former have been perceived to have high persistence and build up in the food chain, and the latter do not. However, even some chlorinated pesticides are persistent in the environment. There is little information available concerning the overall environmental impact of chlorinated pesticides. Far more studies exist concerning the effects of traditional organochlorines in the public domain than on chlorinated pesticides in general. Pesticides that have, for example, active organophosphate (OP), carbamate, or triazine parts of their molecules are chlorinated pesticides and may pose long-lasting environmental dangers.

In the United States, about 30–40% of pesticides are chlorinated. All the top five pesticides are chlorinated. Worldwide, half of the 10 top-selling herbicides are chlorinated (alachlor, metolachlor, 2,4-D, cyanazine, and atrazine). Four of the top 10 insecticides are chlorinated (chlorpyrifos, fenvalerate, endosulfan, and cypermethrin). Four (propiconazole, chlorothalonil, prochloraz, and triadimenol) of the 10 most popular fungicides are chlorinated.

## 32. PLASTICS

Plastics, of which there are six main chemical polymers as given in Table 32.5, generally do not degrade once disposed of and are considered a disposal issue. Disposal

<sup>27</sup>The term *oxidant* sometimes is used to mean the original emission products of NO<sub>x</sub> and hydrocarbons.

<sup>28</sup>Incineration of biosolids (sewage sludge) concentrates trace metals into the combustion ash, which is subsequently landfilled. Due to the high initial investment required, difficulty in using combustion energy, and increasingly stringent air quality and other environmental regulations, biosolid incineration is not widespread.

is not a problem per se, however, since plastics are lightweight, inert, and do not harm the environment when discarded.

**Table 32.5 Polymers**

polymer	plastic ID number	common use
polyethylene terephthalate (PET)	1	clear beverage containers
high-density polyethylene (HDPE)	2	detergent; milk bottles; oil containers; toys
polyvinyl chloride (PVC)	3	clear bottles
low-density polyethylene (LDPE)	4	grocery bags; food wrap
polypropylene (PP)	5	labels; bottles; housewares
polystyrene (PS)	6	styrofoam cups; "clam shell" food containers

A distinction is made between *biodegrading* and *recycling*. Most plastics, such as the polyethylene bags used to protect pressed shirts from the dry cleaner and to mail some magazines, are not biodegradable but are recyclable. Also, all plastics can be burned for their fuel value.

The collection and sorting problems often render low-volume plastic recycling efforts uneconomical. Complicating the drive toward recycling is the fact that many of the six different types cannot easily be distinguished visually, and they cannot be recycled successfully when intermixed. Also, some plastic products consist of layers of different polymers that cannot be separated mechanically. Some plastic products are marked with a plastic type identification number.

Sorting in low-volume applications is performed visually and manually. Commercial high-volume methods include hydrocycloning, flotation with flocculation (for all polymers), X-ray fluorescence (primarily for PVC detection), and near-infrared (NIR) spectroscopy (primarily for separating PVC, PET, PP, PE, and PS). Mass NIR spectroscopy is also promising, but has yet to be commercialized.
